Notation List 1

I Set Theory, Logic, and Foundations 8

1 Sets 8
1.1 Introduction to Sets . . . 8
1.2 Cartesian Products . . . 8
1.3 Subsets and Power Sets . . . 8
1.4 Union, Intersection, Difference, and Complement . . . 9
1.5 Indexed Families and Products . . . 9
1.6 Russell's Paradox and Axioms . . . 10

2 Logic and Proofs 10
2.1 Statements and Well-Formed Language . . . 10
2.2 Connectives and Negation . . . 10
2.3 Quantifiers and Bound Variables . . . 11
2.4 Proof Grammar . . . 11
2.5 Proof by Contradiction . . . 11
2.6 Mathematical Induction and Well-Ordering . . . 12

3 Functions 12
3.1 Functions, Images, and Preimages . . . 12
3.2 Injective, Surjective, and Bijective Maps . . . 13
3.3 Composition, Restriction, and Inverse Functions . . . 13

4 Counting and Finite Sums 14
4.1 Finite Sums . . . 14
4.2 Lists and Counting Principles . . . 14
4.3 Permutations, Subsets, and Binomial Coefficients . . . 16
4.4 Inclusion-Exclusion and Combinatorial Proof . . . 18

5 Relations, Orders, and Lattices 18
5.1 Relations and Equivalence . . . 18
5.2 Partitions and Quotient Sets . . . 19
5.3 Ordered Sets, Well-Orders, and Lattices . . . 20
5.4 Relations Between Sets and Closures . . . 20

6 Cardinality, Choice, and Infinite Sets 22
6.1 Choice and Zorn's Lemma . . . 22
6.2 Same Cardinality, Finite, Countable, and Uncountable . . . 22
6.3 Ordinals, Transfinite Recursion, and Well-Foundedness . . . 26
6.4 Diagonalization and Power Sets . . . 29
6.5 Cardinal Comparison and the Continuum . . . 29
6.6 Cardinal Arithmetic . . . 30

7 Axiomatic and Advanced Set Theory 31
7.1 Extensionality, Specification, and Replacement . . . 31
7.2 Models, Constructibility, and Independence . . . 31
7.3 Baire and Cantor Spaces . . . 33
7.4 Filters, Ultrafilters, and Sets of Reals . . . 35

8 Mathematical Writing and Research Practice 38
8.1 Theorem-Style Results and Formal Statements . . . 38
8.2 Proof Construction and Revision . . . 39
8.3 Methods, Algorithms, and Computational Artifacts . . . 39
8.4 Mathematical Research and Integrity . . . 40
8.5 Machine Learning and AI Research . . . 41
8.6 Reading and Synthesizing Research Papers . . . 41

II Structural Linear Algebra 43

1 Vector Spaces and Linear Structure 43
1.1 Vector Spaces . . . 43
1.2 Subspaces and Spans . . . 43
1.3 Linear Independence and Bases . . . 44
1.4 Dimension and Coordinates . . . 48
1.5 Linear Maps and Operators . . . 49
1.6 Kernels, Ranges, and Map Properties . . . 50
1.7 Rank-Nullity and Dimension Criteria . . . 51

2 Direct Sums, Quotients, and Decomposition **52**
2.1 Sums and Direct Sums . . . 52
2.2 Quotient Spaces . . . 56
2.3 Decomposition and Complementation . . . 59
2.4 Algebraic Projections and Resolutions . . . 61

3 Matrix Representations, Change of Basis, Block Matrices, and Operations **62**
3.1 Matrix Algebra and Linear Systems . . . 62
3.2 Coordinates and Matrix Representations . . . 65
3.3 Matrix-Induced Maps and Rank . . . 66
3.4 Invertibility and the Matrix-Map Dictionary . . . 67
3.5 Change of Basis and Coordinate Transformations . . . 67
3.6 Rank and Invertibility Consequences . . . 68
3.7 Block Matrix Algebra . . . 69
3.8 Matrix Operations and Identities . . . 70

4 Duality and Multilinear Structure **72**
4.1 Dual Spaces and Dual Bases . . . 72
4.2 Double Duals and Dual Maps . . . 74
4.3 Annihilators and Transposes . . . 75
4.4 Multilinear Structure . . . 78

III Linear Maps and Matrix Representations **81**

1 Linear Maps and Operations **81**
1.1 Further Linear Map Operations and Examples . . . 81

2 Kernels, Images, Rank, and Nullity **82**
2.1 Shift Operators and Kernel-Range Examples . . . 82
2.2 Further Rank-Nullity and Invertibility Results . . . 82
2.3 Further Quotients and Isomorphism Theorems . . . 82
2.4 Further Finite-Dimensional Splitting and Isomorphism Tests . . . 82

3 Matrix Representations **82**
3.1 Further Matrix Algebra and Linear Systems . . . 82
3.2 Further Coordinates and Matrix Representations . . . 82
3.3 Further Matrix-Induced Maps and Rank . . . 82
3.4 Further Invertibility and the Matrix-Map Dictionary . . . 82

4 Row Reduction and Elementary Matrices **82**
4.1 Row Reduction and Elementary Matrices . . . 82

5 Change of Basis **84**
5.1 Further Change of Basis and Coordinate Transformations . . . 84

6 Matrix Equivalence and Similarity **84**
6.1 Matrix Equivalence and Rank Normal Forms . . . 84
6.2 Similarity and Operator Coordinates . . . 85

IV Geometric and Spectral Linear Algebra **88**

1 Inner Product Geometry **88**
1.1 Inner Products and Norms . . . 88
1.2 Unit Vectors and Orthogonality . . . 92
1.3 Orthonormal Bases and Gram–Schmidt . . . 93
1.4 Orthonormal Coordinates and Inner-Product Identities . . . 95
1.5 Gram Matrices . . . 96
1.6 Finite-Dimensional Riesz Representation . . . 97

2 Orthogonality, Projections, and Least Squares **98**
2.1 Orthogonal Complements . . . 98
2.2 Orthogonal Projections . . . 99
2.3 Adjoints and Fundamental Subspaces . . . 101
2.4 Least Squares and Metric Optimization . . . 104
2.5 Self-Adjoint Operators and Orthogonal Projections . . . 106
2.6 Isometries and Unitary Matrices . . . 107
2.7 Householder Reflections . . . 109

3 Bilinear and Quadratic Forms **110**
3.1 Bilinear Form Types and Congruence Invariants . . . 110
3.2 Quadratic Forms and Polar Forms . . . 111
3.3 Orthogonality, Radicals, and Nonsingular Metric Spaces . . . 112
3.4 Radicals, Hyperbolic Spaces, and Witt Theory . . . 114
3.5 Symplectic Classification and Transvections . . . 117
3.6 Orthogonal Classification over Common Fields . . . 118
3.7 Quadratic Refinements over $\mathbb{F}_2$ . . . 121
3.8 Orthogonal Isometries and Symmetry Groups . . . 122

4 Affine, Projective, and Convex Geometry **123**
4.1 Affine Flats, Hulls, and Incidence . . . 123
4.2 Affine Independence and Barycentric Coordinates . . . 126
4.3 Affine Maps and Affine Groups . . . 127
4.4 Linear Projective Geometry and Affine Completion . . . 128
4.5 Convex Combinations, Cones, and Hulls . . . 129
4.6 Hyperplanes, Nearest Points, and Separation . . . 130
4.7 Positive Orthants, Alternatives, and Farkas's Lemma . . . 132

5 Eigenstructure and Invariant Subspaces **134**
5.1 Eigenvalues, Eigenspaces, and Spectral Criteria . . . 134
5.2 Invariant Subspaces, Reducing Pairs, and Quotient Operators . . . 135
5.3 Triangularization over Complex and Real Fields . . . 138
5.4 Diagonalization, Commutants, and Simultaneous Forms . . . 142

6 Spectral Theorems and Operator Functions **145**
6.1 Normal, Self-Adjoint, and Spectral Theorems . . . 145
6.2 Normal Operator Consequences . . . 149
6.3 Operator Functions . . . 153

V Polynomial Structure and Canonical Forms **157**

1 Operator Polynomials **157**
1.1 Polynomial Functional Calculus . . . 157

2 Characteristic and Minimal Polynomials **157**
2.1 Characteristic Polynomial Foundations . . . 157
2.2 Minimal Polynomial Foundations . . . 160

3 Cayley-Hamilton and Annihilators **160**
3.1 Cayley-Hamilton and Minimal Polynomials . . . 160
3.2 Diagonalizability and Minimal Polynomial Tests . . . 162
3.3 Annihilators and Spectral Control . . . 163
3.4 Polynomial Spectral Mapping . . . 164
3.5 Polynomial Invariance and Block Separation . . . 164

4 Generalized Eigenspaces **165**
4.1 Generalized Eigenspaces and Nilpotent Structure . . . 165

5 Primary Decomposition **168**
5.1 Primary Decomposition and Spectral Splitting . . . 168
5.2 Real Spectral Data via Complexification . . . 169
5.3 Normal Primary Structure . . . 171

6 Jordan and Canonical Forms **171**
6.1 Jordan Chains and Nilpotent Blocks . . . 171
6.2 Complex and Real Jordan Forms and Block Sizes . . . 173
6.3 Products AB and BA and Jordan Structure . . . 176
6.4 Nonderogatory Matrices and Commutants . . . 177
6.5 Jordan Operator Functions and Square Roots . . . 178

7 Transpose and Conjugate Similarity **182**
7.1 Transpose Similarity and Conjugate Similarity . . . 182

VI Matrix Analysis and Numerical Linear Algebra **185**

1 Trace, Determinant, Rank, and Matrix Invariants **185**
1.1 Trace and Determinant . . . 185
1.2 Minors, Cofactors, and Rank . . . 188
1.3 Commutators and Special Matrix Classes . . . 191

2 Positive Definite and Structured Matrices **193**
2.1 Positive Semidefinite and Positive Definite Matrices . . . 193
2.2 Principal Minors and Inertia . . . 196
2.3 Hermitian and Normal Matrix Structure . . . 198

3 Matrix Products, Vectorization, and Spectral Radius **199**
3.1 Kronecker Products and Vectorization . . . 199
3.2 Hadamard Products . . . 200
3.3 Spectral Radius and Matrix Powers . . . 201

4 Matrix Decompositions **202**
4.1 LU, QR, and Cholesky-Type Decompositions . . . 203
4.2 Polar and Singular Value Decompositions . . . 205

5 Norms, Conditioning, Perturbation, and Stability **209**
5.1 Matrix Norms . . . 209
5.2 Low-Rank Approximation and Pseudoinverses . . . 212
5.3 Conditioning . . . 214
5.4 Perturbation Bounds . . . 215
5.5 Diagonal Dominance and Definiteness . . . 217
5.6 Rayleigh Quotients and Minimax . . . 217
5.7 Eigenvalue and Singular-Value Interlacing . . . 218
5.8 Weyl Eigenvalue Bounds . . . 220
5.9 Brauer Rank-One Spectral Shifts . . . 221

6 Numerical Linear Algebra **221**
6.1 Direct Linear-System Solves . . . 221
6.2 QR Least Squares . . . 222
6.3 Banded and Sparse Direct Methods . . . 222
6.4 Krylov Subspace Methods . . . 223
6.5 Stationary Iterations and Splittings . . . 224
6.6 Hessenberg Reduction and QR Eigenvalue Methods . . . 225
6.7 Power and Shift-Invert Iterations . . . 226
6.8 Numerical SVD Methods . . . 227
6.9 Discrete Fourier Transforms and Circulant Matrices . . . 227
6.10 Fast Fourier Transform . . . 228

VII Groups, Rings, and Fields **229**

1 Algebraic Language and Categories **229**
1.1 Universal Properties and Equivalence-Based Structure . . . 229
1.2 Categories and Functors . . . 229
1.3 Algebraic Structures as Objects . . . 229
1.4 Exactness and Diagrams . . . 229

2 Group Theory **229**
2.1 Groups, Subgroups, and Cyclic Groups . . . 229
2.2 Group Homomorphisms, Kernels, and Images . . . 229
2.3 Cosets, Normality, and Structure Theorems . . . 230
2.4 Group Actions, Orbits, and Stabilizers . . . 230
2.5 Conjugacy Classes and the Class Equation . . . 230
2.6 Sylow Theory and Finite Groups . . . 230
2.7 Representation-Theoretic Preview . . . 230

3 Rings, Ideals, and Polynomial Rings **230**
3.1 Rings, Identities, Fields, and Examples . . . 230
3.2 Ring Homomorphisms and Subrings . . . 231
3.3 Ideals and Generated Ideals . . . 231
3.4 Quotient Rings and Maximal Ideals . . . 231
3.5 Integral Domains and Fields of Quotients . . . 232
3.6 Ring Characteristic . . . 232
3.7 Units, Divisibility, and Factorization Domains . . . 233
3.8 Polynomial Rings, Division, and GCDs . . . 233
3.9 Irreducible Polynomials and Unique Factorization . . . 234
3.10 Principal Ideal Domains and Unique Factorization . . . 235
3.11 Roots of Unity and Cyclotomic Polynomials . . . 236

4 Fields and Galois Theory **237**
4.1 Field Extensions . . . 237
4.2 Splitting Fields and Normality . . . 237
4.3 Galois Groups . . . 237
4.4 Finite Fields and Characteristic . . . 237
4.5 Classical Applications . . . 238

VIII Modules, Multilinear Algebra, and Homological Methods **239**

1 Module Theory **239**
1.1 Modules and Submodules . . . 239
1.2 Generated, Cyclic, and Finitely Generated Modules . . . 240
1.3 Linear Independence in Modules . . . 240
1.4 Module Homomorphisms, Kernels, and Images . . . 241
1.5 Quotient Modules, Correspondence, and Isomorphism . . . 241
1.6 Torsion and Annihilators . . . 242
1.7 Direct Sums and Complements . . . 243
1.8 Retracts, One-Sided Inverses, and Split Maps . . . 244

2 Noetherian Modules and PID Structure Theorems **246**
2.1 Free Modules, Bases, and Universal Property . . . 246
2.2 Rank and Coordinate Models of Free Modules . . . 247
2.3 Free Quotients and Splittings . . . 249
2.4 Noetherian Modules . . . 249
2.5 Orders and Cyclic Modules over a PID . . . 249
2.6 Submodules of Finite Free PID Modules . . . 251
2.7 Smith Normal Form and Module Presentations . . . 252
2.8 Finitely Generated PID Modules . . . 254
2.9 Primary Decomposition and Cyclic Primary Modules . . . 254
2.10 Elementary Divisors and Invariant Factors . . . 256

3 Linear Operators as Modules **259**
3.1 Polynomial Modules from Operators . . . 259
3.2 Invariant Factors . . . 261
3.3 Elementary Divisors . . . 262
3.4 Operator Classification . . . 264

4 Associative Algebras **267**
4.1 Associative Algebra Structures . . . 267
4.2 Algebraic Elements and Minimal Polynomials . . . 269
4.3 Zero Divisors and Spectra of Algebraic Elements . . . 270
4.4 Division Algebras . . . 272

5 Tensor Products **273**
5.1 Tensor Products and Universal Properties . . . 273
5.2 Tensor Product Bases and Maps . . . 274
5.3 Iterated Tensor Products and Tensor Spaces . . . 277

6 Symmetric and Exterior Algebras **279**
6.1 Symmetric and Exterior Powers . . . 279
6.2 Determinants from Exterior Powers . . . 281
6.3 Multilinear Algebra Revisited . . . 282

7 Chain Complexes and Homology **282**
7.1 Chain Complexes . . . 282
7.2 Homology . . . 284
7.3 Derived Functors Preview . . . 285

IX Commutative Algebra **287**

1 Prime Ideals and Spectra **287**
1.1 Prime Ideals . . . 287
1.2 Spectra . . . 287

2 Localization and Local Rings **288**
2.1 Localization . . . 288
2.2 Local Rings . . . 291

3 Noetherian Rings and Modules **291**
3.1 Noetherian Rings . . . 291
3.2 Noetherian Modules . . . 292

4 Integral Dependence and Dimension **293**
4.1 Integral Dependence . . . 293
4.2 Dimension Theory . . . 293

5 Regularity and Singularities **293**
5.1 Regularity . . . 293
5.2 Singularities Preview . . . 294

X Algebraic Geometry **295**

1 Affine Algebraic Sets **295**
1.1 Affine Algebraic Sets . . . 295
1.2 Ideals and Coordinate Rings . . . 295

2 Morphisms and Coordinate Rings **295**
2.1 Regular Maps . . . 295
2.2 Coordinate Ring Functoriality . . . 295

3 Projective Geometry **295**
3.1 Projective Space . . . 295
3.2 Projective Varieties . . . 295

4 Sheaves and Schemes **295**
4.1 Sheaves . . . 295
4.2 Affine Schemes . . . 295
4.3 Gluing and Scheme Morphisms . . . 295

5 Cohomology **295**
5.1 Cohomology Preview . . . 295

6 Dimension, Tangent Spaces, and Smoothness **295**
6.1 Dimension . . . 295
6.2 Tangent Spaces . . . 295
6.3 Smoothness . . . 295

7 Divisors, Line Bundles, and Curves **295**
7.1 Divisors . . . 295
7.2 Line Bundles . . . 295
7.3 Curves . . . 295

XI Real and Topological Analysis 296

1 Number Systems and Completeness **296**
1.1 Ordered Fields, Suprema, and Real Structure . . . 296
1.2 Complex Numbers and Absolute Value . . . 300

2 Real Sequences and Completeness Methods **302**
2.1 Sequences, Cauchy Criteria, and Completeness . . . 302
2.2 Divergence, Upper and Lower Limits, and Sequence Estimates . . . 304

3 Metric Spaces and Euclidean Topology **307**
3.1 Metrics, Open Sets, and Euclidean Topology . . . 307
3.2 Relative Topology . . . 312
3.3 Density, Separability, and Closure Tests . . . 312
3.4 Bounded Sets and Metric Sequences . . . 313

4 Compactness and Completeness **316**
4.1 Compactness, Completeness, and Total Boundedness . . . 316
4.2 Heine–Borel and Euclidean Compactness . . . 322
4.3 Baire Category . . . 324
4.4 Perfect Sets and the Cantor Set . . . 327
4.5 Complete Metric Spaces and Completions . . . 328

5 Connectedness and Continuity **330**
5.1 Connectedness and Continuity . . . 330
5.2 Uniform Continuity and Compactness . . . 337
5.3 One-Sided Limits, Monotone Functions, and Extended Limits . . . 339

6 General Topology for Analysis **341**
6.1 Topological Spaces, Bases, and Separation . . . 341
6.2 Continuity and Topological Constructions . . . 344
6.3 Topological Compactness and Normality Tools . . . 346
6.4 Sequences, Countability, and Metrization . . . 351
6.5 Topological Connectedness and Paths . . . 355

7 Finite-Dimensional Topological Vector Spaces **358**
7.1 Natural Topology and Continuity . . . 358

XII Calculus, Series, and Approximation 360

1 One-Variable Differentiation and Riemann Integration **360**
1.1 Differentiation and Basic Theorems . . . 360
1.2 Riemann Integration . . . 364

2 Riemann-Stieltjes and Improper Integration **365**
2.1 Riemann-Stieltjes Integrability . . . 365
2.2 Fundamental Theorems of Calculus . . . 367
2.3 Step Integrators and Change of Variable . . . 367
2.4 Improper Integrals . . . 368
2.5 Vector-Valued Integrals and Curves . . . 369
2.6 Further Topics in Integration . . . 370

3 Several-Variable Differentiation **370**
3.1 Partial and Total Derivatives . . . 370
3.2 Differentiability and Linear Approximation . . . 371

4 Inverse, Implicit, and Rank Theorems **373**
4.1 Inverse Function Theorem . . . 373
4.2 Implicit Function Theorem . . . 374
4.3 Rank Theorem . . . 375
4.4 Further Topics in Local Differential Theory . . . 375

5 Differential Forms and Stokes Theory **376**
5.1 Multiple Integration and Change of Variables . . . 376
5.2 Differential Forms and Manifolds . . . 379
5.3 Stokes Theory . . . 380
5.4 Further Topics in Differential Forms and Stokes Theory . . . 382

6 Infinite Series and Summability **382**
6.1 Series Tests . . . 382

7 Uniform Convergence **388**
7.1 Uniform Limits . . . 388
7.2 Interchange of Limits . . . 390
7.3 Further Topics in Uniform Convergence . . . 391

8 Function-Space Compactness **391**
8.1 Equicontinuity . . . 391
8.2 Arzela-Ascoli-Type Compactness . . . 392
8.3 Further Topics in Function-Space Compactness . . . 393

9 Power Series and Approximation **393**
9.1 Power Series . . . 393
9.2 Approximation Methods . . . 397
9.3 The Umbral Calculus . . . 400
9.4 Umbral Recurrences and Variants . . . 406

10 Fourier Structure **407**
10.1 Fourier Orthogonality . . . 407
10.2 Fourier Approximation . . . 407
10.3 Further Topics in Fourier Analysis . . . 409

XIII Measure Foundations and Extension 411

1 Sigma-Algebras and Measurable Spaces **411**
1.1 Sigma-Algebras and Measurable Structures . . . 411

2 Measures, Charges, and Basic Examples **412**
2.1 Measures, Charges, and Basic Constructions . . . 412

3 Outer Measures and Caratheodory Extension **414**
3.1 Outer Measures and Extension Theorems . . . 414
3.2 Euclidean Cells and Cell Outer Measure . . . 417
3.3 Caratheodory Measurability and Lebesgue Measure . . . 419
3.4 Caratheodory-Hahn Extension . . . 421
3.5 Metric Outer Measures and Hausdorff Measure . . . 423

4 Borel, Lebesgue, and Stieltjes Measures **424**
4.1 Borel, Lebesgue, and Stieltjes Measure Constructions . . . 424

5 Continuity and Regularity of Measures **427**
5.1 Measure Continuity and Regularity . . . 427
5.2 Radon Measures on Locally Compact Spaces . . . 429
5.3 Invariant Measures on Compact Groups . . . 432

6 Regular Approximation and Caratheodory Tests **434**
6.1 Borel Approximation and Regular Measurable Sets . . . 434
6.2 Compact and Cell Approximation . . . 436
6.3 Caratheodory Tests and Inner Measure . . . 437

7 Vitali, Steinhaus, and Nonmeasurable Sets **438**
7.1 Vitali, Steinhaus, and Nonmeasurability . . . 438

8 Cantor–Lebesgue Singular Function **439**
8.1 Cantor-Lebesgue Singular Function Construction . . . 439

XIV Measure, Integration, and Functional Analysis 441

1 Measurable Functions and Lebesgue Integration **441**
1.1 Measurable Functions . . . 441
1.2 Lebesgue Integration . . . 444
1.3 Convergence Theorems . . . 449
1.4 Parameter Integrals and Differentiation . . . 453
1.5 Riemann-Lebesgue Comparison . . . 454
1.6 Littlewood and Lusin Approximation . . . 455
1.7 Convex Functions and Jensen's Inequality . . . 457

2 Product Measures and Fubini Theory **458**
2.1 Product Measures . . . 458
2.2 Fubini and Tonelli Theorems . . . 459
2.3 Linear Changes of Variables and Euclidean Invariance . . . 463

3 Radon-Nikodym and Differentiation **464**
3.1 Signed and Absolutely Continuous Measures . . . 464
3.2 Radon-Nikodym Theorem . . . 467
3.3 Differentiation of Measures . . . 469
3.4 Monotone and Bounded-Variation Differentiation . . . 471
3.5 Absolute Continuity and BV Decomposition . . . 473
3.6 Nikodym Metric and Setwise Measure Limits . . . 476

4 L^p Spaces and Modes of Convergence **478**
4.1 L^p Spaces . . . 478
4.2 Modes of Convergence . . . 486
4.3 Composition and Convergence Modes . . . 490
4.4 Uniform Integrability and Vitali Convergence . . . 492
4.5 Approximation and Separability in L^p . . . 494
4.6 Weak Convergence in L^p . . . 495

5 Banach and Hilbert Spaces **499**
5.1 Normed and Banach Spaces . . . 499
5.2 Hilbert Spaces . . . 502
5.3 Core Functional Analytic Theorems . . . 510
5.4 Open Mapping, Closed Graph, and Complemented Subspaces . . . 511

6 Weak Topologies, Compact Operators, and Spectral Theory **513**
6.1 Weak Topologies and Duality . . . 513
6.2 Compact Operators . . . 517
6.3 Spectral Theory of Operators . . . 520
6.4 Measure Duality and Riesz Representation . . . 522

XV Probability Foundations and Distributions 524

1 Probability Spaces and Random Variables **524**
1.1 Probability Spaces and Event Algebra . . . 524
1.2 Finite Probability, Counting, and Independence . . . 526
1.3 Random Variables, Laws, and Distribution Functions . . . 527
1.4 Standard Distribution Families and Approximations . . . 529

2 Joint Distributions, Multivariate Laws, and Transformations **531**
2.1 Joint Distributions and Independence . . . 531
2.2 Multivariate Models and Copulas . . . 532
2.3 Transformations of Random Variables . . . 533

3 Expectation and Integration in Probability **534**
3.1 Expectation, Variance, and LOTUS . . . 534
3.2 Moments, Sample Statistics, and Random Vectors . . . 535
3.3 Probability Inequalities . . . 536
3.4 Moment Generating Functions . . . 537

4 Order Statistics, Extrema, and Moment Methods **538**
4.1 Order Statistics, Extrema, and Moment Methods . . . 538

5 Normal-Derived Distributions **540**
5.1 Normal-Derived Distribution Families . . . 540

XVI Probability and Stochastic Systems **542**

1 Conditional Probability and Conditional Expectation **542**
1.1 Conditional Probability . . . 542
1.2 Conditional Expectation . . . 545
1.3 Conditional Moment Methods and Prediction . . . 546

2 Probabilistic Convergence **547**
2.1 Modes of Probabilistic Convergence . . . 547
2.2 Probability on Metric Spaces . . . 548

3 Limit Theorems **548**
3.1 Laws of Large Numbers . . . 548
3.2 Central Limit Theory . . . 549

4 Stochastic Processes **552**
4.1 Process-Level Probability . . . 552
4.2 Filtrations and Adapted Processes . . . 552
4.3 Martingales in Discrete and Continuous Time . . . 552
4.4 Markov Chains and Markov Processes . . . 552
4.5 Stationary Processes and Ergodicity . . . 555
4.6 Gaussian Processes . . . 555
4.7 Point Processes and Renewal Structure . . . 555

5 Stochastic Calculus and SDEs **556**
5.1 Brownian Motion . . . 556
5.2 Stochastic Integration . . . 556
5.3 Itô Calculus . . . 556
5.4 Stochastic Differential Equations . . . 556
5.5 Change of Measure and Girsanov Theory . . . 556
5.6 Diffusions and PDE Connections . . . 556
5.7 Stochastic Flows and Advanced Dynamics . . . 556

XVII Dynamical and PDE Systems **557**

1 Dynamical Systems and ODEs **557**
1.1 ODE Foundations and Flows . . . 557
1.2 Linear Systems and Stability . . . 565
1.3 Nonlinear Stability Theory . . . 569
1.4 Bifurcation Theory . . . 572
1.5 Dynamical Systems Structure . . . 574
1.6 Semigroups and Evolution Viewpoint . . . 575
1.7 Measure-Preserving Dynamics and Ergodicity . . . 575

2 Partial Differential Equations **578**
2.1 First-Order PDE and Characteristics . . . 578
2.2 Elliptic Equations . . . 578
2.3 Parabolic Equations . . . 578
2.4 Hyperbolic Equations . . . 578

3 Weak Solutions and Evolution Equations **578**
3.1 Sobolev Spaces for PDE . . . 578
3.2 Weak Solutions and Variational Methods . . . 578
3.3 Evolution Equations . . . 578

XVIII Numerical and Stochastic Computation **579**

1 Numerical Analysis **579**
1.1 Floating Point and Error Analysis . . . 579
1.2 Nonlinear Equations and Optimization Basics . . . 579
1.3 Interpolation and Approximation . . . 579
1.4 Numerical Differentiation and Quadrature . . . 579
1.5 Numerical Stability and Convergence . . . 579

2 Numerical Differential Systems **579**
2.1 Numerical ODEs . . . 579
2.2 Geometric Numerical Integration . . . 580
2.3 Finite Difference PDE Methods . . . 580
2.4 Finite Element Methods . . . 580
2.5 Numerical SDEs . . . 580
2.6 Computational Stability Across ODE/PDE/SDE . . . 580

3 Monte Carlo and Stochastic Computation **580**
3.1 Monte Carlo Foundations . . . 580
3.2 Variance Reduction . . . 581
3.3 Markov Chain Monte Carlo . . . 582
3.4 Sequential Monte Carlo . . . 582
3.5 Rare-Event Simulation . . . 582
3.6 Stochastic Optimization . . . 582

XIX Statistical Inference and Time Series **584**

1 Statistical Models and Experiments **584**
1.1 Statistical Experiments and Likelihoods . . . 584
1.2 Sufficiency, Exponential Families, and Local Asymptotics . . . 584
1.3 Design, Randomization, and Observational Comparisons . . . 585

2 Estimation Theory **586**
2.1 Estimators, Bias, Variance, and Risk . . . 586
2.2 Information Bounds and Asymptotic Efficiency . . . 587
2.3 Method of Moments and Parametric Likelihood Examples . . . 587

3 Hypothesis Testing and Confidence **588**
3.1 Tests, Likelihood Ratios, and Error Control . . . 588
3.2 Confidence Sets, Pivots, and Asymptotic Intervals . . . 590
3.3 Goodness-of-Fit and Diagnostic Plots . . . 591
3.4 Normal Sampling Pivots . . . 592
3.5 Two-Sample Normal Inference . . . 593
3.6 Paired-Sample Inference . . . 595

4 Decision Theory **596**
4.1 Loss, Risk, Bayes, and Minimax Rules . . . 596
4.2 Shrinkage, Empirical Bayes, and Regularization . . . 596

5 Bayesian Inference **597**
5.1 Priors, Posteriors, and Conjugacy . . . 597
5.2 Computation, Prediction, and Asymptotic Bayes . . . 597
5.3 Bayesian Normal Comparisons . . . 598

6 Nonparametric and High-Dimensional Statistics **599**
6.1 Empirical Processes, Density, and Regression Smoothing . . . 599
6.2 Sparse High-Dimensional Inference . . . 602
6.3 Rank-Based Comparative Tests . . . 603

7 Time Series Models **604**
7.1 Stationarity, Autocovariance, and Linear Processes . . . 604
7.2 ARIMA, State-Space, and Volatility Models . . . 605

8 Sequential Inference and Resampling **605**
8.1 Resampling, Bootstrap, and Permutation Methods . . . 605
8.2 Sequential Experiments, Filtering, and Online Inference . . . 606
8.3 Two-Sample Resampling Methods . . . 607

XX Statistical Data Analysis and Applied Models **608**

1 Survey Sampling **608**
1.1 Finite Population Parameters and Simple Random Sampling . . . 608
1.2 Normal Approximation and Confidence Intervals . . . 610
1.3 Ratio Estimation . . . 610
1.4 Stratified Random Sampling . . . 612

2 Exploratory Data Analysis and Data Summaries **614**
2.1 Empirical Distribution and Survival Summaries . . . 614
2.2 Quantile and Shape Displays . . . 614
2.3 Location, Scale, and Robust Summaries . . . 615
2.4 Boxplots, Scatterplots, and Relationship Summaries . . . 616

3 Categorical Data Analysis **617**
3.1 Fisher's Exact Test and Fixed Margins . . . 617
3.2 Chi-Square Tests for Contingency Tables . . . 618
3.3 Matched Pairs and McNemar's Test . . . 619
3.4 Odds Ratios and Case-Control Sampling . . . 620
3.5 Higher-Order Tables and Sampling Design . . . 621

4 Analysis of Variance and Designed Experiments **621**
4.1 One-Way Layouts and the F Test . . . 621
4.2 Multiple Comparisons After ANOVA . . . 623
4.3 Rank-Based One-Way ANOVA . . . 624
4.4 Two-Way Layouts and Interaction . . . 624
4.5 Randomised Blocks and Friedman's Test . . . 626

5 Linear Models and Regression **627**
5.1 Least Squares Curve Fitting and Linearization . . . 627
5.2 Simple Linear Regression Inference and Diagnostics . . . 628
5.3 Matrix Linear Models and Normal Equations . . . 629
5.4 Inference, Prediction, and Multiple Regression . . . 630
5.5 Random Design, Bootstrap, and Extensions . . . 632

XXI Statistical Learning and Deep Learning **633**

1 Learning Problems and Risk **633**
1.1 Prediction, Loss Functions, and Risk . . . 633
1.2 Empirical Risk Minimization . . . 633
1.3 Surrogate Losses and Calibration . . . 634
1.4 Bias-Variance and Approximation-Estimation Tradeoffs . . . 634

2 Generalization Theory **635**
2.1 Uniform Convergence and VC Theory . . . 635
2.2 Rademacher Complexity and Covering Numbers . . . 636
2.3 Concentration and Stability . . . 636
2.4 PAC-Bayes and Information-Theoretic Bounds . . . 637

3 Unsupervised and Latent-Variable Learning **637**
3.1 Clustering and Mixture Models . . . 637
3.2 Dimension Reduction and Manifold Learning . . . 640
3.3 Matrix Factorization and Topic Models . . . 642
3.4 Representation Learning Objectives . . . 643
3.5 Association Rules and Density-Ratio Views . . . 644
3.6 Graph Ranking and PageRank . . . 645
3.7 Latent Factor and Component Analysis . . . 646

4 Probabilistic Graphical and Causal Learning **646**
4.1 Directed and Undirected Graphical Models . . . 646
4.2 Inference and Learning in Graphical Models . . . 647
4.3 Causal Graphs, Interventions, and Identifiability . . . 648
4.4 Counterfactuals and Policy Evaluation . . . 649

5 Neural Network Foundations **649**
5.1 Network Architectures and Expressivity . . . 649
5.2 Backpropagation and Automatic Differentiation . . . 650
5.3 Optimization for Deep Learning . . . 651
5.4 Regularization, Normalization, and Generalization . . . 651

6 Modern Deep Models **652**
6.1 Convolutional and Geometric Architectures . . . 652
6.2 Sequence Models and Attention . . . 653
6.3 Transformers and Large-Scale Training . . . 653
6.4 Generative Models . . . 653
6.5 Reinforcement Learning and Decision Systems . . . 654

7 Learning Systems and Evaluation **654**
7.1 Data Splitting, Validation, and Benchmarking . . . 654
7.2 Robustness, Shift, and Distributional Uncertainty . . . 655
7.3 Interpretability, Fairness, and Safety . . . 656
7.4 Deployment, Monitoring, and Feedback Loops . . . 656

XXII Classical Supervised Learning **658**

1 Linear Prediction and Generalized Linear Models **658**
1.1 Linear Predictors and Least Squares . . . 658
1.2 Linear Classification and Generalized Linear Models . . . 658
1.3 Discriminant Analysis and Naive Bayes . . . 659

2 Regularisation and Model Selection **659**
2.1 Penalized Linear Estimation . . . 659
2.2 Validation and Selection Bias . . . 660
2.3 Derived Input Directions and Regularization Paths . . . 660
2.4 Effective Degrees and Information Criteria . . . 662

3 Basis Expansions, Splines, and Wavelets **662**
3.1 Basis Expansions, Splines, and Wavelet Features . . . 662

4 Kernel Methods and RKHS Theory **663**
4.1 Kernel Methods and RKHS Representations . . . 663

5 Support Vector Machines and Margin Methods **664**
5.1 Margins and SVM Primal Problems . . . 664
5.2 Dual Problems and Kernelization . . . 665
5.3 Support Vector Regression and Perceptrons . . . 666

6 Trees and Ensemble Averaging **666**
6.1 Tree Models and Bagging . . . 666
6.2 CART Splits and Pruning . . . 667
6.3 Ensembles, Random Forests, and Stacking . . . 667

7 Additive Models and Adaptive Basis Methods **669**
7.1 Generalized Additive Models . . . 669
7.2 Adaptive Basis and Rule Methods . . . 669

8 Boosting and Additive Trees **670**
8.1 Stagewise Boosting . . . 670
8.2 AdaBoost and Exponential Loss . . . 671
8.3 Gradient Boosted Trees and Rule Ensembles . . . 671

9 High-Dimensional Supervised Learning **673**
9.1 High-Dimensional Linear Rules . . . 673
9.2 Sparse and Structured Penalties . . . 674
9.3 Latent Factors and Distance-Based Classifiers . . . 675

10 Prototype and Nearest-Neighbor Methods **675**
10.1 Prototype Classifiers . . . 675
10.2 Nearest Neighbors . . . 676
10.3 Invariant Distances and Adaptive Neighborhoods . . . 677

11 Flexible and Mixture Discriminant Analysis **678**
11.1 Flexible and Mixture Discriminant Rules . . . 678

Notation List

Collision Index and Scope Rules

bare $A, B, \ldots$; $\mathcal{A}, \mathcal{B}, \ldots$	unadorned Latin and calligraphic letters denote local objects unless a decorated form is listed below; local declarations in a theorem, proof, or subsection take precedence
B, $B_r(x)$, $\overline{B}_r(x)$, $\mathrm{B}(x, y)$, $\mathcal{B}(\mathbb{R}^n)$	matrix or set variable / open ball / closed ball / beta function / Borel σ-algebra; font, arguments, and ambient subject determine the referent
$I_{\mathcal{V}}$, I_n, I^k, I_R	identity operator, identity matrix, k-cell, and power-series interval
P, $\mathcal{P}(X)$, $\mathscr{P}$, $P_{\mathcal{U}}$, P_j	locally declared projection or map / power set / umbral polynomial algebra / orthogonal projection / spectral projection
$\mathcal{F}$, $\mathscr{F}$, $\mathcal{F}(K)$, $\mathcal{F}(\mathcal{V})$	local family of functions or operators / umbral formal-series algebra / finite subsets of K / finite-rank operators
$\mathcal{L}(\mathcal{V}, \mathcal{W})$, $\mathcal{L}^n$, $\mathscr{L}^1$, $\mathrm{LS}(A, \mathbf{y})$, $\mathcal{L}(\theta, \alpha)$	linear maps / Lebesgue measurable sets / integrable functions / least-squares solution set / local Lagrangian or loss notation
$R(f, \Pi, \{c_i\})$, R, $R_k(A)$, $A = QR$	Riemann sum, locally declared radius or scalar, row-sum quantity, and QR factorization; arity and argument type disambiguate the notation
Δx_i, ΔA, $\Delta(A)$, $\Delta(\mathcal{V})$, Δ_{k-1}	increment, matrix perturbation, defect from normality, metric discriminant, and coefficient simplex
Ω, Ω_T, Ω_n, $\mathrm{vol}(\Omega)$	local domain or set / finite spectrum of T / primitive roots of unity or DFT diagonal, as specified by context / volume domain
Q^k, Q_n, Φ_n	standard k-simplex / normalized Fourier matrix / cyclotomic polynomial; cyclotomic polynomials use Φ_n
f^{-1}, $f^{-1}(B)$	inverse function when f is bijective / preimage of B under any function f; bijectivity, argument type, and local declaration determine the meaning
$\wedge$, $\vee$, $x \wedge y$, $x \vee y$, $dx_I \wedge dx_J$	logical conjunction and disjunction / lattice meet and join / exterior product; subject and operand types determine the meaning
$\mathrm{supp}(f)$	nonzero set $\{x : f(x) \neq 0\}$ when the codomain has a distinguished zero / its closure when the domain is topological; the local definition determines the meaning
$\overline{z}$, $\overline{E}$, $\overline{\mathcal{A}}$, A^*, $T^*\omega$, f', $\mathcal{V}'$	conjugation, closure, uniform closure, adjoint or conjugate transpose, pullback, derivative, and dual space; the decorated object determines the operation

Global Conventions and Basic Notation

Convention. Notation is scoped by subject, argument type, font, decoration, and any local definition in force. Unadorned letters denote local objects by default; persistent meanings are carried by subscripts, superscripts, operators, fonts, or declared argument patterns. When a glyph is reused, the distinguishing feature is recorded below.

Set, Function, and Logical Notation

$x \in E$, $x \notin E$	membership / non-membership
$E \subseteq F$, $\emptyset$	subset inclusion, not necessarily proper / empty set
$X \times Y$, $f : X \to Y$	Cartesian product / function with domain X and codomain Y
$f(A)$, $f^{-1}(B)$, f^{-1}	image of A / preimage of B / inverse function when f is bijective; argument type and local context distinguish preimages from inverse-function values
$\mathrm{range}(f)$, $f\|_A$	range of f / restriction of f to A
$g \circ f$, id_X	composition of functions with compatible domain and codomain / identity function on X
$\mathbf{1}_E$	indicator of E, equal to 1 on E and 0 outside E
$[x]_\sim$, $X/\sim$	equivalence class of x / quotient set for the relation $\sim$
$\{A_i\}_{i \in I}$, $\bigcup_{i \in I} A_i$, $\bigcap_{i \in I} A_i$	indexed family of sets / set of points lying in some A_i / set of points lying in every A_i
$\sup E$, $\inf E$	least upper bound / greatest lower bound in the ambient ordered set; extended values may be used when explicitly allowed
$x \wedge y$, $x \vee y$, $\bot$, $\top$	meet / join / bottom / top in a lattice
$\neg$, $\wedge$, $\vee$	logical negation / conjunction / inclusive disjunction
$\Rightarrow$, $\Longrightarrow$, $\Longleftrightarrow$	logical implication (either arrow length) / logical equivalence
$\forall$, $\exists$, $\exists!$	universal / existential / unique-existence quantifier
$:=$	definition by equality

Number, Size, and Scalar Notation

$\mathbb{N}$, $\mathbb{N}_0$, $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$	positive integers / nonnegative integers / integers / rationals / reals / complexes
$n!$, $(n)_r$, $\binom{n}{r}$	factorial / falling factorial / binomial coefficient
$\mathfrak{S}_n$, $\mathrm{sign}(\sigma)$	permutations of $\{1, \ldots, n\}$ / sign of a permutation
$\mathbb{F}$, $\mathbb{F}_0$	ambient scalar field unless fixed as $\mathbb{R}$ or $\mathbb{C}$ / prime subfield of $\mathbb{F}$; probabilities use explicit Pr or locally declared probability spaces
$\|x\|$, $\|E\|$, $\|\|x\|\|$	absolute value or complex modulus for scalars; interval length or cardinality according to argument type; norm of a vector, function, or operator
a, b, c	locally declared scalars or interval endpoints

Linear and Operator Structures Notation

Vector Spaces and Lists

$\mathbb{F},\ \mathbb{F}_0$	ambient scalar field, typically $\mathbb{R}$ or $\mathbb{C}$ / prime subfield of $\mathbb{F}$
$V(n,q),\ \mathbb{F}_q^n$	n-dimensional coordinate space over the finite field with q elements
$\mathbb{F}^{(\mathbb{N})}$	vector space of finitely supported sequences over $\mathbb{F}$
$\mathbf{u},\mathbf{v},\mathbf{w},\mathbf{0}$	vectors / zero vector
$\mathcal{U},\mathcal{V},\mathcal{W}$	vector spaces or subspaces; other calligraphic letters such as $\mathcal{A},\mathcal{B},\mathcal{F},\mathcal{M}$ are local unless listed below; umbral algebras use script $\mathscr{P},\mathscr{F}$
$I_{\mathcal{V}},\ I_n,\ 0$	identity operator on $\mathcal{V}$ / identity matrix / zero map or zero matrix; distinct from the cell I^k and interval I_R
$\beta=(\mathbf{v}_1,\dots,\mathbf{v}_m)$	ordered vector list; a basis iff it is linearly independent and spans
$(),\ \beta_{\widehat{j}}$	empty list / list β with the jth entry omitted
$(\beta,\mathbf{v}),\ \beta_{j\leftarrow\mathbf{v}}$	list with $\mathbf{v}$ appended / list with the jth entry replaced by $\mathbf{v}$
$\mathcal{B}$	locally declared basis set, such as a Hamel, Hilbert, module, or affine basis; $\mathcal{B}(\mathbb{R}^n)$ denotes the Borel σ-algebra in analysis
$\operatorname{span}(E),\ \dim(\mathcal{V})$	linear span of E / dimension of $\mathcal{V}$
$\operatorname{codim}_{\mathcal{V}}(\mathcal{U})$	codimension of $\mathcal{U}$ in $\mathcal{V}$; equal to $\dim(\mathcal{V}/\mathcal{U})$ in finite dimension
$\bigwedge_{i\in I}\mathcal{U}_i,\ \bigvee_{i\in I}\mathcal{U}_i$	meet / join of a family of subspaces
$\sum_{i\in I}\mathcal{U}_i$	sum of an indexed family of subspaces; equivalently the join
$\mathcal{U}+\mathcal{W},\ \mathcal{U}\oplus\mathcal{W},\ \mathcal{V}/\mathcal{U}$	sum, direct sum, quotient space
$\mathcal{V}_1\times\cdots\times\mathcal{V}_m$	product vector space with componentwise operations
$\prod_{i\in I}\mathcal{V}_i,\ \bigoplus_{i\in I}^{\text{ext}}\mathcal{V}_i$	external direct product / external direct sum of finite-support families
$\mathcal{V}\cong\mathcal{W},\ \mathbf{e}_{j,k}$	isomorphic vector spaces / basis vector supported in one product component
$\mathbf{v}+\mathcal{U},\ \pi(\mathbf{v})$	coset modulo $\mathcal{U}$ / locally declared quotient map $\mathcal{V}\to\mathcal{V}/\mathcal{U}$

Linear Maps and Duality

$T:\mathcal{V}\to\mathcal{W},\ \mathcal{L}(\mathcal{V},\mathcal{W})$	linear map / vector space of linear maps; distinct from measure-theoretic $\mathcal{L}^n$, least-squares $\mathrm{LS}(A,\mathbf{y})$, and local loss notation $\mathcal{L}(\theta)$
$T_A:\mathbb{F}^n\to\mathbb{F}^m$	linear map $\mathbf{x}\mapsto A\mathbf{x}$ induced by $A\in\mathrm{Mat}(m,n,\mathbb{F})$
$ST,\ T\vert_{\mathcal{U}},\ T/\mathcal{U}$	composition $S\circ T$ / restriction to $\mathcal{U}$ / induced quotient operator
$T^{-1},\ T^m,\ p(T)$	inverse of an invertible map or operator / operator power / polynomial functional calculus
$\ker(T),\ \operatorname{range}(T)$	kernel and range of T
$\operatorname{rank}(T),\ \operatorname{nullity}(T)$	dimensions of the range and kernel of a finite-domain linear map T
$\rho_{\mathcal{U},\mathcal{W}},\ \rho\perp\sigma$	projection onto $\mathcal{U}$ along $\mathcal{W}$ / algebraically orthogonal idempotents satisfying $\rho\sigma=\sigma\rho=0$; geometric orthogonality is listed separately below
$\mathcal{V}_{\mathbb{C}},\ \mathrm{cpx},\ T_{\mathbb{C}}$	complexification of a real vector space / canonical embedding $\mathbf{v}\mapsto\mathbf{v}+i\mathbf{0}$ / complexification of a real operator
$\operatorname{graph}(T),\ [S,T]$	graph of a map / commutator $ST-TS$
$\mathrm{Comm}(\mathcal{F}),\ \mathrm{Comm}(A)$	commutant of a family / commutant of a single matrix or operator
$A\sim_{\text{row}}B,\ S\sim T$	row-equivalent matrices / operator similarity when declared; distinct from cardinal, a.e., and coefficient equivalence
$\mathcal{V}',\ \beta',\ T'$	dual space, dual basis, and dual map; prime denotes duality in this context
$\varphi,\psi,\ \mathcal{U}^0$	linear functionals / annihilator
$\mathcal{V}'',\ \Lambda_{\mathcal{V}}$	double dual / natural evaluation map $\mathcal{V}\to\mathcal{V}''$
$[B]_{\beta,\gamma},\ \Phi_B,\ \Psi_B$	matrix of a bilinear pairing in ordered bases / induced maps $\mathcal{V}\to\mathcal{W}'$ and $\mathcal{W}\to\mathcal{V}'$ in a pairing context; module coordinate maps redeclare Φ_B locally
$[\mathbf{v}]_\beta,\ [T]_{\gamma\leftarrow\beta}$	coordinate vector in basis β / matrix of T from β-coordinates to γ-coordinates
$C_{\gamma\leftarrow\beta}$	change-of-basis matrix sending β-coordinate columns to γ-coordinate columns

Matrices and Entrywise Structure

$A,B,C,\ \mathrm{Mat}(m,n,\mathbb{F})$	matrix variables / space of $m\times n$ matrices over $\mathbb{F}$; decorated forms such as C_f and C_{ij} have separate meanings
$A_{ij},\ A_{j,\cdot},\ A_{\cdot,k}$	entry in row i and column j / jth row / kth column
$[a_{ij}],\ E_{j,k},\ A\mathbf{x}$	matrix with entries a_{ij} / matrix unit / matrix-vector product
$A^{-1},\ \mathrm{Mat}(n,n,\mathbb{F})^\times$	inverse matrix when it exists / set of invertible $n\times n$ matrices
$A^t,\ A^T,\ A^*$	transpose / alternate transpose notation / conjugate transpose or adjoint
$\operatorname{diag}(\lambda_1,\dots,\lambda_n)$	diagonal matrix with diagonal entries $\lambda_1,\dots,\lambda_n$
$\overline{z},\ \operatorname{Re}z,\ \operatorname{Im}z$	complex conjugate / real part / imaginary part; for sets, overline denotes closure
$\operatorname{tr}(A),\det(A)$	trace and determinant
$\operatorname{adj}(A)$	adjugate matrix
$M_{ij},\ C_{ij},\ A_j(\mathbf{b})$	minor matrix / cofactor / matrix obtained from A by replacing column j with $\mathbf{b}$
$\operatorname{col}(A),\ \operatorname{row}(A)$	column space and row space of A
$\operatorname{rank}(A),\ \operatorname{nullity}(A)$	rank and nullity of A
$A\oplus B,\ A\otimes B$	matrix direct sum / Kronecker product; vector-space direct sums use subspace notation
$A\otimes I_q+I_n\otimes B$	Kronecker sum of square matrices A and B in compatible dimensions
$A\circ B,\ \operatorname{vec}(A)$	Hadamard product / column-stacking vectorisation
$M/A,\ M/D$	Schur complement of the block A or D in a compatible block matrix M; distinct from quotient-space notation
$B,\ L=B^tB$	directed incidence matrix / associated incidence Laplacian in a graph context

Inner Product Geometry

$\|\mathbf{v}\|$, $\|T\|_{\mathrm{op}}$	vector norm / operator norm
$\|\cdot\|_1$, $\|\cdot\|_2$, $\|\cdot\|_\infty$	coordinate one-norm / Euclidean or spectral two-norm according to argument type / sup norm
$\|\cdot\|_F$	Frobenius norm
$\langle \mathbf{u}, \mathbf{v}\rangle$, $\langle A, B\rangle_F$	inner product / Frobenius inner product
$\mathbf{u} \perp \mathbf{v}$, $\mathcal{U}^\perp$, δ_{ij}	orthogonal vectors, orthogonal complement, Kronecker delta
$\mathrm{proj}_{\mathbf{v}}(\mathbf{u})$, $P_{\mathcal{U}}$	orthogonal projection of $\mathbf{u}$ onto $\mathrm{span}(\mathbf{v})$ / orthogonal projection onto $\mathcal{U}$
$\mathrm{LS}(A, \mathbf{y})$	least-squares solution set $\arg\min_{\mathbf{x}\in\mathbb{F}^n} \|A\mathbf{x} - \mathbf{y}\|_2$ for $A \in \mathrm{Mat}(m, n, \mathbb{F})$; roman notation avoids collision with $\mathcal{L}$ and $\mathcal{L}^n$
$d(\mathbf{v}, \mathcal{U})$	distance $\inf_{\mathbf{u}\in\mathcal{U}} \|\mathbf{v} - \mathbf{u}\|$ from $\mathbf{v}$ to $\mathcal{U}$
$\mathrm{Gram}(\mathbf{u}_1, \ldots, \mathbf{u}_n)$	Gram matrix of $\mathbf{u}_1, \ldots, \mathbf{u}_n$
$\mathrm{GramDet}(\mathbf{u}_1, \ldots, \mathbf{u}_n)$	Gram determinant
$P_{\mathbf{u}}$, $U_{\mathbf{w}}$	rank-one projection matrix / Householder matrix, with defining vector indicated by the subscript
$\gamma = (\mathbf{e}_1, \ldots, \mathbf{e}_n)$	ordered basis; orthonormal when declared in an inner-product context
$\mathbf{e} = (1, \ldots, 1)^t$	all-ones vector
$\mathrm{Ray}_A(\mathbf{x})$, $\mathbf{x}^* A\mathbf{x}$	Rayleigh quotient notation; for unit $\mathbf{x}$, $\mathrm{Ray}_A(\mathbf{x}) = \mathbf{x}^* A\mathbf{x}$ / Hermitian quadratic form
$\mathrm{Sym}(B)$, $\mathrm{Skew}(B)$, $\mathrm{Alt}(B)$	predicates that the bilinear form B is symmetric, skew-symmetric, or alternating
$\mathrm{rad}_L(B)$, $\mathrm{rad}_R(B)$	left / right radical of a declared bilinear pairing B
$S^{\perp_R}$, ${}^{\perp_L}T$	right / left orthogonal of a subset under a declared bilinear pairing
M_β, $\Delta(\mathcal{V})$, $\mathrm{rad}(\mathcal{V})$	matrix of a square bilinear form in basis β / discriminant set or square class / radical of a metric vector space
$\mathcal{V} = \mathcal{S} \odot \mathcal{T}$, $\mathcal{H}$, $w(\mathcal{V})$	orthogonal direct sum / hyperbolic space or plane in metric-vector-space contexts / Witt index; affine hyperplanes use $\mathcal{H}(\mathbf{N}, b)$
$\mathcal{O}(\mathcal{V})$, $\mathrm{Sp}(\mathcal{V})$, $\tau_{\mathbf{v},a}$, $\sigma_{\mathbf{u}}$	orthogonal group / symplectic group / symplectic transvection / orthogonal symmetry

Affine, Projective, and Convex Geometry

$\mathcal{A}(\mathcal{V})$, $\mathcal{A}_0(\mathcal{V})$, $\mathrm{Sub}(\mathcal{V})$	flats in $\mathcal{V}$ / $\mathcal{A}(\mathcal{V}) \cup \{\emptyset\}$ / subspaces of $\mathcal{V}$; $\mathcal{A}$ without arguments remains local
$\mathrm{affspan}(E)$, $\mathrm{affhull}(E)$	affine span / least flat containing E
$X \parallel Y$, $X \vee Y$	parallel flats / join of flats or projective subspaces; meet is intersection in the relevant lattice
$\mathbb{R}^n_+$, $\mathbb{R}^n_{++}$, $\mathbf{x} \geq \mathbf{0}$, $\mathbf{x} > \mathbf{0}$, $\mathbf{x} \gg \mathbf{0}$	nonzero nonnegative orthant / coordinatewise positive orthant / coordinatewise nonnegative, nonzero nonnegative, and coordinatewise positive inequalities
$\mathrm{conv}(S)$, Δ_{k-1}, C_A	convex hull / coefficient simplex $\{(t_i) : t_i \geq 0, \sum_i t_i = 1\}$ / nonnegative cone generated by the columns of A; distinct from cofactor and companion notation
$\mathcal{H}(\mathbf{N}, b)$, $\mathcal{H}_\pm(\mathbf{N}, b)$, $\langle \mathbf{N}, X\rangle < b$	affine hyperplane / closed half-spaces / setwise inequality, meaning $\langle \mathbf{N}, \mathbf{x}\rangle < b$ for all $\mathbf{x} \in X$

Spectral and Polynomial Structure

$E_\lambda(T)$, $\mathrm{spec}(T)$	eigenspace $\ker(T - \lambda I_{\mathcal{V}})$ / spectrum
$\mathrm{Inv}(T)$	lattice or set of T-invariant subspaces
$\lambda_i(A)$, $m_A(\lambda)$	eigenvalues in the locally declared order / algebraic multiplicity of λ as a root of p_A; distinct from measure notation $m(E)$
$\mathcal{G}_\lambda(T)$, $J_k(\lambda)$	generalized eigenspace for λ / Jordan block of size k and eigenvalue λ
p_A, q_T, χ_T	matrix characteristic polynomial / operator characteristic polynomial / characteristic polynomial determined by elementary divisors
μ_A, μ_T, $w_p(\lambda, A)$	minimal polynomial of a matrix or operator / Weyr count of λ-Jordan blocks of size at least p; distinct from measure notation $\mu(E)$
P_j, $T = \sum_j \mu_j P_j$	spectral projections / spectral decomposition with distinct eigenvalues μ_j
$\sqrt{T}$, $A^{1/2}$, $\rho(A)$	positive square root of a positive operator or matrix / spectral radius of A; distinct from the interval parameter in K_ρ
$\mathbb{F}[z]$	polynomials in z over $\mathbb{F}$
$\mathscr{P} = \mathbb{C}[x]$, $\mathscr{P}'$, $\mathscr{F} = \mathbb{C}[[t]]$	umbral polynomial algebra / algebraic dual / formal power-series algebra; script notation distinguishes these from $\mathcal{P}(X)$ and local families $\mathcal{F}$
$\mathcal{V}_T$, $\mathcal{C}_T(\mathbf{v})$, $\mathrm{ann}_T(\mathbf{v})$	$\mathbb{F}[z]$-module induced by T / T-cyclic subspace generated by $\mathbf{v}$ / annihilator ideal of $\mathbf{v}$
$m_{\mathbf{v}}$, C_f, $\mathrm{InvFact}(T)$, $\mathrm{ElemDiv}(T)$	order polynomial of $\mathbf{v}$ under T / companion matrix of f / invariant factors / elementary divisors
e^{tA}	matrix exponential $\sum_{k\geq 0} (tA)^k/k!$

Matrix Analysis and Numerical Structure

$A \succeq 0,\ A \succ 0$	Hermitian positive semidefinite / Hermitian positive definite
$\mathrm{in}(A),\ n_+(A), n_-(A), n_0(A)$	inertia of a Hermitian matrix / positive, negative, and zero eigenvalue counts
$A = QR,\ A = LL^*,\ A = LDL^t$	QR factorization / Cholesky factorization / symmetric or Hermitian LDL^t factorization
$A = V\Sigma W^*,\ A = X\Sigma_r Y^*$	singular value decomposition / compact SVD with rank r
$\sigma_j(A),\ \sigma_{\max}(A),\ \sigma_{\min}(A)$	singular values and extreme singular values
$\lvert T\rvert,\ \lvert A\rvert,\ \mathrm{vol}(\Omega)$	operator or matrix modulus / volume of a set; scalar absolute value remains $\lvert x\rvert$
$A^\dagger,\ A_k$	Moore–Penrose pseudoinverse / rank-k truncated SVD approximation in an SVD context
$\kappa_2(A),\ \Delta A,\ \Delta\mathbf{x}$	spectral condition number of an invertible matrix / matrix and solution perturbations
$\Delta(A)$	defect from normality; distinct from perturbation notation ΔA
$R_k(A),\ R_k^{\mathrm{off}}(A),\ R_{\max}(A)$	absolute row sum $\sum_j \lvert a_{kj}\rvert$ / deleted row sum $\sum_{j\neq k} \lvert a_{kj}\rvert$ / maximum absolute row sum
$\mathrm{Ger}_k(A),\ \mathrm{Ger}(A)$	kth Gersgorin disk / union of all Gersgorin disks
$\mathrm{tridiag}(a, b, c)$	tridiagonal matrix with subdiagonal a, diagonal b, and superdiagonal c
$w,\ F_n,\ Q_n,\ \omega_n$	half-bandwidth / unnormalised Fourier matrix / normalised Fourier matrix / primitive nth root used for the DFT
$\mathcal{K}_m(A, \mathbf{b})$	Krylov subspace $\mathrm{span}(\mathbf{b}, A\mathbf{b}, \ldots, A^{m-1}\mathbf{b})$
$Q_m,\ H_m$	Krylov basis matrix / projected Hessenberg or tridiagonal matrix
$A = S - T,\ B = S^{-1}T,\ \mathbf{e}_k$	matrix splitting / stationary iteration matrix / kth error vector
$A = D + L + U,\ B_J,\ B_{\mathrm{GS}}$	diagonal, lower, and upper splitting / Jacobi and Gauss–Seidel iteration matrices
$\omega,\ S_\omega,\ T_\omega,\ B_\omega$	SOR parameter / SOR splitting matrices / SOR iteration matrix; distinct from the differential form ω
$M,\ M^{-1}A,\ AM^{-1}$	preconditioner / left and right preconditioned matrices

Algebraic Structures Notation

Algebraic Language and Categories

$\mathcal{C},\ A \xrightarrow{f} B,\ \mathrm{id}_A$	ambient category / morphism $f : A \to B$ / identity morphism of A; $\mathcal{C}$ remains local unless declared
$\mathrm{Hom}_{\mathcal{C}}(A, B),\ g \circ f$	set of morphisms $A \to B$ in $\mathcal{C}$ / composition for compatible morphisms
$A \simeq B,\ F : \mathcal{C} \to \mathcal{D}$	isomorphic objects / functor with domain $\mathcal{C}$ and codomain $\mathcal{D}$

Groups, Actions, Rings, and Ideals

$G, H, K,\ e_G,\ \langle S\rangle$	groups or subgroups / identity element of G / substructure generated by S in the ambient algebraic category
$H \leq G,\ H \trianglelefteq G,\ G/H,\ [G : H]$	subgroup / normal subgroup / quotient group / subgroup index
$\mathrm{ord}(g),\ \mathrm{Aut}(G)$	order of an element / automorphism group
$R, S,\ 0_R,\ 1_R,\ R^\times$	rings / zero and identity elements of R / unit group of R
$Z(R),\ \mathrm{char}(R)$	center of R / characteristic of R
$I, J,\ \mathfrak{a}, \mathfrak{p},\ R/I$	ideals; fraktur letters denote distinguished ideals, such as prime ideals, when declared / quotient ring
$R[x],\ \mathbb{F}[z],\ \deg f$	polynomial rings in the displayed indeterminate / degree of a polynomial
$U_n,\ \Omega_n,\ \Phi_n(x),\ \varphi(n)$	complex nth roots of unity / primitive nth roots / nth cyclotomic polynomial / Euler totient; Ω_n is algebraic root notation, distinct from domain notation

Modules and Associative Algebras

$M, N,\ S \leq M,\ M/N$	modules / submodule S of M / quotient module
$\langle\langle S\rangle\rangle_R$	submodule generated by S over R; double brackets distinguish module generation from group and ideal generation
$\mathrm{Hom}_R(M, N),\ \mathrm{End}_R(M)$	set of R-module homomorphisms $M \to N$ / endomorphism ring of M
$\ker\tau,\ \mathrm{im}\,\tau,\ \overline{\tau}$	kernel / image / quotient-induced map $M/\ker\tau \to \mathrm{im}\,\tau$ for a homomorphism $\tau : M \to N$
$\bigoplus_i M_i,\ M = N \oplus H$	external direct sum of modules / internal direct-sum decomposition
$\mathcal{C}_S(N),\ \mathcal{L}_\sigma,\ \mathcal{R}_\sigma$	set $\{H \leq N : N = S \oplus H\}$ of complements / left inverses of σ / right inverses of σ; subscript distinguishes these from $\mathcal{L}$ and $\mathcal{L}^n$
$\mathcal{F}(\mathcal{V})$	finite-rank operators $\{T \in \mathcal{L}(\mathcal{V}) : \dim\mathrm{im}\,T < \infty\}$ in associative-algebra contexts; distinct from local function-family notation

Algebraic Geometry and Commutative Algebra Notation

Status. This part of the notes is still mostly scaffolded. The entries below reserve the notation promised by the section headings and keep it distinct from already-active algebra and analysis notation.

Commutative Algebra

$\mathrm{Spec}\,R,\ \mathfrak{p} \in \mathrm{Spec}\,R$	set of prime ideals of a commutative ring R / prime ideal $\mathfrak{p} \subseteq R$
$D(f),\ V(I)$	standard open set $\{\mathfrak{p} \in \mathrm{Spec}\,R : f \notin \mathfrak{p}\}$ / Zariski closed set $\{\mathfrak{p} : I \subseteq \mathfrak{p}\}$
$S^{-1}R,\ R_{\mathfrak{p}},\ k(\mathfrak{p})$	localization at a multiplicative set S / localization $(R\setminus\mathfrak{p})^{-1}R$ / residue field $R_{\mathfrak{p}}/\mathfrak{p}R_{\mathfrak{p}}$
$\mathrm{rad}(I),\ \sqrt{I}$	radical ideal $\{r \in R : r^n \in I \text{ for some } n \geq 1\}$; use $\mathrm{rad}(\mathcal{V})$ for metric-vector-space radicals

Affine and Projective Geometry

$\mathbb{A}^n_k,\ \mathbb{P}^n_k$	affine n-space over a field k / projective n-space over k; geometric notation distinct from probability notation
$I(X),\ Z(I),\ k[X]$	vanishing ideal $\{f \in k[x_1,\dots,x_n] : f\vert_X = 0\}$ / zero locus of an ideal / coordinate ring, typically $k[x_1,\dots,x_n]/I(X)$
$f^{\#},\ \varphi^*$	coordinate-ring pullback, e.g. $f^{\#} : k[Y] \to k[X]$ for $f : X \to Y$; distinct from adjoints and differential-form pullbacks by context

Analysis and Continuous Structure Notation

Sets and Functions in Analysis

$\mathcal{P}(X)$	power set $\{A : A \subseteq X\}$; projection symbols use $P_{\mathcal{U}}$ or P_j
$J_n,\ \#E,\ A \sim_{\#} B$	finite initial segment $J_0 = \emptyset$, $J_n = \{1,\dots,n\}$ / cardinality of a finite set / existence of a bijection $A \to B$

Order and Completeness

$\vert x\vert,\ \vert a-b\vert$	real absolute value or complex modulus / usual real-line distance $d(a,b) = \vert a-b\vert$
$\overline{\mathbb{R}}$	extended real line $\mathbb{R} \cup \{-\infty,+\infty\}$ ordered by $-\infty < x < +\infty$ for $x \in \mathbb{R}$; the bar is conventional, not topological closure
$x < y,\ x \le y$	strict order / non-strict order in the ambient ordered set

Sequences and Series

$(a_n),\ a_n \to a$	sequence indexed by $n \in \mathbb{N}$ / convergence of the sequence to a
$(a_{n_k}),\ n_1 < n_2 < \cdots$	subsequence indexed by a strictly increasing sequence (n_k) of positive integers
$s_n = \sum_{k=1}^{n} a_k$	partial-sum sequence associated to $\sum a_k$
$\limsup a_n = s^*,\ \liminf a_n = s_*$	upper and lower limits in $\overline{\mathbb{R}}$, equivalently $\inf_N \sup_{n\ge N} a_n$ and $\sup_N \inf_{n\ge N} a_n$ for real sequences
$\sum_{n=1}^{\infty} a_n,\ \prod_{n=1}^{\infty} a_n$	limit of partial sums / limit of finite partial products when defined

Metric and Topological Notation

$d(x,y),\ B_r(x)$	metric distance / open ball $\{y : d(x,y) < r\}$
τ_d	metric topology induced by the metric d
$B_\varepsilon(a) = V_\varepsilon(a)$	real-line open ball $(a-\varepsilon, a+\varepsilon)$; $V_\varepsilon(a)$ is Abbott's notation
$\overline{B}_r(x),\ \{G_\alpha\}_{\alpha\in A}$	closed ball $\{y : d(x,y) \le r\}$ / indexed open cover
$d_E,\ d_{\max},\ d_{\text{sum}}$	Euclidean, maximum, and sum product metrics on a product space
$E^\circ,\ \overline{E},\ E^{\text{acc}}$	interior / topological closure / set of limit points of E
$\text{bd}(E),\ E^c$	boundary $\overline{E} \setminus E^\circ$ / complement in the ambient space
$\text{diam}\, E$	diameter $\sup\{d(p,q) : p,q \in E\}$ of a nonempty metric set
$X \simeq Y$	homeomorphic topological spaces, i.e. related by a homeomorphism
$A \cap \overline{B} = \emptyset,\ \overline{A} \cap B = \emptyset$	definition of separated subsets A and B
$F_\sigma,\ G_\delta,$ meager/thin/first category	countable union of closed sets / countable intersection of open sets / subset of a countable union of nowhere-dense sets
residual/thick, generic	set containing a countable intersection of dense open sets / property whose truth set is residual

Functions, Differentiation, and Integration

$\lim_{x\to p} f(x),\ f(x+),\ f(x-)$	limit of f at p / right and left limits at x
$C(X),\ C([a,b]),\ C_b(X),\ \Vert f\Vert_\infty$	continuous functions on X and $[a,b]$ / bounded continuous functions / supremum norm
$f_n \to f,\ f_n \rightrightarrows f$	pointwise convergence / uniform convergence on the ambient domain
$f'(x),\ Df(a),\ D_j f_i,\ \partial_i f,\ J_f(x)$	one-variable derivative, total derivative at a, component partial $D_j f_i$, scalar partial, and Jacobian determinant; J_f is distinct from J_n and $J_k(\lambda)$
$\nabla f,\ D_{\mathbf{u}} f,\ C^r,\ C^\infty,\ C^\omega$	gradient, directional derivative, and classes C^r, C^∞, C^ω
$\Pi = \{x_0,\dots,x_n\},\ c_i,\ \Delta x_i,\ \Delta\alpha_i$	partition of $[a,b]$, tags $c_i \in [x_{i-1},x_i]$, and increments $\Delta x_i = x_i - x_{i-1}$, $\Delta\alpha_i = \alpha(x_i) - \alpha(x_{i-1})$
$R(f,\Pi,\{c_i\}),\ \delta,\ \delta(x)$	$R(f,\Pi,\{c_i\}) = \sum_{i=1}^n f(c_i)\Delta x_i$ / constant mesh bound / gauge; uppercase $R(\cdots)$ is local to Riemann sums
$U(\Pi,f,\alpha),\ L(\Pi,f,\alpha)$	Riemann–Stieltjes upper and lower sums with integrator α
$f \in \mathcal{R},\ f \in \mathcal{R}(\alpha)$	ordinary Riemann integrability / Riemann–Stieltjes integrability with respect to α
$\int_a^b f,\ \int_a^b f\,d\alpha,\ \int_E f\,d\mu$	ordinary Riemann integral / Riemann–Stieltjes integral / measure integral
$\int_a^\infty f,\ \int_{-\infty}^\infty f$	one-sided and two-sided improper integrals as limits over finite truncations
$\ell(\Pi,\gamma),\ \ell(\gamma)$	polygonal length of γ along Π / curve length
$I^k,\ Q^k,\ \text{supp}(f)$	k-cell, standard k-simplex, and topological support $\overline{\{x : f(x) \ne 0\}}$; I^k is not an identity operator
$dx_I,\ dx_I \wedge dx_J$	basic form indexed by I / wedge product of basic forms
$\omega,\ d\omega,\ T^*\omega,\ \partial_{\text{ch}}\Psi$	differential form, exterior derivative, pullback by T, and chain boundary
$\int_\Psi \omega,\ \partial_{\text{ch}}[\mathbf{p}_0,\dots,\mathbf{p}_k]$	integral of ω over the chain Ψ / oriented boundary $\sum_{j=0}^k (-1)^j[\mathbf{p}_0,\dots,\widehat{\mathbf{p}_j},\dots,\mathbf{p}_k]$
$dV,\ dA,\ ds$	volume, area, and arc-length elements

Power Series, Fourier, and Special Functions

$\sum_{n\geq 0} c_n(x-a)^n,\ R$	power series centered at a / radius of convergence in this context, distinct from $R(\cdots)$ and the R in QR
$I_R,\ K_\rho$	centered interval $I_R = (-R, R)$ / compact subinterval $K_\rho = [-\rho, \rho] \subset I_R$ for $0 < \rho < R$
$\widehat{f}(m),\ s_N(f;x),\ s_N(f)$	$\widehat{f}(m) = (2\pi)^{-1}\int_{-\pi}^{\pi} f(x)e^{-imx}\,dx$ / $s_N(f;x) = \sum_{\lvert m\rvert\leq N}\widehat{f}(m)e^{imx}$, viewed pointwise or as a function
$f \sim_{\text{coef}} \sum \widehat{f}(n)e^{inx},\ f \sim_{\text{coef}} \sum c_n\phi_n$	formal Fourier or orthonormal coefficient expansion; no convergence assertion is implied
$D_N(t)$	Dirichlet kernel $D_N(t) = \sum_{m=-N}^{N} e^{imt}$; uppercase D_N is not derivative notation
$\mathsf{E},\ \mathsf{L},\ \mathsf{C},\ \mathsf{S}$	power-series exponential, inverse logarithm, cosine, and sine
$\Gamma(x),\ \mathrm{B}(x,y)$	gamma function / beta function in roman type, distinct from balls $B_r(x)$ and variables B

Measure and Function Spaces

$E \in \mathcal{M},\ E \in \mathcal{M}(\mu)$	E measurable in the ambient σ-algebra / Rudin measurable set generated by μ
$\mathcal{B}(\mathbb{R}^n),\ \mathcal{L}^n$	Borel σ-algebra on $\mathbb{R}^n$ / Lebesgue measurable subsets of $\mathbb{R}^n$; not a basis $\mathcal{B}$, a linear-map space $\mathcal{L}$, or a least-squares set LS
$\mathcal{E},\ \mathcal{M}_F(\mu),\ A\triangle B,\ d_\mu(A,B)$	elementary sets, finitely μ-measurable sets, symmetric difference, and $d_\mu(A,B) = \mu^*(A\triangle B)$; $\mathcal{M}$ is measure-theoretic here
$\mu^*(E),\ m^*(E)$	μ-outer measure / Lebesgue outer measure
$\mathrm{vol}_n(B),\ m_n^*(\Omega)$	n-dimensional box volume / box-cover outer measure $\inf\{\sum_{j\in J}\mathrm{vol}_n(B_j) : (B_j)_{j\in J} \text{ covers } \Omega,\ J \text{ at most countable}\}$
$m(E),\ \mu(E)$	Lebesgue or elementary volume of E / measure of E; not algebraic multiplicity $m_A(\lambda)$ or minimal polynomial μ_A
$\lambda^+,\ \lambda^-,\ \lvert\lambda\rvert,\ \lambda \ll \mu,\ \lambda \perp \mu,\ \frac{d\lambda}{d\mu}$	positive variation, negative variation, total variation, absolute continuity, mutual singularity, and Radon–Nikodym derivative
$\bowtie,\ \{f \bowtie a\}$	relation in $\{>, \geq, <, \leq\}$ / level set $\{x : f(x) \bowtie a\}$
$f^+,\ f^-,\ \mathcal{S}^+(f),\ \mathcal{I}_E(s)$	$f^+ = \max(f, 0)$, $f^- = -\min(f, 0)$ / simple minorants of f / simple-function integral on E
$f \sim_{\text{a.e. }} g \text{ on } E,$ a.e.	$\mu(\{x \in E : f(x) \neq g(x)\}) = 0$ / outside a null set
$E_x,\ E^y,\ f_x,\ f^y$	product slices $E_x = \{y : (x,y) \in E\}$, $E^y = \{x : (x,y) \in E\}$, and $f_x(y) = f^y(x) = f(x,y)$
$\mathcal{U}f,\ F_a$	undergraph $\{(x,t) : 0 < t < f(x)\}$ for $f \geq 0$ / superlevel set $F_a = \{x : f(x) > a\}$; $\mathcal{U}f$ is not a vector subspace
$[f : A],\ [B : Q],\ \mathrm{dp}(E)$	$[f : A] = m(A)^{-1}\int_A f$ / $[B : Q] = m(B \cap Q)/m(Q)$ / density-point set of E
$\mathscr{L}^1(\mu),\ \mathscr{L}^1_{\text{loc}}(\mathbb{R}^n)$	measurable f with $\int \lvert f\rvert\,d\mu < +\infty$ / locally integrable functions; script $\mathscr{L}$ is distinct from $\mathcal{L}^n$ and $\mathcal{L}$
$L^p(\mu),\ L^p(E),\ \lVert f\rVert_p$	Lebesgue space modulo a.e. equality with respect to μ or the ambient measure on E / $\lVert f\rVert_p = (\int \lvert f\rvert^p\,d\mu)^{1/p}$

Probability and Stochastic Structure Notation

Probability Spaces and Distributions

$(\Omega, \mathcal{F}, \mathbb{P}),\ \Pr(A)$	probability space / event probability $\Pr(A) = \mathbb{P}(A)$ for $A \in \mathcal{F}$; explicit probability notation keeps $\mathbb{P}_k^n$ and $\mathbb{F}_0$ unambiguous
$X, Y,\ X_*\mathbb{P},\ \mathcal{L}(X)$	random variables / pushforward law $X_*\mathbb{P}(B) = \mathbb{P}(X^{-1}(B))$ / law of X when locally declared; not Lebesgue $\mathcal{L}^n$
$X \sim F,\ X \overset{\text{dist}}{=} Y,\ X_1, \ldots, X_n$ iid	X has distribution F / X and Y have the same distribution / independent and identically distributed sample
$F(t),\ g(t),\ \Phi(t)$	distribution function $F(t) = \Pr(X \leq t)$ / density g / standard normal distribution function in probabilistic contexts
$\mathbb{E}[X],\ \mathrm{Var}(X),\ \mathrm{Cov}(X,Y)$	expectation / $\mathrm{Var}(X) = \mathbb{E}[(X - \mathbb{E}X)^2]$ / $\mathrm{Cov}(X,Y) = \mathbb{E}[(X - \mathbb{E}X)(Y - \mathbb{E}Y)]$, when finite
$\mathrm{Corr}(X,Y),\ \rho,\ \sigma_{XY}$	correlation coefficient / local correlation parameter / covariance shorthand $\sigma_{XY} = \mathrm{Cov}(X,Y)$ when declared
$\psi_X(t)$	moment-generating function $\psi_X(t) = \mathbb{E}e^{tX}$ on its domain of finiteness
$X \perp\!\!\!\perp Y$	independence of random variables, equivalently independence of $\sigma(X)$ and $\sigma(Y)$ when defined
$X \perp\!\!\!\perp Y \mid Z$	conditional independence of X and Y given Z
$X_n \xrightarrow{\mathbb{P}} X,\ X_n \rightsquigarrow X,\ X_n \xrightarrow{L^p} X,\ X_n \xrightarrow{\text{a.s.}} X,\ X_n \xrightarrow{qm} X$	convergence in probability / convergence in distribution / convergence in L^p / almost-sure convergence / convergence in quadratic mean

Stochastic Processes and Markov Structure

$(X_t)_{t\in T},\ \mathcal{F}_t$	stochastic process indexed by T / filtration $(\mathcal{F}_t)$ when locally declared; this $\mathcal{F}_t$ is not the umbral algebra $\mathscr{F}$
$\mathbf{x},\ \mathbf{e},\ A\mathbf{e} = \mathbf{e}$	probability vector $\mathbf{x} \geq 0$, $\sum_i x_i = 1$ / all-ones vector $\mathbf{e} = (1, \ldots, 1)^t$ / row-stochastic Markov convention $A = [a_{ij}] \geq 0$, $A\mathbf{e} = \mathbf{e}$
$\pi,\ \pi A = \pi,\ A^p$	stationary distribution written as a row probability vector / stationarity equation / p-step Markov matrix
$P_t,\ p_t(x,y)$	transition semigroup / transition probability, kernel, or density from x to y, when introduced

Numerical and Computational Mathematics Notation

Status. Apart from numerical linear algebra, already covered under Linear and Operator Structures, the numerical and computational chapters remain placeholders. The entries below reserve notation only; they do not introduce PDE or machine-learning conventions.

Floating Point, Approximation, and Error

$\mathrm{fl}(x),\ u,\ \varepsilon_{\mathrm{mach}}$	floating-point rounded value, unit roundoff, and machine epsilon
$x_h,\ e_h,\ \mathcal{O}(h^p)$	approximation at discretization scale h, corresponding error, and Landau order as $h \to 0$
$\widehat{x},\ \Delta x,\ r = b - A\widehat{x}$	computed approximation, perturbation or error in x, and residual for $Ax = b$

Monte Carlo and Stochastic Computation

$X_1, \ldots, X_N,\ \widehat{\mu}_N$	samples / sample-mean estimator $\widehat{\mu}_N = N^{-1} \sum_{i=1}^{N} X_i$ when estimating $\mu = \mathbb{E}X$
$\mathrm{Var}(\widehat{\mu}_N),\ \mathrm{SE}(\widehat{\mu}_N)$	estimator variance / standard error $\mathrm{SE}(\widehat{\mu}_N) = \sqrt{\mathrm{Var}(\widehat{\mu}_N)}$
$w_i,\ \widehat{I}_N$	importance weights / Monte Carlo estimate of an integral or expectation, when locally introduced

Part I
Set Theory, Logic, and Foundations

Foundational prerequisites collect the logical, set-theoretic, functional, order-theoretic, cardinal, and research-practice language used throughout the notes.

1 Sets

Sets provide the membership language used throughout the notes: elements, subsets, products, power sets, operations, and indexed families.

1.1 Introduction to Sets

Definition 1.1.1. *Sets and Membership*
Sets and the membership relation are taken as primitive notions.

(i) *Membership*: Given an object x and a set E, the assertion $x \in E$ means that x is an element of E; its negation is written $x \notin E$.
(ii) *Empty set*: The symbol $\emptyset$ denotes a set satisfying $x \notin \emptyset$ for every object x.

Definition 1.1.2. *Set-Builder Notation*
For a set X and a condition $P(x)$ on its elements, $\{x \in X : P(x)\}$ denotes the set of all $x \in X$ satisfying $P(x)$.

1.2 Cartesian Products

Definition 1.2.1. *Ordered Pairs and Cartesian Products*
Coordinate order is part of both constructions.

(i) *Ordered pair*: For objects a, b, (a, b) has first coordinate a and second coordinate b.
(ii) *Equality*: For objects a, b, a', b', $(a, b) = (a', b')$ if and only if $a = a'$ and $b = b'$.
(iii) *Cartesian product*: For sets X and Y, $X \times Y := \{(x, y) : x \in X,\ y \in Y\}$.

For intervals A and B, the Cartesian product $A \times B$ has a rectangular geometric representation.

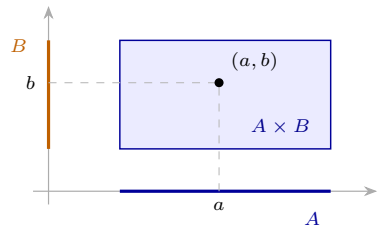

Figure 1: The product region $A \times B$ for horizontal interval A and vertical interval B.

Figure 1 illustrates Definition 1.2.1: $(a, b) \in A \times B$ precisely when $a \in A$ and $b \in B$, in that order.

1.3 Subsets and Power Sets

Definition 1.3.1. *Basic Subset Terminology*
Let A, B be sets.

(i) *Subset*: $A \subseteq B$ if and only if $x \in A$ implies $x \in B$ for every object x.
(ii) *Proper subset*: $A \subsetneq B$ iff $A \subseteq B$ and $A \neq B$.
(iii) *Singleton*: $A = \{x\}$ for some object x.
(iv) *Nonempty*: $A \neq \emptyset$.

Assumption 1.3.2. *Set Extensionality*
Throughout these notes, set equality is governed by extensionality.
For sets A and B, $A = B$ if and only if $A \subseteq B$ and $B \subseteq A$.

Proof Method 1.3.3. *Proof by Two Containments*
To prove equality of sets A and B, discharge the following obligations.

(i) Fix an arbitrary $x \in A$ and prove $x \in B$; this establishes $A \subseteq B$.
(ii) Fix an arbitrary $x \in B$ and prove $x \in A$; this establishes $B \subseteq A$.
(iii) Invoke Assumption 1.3.2 to conclude $A = B$.

If both sets have explicit membership criteria, the two inclusions may be proved together.
Fix an arbitrary object x and prove $x \in A \iff x \in B$.

Definition 1.3.4. *Power Set*
For a set X, its *power set* is $\mathcal{P}(X) := \{S : S \subseteq X\}$. The two smallest cases are as follows.

(i) The empty set has only itself as a subset, so $\mathcal{P}(\emptyset) = \{\emptyset\}$.
(ii) If $X = \{a, b\}$ with $a \neq b$, then $\mathcal{P}(X) = \{\emptyset, \{a\}, \{b\}, X\}$.

1.4 Union, Intersection, Difference, and Complement

Definition 1.4.1. *Elementary Set Operations*
Let X be a set and let $A, B \subseteq X$.

(i) *Union*: $A \cup B := \{x \in X : x \in A \text{ or } x \in B\}$.
(ii) *Intersection*: $A \cap B := \{x \in X : x \in A \text{ and } x \in B\}$.
(iii) *Difference*: $A \setminus B := \{x \in X : x \in A \text{ and } x \notin B\}$.
(iv) *Complement*: $A^c := X \setminus A$, relative to the ambient set X.

Definition 1.4.2. *Symmetric Difference*
Let X be a set and let $A, B \subseteq X$. The *symmetric difference* is $A \triangle B := (A \setminus B) \cup (B \setminus A)$.
It consists exactly of the elements belonging to one of A and B, but not both.

Proposition 1.4.3. *Basic Set Algebra*
Let X be a set and let $A, B, C \subseteq X$. Then

(i) $A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$;
(ii) $A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$;
(iii) $(A \cup B)^c = A^c \cap B^c$;
(iv) $(A \cap B)^c = A^c \cup B^c$;
(v) $A \triangle B = (A \cup B) \setminus (A \cap B)$.

Proof. Fix an arbitrary $x \in X$. By set extensionality, each identity follows once its two membership conditions are equivalent.

(i) Membership in $A \cap (B \cup C)$ means that $x \in A$ and that either $x \in B$ or $x \in C$. This holds exactly when either $x \in A \cap B$ or $x \in A \cap C$. Hence it is equivalent to membership in $(A \cap B) \cup (A \cap C)$.
(ii) Membership in $A \cup (B \cap C)$ means that $x \in A$, or that both $x \in B$ and $x \in C$. This holds exactly when two conditions are satisfied. First, $x \in A$ or $x \in B$; second, $x \in A$ or $x \in C$. Hence it is equivalent to membership in $(A \cup B) \cap (A \cup C)$.
(iii) The condition $x \in (A \cup B)^c$ is equivalent to $x \notin A \cup B$. This means that $x \notin A$ and $x \notin B$, or equivalently $x \in A^c \cap B^c$.
(iv) The condition $x \in (A \cap B)^c$ is equivalent to $x \notin A \cap B$. This means that $x \notin A$ or $x \notin B$, or equivalently $x \in A^c \cup B^c$.
(v) The condition $x \in A \triangle B$ is equivalent to $x \in A \setminus B$ or $x \in B \setminus A$. Thus x belongs to one of A and B, but not both. Equivalently, $x \in A \cup B$ and $x \notin A \cap B$. By the definition of difference, this is equivalent to $x \in (A \cup B) \setminus (A \cap B)$.

Structural Commentary: Each identity reduces to an equivalence of membership conditions.
Key Insight: Membership turns set operations into logical connectives. □

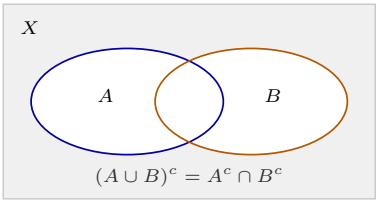

Figure 2: The shaded region represents $(A \cup B)^c = A^c \cap B^c$ inside the ambient set X.

Figure 2 illustrates part (iii). The shaded region lies outside both A and B, so it is outside $A \cup B$.

1.5 Indexed Families and Products

Definition 1.5.1. *Families, Indexed Families, Unions, and Intersections*
Let X be a set and let I be an index set.

(i) *Family*: A set whose members are sets, also called a *collection* of sets.
(ii) *Indexed family*: An assignment $i \mapsto A_i$ over I, written $(A_i)_{i \in I}$ or $\{A_i\}_{i \in I}$. It is an indexed family in X iff $(\forall i \in I)\, A_i \subseteq X$.
(iii) *Indexed union*: For an indexed family $\{A_i\}_{i \in I}$ in X, $\bigcup_{i \in I} A_i := \{x \in X : (\exists i \in I)\, x \in A_i\}$.
(iv) *Indexed intersection*: For an indexed family $\{A_i\}_{i \in I}$ in X, $\bigcap_{i \in I} A_i := \{x \in X : (\forall i \in I)\, x \in A_i\}$.

Theorem 1.5.2. *Arbitrary De Morgan Laws*
Let X and I be sets, and let $\{E_i\}_{i \in I}$ be an indexed family in X. Take all complements relative to X.

(i) $\left(\bigcup_{i \in I} E_i\right)^c = \bigcap_{i \in I} E_i^c$.
(ii) $\left(\bigcap_{i \in I} E_i\right)^c = \bigcup_{i \in I} E_i^c$.

Proof. Fix an arbitrary $x \in X$. Extensionality reduces both identities to pointwise membership equivalences.

(i) $x \in \left(\bigcup_{i \in I} E_i\right)^c \iff (\forall i \in I)\, x \notin E_i \iff (\forall i \in I)\, x \in E_i^c \iff x \in \bigcap_{i \in I} E_i^c$.
(ii) $x \in \left(\bigcap_{i \in I} E_i\right)^c \iff (\exists i \in I)\, x \notin E_i \iff (\exists i \in I)\, x \in E_i^c \iff x \in \bigcup_{i \in I} E_i^c$.

Structural Commentary: The proof checks both identities pointwise and applies quantifier negation.
Key Insight: Complement exchanges existential and universal membership conditions. □

Definition 1.5.3. *Disjoint Families and Parametrizations*
Let I be an index set and let $\mathcal{F}$ be a family of sets. Let $\{A_i\}_{i\in I}$ be an indexed family of sets.

(i) *Pairwise disjoint*: $(\forall E, G \in \mathcal{F})\,(E \neq G \implies E \cap G = \emptyset)$.
(ii) *Parametrization*: $\{A_i\}_{i\in I}$ parametrizes $\mathcal{F}$ iff $\mathcal{F} = \{A_i : i \in I\}$.

Definition 1.5.4. *Cartesian Product of an Indexed Family*
Let I be an index set and let $\{E_i\}_{i\in I}$ be an indexed family of sets.

(i) *Product*: $\prod_{i\in I} E_i := \{(x_i)_{i\in I} : (\forall i \in I)\, x_i \in E_i\}$.
(ii) *Binary case*: If $I = \{1, 2\}$, identify $(x_i)_{i\in I}$ with the ordered pair (x_1, x_2). Under this identification, $\prod_{i\in I} E_i = E_1 \times E_2$.
(iii) *Constant family*: If E is a set and $(\forall i \in I)\, E_i = E$, write $E^I := \prod_{i\in I} E_i$. Thus E^I is the set of I-indexed families in E.
(iv) *Dependence*: Different parametrizations of the same family can yield different products.

1.6 Russell's Paradox and Axioms

Theorem 1.6.1. *Russell's Paradox*
For a condition $P(x)$ on sets, unrestricted comprehension asserts $(\exists R)(\forall x)\,[x \in R \iff P(x)]$.

(i) No set R satisfies $(\forall x)\,[x \in R \iff x \notin x]$.
(ii) The unrestricted comprehension schema is inconsistent.

Proof.

(i) Suppose that such a set R exists. Setting $x = R$ gives $R \in R \iff R \notin R$. If $R \in R$, then $R \notin R$; if $R \notin R$, then $R \in R$. Both cases are contradictory, so no such set exists.
(ii) Take $P(x) := x \notin x$. The corresponding instance asserts $(\exists R)(\forall x)\,[x \in R \iff x \notin x]$. This contradicts (i), proving (ii).

Structural Commentary: Specialize at $x = R$, then apply the matching comprehension instance.
Key Insight: Self-membership makes the defining condition assert its own negation. □

Perspective 1.6.2. *From Comprehension to Axioms*
The obstruction in Theorem 1.6.1 explains the need for controlled set formation.
Separation forms $\{x \in B : P(x)\}$ only after a bounding set B is available. The standard ZFC axioms have the following informal roles.

(i) *Extensionality* makes membership determine set equality.
(ii) *Separation* extracts a condition-defined subset from an existing bounding set.
(iii) *Pairing* supplies $\{a, b\}$ from given sets a and b, including $\{a\}$ when $a = b$.
(iv) *Union* collects into one set the elements of the members of a given set.
(v) *Power set* supplies $\mathcal{P}(A)$, the set of all subsets of a given set A.
(vi) *Infinity* supplies an inductive set from which the natural numbers are constructed.
(vii) *Replacement* forms the image of a set under a definable functional relation.
(viii) *Foundation* requires nonempty sets to contain an $\in$-minimal member.
(ix) *Choice* supplies a choice function on a set-indexed family of nonempty sets.

This perspective is a functional map, not a formal axiom list or a source of proof authority.
Formal statements and dependencies belong to the advanced set-theory section.

2 Logic and Proofs

Logic makes explicit the statement grammar already used informally in the elementary set development and fixes it for the definitions, theorems, and proofs that follow.

2.1 Statements and Well-Formed Language

Definition 2.1.1. *Mathematical Statements and Truth Values*
The *truth values* used here are *true* and *false*.
A *mathematical statement* is a declarative sentence having exactly one truth value.

Principle 2.1.2. *Well-Formed Statements*
A mathematical expression may serve as a statement only when all the following conditions hold.

(i) *Symbols*: All symbols have declared syntactic roles.
(ii) *Meaning*: All constituent expressions have defined meanings.
(iii) *Scope*: All variable occurrences have unambiguous scope.

Failure of any condition makes the expression ill formed rather than false; no truth value is assigned.

2.2 Connectives and Negation

Definition 2.2.1. *Truth-Functional Connectives*
A connective is *truth functional* when its output depends only on input truth values. Let a and b be mathematical statements.

(i) *Negation*: $\neg a$ is true iff a is false.
(ii) *Conjunction*: $a \wedge b$ is true iff both a and b are true.
(iii) *Disjunction*: $a \vee b$ is true iff at least one of a and b is true; both may be true.
(iv) *Implication*: $a \Rightarrow b$ is false iff a is true and b is false. It is true in the remaining cases.
(v) *Equivalence*: $a \iff b$ is true iff a and b have the same truth value.

Proposition 2.2.2. *Negating Truth-Functional Connectives*
For mathematical statements a and b, the following equivalences hold.

(i) $\neg(a \wedge b) \iff (\neg a \vee \neg b)$.

(ii) $\neg(a \vee b) \iff (\neg a \wedge \neg b)$.
(iii) $\neg(a \Rightarrow b) \iff (a \wedge \neg b)$.

Proof. By Definition 2.2.1, the three equivalences reduce to the following truth conditions.

(i) The statement $\neg(a \wedge b)$ is true iff $a \wedge b$ is false. This occurs iff at least one of a and b is false, precisely when $\neg a \vee \neg b$ is true.
(ii) The statement $\neg(a \vee b)$ is true iff $a \vee b$ is false. This occurs iff both a and b are false, precisely when $\neg a \wedge \neg b$ is true.
(iii) The statement $\neg(a \Rightarrow b)$ is true iff $a \Rightarrow b$ is false. This occurs iff a is true and b is false, precisely when $a \wedge \neg b$ is true.

Thus each pair has the same truth value, proving all three equivalences.
Structural Commentary: Each item reduces both sides to one constituent truth-value condition.
Key Insight: Negation selects the cases excluded by the original connective. □

2.3 Quantifiers and Bound Variables

Definition 2.3.1. *Quantifiers, Bound Variables, and Scope*
Let X be a set and let $P(x)$ be a condition on its elements.

(i) *Universal quantifier*: $(\forall x \in X)\, P(x)$ means $\{x \in X : \neg P(x)\} = \emptyset$.
(ii) *Existential quantifier*: $(\exists x \in X)\, P(x)$ means $\{x \in X : P(x)\} \neq \emptyset$.
(iii) *Binding and scope*: A binding declaration governs a region, called the variable's *scope*.
(iv) *Bound occurrence*: An occurrence governed by a binding declaration is *bound*.
(v) *Free occurrence*: An occurrence outside every binding declaration is *free*.
(vi) *Standard binders*: Quantifiers, summation signs, integrals, and set-builder notation bind variables.
(vii) *Renaming*: A bound variable may be renamed consistently within its scope to a fresh symbol.
The statement remains unchanged provided no free occurrence is captured.

Proposition 2.3.2. *Quantifier Order Can Change Truth Value*
There exist sets X, Y and a condition $P(x, y)$ on $X \times Y$ such that

(i) $(\forall x \in X)(\exists y \in Y)\, P(x, y)$ *is true;*
(ii) $(\exists y \in Y)(\forall x \in X)\, P(x, y)$ *is false.*

Consequently, the two quantifier orders are not logically equivalent.

Proof. Take $X = Y = \{0, 1\}$ and let $P(x, y)$ be the condition $x = y$.

(i) The choice $y = x$ verifies $(\forall x \in X)(\exists y \in Y)\, P(x, y)$.
(ii) If $(\exists y \in Y)(\forall x \in X)\, P(x, y)$ were true, choose its witness $y \in Y$. Then $P(0, y) \wedge P(1, y)$, so $y = 0$ and $y = 1$, contradicting $0 \neq 1$.

Thus (i) and (ii) hold, so the quantifier orders are not logically equivalent.
Structural Commentary: The proof separates the orders using equality on a two-point set.
Key Insight: Pointwise witnesses exist, but no single witness works uniformly. □

Remark 2.3.3. *Index Variables*
Let X and I be sets, and let $\{A_i\}_{i \in I}$ be an indexed family in X. For $x \in X$, $x \in \bigcup_{i \in I} A_i \iff (\exists i \in I)\, x \in A_i$.
Likewise, $x \in \bigcap_{i \in I} A_i \iff (\forall i \in I)\, x \in A_i$. The indexed operator binds i in both formulas.
The index may be renamed consistently to any fresh symbol without changing either formula.

2.4 Proof Grammar

Proof Method 2.4.1. *Proof Grammar*
Given a mathematical claim, expose its proof obligations before selecting a proof rule.

(i) *Objects*: Identify the ambient sets or structures and declare the role of each symbol.
(ii) *Logical form*: Separate the hypotheses from the exact conclusion.
(iii) *Quantifiers*: Record the quantifiers in order. Note the permitted dependence of witnesses.
By Proposition 2.3.2, quantifier order can change a statement's truth value.
(iv) *Well-formedness*: Verify that every expression has a defined meaning.
Check that every variable occurrence has unambiguous scope. Principle 2.1.2 records this requirement.

A completed parse specifies the data, hypotheses, quantifier dependencies, and exact conclusion.
An undefined expression is ill formed rather than false and must be repaired before a proof begins.

2.5 Proof by Contradiction

Definition 2.5.1. *Contradiction*
A *contradiction* is a mathematical statement whose truth conditions cannot be satisfied.
For a mathematical statement c, the expression $c \wedge \neg c$ is the canonical contradiction form.
By Definition 2.2.1, its two conjuncts cannot be true simultaneously.

Proof Method 2.5.2. *Proof by Contradiction*
Let a and b be mathematical statements. To prove $a \Rightarrow b$ by classical contradiction, discharge the following obligations.

(i) *Temporary assumption*: Assume $\neg(a \Rightarrow b)$. By Proposition 2.2.2, this is equivalent to assuming $a \wedge \neg b$.
(ii) *Contradiction*: Identify a mathematical statement c. Derive both c and $\neg c$ from the hypotheses and temporary assumption.
(iii) *Conclusion*: Since the temporary assumption yields a contradiction, reject it and conclude $a \Rightarrow b$.

Justify each inference by the hypotheses, definitions, earlier results, or temporary assumption.

2.6 Mathematical Induction and Well-Ordering

Assumption 2.6.1. *Well-Ordering of* $\mathbb{N}$
Throughout these notes, $(\forall S \subseteq \mathbb{N})\,[S \neq \emptyset \Rightarrow (\exists m \in S)(\forall n \in S)\, m \leq n]$.

Theorem 2.6.2. *Mathematical Induction*
Let $(P_n)_{n\in\mathbb{N}}$ be mathematical statements. Suppose the following conditions hold.

(i) Basis: P_1 is true.
(ii) Induction step: $(\forall n \in \mathbb{N})\,(P_n \Rightarrow P_{n+1})$.

Then $(\forall n \in \mathbb{N})\, P_n$.

Proof. Let $F := \{n \in \mathbb{N} : \neg P_n\}$ and suppose $F \neq \emptyset$. By the standing well-ordering assumption, choose the least $m \in F$.
By (i), $1 \notin F$, so $m \neq 1$. Hence $m-1 \in \mathbb{N}$ and $m-1 < m$. Minimality gives $m-1 \notin F$, so P_{m-1} is true.
Applying (ii) at $n = m-1$ gives P_m, contradicting $m \in F$. Thus $F = \emptyset$, so $(\forall n \in \mathbb{N})\, P_n$.
Structural Commentary: Well-ordering supports a least-counterexample contradiction.
Key Insight: A least failure has a smaller successful predecessor. □

3 Functions

Functions assign unique outputs; their images, preimages, restrictions, compositions, and inverses organize nearly every later construction.

3.1 Functions, Images, and Preimages

Definition 3.1.1. *Functions, Images, and Preimages*
Let X, Y be sets. A *function* $f : X \to Y$ assigns a unique value $f(x) \in Y$ to each $x \in X$.

(i) $X = \mathrm{dom}(f)$ is the *domain*, and Y is the *codomain*.
(ii) $\mathrm{range}(f) := f(X) := \{f(x) : x \in X\}$ is the *range* of f.
(iii) If $A \subseteq X$, then $f(A) := \{f(x) : x \in A\}$ is the *image* of A.
(iv) If $B \subseteq Y$, then $f^{-1}(B) := \{x \in X : f(x) \in B\}$ is the *preimage* of B; no inverse function is required.

Assumption 3.1.2. *Function Extensionality*
Let X, Y be sets and let $f, g : X \to Y$. If $(\forall x \in X)\, f(x) = g(x)$, then $f = g$.

Proposition 3.1.3. *Image and Preimage Calculus*
Let X, Y, I be sets with $I \neq \emptyset$, and let $f : X \to Y$. Let $\{A_i\}_{i\in I}$ and $\{B_i\}_{i\in I}$ be indexed families in X and Y, respectively.

(i) $f\left(\bigcup_{i\in I} A_i\right) = \bigcup_{i\in I} f(A_i)$.
(ii) $f\left(\bigcap_{i\in I} A_i\right) \subseteq \bigcap_{i\in I} f(A_i)$.
(iii) $f^{-1}\left(\bigcup_{i\in I} B_i\right) = \bigcup_{i\in I} f^{-1}(B_i)$.
(iv) $f^{-1}\left(\bigcap_{i\in I} B_i\right) = \bigcap_{i\in I} f^{-1}(B_i)$.
(v) $(\forall B \subseteq Y)\, f^{-1}(Y \setminus B) = X \setminus f^{-1}(B)$.
(vi) $(\forall B, C \subseteq Y)\, f^{-1}(B \setminus C) = f^{-1}(B) \setminus f^{-1}(C)$.
(vii) $(\forall B \subseteq Y)\, f(f^{-1}(B)) = B \cap \mathrm{range}(f)$.
(viii) $(\forall A \subseteq X)(\forall B \subseteq Y)\, [f(A) \subseteq B \iff A \subseteq f^{-1}(B)]$.

Proof.

(i) Fix $y \in Y$. Then $y \in f\left(\bigcup_{i\in I} A_i\right) \iff (\exists i \in I)(\exists x \in A_i)\, y = f(x)$. This is equivalent to $y \in \bigcup_{i\in I} f(A_i)$.

(ii) If $y \in f\left(\bigcap_{i\in I} A_i\right)$, choose $x \in \bigcap_{i\in I} A_i$ with $y = f(x)$. Then $(\forall i \in I)\, x \in A_i$, so $(\forall i \in I)\, y \in f(A_i)$ and $y \in \bigcap_{i\in I} f(A_i)$.

(iii) Fix $x \in X$. Then $x \in f^{-1}\left(\bigcup_{i\in I} B_i\right) \iff (\exists i \in I)\, f(x) \in B_i$. This is equivalent to $(\exists i \in I)\, x \in f^{-1}(B_i)$, hence to $x \in \bigcup_{i\in I} f^{-1}(B_i)$.

(iv) Fix $x \in X$. Then $x \in f^{-1}\left(\bigcap_{i\in I} B_i\right) \iff (\forall i \in I)\, f(x) \in B_i$. This is equivalent to $(\forall i \in I)\, x \in f^{-1}(B_i)$, hence to $x \in \bigcap_{i\in I} f^{-1}(B_i)$.

(v) Fix $B \subseteq Y$ and $x \in X$. Then $x \in f^{-1}(Y \setminus B) \iff f(x) \notin B \iff x \notin f^{-1}(B) \iff x \in X \setminus f^{-1}(B)$.

(vi) Fix $B, C \subseteq Y$ and $x \in X$. Then $x \in f^{-1}(B \setminus C) \iff [f(x) \in B \wedge f(x) \notin C]$. This is equivalent to $x \in f^{-1}(B) \setminus f^{-1}(C)$.

(vii) Fix $B \subseteq Y$ and $y \in Y$. Then $y \in f(f^{-1}(B)) \iff (\exists x \in X)\, [f(x) \in B \wedge y = f(x)]$. This is equivalent to $y \in B \cap \mathrm{range}(f)$.

(viii) ($\Rightarrow$) Fix $A \subseteq X$ and $B \subseteq Y$. Suppose $f(A) \subseteq B$ and fix $x \in A$. Then $f(x) \in B$, so $x \in f^{-1}(B)$; hence $A \subseteq f^{-1}(B)$.

(viii) ($\Leftarrow$) Fix $A \subseteq X$ and $B \subseteq Y$. Suppose $A \subseteq f^{-1}(B)$ and fix $y \in f(A)$. Choose $x \in A$ with $y = f(x)$.
Then $x \in f^{-1}(B)$, so $y = f(x) \in B$ and $f(A) \subseteq B$.

Structural Commentary: Membership chains prove the identities; direct containments prove the adjunction.
Key Insight: Preimages translate codomain membership into domain membership. □

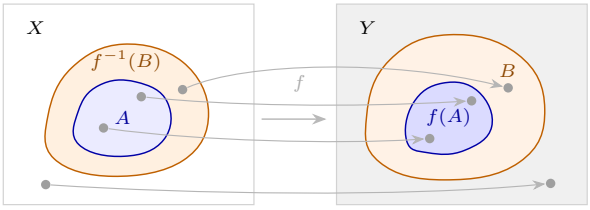

Figure 3: Image–preimage adjunction: $f(A) \subseteq B \iff A \subseteq f^{-1}(B)$.

Figure 3 illustrates Proposition 3.1.3(viii). The labeled regions show that $f(A) \subseteq B$ exactly when $A \subseteq f^{-1}(B)$.

Definition 3.1.4. *Algebraic Support of a Function*
Let $f : X \to Y$ and let $0 \in Y$ be distinguished. The *algebraic support* of f is $\operatorname{supp}(f) := \{x \in X : f(x) \neq 0\}$.

3.2 Injective, Surjective, and Bijective Maps

Definition 3.2.1. *Injective, Surjective, and Bijective Maps*
Let X, Y be sets and let $f : X \to Y$.

(i) *Injective*: $(\forall x_1, x_2 \in X)\,[f(x_1) = f(x_2) \implies x_1 = x_2]$.
(ii) *Surjective*: $\operatorname{range}(f) = Y$.
(iii) *Bijective*: f is both injective and surjective.

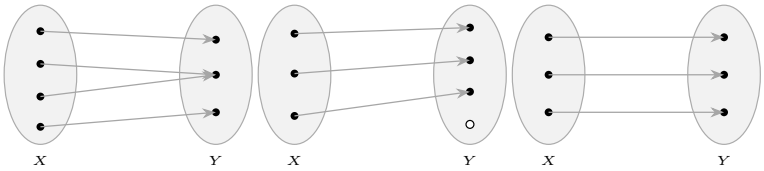

Figure 4: Left: surjective with a collision; center: injective but not surjective; right: bijective.

Figure 4 contrasts the three conditions in Definition 3.2.1. The left map is surjective but not injective, whereas the center map is injective but not surjective. The right map is bijective.

Example 3.2.2. *Image and Preimage for the Square Map*
Define $f : \mathbb{R} \to \mathbb{R}$ by $f(x) := x^2$. If $x \in [-2, 1]$, then $0 \leq f(x) \leq 4$. Conversely, if $y \in [0, 4]$, then $-\sqrt{y} \in [-2, 1]$ and $f(-\sqrt{y}) = y$.
Hence $f([-2, 1]) = [0, 4]$. For $x \in \mathbb{R}$, $x \in f^{-1}([1, 4]) \iff 1 \leq x^2 \leq 4 \iff 1 \leq |x| \leq 2 \iff x \in [-2, -1] \cup [1, 2]$.
Since $f(-1) = f(1)$ and $-1 \neq 1$, the map is not injective. Since $(\forall x \in \mathbb{R})\, f(x) \geq 0$, one has $-1 \notin \operatorname{range}(f)$, so the map is not surjective.
Key Insight: Repeated values obstruct injectivity; omitted codomain values obstruct surjectivity.

3.3 Composition, Restriction, and Inverse Functions

Definition 3.3.1. *Composition, Restriction, Extension, and Identity*
Let X, Y be sets and let $f : X \to Y$.

(i) *Restriction*: If $A \subseteq X$, then $f|_A : A \to Y$ satisfies $(\forall x \in A)\,(f|_A)(x) = f(x)$.
(ii) *Extension*: If U is a set with $X \subseteq U$, an extension of f is a map $\widetilde{f} : U \to Y$ satisfying $\widetilde{f}|_X = f$.
(iii) *Composition*: If C, Z are sets, $g : C \to Z$, and $f(X) \subseteq C$, then $g \circ f : X \to Z$ satisfies $(\forall x \in X)\,(g \circ f)(x) = g(f(x))$.
(iv) *Identity*: The map $\mathrm{id}_X : X \to X$ satisfies $(\forall x \in X)\,\mathrm{id}_X(x) = x$.

Theorem 3.3.2. *Bijective Means Invertible*
Let X, Y be sets and let $f : X \to Y$.

(i) The map f is bijective iff $(\exists g : Y \to X)\,[g \circ f = \mathrm{id}_X \wedge f \circ g = \mathrm{id}_Y]$.
(ii) If $g, h : Y \to X$ both satisfy the two identities in (i), then $g = h$. When it exists, this map is denoted $f^{-1} : Y \to X$.

Proof.

(i) ($\Rightarrow$) Suppose f is bijective. For $y \in Y$, choose $x_y \in X$ with $f(x_y) = y$ by surjectivity; it is unique by injectivity.
Define $g : Y \to X$ by $g(y) := x_y$. For $x \in X$, $g(f(x)) = x$, and for $y \in Y$, $f(g(y)) = y$.
Thus $g \circ f = \mathrm{id}_X$ and $f \circ g = \mathrm{id}_Y$ by function extensionality.
(i) ($\Leftarrow$) Suppose $g : Y \to X$ satisfies the two identities. If $x_1, x_2 \in X$ and $f(x_1) = f(x_2)$, then $x_1 = g(f(x_1)) = g(f(x_2)) = x_2$.
Hence f is injective. For $y \in Y$, $y = f(g(y)) \in \operatorname{range}(f)$, so f is surjective and hence bijective.
(ii) Suppose $g, h : Y \to X$ satisfy the two identities. For $y \in Y$, $g(y) = g(f(h(y))) = h(y)$. Thus $g = h$ by function extensionality.

Structural Commentary: Construction proves existence; cancellation recovers bijectivity and proves uniqueness.
Key Insight: A bijection pairs each output with exactly one input. □

Proposition 3.3.3. *Composition and Restriction Calculus*
Let X, Y, Z, W be sets, and let $f : X \to Y$, $g : Y \to Z$, and $h : Z \to W$.

(i) $h \circ (g \circ f) = (h \circ g) \circ f$.
(ii) $\mathrm{id}_Y \circ f = f$ and $f \circ \mathrm{id}_X = f$.
(iii) $(\forall A \subseteq X)\,(g \circ f)(A) = g(f(A))$.
(iv) $(\forall C \subseteq Z)\,(g \circ f)^{-1}(C) = f^{-1}(g^{-1}(C))$.
(v) $(\forall A \subseteq X)\,(g \circ f)|_A = g \circ (f|_A)$.
(vi) If f and g are bijective, then $g \circ f$ is bijective.

(vii) If f and g are bijective, then $(g \circ f)^{-1} = f^{-1} \circ g^{-1}$.

Proof.

(i) For $x \in X$, both sides evaluate to $h(g(f(x)))$. Hence the two maps are equal by function extensionality.
(ii) For $x \in X$, $(\mathrm{id}_Y \circ f)(x) = f(x) = (f \circ \mathrm{id}_X)(x)$. Hence both identities hold by function extensionality.
(iii) Fix $A \subseteq X$ and $z \in Z$. Then $z \in (g \circ f)(A) \iff (\exists x \in A)\, z = g(f(x)) \iff (\exists y \in f(A))\, z = g(y) \iff z \in g(f(A))$.
(iv) Fix $C \subseteq Z$ and $x \in X$. Then $x \in (g \circ f)^{-1}(C) \iff g(f(x)) \in C \iff f(x) \in g^{-1}(C) \iff x \in f^{-1}(g^{-1}(C))$.
(v) Fix $A \subseteq X$ and $x \in A$. Then $((g \circ f)|_A)(x) = g(f(x)) = (g \circ (f|_A))(x)$, so the restrictions are equal by function extensionality.
(vi) Suppose f and g are bijective. Fix $x_1, x_2 \in X$ and suppose $(g \circ f)(x_1) = (g \circ f)(x_2)$. Then $f(x_1) = f(x_2)$ by the injectivity of g. Hence $x_1 = x_2$ by the injectivity of f, so $g \circ f$ is injective.
For $z \in Z$, choose $y \in Y$ with $g(y) = z$ by the surjectivity of g, then choose $x \in X$ with $f(x) = y$ by the surjectivity of f. Thus $(g \circ f)(x) = z$, so $g \circ f$ is surjective and therefore bijective.
(vii) Suppose f and g are bijective. The inverse functions $f^{-1} : Y \to X$ and $g^{-1} : Z \to Y$ exist by Theorem 3.3.2(i).
For $x \in X$, $(f^{-1} \circ g^{-1})((g \circ f)(x)) = f^{-1}(g^{-1}(g(f(x)))) = f^{-1}(f(x)) = x$.
For $z \in Z$, $(g \circ f)((f^{-1} \circ g^{-1})(z)) = g(f(f^{-1}(g^{-1}(z)))) = g(g^{-1}(z)) = z$. Thus $(g \circ f)^{-1} = f^{-1} \circ g^{-1}$ by Theorem 3.3.2(ii).

Structural Commentary: Pointwise evaluation proves the calculus; injectivity and surjectivity pass through the factors.
Key Insight: Inverse maps cancel compositions in reverse order. □

4 Counting and Finite Sums

Counting records finite constructions before cardinality and infinite sets are treated abstractly.

4.1 Finite Sums

Definition 4.1.1. *Finite Sums Indexed by Integers*
Let $\mathbb{F}$ be a field and let $(a_i)_{i\in\mathbb{Z}}$ be a family in $\mathbb{F}$. Fix $m, n \in \mathbb{Z}$. If $m \le n$, define $\sum_{i=m}^{n} a_i := a_m + a_{m+1} + \cdots + a_n$.

If $m > n$, set $\sum_{i=m}^{n} a_i := 0$; this is the empty sum.

Proposition 4.1.2. *Basic Laws for Finite Sums*
Let $\mathbb{F}$ be a field. Let $(a_i)_{i\in\mathbb{Z}}$ and $(b_i)_{i\in\mathbb{Z}}$ be families in $\mathbb{F}$. Fix $m, n \in \mathbb{Z}$ with $m \le n$.

(i) Splitting: Fix $r \in \mathbb{Z}$ with $m \le r < n$. Then $\sum_{i=m}^{n} a_i = \sum_{i=m}^{r} a_i + \sum_{i=r+1}^{n} a_i$.

(ii) Additivity: $\sum_{i=m}^{n} (a_i + b_i) = \sum_{i=m}^{n} a_i + \sum_{i=m}^{n} b_i$.

(iii) Homogeneity: For $c \in \mathbb{F}$, $\sum_{i=m}^{n} ca_i = c \sum_{i=m}^{n} a_i$.

(iv) Triangle inequality: If $\mathbb{F} = \mathbb{C}$, then $\left|\sum_{i=m}^{n} a_i\right| \le \sum_{i=m}^{n} |a_i|$.

(v) Monotonicity: Suppose $\mathbb{F} = \mathbb{R}$ and $(\forall i \in \mathbb{Z})\,[m \le i \le n \Rightarrow a_i \le b_i]$. Then $\sum_{i=m}^{n} a_i \le \sum_{i=m}^{n} b_i$.

Proof. For (ii)–(v), fix m and set $\ell := n - m + 1$; by Theorem 2.6.2 with induction parameter ℓ, it suffices in each item to verify the case $n = m$ and the step from n to $n + 1$.

(i) By Definition 4.1.1 and associativity of addition in $\mathbb{F}$, $\sum_{i=m}^{n} a_i = \sum_{i=m}^{r} a_i + \sum_{i=r+1}^{n} a_i$.

(ii) If $n = m$, both sides equal $a_m + b_m$. Assume additivity through n. By (i), $\sum_{i=m}^{n+1} (a_i + b_i) = \sum_{i=m}^{n} (a_i + b_i) + a_{n+1} + b_{n+1}$.
Substitute the induction hypothesis and regroup to obtain $\sum_{i=m}^{n+1} a_i + \sum_{i=m}^{n+1} b_i$.

(iii) If $n = m$, both sides equal ca_m. Assume homogeneity through n. By (i), $\sum_{i=m}^{n+1} ca_i = \sum_{i=m}^{n} ca_i + ca_{n+1}$.
The induction hypothesis and distributivity turn the right side into $c(\sum_{i=m}^{n} a_i + a_{n+1})$. By (i), this equals $c \sum_{i=m}^{n+1} a_i$.

(iv) If $n = m$, equality holds. Assume the inequality through n. By (i) and the triangle inequality, $\left|\sum_{i=m}^{n+1} a_i\right| \le \left|\sum_{i=m}^{n} a_i\right| + |a_{n+1}|$.
The induction hypothesis and (i) bound the right side by $\sum_{i=m}^{n+1} |a_i|$.

(v) If $n = m$, the conclusion is the hypothesis $a_m \le b_m$. Assume monotonicity through n. By (i), the sums through $n + 1$ split at n.
The induction hypothesis, order compatibility, and $a_{n+1} \le b_{n+1}$ give $\sum_{i=m}^{n+1} a_i \le \sum_{i=m}^{n+1} b_i$.

Structural Commentary: Splitting reduces each law to one new summand and the scalar axioms.
Key Insight: Finite-sum laws propagate one term at a time. □

4.2 Lists and Counting Principles

Counting represents finite constructions by explicit lists and converts disjoint alternatives or successive choices into cardinality identities.

Definition 4.2.1. *Finite Sets and Standard Index Sets*
Set $J_0 := \emptyset$ and $J_n := \{1, \ldots, n\}$ for $n \in \mathbb{N}$. A set A is *finite* if it admits a bijection $e : J_n \to A$ with $n \in \mathbb{N}_0$.

Proposition 4.2.2. *Finite Cardinality Is Well Defined*
Let A be a set and let $m, n \in \mathbb{N}_0$. If $e : J_m \to A$ and $g : J_n \to A$ are bijections, then $m = n$.
Thus each finite set A admits a unique $n \in \mathbb{N}_0$ such that a bijection $J_n \to A$ exists. Define the finite cardinality of A by $\#A := n$.

Proof. The composite $g^{-1} \circ e : J_m \to J_n$ is bijective.
It therefore suffices to prove that a bijection between two standard index sets forces their indices to agree.
For $r \in \mathbb{N}$, let P_r assert that a bijection $J_{r-1} \to J_k$ with $k \in \mathbb{N}_0$ forces $k = r - 1$. It suffices to prove P_1 and $(\forall r \in \mathbb{N})\,(P_r \Rightarrow P_{r+1})$.
A bijection $J_0 \to J_k$ forces $J_k = \emptyset$, hence $k = 0$; thus P_1 holds. Assume P_r and let $\varphi : J_r \to J_k$ be bijective. Since $J_r \neq \emptyset$, $k \in \mathbb{N}$.
Put $q := \varphi(r)$. The restriction $\varphi|_{J_{r-1}}$ is a bijection $J_{r-1} \to J_k \setminus \{q\}$.
Define $\rho : J_{k-1} \to J_k \setminus \{q\}$ by $\rho(i) := i$ when $i < q$ and $\rho(i) := i + 1$ when $i \geq q$.
Its branch images J_{q-1} and $J_k \setminus J_q$ are disjoint and cover $J_k \setminus \{q\}$. Both branches are injective, so ρ is bijective.
The composite $\rho^{-1} \circ \varphi|_{J_{r-1}} : J_{r-1} \to J_{k-1}$ is therefore bijective. Thus $k - 1 = r - 1$ by P_r. Hence $k = r$, and P_{r+1} holds.
Consequently, $(\forall r \in \mathbb{N})\, P_r$ by Theorem 2.6.2. Finally, $n = m$ by P_{m+1} with the bijection $g^{-1} \circ e$.
Structural Commentary: Induction deletes one matched point and canonically relists the remaining index set.
Key Insight: Deletion reduces both finite indices while preserving bijectivity. □

Definition 4.2.3. *Lists, Words, and Product Sets*
Let $p \in \mathbb{N}$ and let $S_1, \ldots, S_p$ be sets.

(i) A *list* of length p in $S_1 \times \cdots \times S_p$ is a tuple $s = (s_1, \ldots, s_p)$ in that product.
(ii) If $S_1 = \cdots = S_p = S$, a list in S^p is a *word* of length p over the alphabet S.
(iii) A counting model is *ordered* when its outcomes are lists and coordinate positions are retained.
Thus lists $s = (s_1, \ldots, s_p)$ and $t = (t_1, \ldots, t_p)$ are distinct iff $(\exists i \in J_p)\, s_i \neq t_i$.

Proposition 4.2.4. *Addition, Subtraction, and Division Principles*

(i) Addition: Let $r \in \mathbb{N}$ and let $A_1, \ldots, A_r$ be pairwise disjoint finite sets. Then $\bigcup_{i=1}^{r} A_i$ is finite and $\#\big(\bigcup_{i=1}^{r} A_i\big) = \sum_{i=1}^{r} \#A_i$.
(ii) Subtraction: If A is finite and $B \subseteq A$, then B and $A \setminus B$ are finite and $\#(A \setminus B) = \#A - \#B$.
(iii) Division: Let $f : Y \to X$ be a surjection between finite sets. Its fibers are finite.
If $d \in \mathbb{N}$ satisfies $(\forall x \in X)\, \#f^{-1}(\{x\}) = d$, then $\#Y = d\#X$ and $\#X = \frac{\#Y}{d}$.

Proof.

(i) For $k \in \mathbb{N}$, let P_k denote claim (i) for k sets. If $k = 1$, then $\bigcup_{i=1}^{1} A_i = A_1$ and $\sum_{i=1}^{1} \#A_i = \#A_1$, so P_1 holds.
Assume P_k and let $A_1, \ldots, A_{k+1}$ be pairwise disjoint finite sets. Put $U := \bigcup_{i=1}^{k} A_i$. By P_k, U is finite and $\#U = \sum_{i=1}^{k} \#A_i$.
Put $q := \#U$ and $n := \#A_{k+1}$, and choose bijections $e : J_q \to U$ and $g : J_n \to A_{k+1}$.
Define $h : J_{q+n} \to U \cup A_{k+1}$ as follows. Set $h(t) := e(t)$ when $t \in J_q$ and $h(t) := g(t - q)$ when $t \in J_{q+n} \setminus J_q$.
The two domain blocks partition J_{q+n}, and their images are the disjoint sets U and A_{k+1}.
Both restrictions of h are bijective, so h is bijective.
Therefore $U \cup A_{k+1}$ is finite with cardinality $q + n = \sum_{i=1}^{k+1} \#A_i$, so P_{k+1} holds. Hence $(\forall k \in \mathbb{N})\, P_k$ by Theorem 2.6.2.

(ii) For $r \in \mathbb{N}$, let P_r assert claim (ii) whenever $\#A = r - 1$ and $B \subseteq A$. If $r = 1$, then $A = B = \emptyset$, so P_1 holds.
Assume P_r, let $\#A = r$, and choose a bijection $e : J_r \to A$. Put $a := e(r)$ and $A' := A \setminus \{a\}$.
The restriction $e|_{J_{r-1}} : J_{r-1} \to A'$ is bijective, so $\#A' = r - 1$. If $a \in B$, put $B' := B \setminus \{a\}$.
By P_r, the sets B' and $A' \setminus B'$ are finite and $\#(A' \setminus B') = \#A' - \#B'$.
By part (i) for $B = B' \cup \{a\}$, B is finite with $\#B = \#B' + 1$.
Since $A \setminus B = A' \setminus B'$, the set $A \setminus B$ is finite and $\#(A \setminus B) = (r - 1) - (\#B - 1) = \#A - \#B$.
If $a \notin B$, then B and $A' \setminus B$ are finite with $\#(A' \setminus B) = \#A' - \#B$ by P_r.
By part (i) for $A \setminus B = (A' \setminus B) \cup \{a\}$, $\#(A \setminus B) = ((r - 1) - \#B) + 1 = \#A - \#B$.
Thus P_{r+1} holds. Consequently, $(\forall r \in \mathbb{N})\, P_r$ by Theorem 2.6.2.
An arbitrary finite A and subset $B \subseteq A$ satisfy $P_{\#A+1}$, proving claim (ii).

(iii) Put $m := \#X$. If $m = 0$, then $X = \emptyset$ and hence $Y = \emptyset$ because $f : Y \to X$; both identities follow.
Suppose $m \in \mathbb{N}$, choose a bijection $e : J_m \to X$, and set $F_i := f^{-1}(\{e(i)\})$ for $i \in J_m$.
Each F_i is finite by part (ii). The sets $F_1, \ldots, F_m$ are pairwise disjoint with union Y.
The equality $(\forall i \in J_m)\, \#F_i = d$ holds by the uniform-fiber hypothesis.
The identity $\#Y = \sum_{i=1}^{m} \#F_i$ holds by part (i). Hence $\#Y = \sum_{i=1}^{m} d = md = d\#X$. Since $d \neq 0$, $\#X = \frac{\#Y}{d}$.

Structural Commentary: Induction constructs union and complement listings; fiber decomposition supplies division.
Key Insight: Disjoint blocks convert set decompositions into arithmetic. □

Theorem 4.2.5. *Multiplication Principle*
Let $p \in \mathbb{N}$ and let $n_1, \ldots, n_p \in \mathbb{N}_0$.

(i) Successive choices: Set $H_0 := \{\emptyset\}$.
(ii) At stage $i \in J_p$, let $(C_i(h))_{h \in H_{i-1}}$ be a family of finite sets satisfying $(\forall h \in H_{i-1})\, \#C_i(h) = n_i$.
Set $H_i := \{(h, c) : h \in H_{i-1},\ c \in C_i(h)\}$. Then H_p is finite and $\#H_p = \prod_{i=1}^{p} n_i$.
(iii) Finite products: Let $S_1, \ldots, S_p$ be finite sets satisfying $(\forall i \in J_p)\, \#S_i = n_i$.
Then $S_1 \times \cdots \times S_p$ is finite and $\#(S_1 \times \cdots \times S_p) = \prod_{i=1}^{p} n_i$.

Proof.

(i) For $r \in \mathbb{N}$, let P_r denote claim (i) with $p = r$. The map $(\emptyset, c) \mapsto c$ is a bijection $H_1 \to C_1(\emptyset)$.
Thus H_1 is finite with $\#H_1 = n_1$, so P_1 holds. Assume P_r and consider an $(r + 1)$-stage model.

By P_r for its first r stages, H_r is finite with $\#H_r = \prod_{i=1}^{r} n_i$.

If $H_r = \emptyset$, then $H_{r+1} = \emptyset$ and $\#H_{r+1} = 0 = n_{r+1}\#H_r = \prod_{i=1}^{r+1} n_i$, so P_{r+1} holds.

Suppose $H_r \neq \emptyset$. Put $m := \#H_r$; then $m \in \mathbb{N}$. Choose a bijection $e : J_m \to H_r$.
Define the family $(A_j)_{j\in J_m}$ by $A_j := \{e(j)\} \times C_{r+1}(e(j))$. The sets $A_1, \dots, A_m$ are pairwise disjoint and have union H_{r+1}.
The map $c \mapsto (e(j), c)$ is a bijection $C_{r+1}(e(j)) \to A_j$. Thus $A_1, \dots, A_m$ are finite and $(\forall j \in J_m)\, \#A_j = n_{r+1}$.

Therefore $\#H_{r+1} = \sum_{j=1}^{m} \#A_j = mn_{r+1} = \prod_{i=1}^{r+1} n_i$ by Proposition 4.2.4(i). Thus P_{r+1} holds.

Consequently, $(\forall r \in \mathbb{N})\, P_r$ by Theorem 2.6.2; in particular, P_p holds.

(ii) In (i), take the constant families $C_i(h) := S_i$. Then H_p is finite with $\#H_p = \prod_{i=1}^{p} n_i$.

Given $s = (s_1, \dots, s_p) \in S_1 \times \cdots \times S_p$, set $h_0 := \emptyset$. At stage $i \in J_p$, set $h_i := (h_{i-1}, s_i)$, and define $\Psi(s) := h_p$.
The map $\Psi : S_1 \times \cdots \times S_p \to H_p$ is bijective. Indeed, successive first and second coordinates recover the unique tuple s.

Hence $S_1 \times \cdots \times S_p$ is finite. Its cardinality is $\#(S_1 \times \cdots \times S_p) = \#H_p = \prod_{i=1}^{p} n_i$.

Structural Commentary: Induction counts recursive histories; a coordinate bijection transfers the count to products.
Key Insight: Uniform extension fibers multiply the number of histories. □

Example 4.2.6. *Finite Words by the Multiplication Principle*
The following slot counts multiply by Theorem 4.2.5.

(i) A card in a standard deck is a pair consisting of one of 4 suits and one of 13 ranks. Thus the deck has $4 \cdot 13 = 52$ cards.
(ii) For $B := \{0, 1\}$, $\#(B^8) = 2^8 = 256$, so the binary alphabet has 256 words of length 8.
(iii) For $D := \{\mathrm{A}, \mathrm{C}, \mathrm{G}, \mathrm{T}\}$, $(\forall N \in \mathbb{N})\, \#(D^N) = 4^N$. At $N = 3$, the DNA alphabet therefore has 64 codons.

Key Insight: Fixed-size coordinate choices multiply, so constant alphabets produce exponential word counts.

4.3 Permutations, Subsets, and Binomial Coefficients

Definition 4.3.1. *Permutations and Sign*
Let $n \in \mathbb{N}_0$. A *permutation* of J_n is a bijection $\sigma : J_n \to J_n$, and $\mathfrak{S}_n$ denotes the set of all such permutations.
Given $\sigma \in \mathfrak{S}_n$, set $\mathrm{Inv}(\sigma) := \{(j, k) \in J_n^2 : j < k,\ \sigma(j) > \sigma(k)\}$ and define its *sign* by $\mathrm{sign}(\sigma) := (-1)^{\#\,\mathrm{Inv}(\sigma)}$.

Definition 4.3.2. *Factorials and Binomial Coefficients*

(i) *Factorial*: Set $0! := 1$ and $n! := \prod_{j=1}^{n} j$ for $n \in \mathbb{N}$.

(ii) *Falling factorial*: Set $(n)_0 := 1$ for $n \in \mathbb{N}_0$. If $n, r \in \mathbb{N}$ and $r \leq n$, set $(n)_r := \prod_{j=0}^{r-1} (n - j)$.

(iii) *Binomial coefficient*: If $n, r \in \mathbb{N}_0$ and $r \leq n$, set $\binom{n}{r} := \frac{n!}{r!(n-r)!}$; this is read *n choose r*.

Proposition 4.3.3. *Ordered Sampling With and Without Replacement*
Let $n, r \in \mathbb{N}_0$ and let S be finite with $\#S = n$. Set $S^0 := \{()\}$ and use $x^0 := 1$ for $x \in \mathbb{N}_0$.
Define $D_r(S) := \{s = (s_1, \dots, s_r) \in S^r : (\forall i, j \in J_r)\, [i < j \Rightarrow s_i \neq s_j]\}$.

(i) With replacement: The ordered samples form S^r, and $\#(S^r) = n^r$.
(ii) Without replacement: If $r \leq n$, the ordered samples with distinct entries form $D_r(S)$, and $\#D_r(S) = (n)_r$.
(iii) Full orderings: $\#D_n(S) = n!$ and $\#\mathfrak{S}_n = n!$.

Proof.

(i) If $r = 0$, then $\#S^0 = 1 = n^0$. If $r \in \mathbb{N}$, then $\#S^r = \prod_{k=1}^{r} n = n^r$ by Theorem 4.2.5(ii).

(ii) Suppose $r \leq n$. If $r = 0$, then $D_0(S) = S^0$ and $\#D_0(S) = 1 = (n)_0$.
Suppose $r \in \mathbb{N}$. At stage $k \in J_r$, an injective prefix $(s_1, \dots, s_{k-1})$ uses a set of cardinality $k - 1$.
The available set $S \setminus \{s_1, \dots, s_{k-1}\}$ is finite with cardinality $n - k + 1$ by Proposition 4.2.4(ii).

Successive-choice histories flatten bijectively to $D_r(S)$, so $\#D_r(S) = \prod_{k=1}^{r} (n - k + 1) = (n)_r$ by Theorem 4.2.5(i).

(iii) The identity $\#D_n(S) = n!$ holds by (ii). Define $\Phi : \mathfrak{S}_n \to D_n(J_n)$ by $\Phi(\sigma) := (\sigma(i))_{i\in J_n}$.
Given $s \in D_n(J_n)$, the map $i \mapsto s_i$ is injective and its image has cardinality n. Its complement in J_n has cardinality 0 by Proposition 4.2.4(ii), so the map is surjective.
Thus $s \mapsto (i \mapsto s_i)$ is the inverse of Φ. Hence Φ is bijective and $\#\mathfrak{S}_n = \#D_n(J_n) = n!$.

Structural Commentary: Product counting handles all lists; available-set histories handle injective lists.
Key Insight: Removing used entries decreases each successive choice count by one. □

Proposition 4.3.4. *Unordered Samples Without Replacement*
Let $n, r \in \mathbb{N}_0$ with $r \leq n$, let S be finite with $\#S = n$, and set $\mathcal{P}_r(S) := \{A \subseteq S : \#A = r\}$.
Then $\mathcal{P}_r(S)$ is finite and $\#\mathcal{P}_r(S) = \binom{n}{r} = \frac{(n)_r}{r!} = \frac{n!}{(n-r)!\, r!}$.

Proof. Choose a bijection $e : J_n \to S$. Define $\chi : \mathcal{P}_r(S) \to \{0, 1\}^n$ by $\chi(A)_i := 1$ when $e(i) \in A$ and $\chi(A)_i := 0$ otherwise.
If $A \neq B$, choose $x \in (A \setminus B) \cup (B \setminus A)$ and then choose $i \in J_n$ with $e(i) = x$. Thus $\chi(A)_i \neq \chi(B)_i$, so χ is injective.
The set $\{0, 1\}^n$ is finite by Proposition 4.3.3(i). Its subset $\chi(\mathcal{P}_r(S))$ is finite by Proposition 4.2.4(ii).
Hence $\mathcal{P}_r(S)$ is finite because χ is a bijection onto its image. Define $\pi : D_r(S) \to \mathcal{P}_r(S)$ by $\pi(s_1, \dots, s_r) := \{s_1, \dots, s_r\}$.
Given $A \in \mathcal{P}_r(S)$, choose a bijection $f : J_r \to A$. Then $(f(i))_{i\in J_r} \in \pi^{-1}(\{A\})$, so π is surjective.
The fiber $\pi^{-1}(\{A\})$ is bijective with $D_r(A)$, so $\#\pi^{-1}(\{A\}) = r!$ by Proposition 4.3.3(iii).
The identity $\#D_r(S) = (n)_r$ holds by Proposition 4.3.3(ii). The equality $\#D_r(S) = r!\,\#\mathcal{P}_r(S)$ holds by Proposition 4.2.4(iii).
Therefore $\#\mathcal{P}_r(S) = \frac{(n)_r}{r!} = \frac{n!}{(n-r)!\, r!} = \binom{n}{r}$.

Structural Commentary: Binary encoding proves finiteness; uniform ordering fibers convert ordered samples to subsets.
Key Insight: Each subset has exactly $r!$ ordered listings. □

Example 4.3.5. *Committees*
Let C be a class of 20 people. The 3-person committees form $\mathcal{P}_3(C)$. Thus $\#\mathcal{P}_3(C) = \binom{20}{3} = \frac{20\cdot 19\cdot 18}{3\cdot 2\cdot 1} = 1140$ by Proposition 4.3.4.
Key Insight: A committee is an unordered subset, so permutations of its members are not recounted.

Proposition 4.3.6. *Edge Values and Symmetry*
Let $n, k \in \mathbb{N}_0$ with $k \le n$.

(i) Edge values: $\binom{n}{0} = \binom{n}{n} = 1$.
(ii) Symmetry: $\binom{n}{k} = \binom{n}{n-k}$.

Proof.

(i) Since $0! := 1$, $\binom{n}{0} = \frac{n!}{0!\,n!} = 1$ and $\binom{n}{n} = \frac{n!}{n!\,0!} = 1$.
(ii) Since $0 \le n-k \le n$, $\binom{n}{n-k} = \frac{n!}{(n-k)!\,k!} = \frac{n!}{k!\,(n-k)!} = \binom{n}{k}$.

Structural Commentary: Direct factorial simplification proves the edge values and symmetry.
Key Insight: The denominator is invariant under $k \leftrightarrow n-k$. □

Proposition 4.3.7. *Binomial Theorem and Subset Count*
Let $n \in \mathbb{N}$ and let $a, b \in \mathbb{C}$.

(i) Binomial theorem: $(a+b)^n = \sum_{k=0}^{n} \binom{n}{k} a^k b^{n-k}$.

(ii) Subset count: If S is finite with $\#S = n$, then $\mathcal{P}(S)$ is finite and $\#\mathcal{P}(S) = 2^n = \sum_{k=0}^{n} \binom{n}{k}$.

Proof.

(i) Write $(a+b)^n = \prod_{j=1}^{n} (a+b)$. A subset $I \subseteq J_n$ records the factors contributing a; the corresponding term is $a^{\#I} b^{n-\#I}$.
For $k \in \{0, \dots, n\}$, $\#\mathcal{P}_k(J_n) = \binom{n}{k}$ by Proposition 4.3.4. Grouping terms by $k = \#I$ proves the identity.
(ii) Fix a finite set S with $\#S = n$ and choose a bijection $e : J_n \to S$.
Define $\chi : \mathcal{P}(S) \to \{0,1\}^n$ by $\chi(A)_i := 1$ when $e(i) \in A$ and $\chi(A)_i := 0$ otherwise.
The inverse sends $v \in \{0,1\}^n$ to $\{e(i) : i \in J_n,\ v_i = 1\}$, so χ is bijective.
Hence $\mathcal{P}(S)$ is finite with $\#\mathcal{P}(S) = 2^n$ by Proposition 4.3.3(i).
The sets $\mathcal{P}_0(S), \dots, \mathcal{P}_n(S)$ are pairwise disjoint with union $\mathcal{P}(S)$. Hence $\#\mathcal{P}(S) = \sum_{k=0}^{n} \#\mathcal{P}_k(S)$ by Proposition 4.2.4(i).
For $k \in \{0, \dots, n\}$, $\#\mathcal{P}_k(S) = \binom{n}{k}$ by Proposition 4.3.4. Therefore $\#\mathcal{P}(S) = \sum_{k=0}^{n} \binom{n}{k}$.

Structural Commentary: Expansion and subset partitioning classify the same binary choices by cardinality.
Key Insight: Choosing the a-positions is equivalent to choosing a subset of J_n. □

Definition 4.3.8. *Multisets*
Let S be a set. A *multiset on S* is a pair (S_0, m) such that

(i) $S_0 \subseteq S$ is the *underlying set*;
(ii) $m : S_0 \to \mathbb{N}$ is the *multiplicity function*, and $m(s)$ is the *multiplicity* of $s \in S_0$;
(iii) if S_0 is finite, set $E_m := \{(s, j) : s \in S_0,\ j \in J_{m(s)}\}$ and define the *size* by $|m| := \#E_m$.

The graph $\{(s, m(s)) : s \in S_0\}$ is an equivalent record of (S_0, m).

Example 4.3.9. *Multiset Bookkeeping*
The list (a, a, b, b, b, c) determines the multiset (S_0, m) with $S_0 = \{a, b, c\}$, $m(a) = 2$, $m(b) = 3$, and $m(c) = 1$.
The set E_m has $2 + 3 + 1 = 6$ elements, so $|m| = 6$. The same bookkeeping records eigenvalues counted with algebraic multiplicity.
Key Insight: A multiset forgets order while retaining the number of occurrences of each element.

Definition 4.3.10. *Multinomial Coefficients*
Let $r \in \mathbb{N}$ and let $\mathbf{n} = (n_1, \dots, n_r) \in \mathbb{N}_0^r$. Set $n := \sum_{i=1}^{r} n_i$ and define $\binom{n}{n_1, \dots, n_r} := \frac{n!}{n_1! \cdots n_r!}$.

Proposition 4.3.11. *Multinomial Count and Expansion*
Let $r \in \mathbb{N}$, let $\mathbf{n} = (n_1, \dots, n_r) \in \mathbb{N}_0^r$, and let $x_1, \dots, x_r \in \mathbb{C}$. Set $n := \sum_{i=1}^{r} n_i$.

Let $\mathcal{M}_{\mathbf{n}}$ be the set of tuples $(A_1, \dots, A_r)$ of pairwise disjoint subsets of J_n satisfying $\bigcup_{i=1}^{r} A_i = J_n$ and $(\forall i \in J_r)\, \#A_i = n_i$.

Set $K_{r,n} := \{\mathbf{m} = (m_1, \dots, m_r) \in \mathbb{N}_0^r : \sum_{i=1}^{r} m_i = n\}$.

(i) Multinomial count: $\#\mathcal{M}_{\mathbf{n}} = \binom{n}{n_1, \dots, n_r} = \frac{n!}{n_1! \cdots n_r!}$.

(ii) Multinomial expansion: $(x_1 + \cdots + x_r)^n = \sum_{\mathbf{m} \in K_{r,n}} \binom{n}{m_1, \dots, m_r} \prod_{i=1}^{r} x_i^{m_i}$.

Proof.

(i) Set $N_0 := n$ and $N_j := n - \sum_{i=1}^{j} n_i$ for $j \in J_r$; thus $N_r = 0$. After $A_1, \dots, A_{j-1}$ are chosen, put $R_j := J_n \setminus \bigcup_{i=1}^{j-1} A_i$.
The equality $\#R_1 = N_0$ holds directly. If $j \ge 2$, then $\#R_j = N_{j-1}$ by Proposition 4.2.4(i)–(ii).
Since $N_{j-1} = \sum_{i=j}^{r} n_i \ge n_j$, the number of choices for $A_j \in \mathcal{P}_{n_j}(R_j)$ is $\binom{N_{j-1}}{n_j}$ by Proposition 4.3.4.

Since $N_r = 0$, the successive-choice histories are exactly the elements of $\mathcal{M}_{\mathbf{n}}$. Hence $\#\mathcal{M}_{\mathbf{n}} = \prod_{j=1}^{r} \binom{N_{j-1}}{n_j}$ by Theorem 4.2.5(i).

The factorial factors telescope, so $\#\mathcal{M}_{\mathbf{n}} = \prod_{j=1}^{r} \frac{N_{j-1}!}{n_j!\,N_j!} = \frac{n!}{n_1!\cdots n_r!} = \binom{n}{n_1,\ldots,n_r}$.

(ii) Expand $(x_1 + \cdots + x_r)^n = \prod_{k=1}^{n} (x_1 + \cdots + x_r)$. Each term is determined by a function $\phi : J_n \to J_r$ and equals $\prod_{k=1}^{n} x_{\phi(k)}$.
Set $m_i := \#\phi^{-1}(\{i\})$ for $i \in J_r$. Then $\mathbf{m} = (m_1, \ldots, m_r) \in K_{r,n}$. The fibers $(\phi^{-1}(\{1\}), \ldots, \phi^{-1}(\{r\}))$ form an element of $\mathcal{M}_{\mathbf{m}}$. Conversely, each element of $\mathcal{M}_{\mathbf{m}}$ determines a unique function with those fibers.
Thus the number of terms equal to $\prod_{i=1}^{r} x_i^{m_i}$ is $\binom{n}{m_1,\ldots,m_r}$ by (i). Grouping the terms over $\mathbf{m} \in K_{r,n}$ proves the expansion.

Structural Commentary: Successive subset choices count labeled partitions; fiber profiles classify product terms.
Key Insight: Multinomial coefficients count functions with prescribed fiber sizes. □

Example 4.3.12. *Repeated Letters, Committees, and Pairings*

(i) The position sets of the letters in (A, A, G, G, G, G, C, C, C) form a labeled partition of sizes $2, 4, 3$.
Thus the number of arrangements is $\binom{9}{2,4,3} = \frac{9!}{2!\,4!\,3!} = 1260$ by Proposition 4.3.11(i).

(ii) Splitting seven people into labeled subcommittees of sizes $3, 2, 2$ gives $\binom{7}{3,2,2} = \frac{7!}{3!\,2!\,2!} = 210$ assignments by Proposition 4.3.11(i).

(iii) Let $m \in \mathbb{N}$ and let S be finite with $\#S = 2m$.
Let $\mathcal{Q}_m(S)$ be the set of pairwise disjoint m-element families $\mathcal{A} \subseteq \mathcal{P}_2(S)$ satisfying $\bigcup \mathcal{A} = S$; its elements are the pairings of S.
The sets $\mathcal{P}(S)$ and $\mathcal{P}(\mathcal{P}(S))$ are finite by two applications of Proposition 4.3.7(ii). Hence $\mathcal{Q}_m(S)$ is finite by Proposition 4.2.4(ii).
Define $q : D_{2m}(S) \to \mathcal{Q}_m(S)$ by $q(s) := \{\{s_{2j-1}, s_{2j}\} : j \in J_m\}$. Each $s \in D_{2m}(S)$ lists S exactly once, so $q(s) \in \mathcal{Q}_m(S)$.
Given $\mathcal{A} \in \mathcal{Q}_m(S)$, choose a bijection $p : J_m \to \mathcal{A}$. Choose labels $((a_j, b_j))_{j \in J_m}$ satisfying $(\forall j \in J_m)\, p(j) = \{a_j, b_j\}$.
Then $(a_1, b_1, \ldots, a_m, b_m) \in q^{-1}(\{\mathcal{A}\})$, so q is surjective.
Each pairing has $m!\,2^m$ preimages: the m pairs may be ordered arbitrarily, and the two members of each pair may be interchanged.
The identity $\#D_{2m}(S) = (2m)!$ holds by Proposition 4.3.3(iii). Therefore the number of pairings is $\frac{(2m)!}{m!\,2^m}$ by Proposition 4.2.4(iii).

Key Insight: Multinomial counts labeled blocks; quotienting symmetries handles unlabeled blocks.

4.4 Inclusion-Exclusion and Combinatorial Proof

Proposition 4.4.1. *Finite Inclusion-Exclusion for Two and Three Sets*
Let A, B, C be finite sets.

(i) Two sets: The set $A \cup B$ is finite. Its cardinality is $\#(A \cup B) = \#A + \#B - \#(A \cap B)$.

(ii) Three sets: The set $A \cup B \cup C$ is finite.
Its cardinality is $\#(A \cup B \cup C) = \#A + \#B + \#C - \#(A \cap B) - \#(A \cap C) - \#(B \cap C) + \#(A \cap B \cap C)$.

Proof.

(i) Set $D := A \cap B$ and $E := B \setminus D$. The sets D and E are finite with $\#E = \#B - \#D$ by Proposition 4.2.4(ii).
The sets A and E are disjoint with union $A \cup B$. Hence $A \cup B$ is finite and $\#(A \cup B) = \#A + \#E$ by Proposition 4.2.4(i).
Substituting $D = A \cap B$ and $\#E = \#B - \#D$ proves (i).

(ii) The set $A \cup B$ is finite by (i). Set $F := (A \cup B) \cap C$.
The set $A \cup B \cup C$ is finite and $\#(A \cup B \cup C) = \#(A \cup B) + \#C - \#F$ by (i) with $A \cup B$ and C.
The sets $A \cap C$ and $B \cap C$ are finite by two applications of Proposition 4.2.4(ii).
Since $F = (A \cap C) \cup (B \cap C)$, the identity $\#F = \#(A \cap C) + \#(B \cap C) - \#(A \cap B \cap C)$ holds by (i) with $A \cap C$ and $B \cap C$.
The identity $\#(A \cup B) = \#A + \#B - \#(A \cap B)$ holds by (i). Substitution of the three identities proves (ii).

Structural Commentary: The two-set decomposition supplies the three-set formula through distributivity.
Key Insight: Correct each overlap after adding the individual set sizes. □

Method 4.4.2. *Combinatorial Proof by Classification*
Use When: Both sides of a finite identity can be expressed by weighting the same classified outcomes.
Fix target counts $N_L, N_R \in \mathbb{N}_0$.

(i) Choose finite sets Ω and P, a pattern map $p : \Omega \to P$, and weights $w_L, w_R : P \to \mathbb{Z}$.

(ii) Establish the exact fiber decompositions $(\forall \nu \in \{L, R\})\, N_\nu = \sum_{\alpha \in P} w_\nu(\alpha) \#p^{-1}(\{\alpha\})$.

(iii) Prove $(\forall \alpha \in P)\, w_L(\alpha) = w_R(\alpha)$, then substitute into the decompositions to obtain $N_L = N_R$.

Endpoint Check: Confirm that the fibers cover Ω disjointly and that both weight sums record every intended contribution.
Key Idea: Common classification reduces global equality to equality on each pattern.

5 Relations, Orders, and Lattices

Relations package comparisons, identifications, order structures, and quotient constructions.

5.1 Relations and Equivalence

Definition 5.1.1. *Relations*
Let X, Y be sets.

(i) *From X to Y*: A subset $R \subseteq X \times Y$ is a relation from X to Y.

(ii) *Relation notation*: Given a relation R from X to Y, write $xRy \iff (x, y) \in R$ for $(x, y) \in X \times Y$.

(iii) *On X*: A subset $R \subseteq X^2$ is a relation on X.

Definition 5.1.2. *Equivalence Relations*
Let X be a set and let $\sim$ be a relation on X.

(i) *Reflexive*: $\sim$ is reflexive iff $(\forall x \in X)\, x \sim x$.

(ii) *Symmetric*: $\sim$ is symmetric iff $(\forall x, y \in X)\, [x \sim y \Rightarrow y \sim x]$.

(iii) *Transitive*: $\sim$ is transitive iff $(\forall x, y, z \in X)\,[(x \sim y \wedge y \sim z) \Rightarrow x \sim z]$.
(iv) *Equivalence relation*: $\sim$ is an equivalence relation iff conditions (i)–(iii) hold.

Definition 5.1.3. *Equivalence Classes, Invariants, and Canonical Forms*
Let X, Y be sets and let $\sim$ be an equivalence relation on X.

(i) *Equivalence class*: For $x \in X$, set $[x]_\sim := \{y \in X : y \sim x\}$.
(ii) *Invariant*: A map $f : X \to Y$ is an invariant of $\sim$ iff $(\forall x, y \in X)\,[x \sim y \Rightarrow f(x) = f(y)]$.
(iii) *Complete invariant*: A map $f : X \to Y$ is a complete invariant of $\sim$ iff $(\forall x, y \in X)\,[x \sim y \iff f(x) = f(y)]$.
(iv) *Canonical forms*: A subset $\mathcal{C} \subseteq X$ is a set of canonical forms for $\sim$ iff $(\forall x \in X)(\exists! c \in \mathcal{C})\, c \sim x$.

5.2 Partitions and Quotient Sets

Definition 5.2.1. *Partition of a Set*
Let X be a set. A *partition* of X is a set $\mathcal{F} \subseteq \mathcal{P}(X) \setminus \{\emptyset\}$ satisfying $(\forall x \in X)(\exists! B \in \mathcal{F})\, x \in B$.
The members of $\mathcal{F}$ are its *blocks*.

Proposition 5.2.2. *Equivalence Classes Partition the Set*
Let X be a set, let $\sim$ be an equivalence relation on X, and set $\mathcal{F}_\sim := \{[x]_\sim : x \in X\}$. Then $\mathcal{F}_\sim$ is a partition of X.

Proof. For $x \in X$, reflexivity gives $x \in [x]_\sim$; hence the classes are nonempty and cover X.
If $u \in [x]_\sim \cap [y]_\sim$, then $u \sim x$ and $u \sim y$, whence $x \sim y$ and $y \sim x$ by symmetry and transitivity.
If $v \in [x]_\sim$, then $v \sim x \sim y$, so $v \in [y]_\sim$. If $v \in [y]_\sim$, then $v \sim y \sim x$, so $v \in [x]_\sim$.
Thus intersecting classes are equal, proving unique class membership; hence $\mathcal{F}_\sim$ partitions X.
Structural Commentary: Reflexivity supplies classes; symmetry and transitivity collapse intersections.
Key Insight: Two classes sharing an element have the same members. □

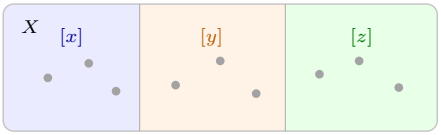

Figure 5: Equivalence classes form disjoint blocks that cover the underlying set.

Figure 5 depicts the partition in Proposition 5.2.2. Every element of X lies in one equivalence class, and distinct classes are disjoint.

Proposition 5.2.3. *Partitions Determine Equivalence Relations*
Let X be a set and let $\mathcal{F}$ be a partition of X. For $x \in X$, let $B_x \in \mathcal{F}$ be the unique block containing x.
For $(x, y) \in X^2$, define $x \sim_{\mathcal{F}} y \iff B_x = B_y$.

(i) Equivalence relation: $\sim_{\mathcal{F}}$ is an equivalence relation on X.
(ii) Classes: $(\forall x \in X)\,[x]_{\sim_{\mathcal{F}}} = B_x$, and $\{[x]_{\sim_{\mathcal{F}}} : x \in X\} = \mathcal{F}$.

Proof.

(i) For $x, y, z \in X$, $B_x = B_x$, so $x \sim_{\mathcal{F}} x$. If $x \sim_{\mathcal{F}} y$, then $B_x = B_y$, hence $B_y = B_x$ and $y \sim_{\mathcal{F}} x$.
Moreover, $(x \sim_{\mathcal{F}} y \wedge y \sim_{\mathcal{F}} z) \Rightarrow B_x = B_y = B_z \Rightarrow x \sim_{\mathcal{F}} z$. Thus $\sim_{\mathcal{F}}$ is reflexive, symmetric, and transitive.
(ii) Fix $x \in X$. If $y \in [x]_{\sim_{\mathcal{F}}}$, then $B_y = B_x$, so $y \in B_y = B_x$. If $y \in B_x$, then B_x is a block containing y.
Uniqueness gives $B_y = B_x$, so $y \sim_{\mathcal{F}} x$ and $y \in [x]_{\sim_{\mathcal{F}}}$. Hence $[x]_{\sim_{\mathcal{F}}} = B_x$. Therefore $\{[x]_{\sim_{\mathcal{F}}} : x \in X\} \subseteq \mathcal{F}$.
If $B \in \mathcal{F}$, then $B \neq \emptyset$; choose $x \in B$. The uniqueness of B_x gives $B = B_x = [x]_{\sim_{\mathcal{F}}}$, so the reverse containment holds.

Structural Commentary: Block equality proves the axioms; uniqueness identifies classes with blocks.
Key Insight: Equivalent elements are assigned to the same block. □

Example 5.2.4. *Rational Equivalence on $\mathbb{R}$*
For $(x, y) \in \mathbb{R}^2$, define $x \sim_{\mathbb{Q}} y \iff x - y \in \mathbb{Q}$. Fix $x, y, z \in \mathbb{R}$.

(i) *Reflexive*: $x - x = 0 \in \mathbb{Q}$.
(ii) *Symmetric*: $x - y \in \mathbb{Q} \Rightarrow y - x = -(x - y) \in \mathbb{Q}$.
(iii) *Transitive*: $(x - y \in \mathbb{Q} \wedge y - z \in \mathbb{Q}) \Rightarrow x - z = (x - y) + (y - z) \in \mathbb{Q}$.

Thus $\sim_{\mathbb{Q}}$ is an equivalence relation, and $[x]_{\sim_{\mathbb{Q}}} = x + \mathbb{Q} = \{x + q : q \in \mathbb{Q}\}$.
A subset $\mathcal{R} \subseteq \mathbb{R}$ is a representative set iff $(\forall x \in \mathbb{R})(\exists! r \in \mathcal{R})\, r \in x + \mathbb{Q}$.
Key Insight: Rational translation orbits are exactly the equivalence classes.

Definition 5.2.5. *Quotient Set*
Let X be a set and let $\sim$ be an equivalence relation on X. The *quotient set* of X by $\sim$ is $X/\!\sim := \{[x]_\sim : x \in X\}$.

Proposition 5.2.6. *Maps Defined on Equivalence Classes*
Let X, Y be sets, let $\sim$ be an equivalence relation on X, and let $f : X \to Y$.
The assignment $g([x]_\sim) := f(x)$ defines $g : X/\!\sim \to Y$ iff $(\forall x, y \in X)\,[x \sim y \Rightarrow f(x) = f(y)]$.

Proof.

($\Rightarrow$) Suppose g is well-defined, $x \sim y$. Then $x \in [x]_\sim \cap [y]_\sim$, so $[x]_\sim = [y]_\sim$ by Proposition 5.2.2. Thus $f(x) = g([x]_\sim) = g([y]_\sim) = f(y)$.
($\Leftarrow$) Suppose $(\forall x, y \in X)\,[x \sim y \Rightarrow f(x) = f(y)]$. If $[x]_\sim = [y]_\sim$, then $x \in [y]_\sim$, whence $x \sim y$ and $f(x) = f(y)$.
Thus the assignment is independent of the representative. Hence it defines a map $g : X/\!\sim \to Y$.

Structural Commentary: Equal classes prove necessity; representative independence proves sufficiency.
Key Insight: A class function cannot distinguish equivalent representatives. □

5.3 Ordered Sets, Well-Orders, and Lattices

Definition 5.3.1. *Ordered Set Vocabulary*
Let S be a set, let $E, C \subseteq S$, and let $\leq_S \subseteq S^2$. Set $x <_S y \iff (x \leq_S y \wedge x \neq y)$.
The relation $\leq_S$ is *antisymmetric* iff $(\forall x, y \in S)\,[(x \leq_S y \wedge y \leq_S x) \Rightarrow x = y]$. Elements $x, y \in S$ are *comparable* iff $x \leq_S y \vee y \leq_S x$.

(i) *Partial order*: The relation $\leq_S$ is a partial order iff it is reflexive, antisymmetric, and transitive. Then $(S, \leq_S)$ is a *poset*.
(ii) *Total order*: A partial order $\leq_S$ is total iff $(\forall x, y \in S)\,(x \leq_S y \vee y \leq_S x)$. Then $(S, \leq_S)$ is an *ordered set*.
(iii) *Chain*: If $\leq_S$ is a partial order, then C is a chain iff $(\forall x, y \in C)\,(x \leq_S y \vee y \leq_S x)$.
(iv) *Well-order*: The order $\leq_S$ well-orders S iff it is total and the following condition holds. $(\forall Y \in \mathcal{P}(S)\setminus\{\emptyset\})(\exists \ell \in Y)(\forall y \in Y)\,\ell \leq_S y$.
(v) *Bounds*: An element $\beta \in S$ is an upper bound of E iff $(\forall x \in E)\,x \leq_S \beta$. It is a lower bound iff $(\forall x \in E)\,\beta \leq_S x$.
(vi) *Boundedness*: The set E is bounded above iff $(\exists \beta \in S)(\forall x \in E)\,x \leq_S \beta$. It is bounded below iff $(\exists \beta \in S)(\forall x \in E)\,\beta \leq_S x$.
(vii) *Supremum*: For $\alpha \in S$, $\alpha = \sup E$ iff the following two conditions hold.
  1. *Upper bound*: $(\forall x \in E)\,x \leq_S \alpha$.
  2. *Upper bound*: $(\forall x \in E)\,x \leq_S \alpha$.
  3. *Least*: $(\forall \beta \in S)\,[((\forall x \in E)\,x \leq_S \beta) \Rightarrow \alpha \leq_S \beta]$.

(viii) *Infimum*: For $\gamma \in S$, $\gamma = \inf E$ iff the following two conditions hold.
  1. *Lower bound*: $(\forall x \in E)\,\gamma \leq_S x$.
  2. *Greatest*: $(\forall \beta \in S)\,[((\forall x \in E)\,\beta \leq_S x) \Rightarrow \beta \leq_S \gamma]$.

(ix) *Maximal and minimal elements*: An element $m \in E$ is maximal iff $(\nexists x \in E)\,m <_S x$. It is minimal iff $(\nexists x \in E)\,x <_S m$.
(x) *Least-upper-bound property*: This property is characterized by the following condition.
$(\forall A \in \mathcal{P}(S) \setminus \{\emptyset\})\,[((\exists \beta \in S)(\forall x \in A)\,x \leq_S \beta) \Rightarrow (\exists \alpha \in S)\,\alpha = \sup A]$.

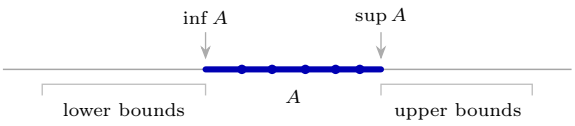

Figure 6: The supremum is the least upper bound, while the infimum is the greatest lower bound.

Figure 6 illustrates the bounds in Definition 5.3.1 for a set A.
It marks $\inf A$ and $\sup A$ as extremal bounds; Example 5.3.2 shows that neither need belong to the set.

Example 5.3.2. *Suprema Need Not Be Elements*
In $\mathbb{Q}$, set $E_1 := \{r \in \mathbb{Q} : r < 0\}$ and $E_2 := \{r \in \mathbb{Q} : r \leq 0\}$. Both sets have supremum 0, but $0 \notin E_1$ and $0 \in E_2$.
For $E := \{\frac{1}{n} : n \in \mathbb{N}\}$, $\sup E = 1 \in E$ and $\inf E = 0 \notin E$.
Key Insight: An extremal bound need not be an element of the set.

Theorem 5.3.3. *Least Upper Bounds Give Greatest Lower Bounds*
Let $(S, \leq)$ be an ordered set with the least-upper-bound property. Let $B \subseteq S$ be nonempty and bounded below. Then $\inf B$ exists in S.

Proof. Set $L := \{\ell \in S : (\forall b \in B)\,\ell \leq b\}$. $L \neq \emptyset$ by the boundedness of B below. Choose $b_0 \in B$.
Then $(\forall \ell \in L)\,\ell \leq b_0$, so L is bounded above. Set $\alpha := \sup L$; it exists in S by the least-upper-bound property.
For $b \in B$, the element b is an upper bound of L, so $\alpha \leq b$. Hence $\alpha \in L$. Moreover, $(\forall \ell \in L)\,\ell \leq \alpha$ by $\alpha = \sup L$.
Thus α is the greatest lower bound of B, and $\alpha = \inf B$.
Structural Commentary: The proof takes the supremum of the lower-bound set.
Key Insight: A nonempty set bounds its lower bounds above. □

Definition 5.3.4. *Lattice Vocabulary*
Let $(L, \leq)$ be a partially ordered set.

(i) *Meet*: For $x, y \in L$, the meet is $x \wedge y := \inf\{x, y\}$ when this infimum exists.
(ii) *Join*: For $x, y \in L$, the join is $x \vee y := \sup\{x, y\}$ when this supremum exists.
(iii) *Lattice*: The partially ordered set L is a lattice iff the following condition holds. $(\forall x, y \in L)\,[x \wedge y \in L \wedge x \vee y \in L]$.
(iv) *Complete lattice*: A lattice L is complete iff $(\forall E \subseteq L)\,[\inf E \in L \wedge \sup E \in L]$.
(v) *Bottom*: An element $\bot \in L$ is a bottom element iff $(\forall x \in L)\,\bot \leq x$.
(vi) *Top*: An element $\top \in L$ is a top element iff $(\forall x \in L)\,x \leq \top$.
(vii) *Modular lattice*: A lattice L is modular iff the following law holds. $(\forall x, y, z \in L)\,[x \leq z \Rightarrow z \wedge (y \vee x) = (z \wedge y) \vee x]$.

5.4 Relations Between Sets and Closures

Definition 5.4.1. *Inverse and Composition of Relations*
Let X, Y, Z be sets, let $R \subseteq X \times Y$, and let $S \subseteq Y \times Z$.

(i) *Inverse*: $R^{-1} := \{(y, x) \in Y \times X : (x, y) \in R\}$.
(ii) *Composition*: $S \circ R := \{(x, z) \in X \times Z : (\exists y \in Y)\,[(x, y) \in R \wedge (y, z) \in S]\}$.
(iii) *Diagonal*: $\Delta_X := \{(x, x) : x \in X\}$.

Proposition 5.4.2. *Inverse and Composition Laws*
Let W, X, Y, Z be sets. Let $R \subseteq X \times Y$, let $S \subseteq Y \times Z$, and let $T \subseteq Z \times W$.

(i) Identity: $\Delta_Y \circ R = R = R \circ \Delta_X$.
(ii) Associativity: $T \circ (S \circ R) = (T \circ S) \circ R$.
(iii) Involution: $(R^{-1})^{-1} = R$.
(iv) Reversal: $(S \circ R)^{-1} = R^{-1} \circ S^{-1}$.

Proof.

(*i*) For $(x,y) \in X \times Y$, $(x,y) \in \Delta_Y \circ R \iff (\exists u \in Y)\,[(x,u) \in R \wedge u = y] \iff (x,y) \in R$.
For the right identity, $(x,y) \in R \circ \Delta_X \iff (\exists v \in X)\,[v = x \wedge (v,y) \in R] \iff (x,y) \in R$.
(*ii*) ($\Rightarrow$) Suppose $(x,w) \in T \circ (S \circ R)$. Choose $z \in Z$ with $(x,z) \in S \circ R$ and $(z,w) \in T$.
Choose $y \in Y$ with $(x,y) \in R$ and $(y,z) \in S$. Thus $(y,w) \in T \circ S$ and $(x,w) \in (T \circ S) \circ R$.
(*ii*) ($\Leftarrow$) Suppose $(x,w) \in (T \circ S) \circ R$. Choose $y \in Y$ with $(x,y) \in R$ and $(y,w) \in T \circ S$.
Choose $z \in Z$ with $(y,z) \in S$ and $(z,w) \in T$. Thus $(x,z) \in S \circ R$ and $(x,w) \in T \circ (S \circ R)$.
(*iii*) For $(x,y) \in X \times Y$, $(x,y) \in (R^{-1})^{-1} \iff (y,x) \in R^{-1} \iff (x,y) \in R$.
(*iv*) ($\Rightarrow$) Suppose $(z,x) \in (S \circ R)^{-1}$. Then $(x,z) \in S \circ R$.
Choose $y \in Y$ with $(x,y) \in R$ and $(y,z) \in S$. Hence $(z,y) \in S^{-1}$ and $(y,x) \in R^{-1}$, so $(z,x) \in R^{-1} \circ S^{-1}$.
(*iv*) ($\Leftarrow$) Suppose $(z,x) \in R^{-1} \circ S^{-1}$. Choose $y \in Y$ with $(z,y) \in S^{-1}$ and $(y,x) \in R^{-1}$.
Then $(y,z) \in S$ and $(x,y) \in R$, so $(x,z) \in S \circ R$ and $(z,x) \in (S \circ R)^{-1}$.

Structural Commentary: Membership expansion and witness comparison prove the four laws.
Key Insight: Composition records witnesses; inversion reverses their order. □

Definition 5.4.3. *Relation Powers and Closures*
Let X be a set and let $R \subseteq X^2$. Set $R^0 := \Delta_X$ and $R^{n+1} := R \circ R^n$ for $n \in \mathbb{N}_0$.

(i) *Reflexive closure*: $\mathrm{Ref}(R) := R \cup \Delta_X$.
(ii) *Transitive closure*: $R^+ := \bigcup_{n \in \mathbb{N}} R^n$.
(iii) *Reflexive-transitive closure*: $R^* := \bigcup_{n \in \mathbb{N}_0} R^n = \Delta_X \cup R^+$.

Lemma 5.4.4. *Addition Law for Relation Powers*
Let X be a set and let $R \subseteq X^2$. Then $(\forall m,n \in \mathbb{N}_0)\, R^n \circ R^m = R^{m+n}$.

Proof. Fix $m \in \mathbb{N}_0$. For $r \in \mathbb{N}$, let P_r assert $R^{r-1} \circ R^m = R^{m+r-1}$.
The identity $R^0 \circ R^m = \Delta_X \circ R^m = R^m$ holds by Proposition 5.4.2(i), so P_1 holds.
Assume P_r. Then $R^r \circ R^m = R \circ (R^{r-1} \circ R^m)$ by Proposition 5.4.2(ii) and the recursion.
Hence $R^r \circ R^m = R \circ R^{m+r-1} = R^{m+r}$ by P_r and the recursion, so P_{r+1} holds.
Consequently, $(\forall r \in \mathbb{N})\, P_r$ by induction. For $n \in \mathbb{N}_0$, take $r = n+1$ to obtain $R^n \circ R^m = R^{m+n}$.
Structural Commentary: Reindexed induction combines the recursive power law with associativity.
Key Insight: Relation composition adds power indices. □

Theorem 5.4.5. *Minimality of Reflexive and Transitive Closures*
Let X be a set and let $R \subseteq X^2$.

(i) Reflexive: $\mathrm{Ref}(R)$ is the smallest reflexive relation on X containing R.
(ii) Transitive: R^+ is the smallest transitive relation on X containing R.
(iii) Reflexive and transitive: R^* is the smallest reflexive and transitive relation on X containing R.

Proof.

(i) The relation $\mathrm{Ref}(R)$ contains R and Δ_X, so it is reflexive.
If $Q \subseteq X^2$ is reflexive and $R \subseteq Q$, then $\Delta_X \subseteq Q$, whence $\mathrm{Ref}(R) = R \cup \Delta_X \subseteq Q$.
(ii) Since $R = R^1$, $R \subseteq R^+$. Suppose $(x,y) \in R^+$ and $(y,z) \in R^+$. Choose $m,n \in \mathbb{N}$ with $(x,y) \in R^m$ and $(y,z) \in R^n$.
Then $(x,z) \in R^{m+n} \subseteq R^+$ by Lemma 5.4.4, so R^+ is transitive. Let $Q \subseteq X^2$ be transitive with $R \subseteq Q$.
For $n \in \mathbb{N}$, let P_n assert $R^n \subseteq Q$. P_1 holds by $R^1 = R \subseteq Q$. Assume P_n. Then $R^{n+1} = R \circ R^n \subseteq Q \circ Q$ by $R \subseteq Q$ and P_n.
Also $Q \circ Q \subseteq Q$ by the transitivity of Q, so P_{n+1} holds. Thus $(\forall n \in \mathbb{N})\, P_n$ by induction, and $R^+ \subseteq Q$.
(iii) The relation R^* contains R and is reflexive by $R^* = \Delta_X \cup R^+$. Suppose $(x,y) \in R^*$ and $(y,z) \in R^*$.
Choose $m,n \in \mathbb{N}_0$ with $(x,y) \in R^m$ and $(y,z) \in R^n$. Then $(x,z) \in R^{m+n} \subseteq R^*$ by Lemma 5.4.4, so R^* is transitive.
If $Q \subseteq X^2$ is reflexive and transitive with $R \subseteq Q$, then $\Delta_X \subseteq Q$ and $R^+ \subseteq Q$ by (ii). Thus $R^* = \Delta_X \cup R^+ \subseteq Q$.

Structural Commentary: Containment, closure, and minimality are verified in parallel.
Key Insight: Closure is generated by diagonal pairs together with finite composites. □

Example 5.4.6. *Closures of the Successor Relation*
Define $R \subseteq \mathbb{Z}^2$ by $m\,R\,n \iff n = m+1$. For $k \in \mathbb{N}$, let P_k assert $(\forall m,n \in \mathbb{Z})\,[m\,R^k\,n \iff n = m+k]$. P_1 holds by the definition of R.
Assume P_k. For $(m,n) \in \mathbb{Z}^2$, $m\,R^{k+1}\,n \iff (\exists u \in \mathbb{Z})\,[u = m+k \wedge n = u+1] \iff n = m+k+1$.
Thus P_{k+1} holds, and $(\forall k \in \mathbb{N})\, P_k$ by induction.

(i) $\mathrm{Ref}(R) = \{(m,n) \in \mathbb{Z}^2 : n = m \vee n = m+1\}$.
(ii) $R^+ = \{(m,n) \in \mathbb{Z}^2 : m < n\}$.
(iii) $R^* = \{(m,n) \in \mathbb{Z}^2 : m \le n\}$.

Key Insight: Finite successor compositions generate the strict and nonstrict integer orders.

Definition 5.4.7. *Order Isomorphism*
Let $(S, \le_S)$ and $(T, \le_T)$ be partially ordered sets.
A bijection $f : S \to T$ is an *order isomorphism* when the following condition holds. $(\forall x,y \in S)\,[x \le_S y \iff f(x) \le_T f(y)]$.
The two partially ordered sets are *order-isomorphic* when such a map exists.

Example 5.4.8. *Basic Order Isomorphisms*

(i) Define $f : \mathbb{Z} \to \{2n : n \in \mathbb{Z}\}$ by $f(n) := 2n$. Its inverse is $2n \mapsto n$, so f is bijective.
Moreover, $m \le n \iff 2m \le 2n$; hence f is an order isomorphism for the usual orders.
(ii) Let X be a set and define $c : \mathcal{P}(X) \to \mathcal{P}(X)$ by $c(A) := X \setminus A$. Since $c(c(A)) = A$, the map is bijective.
Moreover, $A \subseteq B \iff c(A) \supseteq c(B)$. Hence c is an order isomorphism from $(\mathcal{P}(X), \subseteq)$ to $(\mathcal{P}(X), \supseteq)$.
(iii) Let $(S, \le)$ be a poset and set $\downarrow s := \{x \in S : x \le s\}$. Define $\eta : S \to \{\downarrow s : s \in S\}$ by $\eta(s) :=\downarrow s$.
If $s \le t$, then $\downarrow s \subseteq \downarrow t$ by transitivity. If $\downarrow s \subseteq \downarrow t$, then $s \in \downarrow s \subseteq \downarrow t$, so $s \le t$. Thus $s \le t \iff \eta(s) \subseteq \eta(t)$.
If $\eta(s) = \eta(t)$, then $s \le t$ and $t \le s$, so $s = t$ by antisymmetry. Thus η is injective.
It is surjective by the definition of its codomain, so it is an order isomorphism.

Key Insight: Order isomorphisms preserve comparisons while changing their representation.

6 Cardinality, Choice, and Infinite Sets

Choice and maximality principles come first as foundational tools; cardinality then compares sets by functions rather than by informal size.

6.1 Choice and Zorn's Lemma

Definition 6.1.1. *Choice Function*
Let $\mathcal{F}$ be a family of nonempty sets, let I be a set, and let $(X_i)_{i\in I}$ be an indexed family of nonempty sets.

(i) A *choice function* on $\mathcal{F}$ is a map $c : \mathcal{F} \to \bigcup_{F\in\mathcal{F}} F$ satisfying $(\forall F \in \mathcal{F})\, c(F) \in F$.

(ii) An *indexed choice function* for $(X_i)_{i\in I}$ is a map $c : I \to \bigcup_{i\in I} X_i$ satisfying $(\forall i \in I)\, c(i) \in X_i$.

Principle 6.1.2. *Choice Principle*
Let I be a set and let $(X_i)_{i\in I}$ be an indexed family of nonempty sets. The axiom of choice asserts $(\exists c : I \to \bigcup_{i\in I} X_i)(\forall i \in I)\, c(i) \in X_i$. Equivalently, $\prod_{i\in I} X_i \neq \varnothing$. An explicit c proves existence directly; the principle supplies simultaneous choices without an explicit rule.

Principle 6.1.3. *Zorn's Lemma*
Let $(P, \leq)$ be a poset with $P \neq \varnothing$. Assume the following chain-upper-bound condition.
$(\forall C \subseteq P)\,[((\forall x, y \in C)\,(x \leq y \vee y \leq x)) \Rightarrow (\exists u \in P)(\forall c \in C)\, c \leq u]$. Then $(\exists m \in P)(\forall x \in P)\,(m \leq x \Rightarrow x = m)$.

Definition 6.1.4. *Inclusion and Containment Orders*
Let $\mathcal{F}$ be a family of sets and let $\mathcal{A} \subseteq \mathcal{F}$.

(i) *Inclusion*: for $A, B \in \mathcal{F}$, define $A \leq B$ iff $A \subseteq B$. An upper bound of $\mathcal{A}$ is $U \in \mathcal{F}$ satisfying $(\forall A \in \mathcal{A})\, A \subseteq U$.
An element $M \in \mathcal{F}$ is maximal iff $(\forall B \in \mathcal{F})\,(M \subseteq B \Rightarrow B = M)$.

(ii) *Reverse inclusion*: for $A, B \in \mathcal{F}$, define $A \leq B$ iff $B \subseteq A$. An upper bound of $\mathcal{A}$ is $U \in \mathcal{F}$ satisfying $(\forall A \in \mathcal{A})\, U \subseteq A$.
An element $M \in \mathcal{F}$ is maximal iff $(\forall B \in \mathcal{F})\,(B \subseteq M \Rightarrow B = M)$.

Proposition 6.1.5. *Inclusion Orders Are Partial Orders*
Let $\mathcal{F}$ be a family of sets. Inclusion and reverse inclusion are partial orders on $\mathcal{F}$.

Proof. Fix $A, B, C \in \mathcal{F}$. Since $A \subseteq A$, inclusion is reflexive. If $A \subseteq B$ and $B \subseteq C$, then $A \subseteq C$, so inclusion is transitive. If $A \subseteq B$ and $B \subseteq A$, then $A = B$ by Assumption 1.3.2, so inclusion is antisymmetric. Hence inclusion is a partial order.
For reverse inclusion, $A \supseteq A$ gives reflexivity, $A \supseteq B \supseteq C$ gives $A \supseteq C$, and $A \supseteq B \supseteq A$ gives $A = B$ by Assumption 1.3.2. Thus reverse inclusion is also a partial order.
Structural Commentary: Each order law follows from the corresponding containment law and set extensionality.
Key Insight: Reversing containment preserves reflexivity, transitivity, and antisymmetry. □

Proof Method 6.1.6. *Zorn Maximality Template*
Use this method when the target follows from a candidate admitting no proper admissible extension.
Let P be the set of candidates, and let $\leq$ record admissible extension.

(i) Verify that $P \neq \varnothing$ and that $\leq$ is a partial order on P.
(ii) Fix a chain $C \subseteq P$, construct $u \in P$, and prove $(\forall p \in C)\, p \leq u$.
(iii) Obtain a maximal $m \in P$ by Principle 6.1.3, and prove that maximality forces the target property.

For $C \neq \varnothing$, common candidates are $\bigcup_{A\in C} A$ under inclusion and $\bigcap_{A\in C} A$ under reverse inclusion.
Under reverse inclusion, another object contained in every member of C may be necessary.
If $C = \varnothing$, any element of P is an upper bound. In every case, prove $u \in P$; this is the indispensable admissibility check.
Key Idea: A chain bound must preserve every admissibility condition defining the candidate set.

6.2 Same Cardinality, Finite, Countable, and Uncountable

Definition 6.2.1. *Same Cardinality*
For sets A, B, write $A \sim_{\#} B$ iff a bijection $f : A \to B$ exists. Then A and B have *the same cardinality*, or are *equivalent*.

Proposition 6.2.2. *Same Cardinality Is an Equivalence Relation*
Let A, B, C be sets.

(i) $A \sim_{\#} A$.
(ii) $A \sim_{\#} B \Rightarrow B \sim_{\#} A$.
(iii) $(A \sim_{\#} B \wedge B \sim_{\#} C) \Rightarrow A \sim_{\#} C$.

Consequently, $\sim_{\#}$ is an equivalence relation among sets.

Proof.

(i) The identity $\mathrm{id}_A : A \to A$ is bijective, so $A \sim_{\#} A$.
(ii) Suppose $A \sim_{\#} B$ and choose a bijection $f : A \to B$. The inverse $f^{-1} : B \to A$ exists, and f is its two-sided inverse. Hence f^{-1} is bijective by Theorem 3.3.2(i), so $B \sim_{\#} A$.
(iii) Suppose $A \sim_{\#} B$ and $B \sim_{\#} C$, and choose bijections $f : A \to B$ and $g : B \to C$. The composite $g \circ f : A \to C$ is bijective by Proposition 3.3.3(vi), so $A \sim_{\#} C$.

Structural Commentary: Identity, inversion, and composition verify the three equivalence-relation laws.
Key Insight: Bijections are closed under reversal and composition. □

Theorem 6.2.3. *Schroeder–Bernstein Theorem*
Let A, B be sets, and let $f : A \to B$ and $g : B \to A$ be injections. Then $A \sim_{\#} B$.

Proof. Set $A_0 := A \setminus g(B)$ and recursively set $B_n := f(A_n)$ and $A_{n+1} := g(B_n)$ for $n \in \mathbb{N}_0$.
Put $U_A := \bigcup_{n\in\mathbb{N}_0} A_n$, $U_B := \bigcup_{n\in\mathbb{N}_0} B_n$, $A_* := A \setminus U_A$, and $B_* := B \setminus U_B$.
The restriction $f_* := f|_{U_A} : U_A \to U_B$ is bijective because f is injective and $U_B = f(U_A)$. For $b \in B_*$, $g(b) \notin A_0$.
Suppose $g(b) \in A_{n+1} = g(B_n)$ with $n \in \mathbb{N}_0$. Then injectivity of g gives $b \in B_n \subseteq U_B$, a contradiction. Thus $g(b) \in A_*$.
Conversely, if $a \in A_*$, then $a \notin A_0$, so $a \in g(B)$. Choose $b \in B$ satisfying $a = g(b)$. Suppose $b \in B_n$ with $n \in \mathbb{N}_0$.
Then $a \in A_{n+1} \subseteq U_A$, a contradiction. Hence $b \in B_*$. Therefore $g_* := g|_{B_*} : B_* \to A_*$ is bijective.
Define $h : A \to B$ by $h(x) := f_*(x)$ for $x \in U_A$ and $h(x) := g_*^{-1}(x)$ for $x \in A_*$. The domain parts U_A, A_* and image parts U_B, B_* are disjoint partitions, and both branches are bijective. Hence h is bijective, so $A \sim_{\#} B$.
Structural Commentary: Forward layers are matched by f; the complementary remainders are matched by g^{-1}.
Key Insight: Alternate the injections until the unmatched remainder can be reversed. □

Definition 6.2.4. *Finite, Countable, and Uncountable*
Let A be a set.

(i) A is *finite* iff $(\exists n \in \mathbb{N}_0)\, A \sim_{\#} J_n$.
(ii) A is *infinite* iff it is not finite.
(iii) A is *countable* iff $A \sim_{\#} \mathbb{N}$.
(iv) A is *uncountable* iff it is neither finite nor countable.
(v) A is *at most countable* iff it is finite or countable.

Countable sets are also called denumerable. Here *enumerable* more generally describes the image of a sequence.

Proposition 6.2.5. *The Natural Numbers Are Infinite*

(i) $(\forall m \in \mathbb{N}_0)$, *no injection* $\mathbb{N} \to J_m$ *exists.*
(ii) The set $\mathbb{N}$ *is infinite.*
(iii) If A *is countable, then* A *is infinite.*
(iv) If F *is finite and* $A \subseteq F$, *then* A *is not countable.*

Proof.

(i) For $r \in \mathbb{N}$, let Q_r assert that no injection $\mathbb{N} \to J_{r-1}$ exists. Since $J_0 = \emptyset$, no map $\mathbb{N} \to J_0$ exists, so Q_1 holds.
Assume Q_r and suppose $u : \mathbb{N} \to J_r$ is injective. If $r \notin u(\mathbb{N})$, then $u : \mathbb{N} \to J_{r-1}$ contradicts Q_r.
Otherwise let $s \in \mathbb{N}$ be the unique index satisfying $u(s) = r$.
Define $\tau : \mathbb{N} \to \mathbb{N} \setminus \{s\}$ by $\tau(k) := k$ for $k < s$ and $\tau(k) := k + 1$ for $k \geq s$.
The map τ is injective and avoids s, so $u \circ \tau : \mathbb{N} \to J_{r-1}$ is injective, again contradicting Q_r. Thus Q_{r+1} holds.
Hence $(\forall r \in \mathbb{N})\, Q_r$ by Theorem 2.6.2, proving (i).
(ii) If $\mathbb{N}$ were finite, a bijection $J_m \to \mathbb{N}$ would have an inverse injection $\mathbb{N} \to J_m$, contradicting (i).
(iii) Let A be countable. If A were finite, composing a bijection $\mathbb{N} \to A$ with a bijection $A \to J_m$ would contradict (i).
(iv) If a countable A were contained in a finite F, then $\mathbb{N} \to A \hookrightarrow F \to J_m$ would be injective, contradicting (i).

Structural Commentary: Induction deletes the unique preimage of the final point of a finite target.
Key Insight: Removing one domain point leaves $\mathbb{N}$ injectively equivalent to itself. □

Proposition 6.2.6. *Finite Sums Are Invariant under Reindexing*
Let $n \in \mathbb{N}_0$, *let* $c : J_n \to \mathbb{C}$, *and let* $\sigma : J_n \to J_n$ *be a bijection. Then* $\sum_{i=1}^{n} c(\sigma(i)) = \sum_{i=1}^{n} c(i)$.

Proof. For $r \in \mathbb{N}$, let P_r be the assertion of the proposition with $n = r - 1$. Then P_1 is the empty-sum identity.
Assume P_r, put $m := r - 1$, and fix $c : J_{m+1} \to \mathbb{C}$ and a permutation σ of J_{m+1}.
Put $j := \sigma^{-1}(m + 1)$ and define $\theta : J_m \to J_{m+1} \setminus \{j\}$ by $\theta(i) := i$ for $i < j$ and $\theta(i) := i + 1$ for $i \geq j$.
Then θ and $\sigma \circ \theta : J_m \to J_m$ are bijective. Since $\sigma(j) = m + 1$, commutativity gives $\sum_{i=1}^{m+1} c(\sigma(i)) = c(m + 1) + \sum_{i=1}^{m} c(\sigma(\theta(i)))$.
Latter expression equals $c(m + 1) + \sum_{i=1}^{m} c(i) = \sum_{i=1}^{m+1} c(i)$ by P_r. Thus P_{r+1} holds. Hence $(\forall r \in \mathbb{N})\, P_r$ by Theorem 2.6.2, proving P_{n+1}.
Structural Commentary: Induction removes the position mapped to the final index and reindexes the remainder.
Key Insight: A permutation changes positions without changing the multiset of summands. □

Definition 6.2.7. *Summation over a Finite Set*
Let X be finite, put $n := \#X$, let $f : X \to \mathbb{C}$, and choose a bijection $g : J_n \to X$. Define $\sum_{x\in X} f(x) := \sum_{i=1}^{n} f(g(i))$.
If $X = \emptyset$, then $n = 0$ and this value is the empty sum 0. If $k : J_n \to X$ is another bijection, put $\sigma := g^{-1} \circ k$.
Then σ is a permutation of J_n, $k = g \circ \sigma$, and the two listings give equal sums by Proposition 6.2.6.
Key Insight: Reindexing changes the listing, not the sum.

Proposition 6.2.8. *Finite Set Summation Laws*
Let X, Y *be finite sets.*

(i) Well-definedness: If $f : X \to \mathbb{C}$, *then* $\sum_{x\in X} f(x)$ *is independent of the bijection* $J_{\#X} \to X$.
(ii) Substitution: If $h : Y \to X$ *is a bijection and* $f : X \to \mathbb{C}$, *then* $\sum_{x\in X} f(x) = \sum_{y\in Y} f(h(y))$.
(iii) Linearity: If $f, g : X \to \mathbb{C}$, *then* $\sum_{x\in X} (f(x) + g(x)) = \sum_{x\in X} f(x) + \sum_{x\in X} g(x)$. *If* $c \in \mathbb{C}$, *then* $\sum_{x\in X} cf(x) = c \sum_{x\in X} f(x)$.
(iv) Disjoint unions: If $X \cap Y = \emptyset$ *and* $f : X \cup Y \to \mathbb{C}$, *then* $X \cup Y$ *is finite. The identity* $\sum_{z\in X\cup Y} f(z) = \sum_{x\in X} f(x) + \sum_{y\in Y} f(y)$ *holds.*
(v) Finite Fubini: The set $X \times Y$ *is finite. If* $f : X \times Y \to \mathbb{C}$, *then the following identities hold.*
$\sum_{x\in X} \sum_{y\in Y} f(x, y) = \sum_{(x,y)\in X\times Y} f(x, y)$, *and* $\sum_{y\in Y} \sum_{x\in X} f(x, y) = \sum_{(x,y)\in X\times Y} f(x, y)$.

Proof.

(i) Let $g, k : J_{\#X} \to X$ be bijections and put $\sigma := g^{-1} \circ k$. Then $k = g \circ \sigma$, so the two sums agree by Proposition 6.2.6.

(ii) Choose a bijection $g : J_{\#Y} \to Y$. The composite $h \circ g : J_{\#Y} \to X$ is bijective, so $\#Y = \#X$ by Proposition 4.2.2.
After expanding the finite-set sums, $\sum_{x \in X} f(x) = \sum_{i=1}^{\#Y} f(h(g(i))) = \sum_{y \in Y} f(h(y))$ by part (i).

(iii) Put $m := \#X$, choose a bijection $\gamma : J_m \to X$, and set $a_i := f(\gamma(i))$ and $b_i := g(\gamma(i))$ for $i \in J_m$, with $a_i = b_i = 0$ otherwise.
After expanding the three finite-set sums, the first identity holds by Proposition 4.1.2(ii).
After the analogous expansions, the scalar-multiple identity holds by Proposition 4.1.2(iii).

(iv) Put $m := \#X$ and $n := \#Y$. If $m = 0$ or $n = 0$, then one set is empty and both conclusions follow directly.
Suppose $m, n \in \mathbb{N}$, and choose bijections $\alpha : J_m \to X$ and $\beta : J_n \to Y$.
Define $\delta : J_{m+n} \to X \cup Y$ by $\delta(i) := \alpha(i)$ when $i \leq m$ and $\delta(i) := \beta(i - m)$ when $i > m$.
The two branches have disjoint images and make δ bijective because $X \cap Y = \emptyset$. Thus $X \cup Y$ is finite.
The identity in (iv) holds by Proposition 4.1.2(i) after expansion along δ.

(v) Put $m := \#X$ and $n := \#Y$. The set $X \times Y$ is finite with $\#(X \times Y) = mn$ by Theorem 4.2.5(iii).
If $m = 0$ or $n = 0$, all three sums equal 0. Otherwise choose bijections $\alpha : J_m \to X$ and $\beta : J_n \to Y$.
Define bijections $\ell, r : J_{mn} \to X \times Y$ by $\ell((i-1)n + j) := (\alpha(i), \beta(j))$ and $r((j-1)m + i) := (\alpha(i), \beta(j))$ for $i \in J_m$ and $j \in J_n$.
The first identity in (v) holds by Proposition 4.1.2(i) and part (i) after expansion along ℓ.
The second identity in (v) holds by Proposition 4.1.2(i) and part (i) after expansion along r.

Structural Commentary: Reindexing, concatenation, and lexicographic listings transfer ordinary finite-sum laws to sets.
Key Insight: A finite-set sum depends on values, not listing order. □

Definition 6.2.9. *Sequences as Enumerations*
Let A be a set.

(i) A *sequence* in A is a map $x : \mathbb{N} \to A$, written $(x_n)_{n \in \mathbb{N}}$ with $x_n := x(n)$.
(ii) A sequence $x : \mathbb{N} \to A$ *enumerates* A iff $x(\mathbb{N}) = A$.
(iii) A sequence $x : \mathbb{N} \to A$ is a *distinct enumeration* of A iff $x : \mathbb{N} \to A$ is bijective.

Thus A is countable iff it has a distinct enumeration.

Proposition 6.2.10. *The Integers Are Countable*
The set $\mathbb{Z}$ is countable.

Proof. Define $f : \mathbb{N} \to \mathbb{Z}$ by $f(2k) := k$ and $f(2k-1) := 1 - k$ for $k \in \mathbb{N}$.
Define $e : \mathbb{Z} \to \mathbb{N}$ by $e(z) := 2z$ for $z \geq 1$ and $e(z) := 1 - 2z$ for $z \leq 0$.
The even and odd branches partition $\mathbb{N}$, while the positive and nonpositive branches partition $\mathbb{Z}$.
Direct substitution gives $e \circ f = \mathrm{id}_{\mathbb{N}}$ and $f \circ e = \mathrm{id}_{\mathbb{Z}}$. Thus f is bijective by Theorem 3.3.2(i), so $\mathbb{Z}$ is countable.
Structural Commentary: Parity separates the positive and nonpositive integer branches.
Key Insight: Interleave the two one-sided integer lists. □

Theorem 6.2.11. *Infinite Subsets of Countable Sets*
Let A be countable and let $E \subseteq A$ be infinite. Then E is countable.

Proof. Choose a bijection $x : \mathbb{N} \to A$, write $x_n := x(n)$, and set $I_E := \{n \in \mathbb{N} : x_n \in E\}$. The restriction $x|_{I_E} : I_E \to E$ is bijective.
Hence I_E is infinite, since otherwise this bijection would make E finite. Each intersection $I_E \cap J_n$ is finite by Proposition 4.2.4(ii).
For $k \in \mathbb{N}$, set $M_k := \{n \in I_E : \#(I_E \cap J_n) = k\}$. We prove $(\forall k \in \mathbb{N})\, M_k \neq \emptyset$ by induction.
Let $m := \min I_E$ by well-ordering. Then $I_E \cap J_m = \{m\}$, so $m \in M_1$. Suppose $M_k \neq \emptyset$ and choose $m \in M_k$.
The set $I_E \setminus J_m$ is nonempty; otherwise $I_E \subseteq J_m$ would be finite by Proposition 4.2.4(ii). Let $r := \min(I_E \setminus J_m)$ by well-ordering.
Then $I_E \cap J_r = (I_E \cap J_m) \dot\cup \{r\}$, so $\#(I_E \cap J_r) = k + 1$ by Proposition 4.2.4(i). Thus $r \in M_{k+1}$; $(\forall k \in \mathbb{N})\, M_k \neq \emptyset$ by Theorem 2.6.2.
If $n < m$ belong to I_E, then $I_E \cap J_m$ is the disjoint union of $I_E \cap J_n$ and the nonempty set $I_E \cap (J_m \setminus J_n)$.
Hence $\#(I_E \cap J_n) < \#(I_E \cap J_m)$ by Proposition 4.2.4(i), so each M_k is a singleton. Let n_k be its unique element.
If $n \in I_E$ and $k := \#(I_E \cap J_n)$, then $n \in M_k$, so $n = n_k$. Thus $k \mapsto n_k$ is a bijection $\mathbb{N} \to I_E$.
The composite $k \mapsto x_{n_k}$ is a bijection $\mathbb{N} \to E$, so E is countable.
Structural Commentary: Finite initial-segment ranks canonically enumerate the indices that hit the subset.
Key Insight: Rank each selected index by the number of earlier selected indices. □

Proposition 6.2.12. *Subsets and Images of At Most Countable Sets*
Let A be at most countable.

(i) If $B \subseteq A$, then B is at most countable.
(ii) If $f : A \to Y$ is a function, then $f(A)$ is at most countable.

Proof.

(i) Suppose $B \subseteq A$. If A is finite, then B is finite by Proposition 4.2.4(ii).
If A is countable, then B is finite or, when infinite, countable by Theorem 6.2.11. Thus B is at most countable.

(ii) Suppose $f : A \to Y$ and first assume A is finite. Put $m := \#A$, choose a bijection $e : J_m \to A$.
Set $I := \{i \in J_m : (\forall j \in J_m)\, (j < i \Rightarrow f(e(j)) \neq f(e(i)))\}$. The set I is finite by Proposition 4.2.4(ii).
The map $i \mapsto f(e(i))$ on I is injective by the definition of I. Fix $y \in f(A)$. The nonempty set $\{i \in J_m : f(e(i)) = y\}$ has a least element by well-ordering, and that element belongs to I. Thus the map is also surjective onto $f(A)$, so $f(A)$ is finite.
Now suppose A is countable. Choose a bijection $e : \mathbb{N} \to A$ and set $I := \{i \in \mathbb{N} : (\forall j \in \mathbb{N})\, (j < i \Rightarrow f(e(j)) \neq f(e(i)))\}$.
The set I is at most countable by (i). The map $i \mapsto f(e(i))$ on I is injective by the definition of I.
Fix $y \in f(A)$. The nonempty set $\{i \in \mathbb{N} : f(e(i)) = y\}$ has a least element by well-ordering, and that element belongs to I.
Thus the map is also surjective onto $f(A)$, so $f(A)$ is at most countable.

Structural Commentary: Subsets restrict a listing; images retain the first index of each attained value.
Key Insight: Deleting entries or repetitions cannot increase cardinality. □

Proposition 6.2.13. *At Most Countable Sets Are Exactly Enumerable Images*
For a set B, the following are equivalent:

(i) B is at most countable.
(ii) $B = \emptyset$ or a surjection $f : \mathbb{N} \to B$ exists.

Thus a nonempty set is at most countable iff it is the image of a sequence.

Proof.

(*i*) $\Rightarrow$ (*ii*) If $B = \emptyset$, then (ii) holds. If B is countable, any bijection $\mathbb{N} \to B$ is surjective.
If B is finite and nonempty, put $m := \#B$, choose a bijection $e : J_m \to B$.
Define $f : \mathbb{N} \to B$ by $f(n) := e(n)$ for $n \leq m$ and $f(n) := e(m)$ for $n > m$. Then f is surjective.

(*ii*) $\Rightarrow$ (*i*) If $B = \emptyset$, then B is finite. If $f : \mathbb{N} \to B$ is surjective, then $B = f(\mathbb{N})$ is at most countable by Proposition 6.2.12(ii).

Structural Commentary: A finite list can repeat its final term; a countable list already supplies a surjection.
Key Insight: At most countable sets are sequence images or the empty set. □

Proposition 6.2.14. *Pairs of Positive Integers Are Countable*
The set $\mathbb{N} \times \mathbb{N}$ is countable.

Proof. For $r \in \mathbb{N}_0$, put $t_r := \frac{r(r+1)}{2}$. Define $p : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$ by $p(i,j) := t_{i+j-2} + i$.
Fix $(i,j) \in \mathbb{N} \times \mathbb{N}$ and put $r := i + j - 1$; then $t_{r-1} < p(i,j) \leq t_r$. The intervals $(t_{r-1}, t_r]$ are disjoint for $r \in \mathbb{N}$.
Hence equality of two values of p forces equality of the coordinate sums and then equality of the first, and therefore also the second, coordinates. Thus p is injective. Fix $q \in \mathbb{N}$. The set $R_q := \{r \in \mathbb{N} : q \leq t_r\}$ is nonempty because $t_q \geq q$.
Let $r := \min R_q$ by well-ordering. Minimality gives $t_{r-1} < q \leq t_r$. Set $i := q - t_{r-1}$ and $j := r + 1 - i$.
Then $i, j \in \mathbb{N}$ and $p(i,j) = q$, so p is surjective. Hence p is a bijection and $\mathbb{N} \times \mathbb{N}$ is countable.
Structural Commentary: Triangular intervals separate the diagonals and recover both coordinates from each index.
Key Insight: Coordinate-sum diagonals occupy disjoint finite intervals. □

Theorem 6.2.15. *Countable Union of Countable Sets*
Let $(E_n)_{n\in\mathbb{N}}$ be countable sets and set $S := \bigcup_{n\in\mathbb{N}} E_n$. Then S is countable.

Proof. For $n \in \mathbb{N}$, let $\mathcal{B}_n$ be the set of bijections $\mathbb{N} \to E_n$. Then $(\forall n \in \mathbb{N})\, \mathcal{B}_n \neq \emptyset$.
Choose $(x_n)_{n\in\mathbb{N}}$ satisfying $(\forall n \in \mathbb{N})\, x_n \in \mathcal{B}_n$ by the axiom of choice, and write $x_{n,k} := x_n(k)$.
Choose a bijection $d : \mathbb{N} \to \mathbb{N} \times \mathbb{N}$ by Proposition 6.2.14. For $t \in \mathbb{N}$, write $d(t) = (n_t, k_t)$ and define $a : \mathbb{N} \to S$ by $a(t) := x_{n_t,k_t}$.
Then $a(\mathbb{N}) = S$, so S is at most countable by Proposition 6.2.13.
The countable set E_1 is contained in S, so S is not finite by Proposition 6.2.5(iv). Hence S is countable.
Structural Commentary: Choice selects row enumerations, and a pairing bijection flattens their two indices.
Key Insight: A countable array becomes one sequence after pairing its indices. □

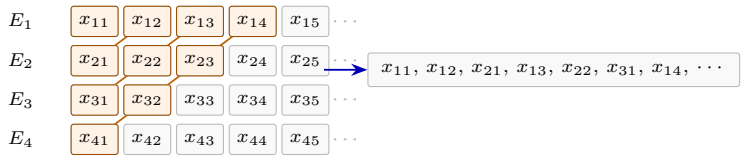

Figure 7: Diagonal scan of countable rows into one surjective sequence.

Figure 7 illustrates the scan used in Theorem 6.2.15.
Every indexed entry occurs on a finite diagonal; repeated values do not affect surjectivity.

Corollary 6.2.16. *At Most Countable Unions*
Let A be at most countable and let $(B_\alpha)_{\alpha\in A}$ be an indexed family of at most countable sets. Then $\bigcup_{\alpha\in A} B_\alpha$ is at most countable.

Proof. Set $T := \bigcup_{\alpha\in A} B_\alpha$. If $T = \emptyset$, then the conclusion holds. Suppose $T \neq \emptyset$ and set $I := \{\alpha \in A : B_\alpha \neq \emptyset\}$.
The set I is nonempty and at most countable by Proposition 6.2.12(i).
Choose a surjection $e : \mathbb{N} \to I$ by Proposition 6.2.13, and put $\alpha_j := e(j)$. For $j \in \mathbb{N}$, let $\mathcal{S}_j$ be the set of surjections $\mathbb{N} \to B_{\alpha_j}$.
Then $(\forall j \in \mathbb{N})\, \mathcal{S}_j \neq \emptyset$ by Proposition 6.2.13. Choose $(b_j)_{j\in\mathbb{N}}$ satisfying $(\forall j \in \mathbb{N})\, b_j \in \mathcal{S}_j$ by the axiom of choice, and write $b_{j,k} := b_j(k)$.
Choose a bijection $d : \mathbb{N} \to \mathbb{N} \times \mathbb{N}$ by Proposition 6.2.14. For $t \in \mathbb{N}$, write $d(t) = (j_t, k_t)$ and define $a : \mathbb{N} \to T$ by $a(t) := b_{j_t,k_t}$.
Then $a(\mathbb{N}) = T$, so T is at most countable by Proposition 6.2.13.
Structural Commentary: Surjections index the nonempty pieces and their elements before a pairing map flattens both indices.
Key Insight: Empty pieces can be discarded; all remaining rows admit sequence images. □

Corollary 6.2.17. *Countable Cartesian Products*
Let A, B be sets.

(i) If A and B are at most countable, then $A \times B$ is at most countable.
(ii) If A and B are countable, then $A \times B$ is countable.

Proof.

(i) For $a \in A$, set $S_a := \{a\} \times B$. The map $b \mapsto (a,b)$ is a bijection $B \to S_a$, so $(S_a)_{a\in A}$ is an indexed family of at-most-countable sets. Since $A \times B = \bigcup_{a\in A} S_a$, the product is at most countable by Corollary 6.2.16.

(ii) By (i), $A \times B$ is at most countable. Choose $b_0 \in B$. The map $a \mapsto (a, b_0)$ is a bijection $A \to A \times \{b_0\}$, so $A \times B$ contains the countable subset $A \times \{b_0\}$. Thus $A \times B$ is not finite by Proposition 6.2.5(iv), and it is therefore countable.

Structural Commentary: Slicing proves at-most-countability; one fixed-coordinate slice rules out finiteness.
Key Insight: A product is a union of copies of either factor. □

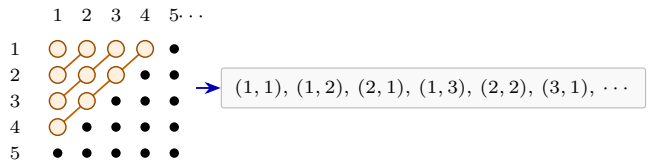

Figure 8: Diagonal enumeration of $\mathbb{N} \times \mathbb{N}$ by finite $i + j$ diagonals.

Figure 8 depicts the $\mathbb{N} \times \mathbb{N}$ pairing in Proposition 6.2.14.
Each pair lies on one finite coordinate-sum diagonal, which determines its interval of indices.

Theorem 6.2.18. *Finite Tuples over a Countable Set*
Let A be countable. For $n \in \mathbb{N}$, set $T_n := \{(a_1, \dots, a_n) : (\forall k \in J_n)\, a_k \in A\}$. Then T_n is countable.

Proof. For $r \in \mathbb{N}$, let P_r assert that T_r is countable. The map $a \mapsto (a)$ is a bijection $A \to T_1$, so P_1 holds. Assume P_r.
The product $T_r \times A$ is countable by Corollary 6.2.17(ii), and concatenation bijects $T_r \times A$ with T_{r+1}.
Thus P_{r+1} holds, so $(\forall r \in \mathbb{N})\, P_r$ by Theorem 2.6.2.
Structural Commentary: Induction appends one coordinate and transfers countability across a binary product bijection.
Key Insight: Every fixed finite product is built one coordinate at a time. □

Corollary 6.2.19. *The Rationals Are Countable*
The set $\mathbb{Q}$ is countable.

Proof. Set $D := \{(p, q) \in \mathbb{Z} \times \mathbb{Z} : q \neq 0\}$ and define $\pi : D \to \mathbb{Q}$ by $\pi(p, q) := \frac{p}{q}$.
The set $\mathbb{Z} \times \mathbb{Z}$ is countable by Proposition 6.2.10 and Corollary 6.2.17(ii), so D is at most countable by Proposition 6.2.12(i).
Since $\mathbb{Q} = \pi(D)$, the set $\mathbb{Q}$ is at most countable by Proposition 6.2.12(ii).
The inclusion $\mathbb{Z} \hookrightarrow \mathbb{Q}$ identifies a countable subset, so $\mathbb{Q}$ is not finite by Proposition 6.2.5(iv), and therefore $\mathbb{Q}$ is countable.
Structural Commentary: Integer pairs form an at-most-countable parameter set whose quotient map covers $\mathbb{Q}$.
Key Insight: Fractions are images of nonzero-denominator integer pairs. □

Proof Method 6.2.20. *Cardinality Proof Patterns*
Let A, B be sets. Choose the route matching the target cardinality claim.

(i) *Same cardinality*: Construct $f : A \to B$, then verify that f is injective and surjective.
(ii) *Countable*: Construct a bijection $\mathbb{N} \to A$. Alternatively, prove that A is at most countable and not finite.
(iii) *Uncountable*: Prove $A \neq \emptyset$. Fix an arbitrary map $s : \mathbb{N} \to A$ and construct $a_s \in A \setminus s(\mathbb{N})$.
Then no sequence surjects onto A, so A is not at most countable by Proposition 6.2.13.

Key Idea: Bijections certify equal cardinality; diagonal witnesses obstruct every proposed enumeration.

6.3 Ordinals, Transfinite Recursion, and Well-Foundedness

Definition 6.3.1. *Ordinals and Order Types*

(i) A set T is *transitive* iff $(\forall x \in T)\, x \subseteq T$.
(ii) An *ordinal* is a transitive set α on which $\in$ is a strict well-order. The relation $\in$ is irreflexive and transitive on α, distinct elements are $\in$-comparable, and each nonempty $A \subseteq \alpha$ contains m satisfying $(\forall a \in A)\, a \notin m$.
(iii) For ordinals α, β, write $\alpha < \beta$ iff $\alpha \in \beta$ and $\alpha \leq \beta$ iff $\alpha \subseteq \beta$.
(iv) Set $0 := \emptyset$. The *successor* of α is $\alpha + 1 := \alpha \cup \{\alpha\}$. The *finite ordinals* are 0 and its finite iterated successors.
An ordinal is *infinite* iff it is not finite. It is a *limit ordinal* iff it is nonzero and is not a successor.
(v) The least infinite ordinal is ω; its elements are the finite ordinals $0, 1, 2, \dots$.
If a well-ordered set $(S, \leq_S)$ is order-isomorphic to an ordinal δ in the sense of Definition 5.4.7, then δ is the *order type* of $(S, \leq_S)$.

Principle 6.3.2. *Ordinal Foundation Principles*
The following standard properties of von Neumann ordinals form the ordinal framework used below.

(i) *Ordinal comparison*: two ordinals are equal or one belongs to the other, and each nonempty set of ordinals has a least member.
(ii) *Strong transfinite induction*: if P is a property of ordinals satisfying $(\forall \alpha)\, [((\forall \beta < \alpha)\, P(\beta)) \Rightarrow P(\alpha)]$, then $(\forall \alpha)\, P(\alpha)$.
(iii) *Order types*: a well-ordered set is order-isomorphic to a unique ordinal.
(iv) *Well-ordering theorem*: under Principle 6.1.2, each set admits a well-order and is therefore bijective with an ordinal by (iii).

These principles concern ordinal comparison and recursive construction; do not prescribe a particular well-order on an arbitrary set.

Definition 6.3.3. *Well-Founded Relation*
Let $\prec$ be a relation on a set X.

(i) The *predecessor set* of $x \in X$ is $\mathrm{Pred}_{\prec}(x) := \{y \in X : y \prec x\}$.
(ii) For $A \subseteq X$, an element $m \in A$ is *$\prec$-minimal in A* iff $\mathrm{Pred}_{\prec}(m) \cap A = \emptyset$.
(iii) The relation $\prec$ is *well-founded* iff $(\forall A \subseteq X)\, [A \neq \emptyset \Rightarrow (\exists m \in A)\ \mathrm{Pred}_{\prec}(m) \cap A = \emptyset]$.

Neither totality nor transitivity is required.

Theorem 6.3.4. *Well-Founded Induction*
Let $\prec$ be a well-founded relation on X, and let P be a property of elements of X.
If $(\forall x \in X)\, [((\forall y \in \mathrm{Pred}_{\prec}(x))\, P(y)) \Rightarrow P(x)]$, then $(\forall x \in X)\, P(x)$.

Proof. Set $B := \{x \in X : \neg P(x)\}$. Suppose $B \neq \emptyset$, and choose a $\prec$-minimal $b \in B$. If $y \in \mathrm{Pred}_{\prec}(b)$, then $y \notin B$ by minimality.
Thus $(\forall y \in \mathrm{Pred}_{\prec}(b))\, P(y)$. The induction premise gives $P(b)$, contradicting $b \in B$. Hence $B = \emptyset$ and $(\forall x \in X)\, P(x)$.
Structural Commentary: A least-counterexample contradiction applies the induction premise at one minimal failure.
Key Insight: A minimal failure has only successful predecessors. □

Principle 6.3.5. *Transfinite and Well-Founded Recursion*
Recursive values may depend on the full restriction of the desired function to earlier arguments.

(i) *Ordinal recursion*: let θ be an ordinal, and suppose $G(\alpha, g)$ is assigned whenever $\alpha < \theta$ and $\operatorname{dom} g = \alpha$.
Then $(\exists! F)\,[\operatorname{dom} F = \theta \wedge (\forall \alpha < \theta)\, F(\alpha) = G(\alpha, F|_\alpha)]$.

(ii) *Well-founded recursion*: let $\prec$ be well-founded on X, and suppose $H(x, g)$ is assigned whenever $x \in X$ and $\operatorname{dom} g = \operatorname{Pred}_\prec(x)$.
Then $(\exists! F)\,[\operatorname{dom} F = X \wedge (\forall x \in X)\, F(x) = H(x, F|_{\operatorname{Pred}_\prec(x)})]$.

In (i), the least disagreement proves uniqueness; in (ii), uniqueness follows by Theorem 6.3.4 for the property that two candidates agree. The rules apply only when the value at an argument depends on values at its predecessors.

Definition 6.3.6. *Ordinal Arithmetic*
For a set A of ordinals, set $\sup A := \bigcup A$. Fix an ordinal α.
Transfinite recursion in the second argument defines the following operations.
Each limit clause assumes that λ is a nonzero limit ordinal.

(i) *Addition*: $\alpha + 0 := \alpha$ and $\alpha + (\beta + 1) := (\alpha + \beta) + 1$. For a limit λ, $\alpha + \lambda := \sup\{\alpha + \beta : \beta < \lambda\}$.
(ii) *Multiplication*: $\alpha \cdot 0 := 0$ and $\alpha \cdot (\beta + 1) := \alpha \cdot \beta + \alpha$. For a limit λ, $\alpha \cdot \lambda := \sup\{\alpha \cdot \beta : \beta < \lambda\}$.
(iii) *Exponentiation*: $\alpha^0 := 1$ and $\alpha^{\beta+1} := \alpha^\beta \cdot \alpha$. For a limit λ, $\alpha^\lambda := \sup\{\alpha^\beta : \beta < \lambda\}$.

The successor clause for addition agrees with Definition 6.3.1.

Example 6.3.7. *Ordinal Arithmetic Remembers Order*
The limit clauses give $1 + \omega = \sup\{1 + n : n < \omega\} = \omega$ and $2 \cdot \omega = \sup\{2 \cdot n : n < \omega\} = \omega$.
The successor clauses give $\omega + 1 > \omega$ and $\omega \cdot 2 = \omega + \omega > \omega$. Thus $1 + \omega < \omega + 1$ and $2 \cdot \omega < \omega \cdot 2$.
Ordinal addition and multiplication retain the order of concatenation and are not commutative.

Definition 6.3.8. *Cardinals as Initial Ordinals*

(i) An ordinal κ is a *cardinal*, or *initial ordinal*, iff $(\forall \beta < \kappa)\, \beta \not\sim_\# \kappa$.
(ii) If a set X is bijective with an ordinal, its *cardinality* $|X|$ is the least such ordinal.
The minimum exists by Principle 6.3.2(i), applied to the nonempty set of candidates no larger than a fixed witness.
Under Principle 6.1.2, every set has a cardinality by Principle 6.3.2(iv).
(iii) A cardinal is *infinite* iff it is not a finite ordinal, and $\aleph_0 := |\omega|$.

Definition 6.3.9. *Cofinal Subsets and Cofinality*
Let α be an ordinal.

(i) A subset $C \subseteq \alpha$ is *cofinal in* α, or *unbounded in* α, iff $(\forall \beta < \alpha)(\exists \gamma \in C)\, \beta \le \gamma$.
(ii) A function $f : \delta \to \alpha$ is *cofinal* iff $f(\delta)$ is cofinal in α.
(iii) The *cofinality* of α is $\operatorname{cf}(\alpha) := \min\{\delta : (\exists f : \delta \to \alpha)(\forall \beta < \alpha)(\exists \xi < \delta)\, \beta \le f(\xi)\}$.

The minimum exists because id_α is cofinal and nonempty sets of ordinals have least elements.
If α is a limit ordinal, then C is cofinal iff $\sup C = \alpha$. Indeed, if C is not cofinal, then some member of α strictly bounds C from above. Conversely, cofinality above each successor below α forces $\bigcup C = \alpha$. The empty function is cofinal in 0, while $0 \mapsto \alpha$ is cofinal from 1 to $\alpha + 1$. Since an empty range is not cofinal in a successor, $\operatorname{cf}(0) = 0$ and $\operatorname{cf}(\alpha + 1) = 1$.

Lemma 6.3.10. *Nondecreasing Cofinal Witness*
Let λ be a nonzero limit ordinal and set $\delta := \operatorname{cf}(\lambda)$.

(i) The ordinal δ is nonzero and is a limit ordinal.
(ii) There is a cofinal function $f : \delta \to \lambda$ satisfying $(\forall \xi \le \eta < \delta)\, f(\xi) \le f(\eta)$.

Proof.

(i) Choose a cofinal function $h : \delta \to \lambda$. Since an empty range is not cofinal in λ, $\delta \neq 0$.
Suppose $\delta = \varepsilon + 1$. The restriction $h|_\varepsilon$ is not cofinal by the minimality of δ, so $(\exists \beta < \lambda)(\forall \eta < \varepsilon)\, h(\eta) < \beta$.
Set $\rho := \max\{\beta, h(\varepsilon)\} + 1$. Since λ is a limit ordinal, $\rho < \lambda$ and $(\forall \eta < \delta)\, h(\eta) < \rho$, contradicting the cofinality of h. QED.
(ii) For $\xi < \delta$, set $f(\xi) := \sup\{h(\eta) : \eta \le \xi\}$. Since $\xi + 1 < \delta$, range of $h|_{\xi+1}$ is not cofinal and is bounded below λ; hence $f(\xi) < \lambda$.
If $\xi \le \eta < \delta$, then the set defining $f(\xi)$ is contained in the set defining $f(\eta)$, so $f(\xi) \le f(\eta)$.
Finally, $h(\xi) \le f(\xi)$ for $\xi < \delta$, and therefore f is cofinal.

Structural Commentary: Minimality first excludes successor domains, then successive suprema monotone-ize a cofinal witness.
Key Insight: No proper initial segment of a minimal cofinal domain is cofinal. □

Definition 6.3.11. *Regular and Singular Cardinals*
An infinite cardinal κ is *regular* iff $\operatorname{cf}(\kappa) = \kappa$, and it is *singular* iff $\operatorname{cf}(\kappa) < \kappa$.

Theorem 6.3.12. *Idempotence and Cardinality of Cofinality*
Let α be an ordinal and set $\delta := \operatorname{cf}(\alpha)$.

(i) $\operatorname{cf}(\delta) = \delta$.
(ii) The ordinal δ is a cardinal.
(iii) If α is a nonzero limit ordinal, then δ is an infinite regular cardinal.

Proof.

(i) If $\alpha = 0$, then $\delta = 0$ and $\operatorname{cf}(\delta) = 0$. If α is a successor, then $\delta = 1$ and $\operatorname{cf}(\delta) = 1$.
Suppose α is a nonzero limit ordinal. A nondecreasing cofinal function $f : \delta \to \alpha$ exists by Lemma 6.3.10(ii); fix one.
The ordinal δ is a nonzero limit ordinal by Lemma 6.3.10(i).
A nondecreasing cofinal function $g : \operatorname{cf}(\delta) \to \delta$ therefore exists by Lemma 6.3.10(ii).
For $\beta < \alpha$, choose $\xi < \delta$ with $\beta \le f(\xi)$ and then $\eta < \operatorname{cf}(\delta)$ with $\xi \le g(\eta)$. Monotonicity gives $\beta \le f(g(\eta))$, so $f \circ g$ is cofinal in α.
The minimality of δ gives $\delta \le \operatorname{cf}(\delta)$, while id_δ gives $\operatorname{cf}(\delta) \le \delta$. Hence $\operatorname{cf}(\delta) = \delta$.
(ii) If δ were not a cardinal, choose $\beta < \delta$ and a bijection $b : \beta \to \delta$. Its range is cofinal, so $\operatorname{cf}(\delta) \le \beta < \delta$, contradicting (i). QED.
(iii) Let α be a nonzero limit ordinal. The ordinal δ is nonzero and limit by Lemma 6.3.10(i), hence it is infinite.
It is a cardinal by (ii), and $\operatorname{cf}(\delta) = \delta$ by (i), so it is regular.

Structural Commentary: Composition forbids cofinality from shrinking twice; initiality and regularity then follow.
Key Insight: Minimal cofinal domains are fixed points of cofinality. □

Example 6.3.13. *Basic Ordinal Cofinalities*
An empty range is bounded. For a nonempty finite range in a limit ordinal, recursion produces a maximum; its successor still lies below the limit and bounds the range. Hence no finite ordinal is a cofinal domain for a nonzero limit ordinal.
The maps $n \mapsto n$, $n \mapsto \omega + n$, and $n \mapsto \omega^n$ from ω are cofinal in ω, $\omega \cdot 2$, and ω^ω, respectively.
Each target therefore has cofinality at most ω and no finite cofinality. Thus $\mathrm{cf}(\omega) = \mathrm{cf}(\omega \cdot 2) = \mathrm{cf}(\omega^\omega) = \omega$.
Cofinality measures the shortest unbounded approach, not the order type or cardinality of its target.

Proposition 6.3.14. *Cardinality Is Canonical and Bijection-Invariant*
Assume Principle 6.1.2. For sets X, Y:

(i) $X \sim_\# |X|$, *and* $|X|$ *is a cardinal.*
(ii) $|X| = |Y| \iff X \sim_\# Y$.

Proof.

(*i*) The relation $X \sim_\# |X|$ holds by the definition of $|X|$. If $\beta < |X|$ and $\beta \sim_\# |X|$, then $\beta \sim_\# X$ by Proposition 6.2.2, contradicting the minimality of $|X|$. Thus $|X|$ is a cardinal.
(*ii*) ($\Rightarrow$) If $|X| = |Y|$, then $X \sim_\# |X| = |Y| \sim_\# Y$, so $X \sim_\# Y$ by Proposition 6.2.2.
(*ii*) ($\Leftarrow$) If $X \sim_\# Y$, then $(\forall \gamma)\,[\gamma \sim_\# X \iff \gamma \sim_\# Y]$ by Proposition 6.2.2.
The least ordinals satisfying these equivalent conditions are equal, so $|X| = |Y|$.

Structural Commentary: Minimal ordinal representatives identify exactly the equivalence classes of bijections.
Key Insight: Cardinality retains only bijection type. □

Proposition 6.3.15. *Finite Cardinality and $\aleph_0$ Agree with Earlier Notation*
Assume Principle 6.1.2.

(i) If X is finite and $\#X = n$, then $|X| = n$, where n on the right is the corresponding finite ordinal.
(ii) $\aleph_0 = \omega$.
(iii) A set X is countable iff $|X| = \aleph_0$.
(iv) The cardinal $\aleph_0$ is the least infinite cardinal.

Proof.

(*i*) The unique map $J_0 \to 0$ is bijective, and for $n \in \mathbb{N}$ the map $q_n : J_n \to n$ defined by $q_n(k) := k - 1$ is bijective.
Since $X \sim_\# J_n$ and $J_n \sim_\# n$, $X \sim_\# n$ by Proposition 6.2.2.
If $\beta < n$ and $\beta \sim_\# X$, choose $m < n$ with $\beta = m$. Then $J_m \sim_\# J_n$ by Proposition 6.2.2.
Hence $m = n$ by Proposition 4.2.2, contradicting $m < n$. Thus n is the least ordinal bijective with X, so $|X| = n$.
(*ii*) The map $q : \mathbb{N} \to \omega$ defined by $q(k) := k - 1$ is bijective. If $\beta < \omega$, choose $m \in \mathbb{N}_0$ with $\beta = m$.
If $\beta \sim_\# \omega$, then a witnessing bijection, q, and the bijection $J_m \to m$ from (i) compose to give an injection $\mathbb{N} \to J_m$, which is impossible by Proposition 6.2.5(i). Hence ω is the least ordinal bijective with itself, so $\aleph_0 = |\omega| = \omega$.
(*iii*) ($\Rightarrow$) If X is countable, then $X \sim_\# \mathbb{N}$ by Definition 6.2.4. Since $\mathbb{N} \sim_\# \omega$ by (ii), $X \sim_\# \omega$ by Proposition 6.2.2.
Hence $|X| = \aleph_0$ by Proposition 6.3.14(ii) and (ii).
(*iii*) ($\Leftarrow$) If $|X| = \aleph_0$, then $X \sim_\# \omega$ by Proposition 6.3.14(ii) and (ii). Since $\omega \sim_\# \mathbb{N}$ by (ii), $X \sim_\# \mathbb{N}$ by Proposition 6.2.2.
Thus X is countable by Definition 6.2.4.
(*iv*) An infinite cardinal is an infinite ordinal and is therefore at least the least infinite ordinal $\omega = \aleph_0$.

Structural Commentary: Explicit finite and countable bijections identify the initial ordinals selected by cardinality.
Key Insight: General cardinality extends both finite size and countability. □

Proposition 6.3.16. *Cardinality Comparison by Injections*
Assume Principle 6.1.2. For sets X, Y, $|X| \le |Y|$ iff an injection $X \to Y$ exists.

Proof. Set $\kappa := |X|$ and $\lambda := |Y|$. The ordinals κ, λ are cardinals and satisfy $X \sim_\# \kappa$ and $Y \sim_\# \lambda$ by Proposition 6.3.14(i).
Choose bijections $u : X \to \kappa$ and $v : Y \to \lambda$.
($\Rightarrow$) If $\kappa \le \lambda$, then $v^{-1} \circ \iota \circ u : X \to Y$ is injective, where $\iota : \kappa \hookrightarrow \lambda$ is inclusion.
($\Leftarrow$) Suppose $e : X \to Y$ is injective. Then $v \circ e \circ u^{-1} : \kappa \to \lambda$ is injective.
If $\lambda < \kappa$, inclusion injects λ into κ, so $\kappa \sim_\# \lambda$ by Theorem 6.2.3.
This contradicts the initiality of κ. Hence ordinal comparison gives $\kappa \le \lambda$.

Structural Commentary: Conjugate an injection to initial ordinals and exclude the reverse strict comparison.
Key Insight: Schroeder–Bernstein prevents a cardinal from embedding into a smaller cardinal. □

Lemma 6.3.17. *Infinite Cardinals Are Limit Ordinals*
Every infinite cardinal is a limit ordinal.

Proof. Suppose an infinite cardinal has the form $\kappa = \alpha + 1$. The ordinal α is infinite, otherwise its successor would be finite, so $\omega \le \alpha$.
Define $f : \alpha + 1 \to \alpha$ by $f(\alpha) := 0$, by $f(\xi) := \xi + 1$ when $\xi < \omega$, and by $f(\xi) := \xi$ when $\omega \le \xi < \alpha$.
The three domain pieces are disjoint, and their images are $\{0\}$, $\omega \setminus \{0\}$, and $\{\xi : \omega \le \xi < \alpha\}$.
These images are disjoint and cover α, so f is bijective. Thus κ is bijective with the smaller ordinal α, contradicting that κ is a cardinal.
Hence κ is neither zero nor a successor ordinal, and therefore it is a limit ordinal.
Structural Commentary: A direct folding bijection contradicts initiality for any alleged infinite successor cardinal.
Key Insight: An infinite successor ordinal absorbs its final endpoint. □

6.4 Diagonalization and Power Sets

Theorem 6.4.1. *Cantor's Theorem*
Let X be a set. No function $f : X \to \mathcal{P}(X)$ is surjective; hence $X \not\sim_{\#} \mathcal{P}(X)$.

Proof. Fix $f : X \to \mathcal{P}(X)$ and set $D_f := \{x \in X : x \notin f(x)\}$. Then $D_f \subseteq X$, so $D_f \in \mathcal{P}(X)$.
If $a \in X$ and $D_f = f(a)$, then $a \in D_f \iff a \in f(a)$, contrary to $a \in D_f \iff a \notin f(a)$.
Hence $(\forall a \in X)\, D_f \neq f(a)$, so $D_f \notin f(X)$ and f is not surjective. Since a bijection must be surjective, $X \not\sim_{\#} \mathcal{P}(X)$.
Structural Commentary: The diagonal subset differs from each image set at its own indexing element.
Key Insight: Diagonal self-membership forces $(\forall a \in X)\, D_f \neq f(a)$. □

Proposition 6.4.2. *Binary Sequences Model a Power Set*
Let $A := \{0,1\}^{\mathbb{N}}$. Define $\Phi : A \to \mathcal{P}(\mathbb{N})$ by $\Phi(s) := \{n \in \mathbb{N} : s(n) = 1\}$. Then Φ is bijective.

Proof. For $E \subseteq \mathbb{N}$, define $\chi_E : \mathbb{N} \to \{0,1\}$ by $\chi_E(n) := 1$ when $n \in E$ and $\chi_E(n) := 0$ otherwise. Define $\Psi : \mathcal{P}(\mathbb{N}) \to A$ by $\Psi(E) := \chi_E$.
If $E \subseteq \mathbb{N}$ and $n \in \mathbb{N}$, then $n \in \Phi(\Psi(E)) \iff \chi_E(n) = 1 \iff n \in E$. Hence $\Phi(\Psi(E)) = E$ by Assumption 1.3.2.
If $s \in A$ and $n \in \mathbb{N}$, then $\chi_{\Phi(s)}(n) = 1 \iff s(n) = 1$. Both values lie in $\{0,1\}$, so $\chi_{\Phi(s)}(n) = s(n)$. Thus $(\forall n \in \mathbb{N})\, \chi_{\Phi(s)}(n) = s(n)$.
Hence $\Psi(\Phi(s)) = s$ by Assumption 3.1.2. The maps Φ and Ψ are inverse, so Φ is bijective by Theorem 3.3.2.
Structural Commentary: Characteristic functions construct a two-sided inverse to the subset-extraction map.
Key Insight: A membership bit records exactly one subset decision. □

Theorem 6.4.3. *Binary Sequences Are Uncountable*
Let $A := \{0,1\}^{\mathbb{N}}$. Then A is uncountable.

Proof. Define $j : \mathbb{N} \to \mathcal{P}(\mathbb{N})$ by $j(n) := \{n\}$, and define $\Phi : A \to \mathcal{P}(\mathbb{N})$ by $\Phi(s) := \{n \in \mathbb{N} : s(n) = 1\}$.
The map j is injective because $j(m) = j(n)$ implies $m = n$. The map Φ is bijective by Proposition 6.4.2, so $\Phi^{-1} \circ j : \mathbb{N} \to A$ is injective.
If A were finite, choose $m \in \mathbb{N}_0$ and a bijection $q : A \to J_m$.
Then $q \circ \Phi^{-1} \circ j : \mathbb{N} \to J_m$ would be injective. No such injection exists by Proposition 6.2.5(i), a contradiction.
Thus A is not finite. Suppose A were countable. Choose a bijection $e : \mathbb{N} \to A$, and write $s_n := e(n)$.
Define $s : \mathbb{N} \to \{0,1\}$ by $s(k) := 1 - s_k(k)$. Then $s \in A$ and $(\forall n \in \mathbb{N})\, s(n) \neq s_n(n)$, so $(\forall n \in \mathbb{N})\, s \neq e(n)$.
This contradicts the surjectivity of e. Hence A is neither finite nor countable, so it is uncountable.
Structural Commentary: An embedded copy of $\mathbb{N}$ excludes finiteness; a diagonal flip excludes enumerability.
Key Insight: The nth flipped bit separates the new sequence from row n. □

$$
\begin{array}{lcl}
s_1 & = & \boxed{a_{11}}\, a_{12}\ a_{13}\ a_{14}\ a_{15} \\
s_2 & = & a_{21}\ \boxed{a_{22}}\, a_{23}\ a_{24}\ a_{25} \\
s_3 & = & a_{31}\ a_{32}\ \boxed{a_{33}}\, a_{34}\ a_{35} \quad \cdots \\
s_4 & = & a_{41}\ a_{42}\ a_{43}\ \boxed{a_{44}}\, a_{45} \\
s_5 & = & a_{51}\ a_{52}\ a_{53}\ a_{54}\ \boxed{a_{55}}
\end{array}
$$

Figure 9: Boxed entries $a_{nn} = s_n(n)$ whose bit flips define a sequence distinct from every listed row.

Figure 9 marks the diagonal entries used in Theorem 6.4.3.
Flipping the nth boxed bit forces $s(n) \neq s_n(n)$, so the constructed sequence cannot equal row n.

6.5 Cardinal Comparison and the Continuum

Throughout this subsection, assume Principle 6.1.2 and use the initial-ordinal cardinality $|X|$ from Definition 6.3.8.

Definition 6.5.1. *Cardinal Comparison and Arithmetic*
For sets A, B, define the *function set* by $A^B := \{f \mid f : B \to A\}$. Let κ, λ be cardinals.

(i) *Comparison*: the relations $\kappa \leq \lambda$ and $\kappa < \lambda$ are the corresponding ordinal comparisons.
(ii) The *cardinal sum* is $\kappa + \lambda := |(\{0\} \times \kappa) \cup (\{1\} \times \lambda)|$.
(iii) The *cardinal product* is $\kappa\lambda := |\kappa \times \lambda|$.
(iv) The *cardinal power* is $\kappa^\lambda := |\{f \mid f : \lambda \to \kappa\}|$.

These are cardinal operations. Cardinal arguments distinguish them from the ordinal operations of Definition 6.3.6.

Proposition 6.5.2. *Cardinal Comparison and Operations on Representatives*
Let A, B be sets, and set $\kappa := |A|$ and $\lambda := |B|$.

(i) $\kappa \leq \lambda$ iff an injection $A \to B$ exists.
(ii) $\kappa < \lambda$ iff an injection $A \to B$ exists and $A \not\sim_{\#} B$.
(iii) $\kappa + \lambda = |(\{0\} \times A) \cup (\{1\} \times B)|$. If $A \cap B = \emptyset$, then $\kappa + \lambda = |A \cup B|$.
(iv) $\kappa\lambda = |A \times B|$.
(v) $\kappa^\lambda = |A^B|$.

Proof. Choose bijections $u : A \to \kappa$ and $v : B \to \lambda$ by Proposition 6.3.14(i).

(i) ($\Rightarrow$) If $\kappa \leq \lambda$, then an injection $A \to B$ exists by Proposition 6.3.16.
(i) ($\Leftarrow$) If an injection $A \to B$ exists, then $\kappa \leq \lambda$ by Proposition 6.3.16.
(ii) ($\Rightarrow$) Suppose $\kappa < \lambda$. Then $\kappa \leq \lambda$ and $\kappa \neq \lambda$. An injection $A \to B$ exists by (i), and $A \not\sim_{\#} B$ by Proposition 6.3.14(ii).
(ii) ($\Leftarrow$) Suppose an injection $A \to B$ exists and $A \not\sim_{\#} B$. Then $\kappa \leq \lambda$ by (i) and $\kappa \neq \lambda$ by Proposition 6.3.14(ii), so $\kappa < \lambda$.
(iii) Set $U := (\{0\} \times A) \cup (\{1\} \times B)$ and $V := (\{0\} \times \kappa) \cup (\{1\} \times \lambda)$. Define $F : U \to V$ by $F(0,a) := (0, u(a))$ and $F(1,b) := (1, v(b))$.
The inverse sends $(0,\xi)$ to $(0, u^{-1}(\xi))$ and $(1,\eta)$ to $(1, v^{-1}(\eta))$, so F is bijective by Theorem 3.3.2.
Hence $|U| = |V|$ by Proposition 6.3.14(ii), proving the first equality.
If $A \cap B = \emptyset$, define $G : U \to A \cup B$ by $G(0,a) := a$ and $G(1,b) := b$.
Its inverse sends $x \in A$ to $(0,x)$ and $x \in B$ to $(1,x)$, so G is bijective. Thus $\kappa + \lambda = |A \cup B|$ by Proposition 6.3.14(ii).

(iv) Define $P : A \times B \to \kappa \times \lambda$ by $P(a,b) := (u(a), v(b))$. Its inverse is $(\xi,\eta) \mapsto (u^{-1}(\xi), v^{-1}(\eta))$, so P is bijective by Theorem 3.3.2. Therefore $\kappa\lambda = |A \times B|$ by Proposition 6.3.14(ii).
(v) Define $T : A^B \to \{g \mid g : \lambda \to \kappa\}$ by $T(f) := u \circ f \circ v^{-1}$. Its inverse sends $g : \lambda \to \kappa$ to $u^{-1} \circ g \circ v$, so T is bijective by Theorem 3.3.2.
Hence $\kappa^\lambda = \left|A^B\right|$ by Proposition 6.3.14(ii).

Structural Commentary: Chosen bijections transport comparison and all three cardinal operations.
Key Insight: Bijections act coordinatewise on tags, pairs, and functions. □

Definition 6.5.3. *Continuum Cardinal*
The *continuum cardinal* is $\mathfrak{c} := 2^{\aleph_0}$.

Proposition 6.5.4. *Models of the Continuum Cardinal*
$\mathfrak{c} = \left|\{0,1\}^{\mathbb{N}}\right| = |\mathcal{P}(\mathbb{N})|$.

Proof. The map $q : J_2 \to \{0,1\}$ defined by $q(k) := k - 1$ is bijective. Thus $|\{0,1\}| = 2$ and $|\mathbb{N}| = \aleph_0$ by Proposition 6.3.15(i),(iii).
Hence $\mathfrak{c} = \left|\{0,1\}^{\mathbb{N}}\right|$ by Proposition 6.5.2(v). The relation $\{0,1\}^{\mathbb{N}} \sim_{\#} \mathcal{P}(\mathbb{N})$ holds by Proposition 6.4.2.
Hence $\left|\{0,1\}^{\mathbb{N}}\right| = |\mathcal{P}(\mathbb{N})|$ by Proposition 6.3.14(ii).
Structural Commentary: Finite and countable representatives reduce cardinal exponentiation to binary functions and subsets.
Key Insight: A binary function is the characteristic function of one subset. □

Corollary 6.5.5. *The Continuum Strictly Exceeds $\aleph_0$*
$\aleph_0 < \mathfrak{c}$.

Proof. The map $j : \mathbb{N} \to \mathcal{P}(\mathbb{N})$, $j(n) := \{n\}$, is injective since $j(m) = j(n) \Rightarrow m = n$.
No bijection $\mathbb{N} \to \mathcal{P}(\mathbb{N})$ exists by Theorem 6.4.1. Therefore $|\mathbb{N}| < |\mathcal{P}(\mathbb{N})|$ by Proposition 6.5.2(ii).
The identities $|\mathbb{N}| = \aleph_0$ and $|\mathcal{P}(\mathbb{N})| = \mathfrak{c}$ hold by Proposition 6.3.15(iii) and Proposition 6.5.4, respectively. Hence $\aleph_0 < \mathfrak{c}$.
Structural Commentary: Singleton embedding gives weak comparison, while Cantor's theorem rules out equality.
Key Insight: The diagonal obstruction makes the continuum strictly larger. □

6.6 Cardinal Arithmetic

Throughout this subsection, assume Principle 6.1.2 and use the cardinal operations from Definition 6.5.1.

Proposition 6.6.1. *Cardinal Arithmetic Reference Laws*
Let κ, λ, μ be cardinals.
(i) $\kappa + \lambda = \lambda + \kappa$ *and* $\kappa\lambda = \lambda\kappa$.
(ii) $\kappa + (\lambda + \mu) = (\kappa + \lambda) + \mu$ *and* $\kappa(\lambda\mu) = (\kappa\lambda)\mu$.
(iii) $\kappa(\lambda + \mu) = \kappa\lambda + \kappa\mu$.
(iv) $\kappa^{\lambda+\mu} = \kappa^\lambda \kappa^\mu$, $(\kappa^\lambda)^\mu = \kappa^{\lambda\mu}$, *and* $(\kappa\lambda)^\mu = \kappa^\mu \lambda^\mu$.

Proof. Set $A := \{0\} \times \kappa$, $B := \{1\} \times \lambda$, and $C := \{2\} \times \mu$.
The sets are pairwise disjoint, and their coordinate projections are bijections onto κ, λ, μ, respectively.
Thus $|A| = \kappa$, $|B| = \lambda$, and $|C| = \mu$ by Proposition 6.3.14(ii) and Definition 6.3.8.
(i) The identity is a bijection $A \cup B \to B \cup A$. The map $(a,b) \mapsto (b,a)$ is a bijection $A \times B \to B \times A$ with itself as inverse.
(ii) The equality $A \cup (B \cup C) = (A \cup B) \cup C$ holds.
The map $(a,(b,c)) \mapsto ((a,b),c)$ is a bijection $A \times (B \times C) \to (A \times B) \times C$ with inverse $((a,b),c) \mapsto (a,(b,c))$.
(iii) The equality $A \times (B \cup C) = (A \times B) \cup (A \times C)$ holds. The union on the right is disjoint because $B \cap C = \emptyset$.
(iv) Define $R : A^{B \cup C} \to A^B \times A^C$ by $R(f) := (f|_B, f|_C)$. Its inverse is $R^{-1}(g,h) := g \cup h$; disjointness makes this union a function.
Define $Q : (A^B)^C \to A^{B \times C}$ by $Q(F)(b,c) := F(c)(b)$. Its inverse sends h to $c \mapsto (b \mapsto h(b,c))$. Let $\pi_A(a,b) := a$ and $\pi_B(a,b) := b$.
The map $D : (A \times B)^C \to A^C \times B^C$ defined by $D(h) := (\pi_A \circ h, \pi_B \circ h)$ has inverse $D^{-1}(f,g)(c) := (f(c), g(c))$.
Claims (i)–(iv) follow from these set equalities and bijections by Proposition 6.5.2(iii)–(v).
Structural Commentary: Set identities and explicit bijections transport representative arithmetic to cardinal laws.
Key Insight: Restriction, currying, and projections control the exponent laws. □

Theorem 6.6.2. *Infinite Cardinal Square Law*
If κ is an infinite cardinal, then $|\kappa \times \kappa| = \kappa$.

Proof.
(i) *Induction setup*: For an ordinal α, let $P(\alpha)$ mean that, if α is an infinite cardinal, then $|\alpha \times \alpha| = \alpha$.
Fix an ordinal κ and assume $(\forall \beta < \kappa)\, P(\beta)$. It suffices by Principle 6.3.2(ii) to prove $P(\kappa)$.
The assertion $P(\kappa)$ is vacuous unless κ is an infinite cardinal, so assume that it is.
(ii) *Well-order construction*: Define $r : \kappa \times \kappa \to \kappa$ by $r(\xi,\eta) := \max\{\xi,\eta\}$.
For $p = (\beta,\beta')$ and $q = (\gamma,\gamma')$ in $\kappa \times \kappa$, declare $p \prec q$ when the first applicable condition holds:
  (a) $r(p) < r(q)$;
  (b) $r(p) = r(q)$ and $\beta < \gamma$;
  (c) $r(p) = r(q)$, $\beta = \gamma$, and $\beta' < \gamma'$.

Put $p \preceq q$ iff $p = q$ or $p \prec q$. Ordinal comparison makes these clauses exhaustive for distinct pairs.
Comparison by the first differing entry of $(r(p), \beta, \beta')$ is transitive and antisymmetric; hence $\preceq$ is a total order.
If $\emptyset \neq S \subseteq \kappa \times \kappa$, set $R_S := \{r(p) : p \in S\}$. The nonempty set R_S has a least element ρ by Principle 6.3.2(i).
Set $I_S := \{\xi < \kappa : (\exists \eta < \kappa)\,[(\xi,\eta) \in S \wedge r(\xi,\eta) = \rho]\}$; it is nonempty by the definition of ρ.
The minimum $\xi_0 := \min I_S$ exists by Principle 6.3.2(i).
Set $J_S := \{\eta < \kappa : (\xi_0,\eta) \in S \wedge r(\xi_0,\eta) = \rho\}$; it is nonempty by the definition of I_S.
The minimum $\eta_0 := \min J_S$ exists by Principle 6.3.2(i). Then (ξ_0,η_0) is least in S, so $\preceq$ is a well-order.
(iii) *Ordinal comparison*: Choose an ordinal δ and an order isomorphism $f : (\delta, \leq) \to (\kappa \times \kappa, \preceq)$ by Principle 6.3.2(iii).
The map $\xi \mapsto (\xi, 0)$ injects κ into $\kappa \times \kappa$. Since $|\kappa| = \kappa$ by Definition 6.3.8, $\kappa \leq |\kappa \times \kappa|$ by Proposition 6.3.16.
The equality $|\kappa \times \kappa| = |\delta|$ holds by Proposition 6.3.14(ii), and $|\delta| \leq \delta$ by Definition 6.3.8. Thus $\kappa \leq |\kappa \times \kappa| = |\delta| \leq \delta$.

(iv) *Initial-segment contradiction*: Suppose $\kappa < \delta$. Write $f(\kappa) = (\beta, \beta')$ and set $X := \{q \in \kappa \times \kappa : q \prec (\beta, \beta')\}$.
The restriction $f|_\kappa : \kappa \to X$ is bijective because f preserves and reflects order.
Hence $|X| = \kappa$ by Proposition 6.3.14(ii) and Definition 6.3.8.
Set $\alpha := \max\{\beta, \beta'\} + 1$. Since $\beta, \beta' < \kappa$ and κ is a limit ordinal by Lemma 6.3.17, $\alpha < \kappa$.
Set $\lambda := |\alpha|$. Then λ is a cardinal, and a bijection $u : \alpha \to \lambda$ exists by Proposition 6.3.14(i).
Since $\lambda \leq \alpha$ by Definition 6.3.8, $\lambda < \kappa$. If $q \in X$, then $r(q) \leq \max\{\beta, \beta'\} < \alpha$, so $q \in \alpha \times \alpha$.
The coordinate map $(\xi, \eta) \mapsto (u(\xi), u(\eta))$ is a bijection $\alpha \times \alpha \to \lambda \times \lambda$, whose restriction to X is injective.
Thus $\kappa = |X| \leq |\lambda \times \lambda|$ by Proposition 6.3.16. If λ is finite, then $|\lambda \times \lambda| < \aleph_0 \leq \kappa$ by Theorem 4.2.5 and Proposition 6.3.15.
If λ is infinite, then $|\lambda \times \lambda| = \lambda < \kappa$ by induction hypothesis. In either case, $|\lambda \times \lambda| < \kappa$, contradicting $\kappa \leq |\lambda \times \lambda|$; hence $\kappa \not< \delta$.
(v) *Conclusion*: Since $\kappa \leq \delta$, $\delta = \kappa$ by Principle 6.3.2(i). Thus f is a bijection $\kappa \to \kappa \times \kappa$, so $|\kappa \times \kappa| = \kappa$ by Proposition 6.3.14(ii) and Definition 6.3.8. Hence $P(\kappa)$ holds, completing the induction.

Structural Commentary: Strong induction bounds max-ranked initial segments by smaller cardinal squares.
Key Insight: Every predecessor lies in a square of smaller cardinality. □

Theorem 6.6.3. *Infinite Cardinal Absorption*
Let κ, λ be cardinals, and let $\mu := \max\{\kappa, \lambda\}$ be infinite.

(i) $\kappa + \lambda = \mu$.
(ii) If $\kappa, \lambda > 0$, *then* $\kappa\lambda = \mu$.
(iii) $\aleph_0 + \aleph_0 = \aleph_0\aleph_0 = \aleph_0$.

Proof. The equality $|\mu \times \mu| = \mu$ holds by Theorem 6.6.2. Set $U := (\{0\} \times \mu) \cup (\{1\} \times \mu)$.
Since $0, 1 \in \mu$, the maps $\xi \mapsto (0, \xi)$ and $(i, \xi) \mapsto (\xi, i)$ inject μ into U and U into $\mu \times \mu$, respectively.
The identities $|U| = \mu + \mu$ and $|\mu| = \mu$ hold by Definition 6.5.1 and Definition 6.3.8, respectively.
Thus $\mu \leq \mu + \mu \leq |\mu \times \mu| = \mu$ by Proposition 6.3.16, so $\mu + \mu = \mu$.

(i) Set $V := (\{0\} \times \kappa) \cup (\{1\} \times \lambda)$. If $\mu = \kappa$, then $\xi \mapsto (0, \xi)$ injects μ into V; if $\mu = \lambda$, then $\xi \mapsto (1, \xi)$ does so.
The inclusions $\kappa \hookrightarrow \mu$ and $\lambda \hookrightarrow \mu$ induce an injection $V \to U$, and $|V| = \kappa + \lambda$ by Definition 6.5.1.
Thus $\mu \leq \kappa + \lambda \leq \mu + \mu = \mu$ by Proposition 6.3.16, so $\kappa + \lambda = \mu$.
(ii) Assume $\kappa, \lambda > 0$, so $0 \in \kappa \cap \lambda$. If $\mu = \kappa$, then $\xi \mapsto (\xi, 0)$ injects μ into $\kappa \times \lambda$; if $\mu = \lambda$, then $\xi \mapsto (0, \xi)$ does so.
The coordinate inclusions induce an injection $\kappa \times \lambda \to \mu \times \mu$, and $\kappa\lambda = |\kappa \times \lambda|$ by Definition 6.5.1.
Thus $\mu \leq \kappa\lambda \leq |\mu \times \mu| = \mu$ by Proposition 6.3.16, so $\kappa\lambda = \mu$.
(iii) The cardinal $\aleph_0$ is infinite by Proposition 6.3.15(iv). The asserted equalities follow by (i),(ii) with $\kappa = \lambda = \aleph_0$.

Structural Commentary: The square law sandwiches each sum and nonzero product between μ and itself.
Key Insight: An infinite maximum absorbs every bounded factor. □

7 Axiomatic and Advanced Set Theory

This section reserves space for deeper axiomatic and metatheoretic material: formal set axioms, models, forcing, large cardinals, and sets of reals.

7.1 Extensionality, Specification, and Replacement

Variables range over sets; formulas use first-order logic with equality and the sole nonlogical symbol $\in$.
For y' fresh in $\varphi(y)$, use $(\exists! y)\,\varphi(y) := (\exists y)[\varphi(y) \wedge (\forall y')(\varphi(y') \Rightarrow y' = y)]$.

Assumption 7.1.1. *Axiom of Extensionality*
Assume $(\forall A)(\forall B)[(\forall x)(x \in A \iff x \in B) \Rightarrow A = B]$.
The converse is equality substitution, so this axiom is the formal source of Assumption 1.3.2.

Assumption 7.1.2. *Separation/Specification Schema*
Fix $n \in \mathbb{N}_0$, put $\mathbf{z} = (z_1, \ldots, z_n)$, and let $\varphi(x, \mathbf{z})$ have no other free variables.
Require B not free in φ; the associated axiom is the universal closure in $A, \mathbf{z}$ of the next formula. $(\exists B)(\forall x)[x \in B \iff (x \in A \wedge \varphi(x, \mathbf{z}))]$.
In set-builder notation, its witness is $B = \{x \in A : \varphi(x, \mathbf{z})\} \subseteq A$.

Assumption 7.1.3. *Replacement Schema*
Fix $n \in \mathbb{N}_0$, put $\mathbf{z} = (z_1, \ldots, z_n)$, and let $\varphi(x, y, \mathbf{z})$ have no other free variables.
Require B not free in φ; the associated axiom is the universal closure in $A, \mathbf{z}$ of the next implication.
$[(\forall x \in A)(\exists! y)\,\varphi(x, y, \mathbf{z})] \Rightarrow (\exists B)(\forall y)[y \in B \iff (\exists x \in A)\,\varphi(x, y, \mathbf{z})]$.
The antecedent makes φ functional on A; the consequent collects its full range into a set.

Perspective 7.1.4. *Selection versus Functional Image*
Assumption 7.1.2 selects elements of a bounding set A, so its witness satisfies $B \subseteq A$.
Assumption 7.1.3 collects the range of a definable function on A, whose values may lie outside A.
An axiom schema comprises one first-order axiom per permitted formula and finite parameter list.

7.2 Models, Constructibility, and Independence

Fix a classical proof calculus with assumption discharge and double-negation elimination.
Use a ZFC metatheory formalizing first-order syntax, satisfaction, and the required set constructions.
Write Ord for the class of ordinals. The theories ZF, ZFC, and their extensions are *object theories* interpreted in models.
No claim below assumes that the metatheory proves its own consistency.

Definition 7.2.1. *Models and Inner Models of Set Theory*
Fix an object theory T in the first-order language of membership.
Let $\mathcal{M} = (M, E)$ satisfy $\emptyset \neq M$ and $E \subseteq M \times M$.

(i) The structure $\mathcal{M}$ is a *set model* of T iff $(\forall \sigma \in T)\,\mathcal{M} \models \sigma$.
(ii) It is a *transitive set model* of T iff it is a set model, $(\forall x \in M)\,x \subseteq M$, and $E = \{(x, y) \in M \times M : x \in y\}$.
(iii) A class N is an *inner model* of T iff $(\forall x \in N)\,x \subseteq N$, $\mathrm{Ord} \subseteq N$, and $(N, \in) \models T$.

Countability of a set model is an external metatheoretic property.
Thus it can regard one of its sets as uncountable when the relevant bijection is external.

Definition 7.2.2. *Relative Consistency, Consistency Strength, and Independence*
Let T, U be object theories in the fixed proof calculus; for a sentence φ, set $T + \varphi := T \cup \{\varphi\}$.

(i) $\mathrm{Con}(T)$ abbreviates $T \nvdash \bot$.
(ii) A *relative-consistency result from T to U* is a metatheoretic proof of $\mathrm{Con}(T) \Longrightarrow \mathrm{Con}(U)$.
(iii) The theories T and U are *equiconsistent* iff $[\mathrm{Con}(T) \Longrightarrow \mathrm{Con}(U)] \wedge [\mathrm{Con}(U) \Longrightarrow \mathrm{Con}(T)]$ is metatheoretically provable.
(iv) The theory U has at least the *consistency strength* of T iff the metatheory proves $\mathrm{Con}(U) \Longrightarrow \mathrm{Con}(T)$.
(v) A sentence φ is *independent of T* iff $T \nvdash \varphi$ and $T \nvdash \neg\varphi$.

Relative consistency does not assert its antecedent; independence selects no ambient truth.
The sentence CH asserts $2^{\aleph_0} = \aleph_1$. For a cardinal κ, let κ^+ be the least cardinal strictly greater than κ.
The sentence GCH asserts $(\forall \kappa \geq \aleph_0)\, 2^\kappa = \kappa^+$, with the quantifier restricted to cardinals.

Proposition 7.2.3. *Independence via Two Consistent Extensions*
Let T be a classical object theory and let φ be a sentence.
Then φ is independent of T iff $\mathrm{Con}(T + \varphi) \wedge \mathrm{Con}(T + \neg\varphi)$.

Proof.

($\Rightarrow$) Assume $T \nvdash \varphi$ and $T \nvdash \neg\varphi$. By assumption discharge, $T + \varphi \vdash \bot \Longrightarrow T \vdash \neg\varphi$.
By assumption discharge and double-negation elimination, $T + \neg\varphi \vdash \bot \Longrightarrow T \vdash \neg\neg\varphi \Longrightarrow T \vdash \varphi$.
Both consequents contradict the hypothesis, so $\mathrm{Con}(T + \varphi)$ and $\mathrm{Con}(T + \neg\varphi)$.
($\Leftarrow$) Assume $\mathrm{Con}(T + \varphi)$ and $\mathrm{Con}(T + \neg\varphi)$. Then $T \vdash \varphi \Longrightarrow T + \neg\varphi \vdash \bot$ and $T \vdash \neg\varphi \Longrightarrow T + \varphi \vdash \bot$.
Thus $T \nvdash \varphi$ and $T \nvdash \neg\varphi$, so φ is independent of T.

Structural Commentary: The two directions translate extension consistency into the two nonprovability obligations.
Key Insight: Opposite consistent extensions encode both nonprovability conditions. □

Definition 7.2.4. *Constructible Hierarchy*
For a set M, fix $n \in \mathbb{N}_0$ and $\mathbf{p} = (p_1, \ldots, p_n) \in M^n$. Let $\varphi(x, z_1, \ldots, z_n)$ be a formula with no other free variables.
For these data, set $A := \{x \in M : (M, \in) \models \varphi(x, p_1, \ldots, p_n)\}$. The family $\mathrm{Def}(M)$ consists exactly of these sets as the data vary.
Transfinite recursion sets $L_0 := \emptyset$ and $L_{\alpha+1} := \mathrm{Def}(L_\alpha)$. At a nonzero limit ordinal λ, set $L_\lambda := \bigcup_{\beta<\lambda} L_\beta$.

The *constructible universe* is $L := \bigcup_{\alpha \in \mathrm{Ord}} L_\alpha$; a set is *constructible* iff it belongs to L.

Proposition 7.2.5. *Basic Properties of the Constructible Hierarchy*
For ordinals $\alpha \leq \beta$:

(i) L_α is transitive;
(ii) $L_\alpha \subseteq L_\beta$;
(iii) L is transitive;
(iv) $L_\alpha \cap \mathrm{Ord} = \alpha$;
(v) $\mathrm{Ord} \subseteq L$.

Proof.

(i) Set $\mathrm{Trans}(M) := (\forall x \in M)\, x \subseteq M$ and $P(\gamma) := [\mathrm{Trans}(L_\gamma) \wedge L_\gamma \subseteq L_{\gamma+1}]$. To prove $(\forall \gamma \in \mathrm{Ord})\, P(\gamma)$ by transfinite induction.
Since $L_0 = \emptyset$ is transitive and $L_0 \subseteq L_1$, the assertion $P(0)$ holds. Assume $P(\gamma)$.
If $x \in y \in L_{\gamma+1}$, then $y \subseteq L_\gamma$ and $x \in L_\gamma \subseteq L_{\gamma+1}$; hence $L_{\gamma+1}$ is transitive.
For $x \in L_{\gamma+1}$, the parameter x and formula $z \in x$ define x over $L_{\gamma+1}$. Thus $x \in L_{\gamma+2}$ and $P(\gamma+1)$ holds.
At a nonzero limit ordinal λ, assume $(\forall \gamma < \lambda)\, P(\gamma)$. If $x \in y \in L_\lambda$, choose $\gamma < \lambda$ with $y \in L_\gamma$.
Then $x \in L_\gamma \subseteq L_\lambda$ by $P(\gamma)$, so L_λ is transitive. For $x \in L_\lambda$, the parameter x and formula $z \in x$ define x over L_λ.
Thus $L_\lambda \subseteq L_{\lambda+1}$ and $P(\lambda)$ holds. Thus $(\forall \alpha \in \mathrm{Ord})\ \mathrm{Trans}(L_\alpha)$.
(ii) Fix α and prove $(\forall \beta \in \mathrm{Ord})\, [\alpha \leq \beta \Rightarrow L_\alpha \subseteq L_\beta]$ by transfinite induction.
At $\beta = 0$, the premise $\alpha \leq 0$ gives $\alpha = 0$, so the inclusion is equality. If $\beta = \gamma + 1$ and $\alpha \leq \beta$, then either $\alpha = \beta$ or $\alpha \leq \gamma$.
In the latter case, $L_\alpha \subseteq L_\gamma \subseteq L_{\gamma+1}$ by the induction hypothesis and the simultaneous induction in (i).
At a nonzero limit β, the case $\alpha = \beta$ is trivial.
If $\alpha < \beta$, then $\alpha + 1 < \beta$ and $L_\alpha \subseteq L_{\alpha+1} \subseteq L_\beta$ by the simultaneous induction in (i) and the definition of L_β.
(iii) If $x \in y \in L$, choose $\gamma \in \mathrm{Ord}$ with $y \in L_\gamma$. Then $x \in L_\gamma \subseteq L$ by (i), so L is transitive.
(iv) Set $Q(\gamma) := [L_\gamma \cap \mathrm{Ord} = \gamma]$ and proceed by transfinite induction. At 0, $L_0 \cap \mathrm{Ord} = 0$.
At a nonzero limit ordinal λ, $L_\lambda \cap \mathrm{Ord} = \bigcup_{\xi<\lambda} (L_\xi \cap \mathrm{Ord}) = \bigcup_{\xi<\lambda} \xi = \lambda$ by the induction hypothesis.
Assume $Q(\gamma)$. If $\delta \in L_{\gamma+1} \cap \mathrm{Ord}$, then $\delta \subseteq L_\gamma \cap \mathrm{Ord} = \gamma$, so $\delta \leq \gamma$. Conversely, $\delta < \gamma \Longrightarrow \delta \in \gamma = L_\gamma \cap \mathrm{Ord} \subseteq L_{\gamma+1}$.
Ordinalhood is bounded and defines $\gamma = L_\gamma \cap \mathrm{Ord}$ over the transitive set L_γ; hence $\gamma \in L_{\gamma+1}$.
Therefore $L_{\gamma+1} \cap \mathrm{Ord} = \gamma + 1$, which proves $Q(\gamma + 1)$.
(v) $(\forall \alpha \in \mathrm{Ord})\, \alpha \in L_{\alpha+1}$ by (iv); hence $\mathrm{Ord} \subseteq L$.

Structural Commentary: Simultaneous induction gives transitivity and nesting; a second induction identifies the stage ordinals.
Key Insight: Definability carries each stage and its index forward. □

Principle 7.2.6. *Constructible Inner Model Result*

(i) The theory ZF proves that L is an inner model of ZFC + GCH.
(ii) The metatheory proves $\mathrm{Con}(\mathrm{ZF}) \Longrightarrow \mathrm{Con}(\mathrm{ZFC} + \mathrm{GCH})$.
(iii) The reverse consistency implication holds because ZFC + GCH contains ZF; hence the theories are equiconsistent.

Reflection and condensation are not developed here, so this principle records framework and supplies no proof authority.

Definition 7.2.7. *Forcing Posets, Generic Filters, and Extensions*
Let M be a transitive set. Let $\mathbb{P} = (P, \leq, 1_\mathbb{P}) \in M$ be a partial order whose greatest element is $1_\mathbb{P}$.
The element $1_\mathbb{P}$ is the weakest condition, and $p \leq q$ means that p is stronger than q.

(i) A set D is *dense in P*, written $\mathrm{Dense}_P(D)$, iff $D \subseteq P$ and $(\forall p \in P)(\exists q \in D)\, q \leq p$.

(ii) A *filter on P* is a set $\emptyset \neq G \subseteq P$ satisfying $(\forall p \in G)(\forall q \in P)\,[p \leq q \Rightarrow q \in G]$.
Its directedness condition is $(\forall p, q \in G)(\exists r \in G)\,[r \leq p \wedge r \leq q]$.
(iii) The filter G is *M-generic* iff $(\forall D \in M)\,[\mathrm{Dense}_P(D) \Rightarrow G \cap D \neq \emptyset]$.
(iv) Transfinite recursion defines $\mathcal{N}_0^P := \emptyset$ and $\mathcal{N}_{\alpha+1}^P := \mathcal{P}(\mathcal{N}_\alpha^P \times P)$.
At a nonzero limit ordinal λ, set $\mathcal{N}_\lambda^P := \bigcup_{\beta<\lambda} \mathcal{N}_\beta^P$. Set $\mathcal{N}^P := \bigcup_{\alpha \in \mathrm{Ord}} \mathcal{N}_\alpha^P$; its elements are the *$P$-names*.
(v) For a filter G and $\tau \in \mathcal{N}^P$, recursion on name rank defines $\tau^G := \{\sigma^G : (\exists p \in G)\,[(\sigma, p) \in \tau]\}$.
(vi) For an M-generic filter G, the *forcing extension* is $M[G] := \{\tau^G : \tau \in M \cap \mathcal{N}^P\}$.

Theorem 7.2.8. *Existence of Generic Filters over Countable Transitive Sets*
In the metatheory, let M be a countable transitive set. Let $\mathbb{P} = (P, \leq, 1_{\mathbb{P}}) \in M$ be a partial order, and fix $p \in P$. Then an M-generic filter $G \subseteq P$ satisfying $p \in G$ exists.

Proof.
(i) *Enumeration*: External countability gives $(D_n)_{n<\omega}$ enumerating $\{D \in M : \mathrm{Dense}_P(D)\}$. Repetitions are allowed; set $p_0 := p$.
(ii) *Descending construction*: Recursively choose $p_{n+1} \in D_n$ with $p_{n+1} \leq p_n$ by the density of D_n.
(iii) *Filter verification*: Set $G := \{q \in P : (\exists n < \omega)\, p_n \leq q\}$. Then $p = p_0 \in G$.
If $q \in G$, $q \leq r$, and $r \in P$, choose $n < \omega$ with $p_n \leq q$; transitivity gives $p_n \leq r$, so $r \in G$.
If $q_1, q_2 \in G$, choose $i, j < \omega$ with $p_i \leq q_1$ and $p_j \leq q_2$.
Set $k := \max\{i, j\}$. Then $p_k \in G$, $p_k \leq q_1$, and $p_k \leq q_2$ by the descending construction. Thus G is a filter on P.
(iv) *Genericity*: The construction gives $(\forall n < \omega)\, p_{n+1} \in G \cap D_n$.
If $D \in M$ and $\mathrm{Dense}_P(D)$, then $(\exists n < \omega)\, D = D_n$; hence $G \cap D \neq \emptyset$. Therefore G is M-generic and contains p.

Structural Commentary: A descending chain turns enumerated dense sets into one filter.
Key Insight: Later conditions strengthen all earlier choices. □

Principle 7.2.9. *Forcing Extension Framework*
Let M be a countable transitive model of ZFC. Let $\mathbb{P} = (P, \leq, 1_{\mathbb{P}}) \in M$, and let $G \subseteq P$ be M-generic.
The forcing theorem has the following conclusions.

(i) $M \subseteq M[G]$.
(ii) $M \cap \mathrm{Ord} = M[G] \cap \mathrm{Ord}$.
(iii) $M[G] \models \mathrm{ZFC}$.

Its proof recursively defines the forcing relation on formulas and names before proving the Truth Lemma.
That machinery is not developed here, so this principle supplies no proof authority.

Principle 7.2.10. *Relative Consistency and Independence of the Continuum Hypothesis*
The constructible-inner-model and forcing constructions establish the following relative-consistency implications.

(i) $\mathrm{Con}(\mathrm{ZFC}) \Longrightarrow \mathrm{Con}(\mathrm{ZFC} + \mathrm{CH})$.
(ii) $\mathrm{Con}(\mathrm{ZFC}) \Longrightarrow \mathrm{Con}(\mathrm{ZFC} + \neg\mathrm{CH})$.

Under Con(ZFC), the sentence CH is independent of ZFC by Proposition 7.2.3.
Each extension contains ZFC, so both are equiconsistent with ZFC. The constructible universe supplies (i).
For (ii), conditions are finite partial functions from $\omega \times \omega_2$ to 2.
Reverse inclusion orders them, and the resulting poset has the countable chain condition.
It preserves ω_1 and ω_2 and adds ω_2 distinct subsets of ω.
The relative-consistency proof is syntactic, or equivalently Boolean-valued. It does not assume a transitive model of all ZFC.
The required constructibility and forcing theorems are not proved here, so this principle supplies no proof authority.

7.3 Baire and Cantor Spaces

Definition 7.3.1. *Sequence Spaces and Cylinders*
Let $A \in \{2, \omega\}$, where $2 = \{0, 1\}$.

(i) For $n < \omega$, let A^n be the set of functions $n \to A$, and let A^ω be the set of functions $\omega \to A$. Set $A^{<\omega} := \bigcup_{n<\omega} A^n$.
(ii) For $s \in A^{<\omega}$, its *length* is $|s| := \mathrm{dom}\, s$. For $u \in A^{<\omega} \cup A^\omega$, write $s \sqsubseteq u$ iff $s = u|_{|s|}$; then s is an *initial segment of u*.
(iii) Strings $s, t \in A^{<\omega}$ are *compatible* iff $s \sqsubseteq t$ or $t \sqsubseteq s$; otherwise they are *incompatible*.
The *basic cylinder* determined by s is $N_s^A := \{x \in A^\omega : s \sqsubseteq x\}$.
(iv) A set $U \subseteq A^\omega$ is *open* iff it is a union of basic cylinders. It is *closed* iff $A^\omega \setminus U$ is open and *clopen* iff it is both open and closed.
(v) The spaces 2^ω and ω^ω are *Cantor space* and *Baire space*, respectively. Write N_s for N_s^A when A is fixed.

Proposition 7.3.2. *Basic Cylinders Form a Clopen Basis*
Let $A \in \{2, \omega\}$, let $s, t \in A^{<\omega}$, and let $U \subseteq A^\omega$ be open.

(i) If $s \sqsubseteq t$, then $N_s^A \cap N_t^A = N_t^A$. If $t \sqsubseteq s$, then $N_s^A \cap N_t^A = N_s^A$. If s, t are incompatible, then $N_s^A \cap N_t^A = \emptyset$.
(ii) The cylinder N_s^A is clopen.
(iii) $(\forall x \in U)(\exists n < \omega)\, x \in N_{x|_n}^A \subseteq U$.

Proof.
(i) If $s \sqsubseteq t$, then $(\forall x \in N_t^A)\, s = t|_{|s|} = x|_{|s|}$; hence $N_t^A \subseteq N_s^A$ and $N_s^A \cap N_t^A = N_t^A$.
If $t \sqsubseteq s$, then $(\forall x \in N_s^A)\, t = s|_{|t|} = x|_{|t|}$; hence $N_s^A \subseteq N_t^A$ and $N_s^A \cap N_t^A = N_s^A$.
If $x \in N_s^A \cap N_t^A$, then s, t are finite initial segments of x and are comparable by length.
Thus incompatible s, t have disjoint cylinders.
(ii) The cylinder N_s^A is open because it is a union of itself. Fix $x \notin N_s^A$. Since $s \neq x|_{|s|}$, choose $j < |s|$ with $x(j) \neq s(j)$.
If $y \in N_{x|_{j+1}}^A$, then $y(j) = x(j) \neq s(j)$. Therefore $N_{x|_{j+1}}^A \subseteq A^\omega \setminus N_s^A$.
The complement is a union of cylinders and is open, so N_s^A is clopen.
(iii) Fix $x \in U$. Since U is a union of cylinders, choose $r \in A^{<\omega}$ with $x \in N_r^A \subseteq U$. Then $r = x|_{|r|}$, so $n := |r|$ has required property.

Structural Commentary: Comparability controls intersections; first disagreements construct complementary cylinders.
Key Insight: Finite prefixes determine all basic neighborhoods. □

Definition 7.3.3. *Prefix Metric and Polish Space*
Let $A \in \{2, \omega\}$.

(i) For distinct $x, y \in A^\omega$, set $\Delta_A(x,y) := \min\{n < \omega : x(n) \neq y(n)\}$. Define $d_A(x,x) := 0$ and $d_A(x,y) := 2^{-(\Delta_A(x,y)+1)}$ for $x \neq y$.
(ii) A metric d on X is an *ultrametric* iff $(\forall x, y, z \in X)\, d(x,z) \leq \max\{d(x,y), d(y,z)\}$.
(iii) A sequence $(x_k)_{k<\omega} \in X^\omega$ is *d-Cauchy* iff $(\forall \varepsilon > 0)(\exists K < \omega)(\forall k, \ell \geq K)\, d(x_k, x_\ell) < \varepsilon$.
It *converges to $x \in X$* iff $(\forall \varepsilon > 0)(\exists K < \omega)(\forall k \geq K)\, d(x_k, x) < \varepsilon$.
The metric d is *complete* iff each d-Cauchy sequence in X converges to a point of X.
(iv) A set $D \subseteq A^\omega$ is *dense* iff $(\forall s \in A^{<\omega})\, D \cap N_s^A \neq \emptyset$.
(v) A topological space is *Polish* iff its topology is induced by some complete metric and it has a countable dense subset.

Theorem 7.3.4. *Baire and Cantor Spaces Are Polish*
For $A \in \{2, \omega\}$, set $E_A := \{x \in A^\omega : (\exists n < \omega)(\forall k \in \omega \setminus n)\, x(k) = 0\}$.

(i) The prefix metric d_A is an ultrametric.
(ii) The metric d_A is complete.
(iii) The metric d_A induces the cylinder topology on A^ω.
(iv) The eventually-zero set E_A is countable.
(v) The set E_A is dense in A^ω.
(vi) The space A^ω is Polish.

Proof.

(i) Symmetry of the disagreement set makes d_A symmetric. By definition, $(\forall x, y \in A^\omega)\, [d_A(x,y) \geq 0 \wedge (d_A(x,y) = 0 \iff x = y)]$.
Fix $x, y, z \in A^\omega$ and set $r := \max\{d_A(x,y), d_A(y,z)\}$. If $r = 0$, then $x = y = z$. If $r > 0$, choose $m < \omega$ with $r = 2^{-(m+1)}$.
Both pairs x, y and y, z agree below m, so $d_A(x,z) \leq r$. Thus the strong triangle inequality holds.
The ordinary triangle inequality follows from $r \leq d_A(x,y) + d_A(y,z)$, so d_A is an ultrametric.
(ii) Let $(x_k)_{k<\omega}$ be d_A-Cauchy. For $m < \omega$, choose $K_m < \omega$ such that $(\forall k, \ell \geq K_m)\, d_A(x_k, x_\ell) < 2^{-m}$.
Set $s_m := x_{K_m}|_m \in A^m$. If $k \geq K_m$, then $x_k|_m = s_m$. If $m \leq n$, comparison at an index $k \geq \max\{K_m, K_n\}$ gives $s_m = s_n|_m$.
Hence $x := \bigcup_{m<\omega} s_m$ is a function $\omega \to A$. Given $\varepsilon > 0$, choose $m < \omega$ with $2^{-m} < \varepsilon$.
For $k \geq K_m$, the sequences x_k, x agree below m, so $d_A(x_k, x) < 2^{-m} < \varepsilon$. Thus $x_k \to x$, and d_A is complete.
(iii) For $x \in A^\omega$ and $m < \omega$, $N^A_{x|_m} = \{y \in A^\omega : d_A(x,y) < 2^{-m}\}$.
Both sides require agreement below m, so each cylinder containing x is a metric ball.
Conversely, given $\varepsilon > 0$, choose $m < \omega$ with $2^{-m} < \varepsilon$.
Then $N^A_{x|_m} \subseteq \{y \in A^\omega : d_A(x,y) < \varepsilon\}$, so the metric and cylinder topologies coincide.
(iv) The map $k \mapsto k - 1$ is a bijection $\mathbb{N} \to \omega$, so ω is countable.
For $n \in \mathbb{N}$, the coordinate map $f \mapsto (f(0), \ldots, f(n-1))$ bijects ω^n with the n-tuples over ω.
Hence ω^n is countable by Theorem 6.2.18. Since $A^n \subseteq \omega^n$, the set A^n is at most countable by Proposition 6.2.12(i).
The set $A^0 = \{\emptyset\}$ is finite, so $A^{<\omega}$ is at most countable by Corollary 6.2.16.
For $s \in A^{<\omega}$, let $\widehat{s} \in A^\omega$ extend s and equal 0 on $\omega \setminus |s|$. Then $E_A = \{\widehat{s} : s \in A^{<\omega}\}$.
Thus E_A is at most countable by Proposition 6.2.12(ii), applied to the image of $s \mapsto \widehat{s}$.
For $j < \omega$, let $e_j \in A^\omega$ equal 1 at j and 0 elsewhere.
Distinct indices give distinct $e_j \in E_A$, so E_A is infinite and therefore countable.
(v) The relation $(\forall s \in A^{<\omega})\, \widehat{s} \in E_A \cap N_s^A$ holds, so E_A is dense.
(vi) The complete metric d_A induces the cylinder topology by (ii) and (iii).
The set E_A is a countable dense subset by (iv) and (v). Hence A^ω is Polish.

Structural Commentary: Prefix stabilization proves completeness; finite supports supply a countable dense set.
Key Insight: Finite information controls both distance and density. □

Definition 7.3.5. *Products, Projections, and Continuity*
Let $A, B \in \{2, \omega\}$.

(i) The *product topology* on $A^\omega \times B^\omega$ has basis $\{N_s^A \times N_t^B : s \in A^{<\omega},\ t \in B^{<\omega}\}$. Its open sets are the unions of these rectangles.
(ii) For $E \subseteq A^\omega \times B^\omega$, its first-coordinate projection is $\pi_A(E) := \{x \in A^\omega : (\exists y \in B^\omega)\, (x,y) \in E\}$.
(iii) A function $f : A^\omega \to B^\omega$ is *continuous* iff $(\forall t \in B^{<\omega})\, f^{-1}(N_t^B)$ is open.

Proposition 7.3.6. *Continuity by Finite Prefixes*
Let $A, B \in \{2, \omega\}$ and let $f : A^\omega \to B^\omega$. Then f is continuous iff the following finite-prefix condition holds.
$(\forall x \in A^\omega)(\forall m < \omega)(\exists n < \omega)(\forall y \in A^\omega)\, [y|_n = x|_n \implies f(y)|_m = f(x)|_m]$.

Proof.

($\Rightarrow$) Assume f is continuous, and fix $x \in A^\omega$ and $m < \omega$. Set $V := f^{-1}(N^B_{f(x)|_m})$. Then V is open and $x \in V$.
Choose $n < \omega$ with $x \in N^A_{x|_n} \subseteq V$ by Proposition 7.3.2(iii). If $y|_n = x|_n$, then $y \in V$ and $f(y)|_m = f(x)|_m$.
($\Leftarrow$) Assume the prefix condition, fix $t \in B^{<\omega}$, and set $m := |t|$.
For $x \in f^{-1}(N_t^B)$, choose $n < \omega$ such that $(\forall y \in A^\omega)\, [y|_n = x|_n \Rightarrow f(y)|_m = f(x)|_m]$ by the prefix condition.
If $y \in N^A_{x|_n}$, then $f(y)|_m = f(x)|_m = t$, so $N^A_{x|_n} \subseteq f^{-1}(N_t^B)$.
Thus $f^{-1}(N_t^B)$ is a union of cylinders and is open; hence f is continuous.

Structural Commentary: Each direction translates target prefixes into source-cylinder neighborhoods.
Key Insight: Finite output information depends on finite input information. □

Definition 7.3.7. *Trees and Infinite Branches*
Let $A \in \{2, \omega\}$, let T be a set, and let $C \subseteq A^\omega$.

(i) A *tree on A* is a possibly empty set $T \subseteq A^{<\omega}$ satisfying the next condition; write $\mathrm{Tree}_A(T)$. $(\forall t \in T)(\forall s \in A^{<\omega})\, [s \sqsubseteq t \implies s \in T]$.
(ii) The *body* of T is $[T] := \{x \in A^\omega : (\forall n < \omega)\, x|_n \in T\}$.
(iii) The *tree of initial segments* of C is $T_C := \{x|_n : x \in C,\ n < \omega\}$.

Theorem 7.3.8. *Closed Sets Are Exactly Tree Bodies*
Let $A \in \{2, \omega\}$, let $T \subseteq A^{<\omega}$, and let $C \subseteq A^{\omega}$.

(i) If $\mathrm{Tree}_A(T)$, then $[T]$ is closed.
(ii) $\mathrm{Tree}_A(T_C)$.
(iii) If C is closed, then $C = [T_C]$.
(iv) The set C is closed iff $(\exists S \subseteq A^{<\omega})\,[\mathrm{Tree}_A(S) \wedge C = [S]]$.

Proof.

(i) Fix $x \notin [T]$ and choose $n < \omega$ with $x|_n \notin T$. The cylinder $N^A_{x|_n}$ lies in $A^{\omega} \setminus [T]$ because each $y \in N^A_{x|_n}$ satisfies $y|_n = x|_n \notin T$. Thus the complement of $[T]$ is open.
(ii) By definition, $T_C \subseteq A^{<\omega}$. If $t = x|_n \in T_C$ and $s \in A^{<\omega}$ satisfies $s \sqsubseteq t$, then $s = x|_{|s|} \in T_C$; hence $\mathrm{Tree}_A(T_C)$.
(iii) By definition, $C \subseteq [T_C]$. Fix $x \notin C$ and choose $n < \omega$ with $x \in N^A_{x|_n} \subseteq A^{\omega} \setminus C$ by Proposition 7.3.2(iii).
If $x|_n \in T_C$, then some $y \in C$ extends $x|_n$, contradicting $N^A_{x|_n} \cap C = \emptyset$. Hence $x \notin [T_C]$, so $[T_C] \subseteq C$.
(iv) ($\Rightarrow$) If C is closed, then $\mathrm{Tree}_A(T_C)$ by (ii) and $C = [T_C]$ by (iii).
(iv) ($\Leftarrow$) If $\mathrm{Tree}_A(S)$ and $C = [S]$, then C is closed by (i) with $T = S$.

Structural Commentary: Complement cylinders prove closure; realized prefixes construct the representing tree.
Key Insight: Closed membership is determined by all finite approximations. □

7.4 Filters, Ultrafilters, and Sets of Reals

Definition 7.4.1. *Filters, Ideals, and Duality*
Let X be a set, let $\mathcal{F}, \mathcal{I} \subseteq \mathcal{P}(X)$, and let $A \subseteq X$.

(i) The family $\mathcal{F}$ is a *filter* on X iff $X \in \mathcal{F}$, $\emptyset \notin \mathcal{F}$, $(\forall B, C \in \mathcal{F})\, B \cap C \in \mathcal{F}$, and $(\forall B \in \mathcal{F})(\forall C \subseteq X)\,[B \subseteq C \Rightarrow C \in \mathcal{F}]$.
(ii) The family $\mathcal{I}$ is an *ideal* on X iff $\emptyset \in \mathcal{I}$, $X \notin \mathcal{I}$, $(\forall B, C \in \mathcal{I})\, B \cup C \in \mathcal{I}$, and $(\forall B \in \mathcal{I})(\forall C \subseteq B)\, C \in \mathcal{I}$.
(iii) If $\mathcal{F}$ is a filter, its *dual ideal* is $\mathcal{I}_{\mathcal{F}} := \{X \setminus B : B \in \mathcal{F}\}$. If $\mathcal{I}$ is an ideal, its *dual filter* is $\mathcal{F}_{\mathcal{I}} := \{X \setminus B : B \in \mathcal{I}\}$.
(iv) If $\mathcal{I}$ is an ideal, then A is *$\mathcal{I}$-positive* iff $A \notin \mathcal{I}$.

Definition 7.4.2. *Generated, Principal, and Fréchet Filters*
Let X be a set and let $\mathcal{B} \subseteq \mathcal{P}(X)$ satisfy $\mathcal{B} \neq \emptyset$, $\emptyset \notin \mathcal{B}$, and $(\forall B_0, B_1 \in \mathcal{B})\, B_0 \cap B_1 \in \mathcal{B}$.

(i) The *filter generated by $\mathcal{B}$* is $\langle \mathcal{B} \rangle := \{A \subseteq X : (\exists B \in \mathcal{B})\, B \subseteq A\}$.
(ii) For $\emptyset \neq D \subseteq X$, the *principal filter generated by D* is $\mathcal{F}_D := \{A \subseteq X : D \subseteq A\}$.
(iii) For infinite X, the *Fréchet filter*, or *cofinite filter*, is $\mathrm{Fr}(X) := \{A \subseteq X : X \setminus A \text{ is finite}\}$.

Definition 7.4.3. *κ-Complete Filter*
Let X be a set, let κ be an infinite cardinal, and let $\mathcal{F}$ be a filter on X.
The filter $\mathcal{F}$ is *κ-complete* iff $(\forall \lambda < \kappa)(\forall A \in \mathcal{F}^{\lambda})\, \bigcap_{\xi < \lambda} A(\xi) \in \mathcal{F}$.

Proposition 7.4.4. *Basic Filter and Ideal Constructions*
Let X be a set, let $\mathcal{F}$ be a filter on X, let $\mathcal{I}$ be an ideal on X, and let $\emptyset \neq D \subseteq X$.
Let $\mathcal{B} \subseteq \mathcal{P}(X)$ satisfy $\mathcal{B} \neq \emptyset$, $\emptyset \notin \mathcal{B}$, and $(\forall B_0, B_1 \in \mathcal{B})\, B_0 \cap B_1 \in \mathcal{B}$.

(i) $\mathcal{I}_{\mathcal{F}}$ is an ideal and $\mathcal{F}_{\mathcal{I}}$ is a filter on X.
(ii) $\langle \mathcal{B} \rangle$ is the least filter containing $\mathcal{B}$.
(iii) $\mathcal{F}_D$ is a filter; if X is infinite, then $\mathrm{Fr}(X)$ is a filter whose dual ideal is the family of finite subsets of X.
(iv) The filter $\mathcal{F}$ is $\aleph_0$-complete.

Proof.

(i) The equalities $X \setminus X = \emptyset$ and $X \setminus \emptyset = X$ show that $\mathcal{I}_{\mathcal{F}}$ contains $\emptyset$ but not X. If $A, B \in \mathcal{F}$, then $(X \setminus A) \cup (X \setminus B) = X \setminus (A \cap B) \in \mathcal{I}_{\mathcal{F}}$.
Let $A \in \mathcal{F}$ and $E \subseteq X \setminus A$. Then $A \subseteq X \setminus E$, so $X \setminus E \in \mathcal{F}$ and $E \in \mathcal{I}_{\mathcal{F}}$. Thus $\mathcal{I}_{\mathcal{F}}$ is an ideal.
The same two complement equalities give $X \in \mathcal{F}_{\mathcal{I}}$ and $\emptyset \notin \mathcal{F}_{\mathcal{I}}$. If $A, B \in \mathcal{I}$, then $(X \setminus A) \cap (X \setminus B) = X \setminus (A \cup B) \in \mathcal{F}_{\mathcal{I}}$.
Let $A \in \mathcal{I}$ and $X \setminus A \subseteq E \subseteq X$. Then $X \setminus E \subseteq A$, so $X \setminus E \in \mathcal{I}$ and $E \in \mathcal{F}_{\mathcal{I}}$. Hence $\mathcal{F}_{\mathcal{I}}$ is a filter.
(ii) Choose $B_0 \in \mathcal{B}$. Then $B_0 \subseteq X$ gives $X \in \langle \mathcal{B} \rangle$. Since no member of $\mathcal{B}$ is contained in $\emptyset$, one has $\emptyset \notin \langle \mathcal{B} \rangle$.
If $A, A' \in \langle \mathcal{B} \rangle$, choose $B, B' \in \mathcal{B}$ with $B \subseteq A$ and $B' \subseteq A'$. Then $B \cap B' \in \mathcal{B}$ and $B \cap B' \subseteq A \cap A'$.
Thus $\langle \mathcal{B} \rangle$ is closed under intersections, and upward closure follows from transitivity of inclusion. The inclusion $\mathcal{B} \subseteq \langle \mathcal{B} \rangle$ holds.
If a filter $\mathcal{G}$ contains $\mathcal{B}$ and $A \in \langle \mathcal{B} \rangle$, choose $B \in \mathcal{B}$ with $B \subseteq A$. Then $A \in \mathcal{G}$, so $\langle \mathcal{B} \rangle \subseteq \mathcal{G}$.
(iii) Since $\mathcal{F}_D = \langle \{D\} \rangle$, the family $\mathcal{F}_D$ is a filter by (ii). Suppose X is infinite. The set X is cofinite, whereas $\emptyset$ is not. The intersection of two cofinite sets is cofinite because its complement is the union of two finite sets, and every superset of a cofinite set is cofinite. Thus $\mathrm{Fr}(X)$ is a filter. Its complement transform is $\{A \subseteq X : A \text{ is finite}\}$.
(iv) Let $\lambda < \aleph_0$ and $A \in \mathcal{F}^{\lambda}$. The ordinal λ is finite because $\aleph_0$ is the least infinite cardinal. The empty intersection is $X \in \mathcal{F}$, and adjoining one $A(\xi)$ preserves membership by binary closure. Hence the required intersection belongs to $\mathcal{F}$ by induction on λ.

Structural Commentary: Complementation proves duality; base closure and finite induction handle the filter constructions.
Key Insight: Upward closure turns finite-intersection bases into filters. □

Definition 7.4.5. *Ultrafilters and Principal Ultrafilters*
Let X be a set and let $\mathcal{U}$ be a filter on X.

(i) The filter $\mathcal{U}$ is an *ultrafilter* iff $(\forall A \subseteq X)\, \#(\mathcal{U} \cap \{A, X \setminus A\}) = 1$.
(ii) The ultrafilter $\mathcal{U}$ is *principal* iff $(\exists x \in X)\, \mathcal{U} = \{A \subseteq X : x \in A\}$; otherwise it is *nonprincipal*.

Theorem 7.4.6. *Ultrafilters Are Exactly the Maximal Filters*
Let X be a set and let $\mathcal{F}$ be a filter on X. Then $\mathcal{F}$ is an ultrafilter iff $(\forall \mathcal{G} \subseteq \mathcal{P}(X))\,[\mathcal{G}$ is a filter on $X \wedge \mathcal{F} \subseteq \mathcal{G} \Rightarrow \mathcal{G} = \mathcal{F}]$.

Proof.

($\Rightarrow$) Suppose $\mathcal{F}$ is an ultrafilter and let $\mathcal{G}$ be a filter with $\mathcal{F} \subseteq \mathcal{G}$
If $A \in \mathcal{G} \setminus \mathcal{F}$, then $X \setminus A \in \mathcal{F} \subseteq \mathcal{G}$, so $\emptyset = A \cap (X \setminus A) \in \mathcal{G}$, contradicting properness. Thus $\mathcal{G} = \mathcal{F}$.

($\Leftarrow$) Suppose the displayed maximality condition holds, and fix $A \subseteq X$. Assume $A, X \setminus A \notin \mathcal{F}$, and set $\mathcal{B}_A := \{B \cap A : B \in \mathcal{F}\}$.
The relation $A = X \cap A$ gives $\mathcal{B}_A \neq \emptyset$, and $(B \cap A) \cap (C \cap A) = (B \cap C) \cap A \in \mathcal{B}_A$ for $B, C \in \mathcal{F}$.
If $\emptyset \in \mathcal{B}_A$, choose $B \in \mathcal{F}$ with $B \cap A = \emptyset$. Then $B \subseteq X \setminus A$, so $X \setminus A \in \mathcal{F}$, a contradiction.
Hence $\langle \mathcal{B}_A \rangle$ is a filter by Proposition 7.4.4(ii). For $B \in \mathcal{F}$, the relation $B \cap A \subseteq B$ gives $B \in \langle \mathcal{B}_A \rangle$, so $\mathcal{F} \subseteq \langle \mathcal{B}_A \rangle$.
Since $A \in \mathcal{B}_A \subseteq \langle \mathcal{B}_A \rangle$ but $A \notin \mathcal{F}$, the containment is proper, contradicting maximality.
Thus $A \in \mathcal{F}$ or $X \setminus A \in \mathcal{F}$; properness prevents both, so $\mathcal{F}$ is an ultrafilter.

Structural Commentary: One direction excludes proper extensions; the other adjoins any undecided set through a filter base.
Key Insight: Maximality is equivalent to deciding every complementary pair. □

Principle 7.4.7. *Ultrafilter Lemma*
Let X be a set and let $\mathcal{F}$ be a filter on X. The Ultrafilter Lemma asserts $(\exists \mathcal{U} \subseteq \mathcal{P}(X))\,[\mathcal{U}$ is an ultrafilter on $X \wedge \mathcal{F} \subseteq \mathcal{U}]$.

Theorem 7.4.8. *Ultrafilter Extension under Zorn's Lemma*
Principle 6.1.3 implies Principle 7.4.7.

Proof.
(i) *Extension poset*: Assume Zorn's Lemma, let X be a set, and let $\mathcal{F}$ be a filter on X.
Let $\mathscr{P}$ be the set of filters on X containing $\mathcal{F}$, ordered by inclusion.
Then $\mathcal{F} \in \mathscr{P}$, and inclusion is a partial order on $\mathscr{P}$ by Proposition 6.1.5.
(ii) *Chain bounds*: The filter $\mathcal{F}$ bounds the empty chain. Let $\mathcal{C} \subseteq \mathscr{P}$ be a nonempty chain and set $\mathcal{G} := \bigcup_{\mathcal{H} \in \mathcal{C}} \mathcal{H}$.
Then $X \in \mathcal{G}$, $\emptyset \notin \mathcal{G}$, and $\mathcal{F} \subseteq \mathcal{G}$. If $A, B \in \mathcal{G}$, choose $\mathcal{H}_0, \mathcal{H}_1 \in \mathcal{C}$ with $A \in \mathcal{H}_0$ and $B \in \mathcal{H}_1$.
Since $\mathcal{C}$ is a chain, one of these filters contains both A and B, so $A \cap B \in \mathcal{G}$.
Upward closure passes from any member of $\mathcal{C}$ containing A. Thus $\mathcal{G} \in \mathscr{P}$ and it bounds $\mathcal{C}$.
(iii) *Maximal extension*: Every chain in $\mathscr{P}$ has an upper bound in $\mathscr{P}$, so a maximal $\mathcal{U} \in \mathscr{P}$ exists by Zorn's Lemma.
The filter $\mathcal{U}$ is an ultrafilter by Theorem 7.4.6, and $\mathcal{F} \subseteq \mathcal{U}$ by the definition of $\mathscr{P}$.

Structural Commentary: Unions preserve filters along chains, so Zorn produces a maximal extension.
Key Insight: Chain compatibility makes binary filter closure survive union. □

Remark 7.4.9. *Choice Strength of Ultrafilter Extension*
Over ZF, Principle 7.4.7 is equivalent to the Boolean Prime Ideal Theorem and is strictly weaker than the full Axiom of Choice. This metamathematical comparison is not used below as proof authority. Theorem 7.4.8 establishes only the implication from the stronger Zorn principle available earlier. No choice principle enters Theorem 7.4.6 or the definition of principal ultrafilters.

Corollary 7.4.10. *Nonprincipal Ultrafilters on Infinite Sets*
Assume Principle 7.4.7, and let X be infinite. Then $(\exists \mathcal{U} \subseteq \mathcal{P}(X))\,[\mathcal{U}$ is a nonprincipal ultrafilter on $X]$.

Proof. The family $\mathrm{Fr}(X)$ is a filter by Proposition 7.4.4(iii). Choose an ultrafilter $\mathcal{U} \supseteq \mathrm{Fr}(X)$ by the hypothesis of the corollary.
If $\mathcal{U}$ were principal at $x \in X$, then $\{x\} \in \mathcal{U}$. Since $X \setminus \{x\} \in \mathrm{Fr}(X) \subseteq \mathcal{U}$, closure under intersections would give $\emptyset \in \mathcal{U}$, contradicting properness. Hence $\mathcal{U}$ is nonprincipal.
Structural Commentary: Extend the cofinite filter and exclude principality by intersecting complementary singleton data.
Key Insight: Cofinite membership prevents concentration at one point. □

Definition 7.4.11. *Measurable Cardinal*
Let κ be an uncountable cardinal. In ZFC, the cardinal κ is *measurable* iff $(\exists \mathcal{U} \subseteq \mathcal{P}(\kappa))\,[\mathcal{U}$ is a nonprincipal κ-complete ultrafilter on $\kappa]$.

Remark 7.4.12. *Large-Cardinal Assumption Boundary*
The assertion that a measurable cardinal exists is an additional large-cardinal hypothesis; it is not assumed elsewhere in this part. The ordinary Ultrafilter Lemma does not supply such a cardinal, as extending a filter to an ultrafilter need not preserve κ-completeness. Thus the large-cardinal connection enters through the extra completeness requirement, not through ultrafilter maximality alone.

Assumption 7.4.13. *Club and Stationary Setting*
For the club-and-stationary results below, assume Principle 6.1.2 and fix a regular cardinal $\kappa > \omega$.

Definition 7.4.14. *Closed Unbounded Subset*
A set $C \subseteq \kappa$ is *closed in κ* iff $(\forall \nu < \kappa)\,[\nu$ is a nonzero limit ordinal $\wedge\, C \cap \nu$ is cofinal in $\nu \Rightarrow \nu \in C]$.
It is *unbounded in κ* iff it is cofinal in κ, and it is a *club subset of κ* iff it is both closed and unbounded.

Theorem 7.4.15. *Intersection of Fewer Than κ Clubs*
If $0 < \lambda < \kappa$ and $(C_i)_{i<\lambda}$ is a family of club subsets of κ, then $\bigcap_{i<\lambda} C_i$ is club in κ.

Proof. Set $C := \bigcap_{i<\lambda} C_i$. If $\nu < \kappa$ is a nonzero limit ordinal and $C \cap \nu$ is cofinal in ν, then $(\forall i < \lambda)\, C_i \cap \nu$ is cofinal in ν.
Hence $(\forall i < \lambda)\, \nu \in C_i$, so $\nu \in C$ and C is closed.
If $\theta < \kappa$ and $g : \theta \to \kappa$, then $\sup g(\theta) < \kappa$; otherwise g would be cofinal and $\mathrm{cf}(\kappa) \leq \theta < \kappa$, contradicting regularity.
Fix $\beta < \kappa$ and set $\beta_0 := \beta + 1 < \kappa$ by Lemma 6.3.17.
Recursively, after β_n is defined, choose $(\gamma_{n,i})_{i<\lambda}$ with $(\forall i < \lambda)\, \gamma_{n,i} \in C_i \setminus (\beta_n + 1)$ by the standing Choice Principle.
Set $\beta_{n+1} := \sup_{i<\lambda}(\gamma_{n,i} + 1)$. The limit-ordinal property of κ gives $(\forall i < \lambda)\, \gamma_{n,i} + 1 < \kappa$, so the preceding bound gives $\beta_{n+1} < \kappa$.
Set $\delta := \sup_{n<\omega} \beta_n$. The same observation with $\theta = \omega$ gives $\delta < \kappa$.
Fix $i < \lambda$. Since $(\forall n < \omega)\, \beta_n < \gamma_{n,i} < \beta_{n+1} \leq \delta$, the sequence $(\gamma_{n,i})_{n<\omega}$ is cofinal in the nonzero limit ordinal δ.
Closedness of C_i gives $\delta \in C_i$. As $i < \lambda$ was arbitrary, $\delta \in C$; moreover, $\beta < \delta$, so C is unbounded.
Structural Commentary: Regularity bounds a countable recursion whose stages visit every club.
Key Insight: Each club contributes a cofinal subsequence to one common limit. □

Definition 7.4.16. *Club Filter, Stationary Sets, and the Nonstationary Ideal*
(i) The *club filter* on κ is $\mathcal{F}_{\mathrm{club}}(\kappa) := \{A \subseteq \kappa : (\exists C \subseteq A)\, C$ is club in $\kappa\}$.
(ii) A set $S \subseteq \kappa$ is *stationary* iff $(\forall C \subseteq \kappa)\,[C$ is club in $\kappa \Rightarrow S \cap C \neq \emptyset]$.
(iii) The *nonstationary ideal* is $\mathrm{NS}_\kappa := \{A \subseteq \kappa : (\exists C \subseteq \kappa)\,[C$ is club in $\kappa \wedge A \cap C = \emptyset]\}$. Thus S is stationary iff $S \notin \mathrm{NS}_\kappa$.

Proposition 7.4.17. *Club-Filter Completeness and Stationary-Set Basics*
Let $C, S \subseteq \kappa$.

(i) The family $\mathcal{F}_{\mathrm{club}}(\kappa)$ is a κ-complete filter.
(ii) The ideal NS_κ is dual to $\mathcal{F}_{\mathrm{club}}(\kappa)$.
(iii) If C is club and S is stationary, then $C \cap S$ is stationary.
(iv) If S is stationary, then S is unbounded.
(v) If S is stationary, then $\{\nu \in S : \nu$ is a nonzero limit ordinal$\}$ is stationary.

Proof.

(i) The set κ is club in itself, so $\kappa \in \mathcal{F}_{\mathrm{club}}(\kappa)$. No club is empty, so $\emptyset \notin \mathcal{F}_{\mathrm{club}}(\kappa)$, and upward closure follows from the definition.
Let $\lambda < \kappa$ and $(A_i)_{i<\lambda} \in \mathcal{F}_{\mathrm{club}}(\kappa)^\lambda$. If $\lambda = 0$, then $\bigcap_{i<\lambda} A_i = \kappa$. If $\lambda > 0$, choose clubs $C_i \subseteq A_i$ by the standing Choice Principle.
The intersection $\bigcap_{i<\lambda} C_i$ is club by Theorem 7.4.15, and it is contained in $\bigcap_{i<\lambda} A_i$. Thus the club filter is κ-complete.

(ii) For $A \subseteq \kappa$, $\kappa \setminus A \in \mathcal{F}_{\mathrm{club}}(\kappa)$ iff $(\exists C \subseteq \kappa \setminus A)\,[C$ is club$]$, equivalently iff $A \in \mathrm{NS}_\kappa$.
Hence $\mathrm{NS}_\kappa = \mathcal{I}_{\mathcal{F}_{\mathrm{club}}(\kappa)}$, which is an ideal by (i) and Proposition 7.4.4(i).

(iii) Fix a club $D \subseteq \kappa$. The intersection $C \cap D$ is club by Theorem 7.4.15 with $\lambda = 2$, so $(C \cap S) \cap D \neq \emptyset$.
As D was arbitrary, $C \cap S$ is stationary.

(iv) Suppose $S \subseteq \kappa$ is bounded, and choose $\beta < \kappa$ with $S \subseteq \beta + 1$. Set $D_\beta := \{\xi < \kappa : \beta < \xi\}$.
Since κ is a limit ordinal, $(\forall \eta < \kappa)\ \max\{\eta, \beta\} + 1 \in D_\beta$, so D_β is unbounded.
If $D_\beta \cap \nu$ is cofinal in a nonzero limit ordinal $\nu < \kappa$, then $D_\beta \cap \nu \neq \emptyset$, so $\beta < \nu$ and $\nu \in D_\beta$.
Hence D_β is closed and therefore club. Since $S \cap D_\beta = \emptyset$, the set S is not stationary.

(v) Set $L := \{\nu < \kappa : \nu$ is a nonzero limit ordinal$\}$. If $L \cap \nu$ is cofinal in a nonzero limit ordinal $\nu < \kappa$, then $\nu \in L$, so L is closed.
For $\beta < \kappa$, the sequence $(\beta + n)_{n<\omega}$ is bounded below κ by regularity, so $\beta + \omega < \kappa$.
Since $\beta + \omega \in L$ lies above β, the set L is unbounded and therefore club. The set $S \cap L$ is stationary by (iii).

Structural Commentary: Club intersections prove completeness; closed tails and limit ordinals test stationarity.
Key Insight: Stationary sets survive every additional club restriction. □

Definition 7.4.18. *Diagonal Intersection and Normality*

(i) For $(X_\xi)_{\xi<\kappa} \in \mathcal{P}(\kappa)^\kappa$, its *diagonal intersection* is $\triangle_{\xi<\kappa} X_\xi := \{\beta < \kappa : (\forall \xi < \beta)\ \beta \in X_\xi\}$.

(ii) A filter $\mathcal{F}$ on κ is *normal* iff $(\forall (X_\xi)_{\xi<\kappa} \in \mathcal{F}^\kappa)\ \triangle_{\xi<\kappa} X_\xi \in \mathcal{F}$.

Theorem 7.4.19. *The Club Filter Is Normal*

(i) If $(C_\xi)_{\xi<\kappa}$ is a sequence of clubs in κ, then $\triangle_{\xi<\kappa} C_\xi$ is club.
(ii) The club filter on κ is normal.

Proof.

(i) We prove clubness through decreasing refinement, closure, and recursive unboundedness.

(a) *Decreasing refinement*: Define $(C'_\xi)_{\xi<\kappa}$ by $C'_\xi := \bigcap_{\eta\le\xi} C_\eta$.
Each C'_ξ is club by Theorem 7.4.15 with $\lambda = \xi + 1$, since $0 < \xi + 1 < \kappa$; moreover, $(C'_\xi)_{\xi<\kappa}$ is decreasing.
Fix $\rho < \kappa$. Then $(\forall \xi < \rho)\ \rho \in C'_\xi$ iff $(\forall \xi < \rho)(\forall \eta \le \xi)\ \rho \in C_\eta$ iff $(\forall \eta < \rho)\ \rho \in C_\eta$.
As $\rho < \kappa$ was arbitrary, the diagonal intersections agree. Hence assume $(C_\xi)_{\xi<\kappa}$ is decreasing and set $D := \triangle_{\xi<\kappa} C_\xi$.

(b) *Closedness*: Suppose $\nu < \kappa$ is a nonzero limit ordinal and $D \cap \nu$ is cofinal in ν. Fix $\xi < \nu$.
Then $\{\rho \in D \cap \nu : \xi < \rho\} \subseteq C_\xi$ is cofinal in ν, so $\nu \in C_\xi$ by closedness.
As $\xi < \nu$ was arbitrary, $\nu \in D$; thus D is closed.

(c) *Unboundedness*: Fix $\eta < \kappa$ and set $\beta_0 := \eta + 1 < \kappa$.
Recursively set $\beta_{n+1} := \min(C_{\beta_n} \setminus (\beta_n + 1))$; unboundedness of C_{β_n} makes the defining set nonempty.
Set $\beta := \sup_{n<\omega} \beta_n < \kappa$; otherwise $n \mapsto \beta_n$ would be cofinal in κ, contrary to $\mathrm{cf}(\kappa) = \kappa > \omega$.
The strict increase makes β a nonzero limit ordinal. Fix $\xi < \beta$ and choose $n < \omega$ with $\xi < \beta_n$.
Decreasingness gives $(\forall m \ge n)\ \beta_{m+1} \in C_{\beta_m} \subseteq C_\xi$. This tail is cofinal in β, so $\beta \in C_\xi$ by closedness.
As $\xi < \beta$ was arbitrary, $\beta \in D$; since $\eta < \beta$, the set D is unbounded and therefore club.

(ii) Let $(A_\xi)_{\xi<\kappa} \in \mathcal{F}_{\mathrm{club}}(\kappa)^\kappa$, and choose clubs $C_\xi \subseteq A_\xi$ by the standing Choice Principle.
The set $\triangle_{\xi<\kappa} C_\xi$ is club by (i), and $\triangle_{\xi<\kappa} C_\xi \subseteq \triangle_{\xi<\kappa} A_\xi$. Hence $\triangle_{\xi<\kappa} A_\xi \in \mathcal{F}_{\mathrm{club}}(\kappa)$.

Structural Commentary: Decreasing refinement separates closure from recursive unboundedness; contained clubs establish normality.
Key Insight: Each point satisfies only club conditions indexed below it. □

Theorem 7.4.20. *Fodor's Pressing-Down Lemma*
Let $S \subseteq \kappa$ be stationary and let $f : S \to \kappa$ be regressive, meaning $(\forall \alpha \in S)\ f(\alpha) < \alpha$. Then $(\exists \gamma < \kappa)\,[\{\alpha \in S : f(\alpha) = \gamma\}$ is stationary$]$.

Proof. For $\gamma < \kappa$, set $S_\gamma := \{\alpha \in S : f(\alpha) = \gamma\}$. Suppose $(\forall \gamma < \kappa)\,[S_\gamma$ is nonstationary$]$.
Choose $(C_\gamma)_{\gamma<\kappa}$ satisfying $(\forall \gamma < \kappa)\,[C_\gamma$ is club $\wedge\ C_\gamma \cap S_\gamma = \emptyset]$ by the standing Choice Principle.
The set $D := \triangle_{\gamma<\kappa} C_\gamma$ is club by Theorem 7.4.19(i). Choose $\alpha \in S \cap D$ and set $\gamma := f(\alpha)$. Then $\gamma < \alpha$ and $\alpha \in D$, so $\alpha \in C_\gamma$.
Since $\alpha \in S_\gamma$, this contradicts $C_\gamma \cap S_\gamma = \emptyset$. Hence $(\exists \gamma < \kappa)\,[S_\gamma$ is stationary$]$.
Structural Commentary: Avoid every fiber by a club, combine the clubs diagonally, and use regressiveness.
Key Insight: The regressive value indexes a club already tested at its argument. □

Assumption 7.4.21. *Descriptive-Set-Theory Setting*
The cardinal fixed in Assumption 7.4.13 is no longer in force. Work in ZFC, and let X be Baire space, Cantor space, or a finite product of these spaces with its product topology.

Definition 7.4.22. *Borel Sets and the Borel Pointclasses*
The *Borel σ-algebra* $\mathcal{B}(X)$ is the least family of subsets of X containing all open sets and closed under complements and countable unions. Its members are the *Borel sets*.
Let ω_1 be the least uncountable ordinal. The *Borel pointclasses* are defined recursively for $0 < \alpha < \omega_1$.

(i) $\mathbf{\Sigma}^0_1(X) := \{A \subseteq X : A \text{ is open}\}$ and $\mathbf{\Pi}^0_1(X) := \{X \setminus A : A \in \mathbf{\Sigma}^0_1(X)\}$.
(ii) Fix $1 < \alpha < \omega_1$ after all lower levels have been defined.
Set $\mathbf{\Sigma}^0_\alpha(X) := \{ \bigcup_{n<\omega} A(n) : A \in (\bigcup_{0<\beta<\alpha} \mathbf{\Pi}^0_\beta(X))^\omega\}$. Set $\mathbf{\Pi}^0_\alpha(X) := \{X \setminus A : A \in \mathbf{\Sigma}^0_\alpha(X)\}$.
(iii) $\mathbf{\Delta}^0_\alpha(X) := \mathbf{\Sigma}^0_\alpha(X) \cap \mathbf{\Pi}^0_\alpha(X)$.

Thus $\mathbf{\Sigma}^0_1(X)$, $\mathbf{\Pi}^0_1(X)$, and $\mathbf{\Delta}^0_1(X)$ are the open, closed, and clopen subsets of X, respectively.

Theorem 7.4.23. *The Borel Hierarchy Exhausts the Borel Sets*
A set $A \subseteq X$ is Borel iff $(\exists \alpha < \omega_1)\,[0 < \alpha \wedge A \in \mathbf{\Sigma}^0_\alpha(X)]$.

Proof.
($\Rightarrow$) Set $\mathcal{H} := \bigcup_{0<\alpha<\omega_1} \mathbf{\Sigma}^0_\alpha(X)$. Then $\mathbf{\Sigma}^0_1(X) \subseteq \mathcal{H}$.
The relation $(\forall \alpha < \omega_1)\,[0 < \alpha \Rightarrow \mathbf{\Pi}^0_\alpha(X) \subseteq \mathbf{\Sigma}^0_{\alpha+1}(X)]$ holds by constant unions, so $\mathcal{H}$ is complement-closed.
Fix $B \in \mathcal{H}^\omega$ and choose $\alpha \in (\omega_1 \setminus \{0\})^\omega$ satisfying $(\forall n < \omega)\, B(n) \in \mathbf{\Sigma}^0_{\alpha(n)}(X)$ by Choice.
One has $(\forall n < \omega)\, B(n) \in \mathbf{\Pi}^0_{\alpha(n)+1}(X)$ by constant unions and complementation.
Set $\gamma := \sup_{n<\omega}(\alpha(n)+1) + 1 < \omega_1$ by Corollary 6.2.16. Since $(\forall n < \omega)\,\alpha(n) + 1 < \gamma$, one has $\bigcup_{n<\omega} B(n) \in \mathbf{\Sigma}^0_\gamma(X) \subseteq \mathcal{H}$.
Thus $\mathcal{H}$ is a σ-algebra containing $\mathbf{\Sigma}^0_1(X)$, so $\mathcal{B}(X) \subseteq \mathcal{H}$ by minimality.
($\Leftarrow$) Set $P(\alpha) := \mathbf{\Sigma}^0_\alpha(X) \cup \mathbf{\Pi}^0_\alpha(X) \subseteq \mathcal{B}(X)$. We prove $(\forall \alpha < \omega_1)\,[0 < \alpha \Rightarrow P(\alpha)]$ by strong transfinite induction.
The property $P(1)$ holds by the definition of $\mathcal{B}(X)$. Fix $1 < \alpha < \omega_1$ and assume $(\forall \beta < \alpha)\,[0 < \beta \Rightarrow P(\beta)]$.
The inclusion $\mathbf{\Sigma}^0_\alpha(X) \subseteq \mathcal{B}(X)$ holds by the recursive definition, induction hypothesis, and countable-union closure.
Thus $\mathbf{\Pi}^0_\alpha(X) \subseteq \mathcal{B}(X)$ by complementation. Hence $P(\alpha)$.

Structural Commentary: Forward closure identifies the generated σ-algebra; transfinite induction proves the reverse inclusion.
Key Insight: Countable Borel operations have ranks below ω_1. □

Definition 7.4.24. *The Projective Pointclasses*
For $E \subseteq X \times \omega^\omega$, set $\pi_X(E) := \{x \in X : (\exists y \in \omega^\omega)\,(x, y) \in E\}$. Define the projective pointclasses recursively.

(i) $\mathbf{\Sigma}^1_1(X) := \{\pi_X(E) : E \in \mathcal{B}(X \times \omega^\omega)\}$; its members are the *analytic sets*.
(ii) For $n \in \mathbb{N}$, $\mathbf{\Pi}^1_n(X) := \{X \setminus A : A \in \mathbf{\Sigma}^1_n(X)\}$.
(iii) For $n \in \mathbb{N}$, $\mathbf{\Sigma}^1_{n+1}(X) := \{\pi_X(E) : E \in \mathbf{\Pi}^1_n(X \times \omega^\omega)\}$.
(iv) For $n \in \mathbb{N}$, $\mathbf{\Delta}^1_n(X) := \mathbf{\Sigma}^1_n(X) \cap \mathbf{\Pi}^1_n(X)$.

The members of $\mathbf{\Pi}^1_1(X)$ are the *coanalytic sets*. A set $A \subseteq X$ is *projective* iff $(\exists n \in \mathbb{N})\,[A \in \mathbf{\Sigma}^1_n(X) \vee A \in \mathbf{\Pi}^1_n(X)]$.

Proposition 7.4.25. *Borel Sets Are Analytic and Coanalytic*
(i) $\mathcal{B}(X) \subseteq \mathbf{\Delta}^1_1(X)$.
(ii) The class $\bigcup_{n\in\mathbb{N}} (\mathbf{\Sigma}^1_n(X) \cup \mathbf{\Pi}^1_n(X))$ *is closed under complements.*

Proof.
(i) Set $Y := \omega^\omega$ and $\mathscr{S} := \{C \subseteq X : C \times Y \in \mathcal{B}(X \times Y)\}$.
Then $(\forall C \in \mathscr{S})\,[(X \setminus C) \times Y = (X \times Y) \setminus (C \times Y) \in \mathcal{B}(X \times Y)]$, so $\mathscr{S}$ is complement-closed.
One has $(\forall C \in \mathscr{S}^\omega)\,[(\bigcup_{n<\omega} C(n)) \times Y = \bigcup_{n<\omega} (C(n) \times Y) \in \mathcal{B}(X \times Y)]$. Thus $\mathscr{S}$ is countable-union-closed.
The inclusion $\mathbf{\Sigma}^0_1(X) \subseteq \mathscr{S}$ holds because products of open sets are open. Thus $\mathscr{S}$ is a σ-algebra and $\mathcal{B}(X) \subseteq \mathscr{S}$ by minimality.
Since $Y \neq \emptyset$, $(\forall C \in \mathcal{B}(X))\, C = \pi_X(C \times Y) \in \mathbf{\Sigma}^1_1(X)$ by the definition of $\mathbf{\Sigma}^1_1(X)$.
Consequently, $(\forall A \in \mathcal{B}(X))\, A \in \mathbf{\Sigma}^1_1(X) \cap \mathbf{\Pi}^1_1(X) = \mathbf{\Delta}^1_1(X)$ by the pointclass definitions.
(ii) Set $\mathscr{P} := (\mathbf{\Sigma}^1_n(X) \cup \mathbf{\Pi}^1_n(X))_{n\in\mathbb{N}}$.
Then $(\forall n \in \mathbb{N})(\forall A \in \mathscr{P}(n))\, X \setminus A \in \mathscr{P}(n)$ by the definition of $\mathbf{\Pi}^1_n(X)$. Thus $\bigcup_{n\in\mathbb{N}} \mathscr{P}(n)$ is complement-closed.

Structural Commentary: Product closure proves the level-one inclusion; pointclass duality proves complement closure.
Key Insight: A constant witness realizes every Borel set as a projection. □

Remark 7.4.26. *Determinacy and Large-Cardinal Boundary*
The material from Definition 7.4.22 through Proposition 7.4.25 is developed in ZFC alone, without measurable-cardinal or determinacy hypotheses. No projective-regularity theorem is asserted; any later theorem of that kind must state its additional hypothesis explicitly.

8 Mathematical Writing and Research Practice

This section fixes the communication, evidence, integrity, and reading practices used to create and evaluate mathematical and machine-learning research.

8.1 Theorem-Style Results and Formal Statements

Formal environments identify a block's function, evidential status, and permissible use as authority.

Convention 8.1.1. *Theorem-Style Result Hierarchy*
In these notes, the theorem-style result environments are exactly the following; each contains a proved claim.

(i) *Theorem*: a major result that advances a principal objective of the surrounding work.
(ii) *Proposition*: an independently useful result of smaller local weight.
(iii) *Lemma*: a subsidiary result introduced primarily to support a later proof.
(iv) *Corollary*: a direct consequence of an earlier proved result that requires little additional argument.

These names record local structural roles, not a universal ranking of importance.
Definitions stipulate objects or terminology, whereas conjectures record unproved claims.
Convention follows standard mathematical-writing guidance (MIT Department of Mathematics, 1998).

Process 8.1.2. *Theorem-Statement Construction and Audit*
Given a candidate conclusion and its supporting argument, produce a self-contained theorem-style statement that can be cited and proved without hidden context.

(i) *Purpose*: isolate the reusable conclusion and identify its role in the dependency chain.
(ii) *Objects*: bind every ambient set, structure, parameter, map, and index before its first use.
(iii) *Hypotheses*: retain only the argument's exact domain, regularity, finiteness, independence, and boundary conditions.
(iv) *Conclusion*: state existence, uniqueness, characterization, bound, convergence, or other claim explicitly.
(v) *Claim census*: itemize each conclusion whose omission would remove a distinct proof obligation.
(vi) *Role*: select theorem, proposition, lemma, or corollary by Convention 8.1.1.
(vii) *Locality*: move motivation, examples, and proof machinery outside the statement, and delete unused assumptions.
(viii) *Traceability*: attach a stable title and label, and cite the external owner of a nonoriginal result.

The audit passes only when the statement remains intelligible apart from the preceding paragraph and every symbol is defined at first use. These are central expository checks (Knuth et al., 1988).

Principle 8.1.3. *Claim–Authority Separation*
Match each formal block's environment and evidence to its epistemic status. A definition stipulates meaning; an assumption declares a condition; a conjecture remains unproved; a theorem-style result requires a proof; and an empirical statement requires data and a protocol. Only proved theorem-style results may serve as mathematical proof authority. A citation records prior ownership but does not discharge a proof obligation when the present work claims to establish the result.

Warning 8.1.4. *Statement–Proof Contamination*
If a theorem-style statement contains a proof plan, auxiliary construction, example, or claim of obviousness, its logical contract becomes obscure and later citation becomes unreliable. Move proof-specific objects into the proof, place explanatory material after the formal owner, and delete hypotheses unused by the proof.

8.2 Proof Construction and Revision

A proof is a checkable argument that derives the stated conclusion from declared hypotheses, definitions, and earlier proved results.

Proof Method 8.2.1. *Proof Construction and Audit*
Given an audited theorem-style statement, construct a proof with independently checkable dependencies and obligations.

(i) *Parse*: identify the objects, hypotheses, quantifier dependencies, and conclusion by Proof Method 2.4.1.
(ii) *Plan*: select a direct argument, cases, two inclusions, induction, contradiction, construction, or another fitting architecture.
(iii) *Dependencies*: record only earlier results whose hypotheses are verified at their citation points.
(iv) *Obligations*: assign each numbered claim, implication direction, existence witness, and uniqueness assertion to a proof unit.
(v) *Execution*: bind variables before use and justify every inference by a definition, calculation, hypothesis, or earlier result.
(vi) *Boundaries*: handle empty, zero, singular, endpoint, and other degenerate cases that affect an argument.
(vii) *Closure*: verify that the final sentence discharges the original conclusion rather than a nearby surrogate.
(viii) *Cold read*: test notation, citations, and transitions without relying on memory of the intended argument.

The audit passes only when every obligation is discharged and each dependency is valid at its point of use. When the route is not apparent, expose the plan while retaining every step needed for verification. Mathematical-writing guidance likewise emphasizes status, motivation, and conceptual structure (MIT Department of Mathematics, 1998; Knuth et al., 1988).

Process 8.2.2. *Proof Revision Passes*
Revise a completed proof in three ordered passes.

(i) *Validity*: check every dependency, implication, case split, witness, index, limit, and exceptional case.
(ii) *Architecture*: align proof units with statement claims and make long operative stages visible.
(iii) *Exposition*: remove repetition, bind notation before use, compress routine algebra, and expand decisive unfamiliar steps.

Review typography only after the mathematical and logical structure is stable.

Warning 8.2.3. *Evidence Is Not Proof*
Finite testing, a diagram, numerical agreement, or a successful program run supports only the cases and conditions examined. Such evidence cannot close an unrestricted quantified claim without an exhaustive argument and a proof that the tested cases cover the domain. Computation may discover a conjecture, locate a counterexample, or verify a formally specified finite case; otherwise provide a complete proof or narrow the claim to the verified scope.

Principle 8.2.4. *Proof Detail Proportionality*
Allocate detail where correctness or understanding depends on it. Expand novel constructions, fragile estimates, changes of quantifier, and boundary arguments; compress familiar algebra only while the remaining chain is checkable. The target is a reproducible mathematical argument, neither maximal formality nor persuasive rhetoric.

8.3 Methods, Algorithms, and Computational Artifacts

Procedural blocks separate conceptual guidance, algorithm specifications, implementations, and correctness or performance evidence.

Convention 8.3.1. *Procedural Environment Roles*
Use the following procedural roles throughout these notes.

(i) *Proof method*: a reusable proof route, reduction, recognition criterion, or obligation checklist.
(ii) *Computation method*: a reusable construction, calculation, approximation, diagnostic, or test.
(iii) *Method*: a short convention, classification workflow, or inseparable hybrid with no clearer subtype.
(iv) *Process*: an organizational workflow for research, writing, review, or documentation.
(v) *Algorithm*: executable pseudocode with declared inputs, outputs, control flow, and termination behavior when applicable.

Worked instances belong in examples, completed arguments in proofs, and implementation-specific behavior in code or artifact records.

Process 8.3.2. *Algorithm Specification and Audit*
Before publishing pseudocode, record its contract and associated verification obligations.

(i) *Problem*: state the task and the abstraction level at which the algorithm operates.
(ii) *Input*: specify types, dimensions, admissibility, representation, and malformed-input behavior.
(iii) *Output*: specify the returned object and a postcondition that characterizes success.
(iv) *State*: define initialization, mutable state, determinism or randomness, and any invariant used for correctness.
(v) *Steps*: write one unambiguous action per step with readable branches and loops.
(vi) *Termination*: state the stopping rule and prove termination when it is claimed.
(vii) *Correctness*: state the proof obligations and keep the proof of the postcondition separate from the pseudocode.
(viii) *Resources*: state complexity only with an input-size parameter, cost model, resource, and case type.
(ix) *Limits*: record numerical, memory, precision, platform, approximation, and applicability boundaries.

Labeled steps and explanatory invariants clarify the distinction between an algorithm and program text (Knuth et al., 1988).

Principle 8.3.3. *Formal and Informal Procedural Views*
Use complementary formal and informal views when a procedure is complex. The formal view fixes inputs, outputs, updates, and stopping conditions; the informal view explains the invariant, decomposition, or design choice. The views should not duplicate one another, and only a separate proof can establish mathematical correctness.

Process 8.3.4. *Computational Artifact Record*
For code supporting a reported result, preserve an auditable artifact record.

(i) *Identity*: archive the exact source revision and data identifiers.
(ii) *Environment*: record dependencies, runtime, platform, configuration, and random seeds.
(iii) *Access*: state licenses, unavailable components, and access restrictions.
(iv) *Execution*: record the commands and expected outputs.
(v) *Traceability*: map each reported figure, table, or metric to its generating command.

The 2026 NeurIPS checklist requests exact execution instructions and sufficient experimental detail for interpreting results (Neural Information Processing Systems Foundation, 2026).

Warning 8.3.5. *Algorithm Evidence Boundaries*
Passing tests does not establish correctness outside the tested cases, and an asymptotic bound does not predict wall-clock performance without a cost model and operating conditions. Keep specification, proof, implementation, benchmark, and interpretation distinct, and restrict each claim to the evidence that supports it.

8.4 Mathematical Research and Integrity

Mathematical research cycles through discovery, attempted refutation, proof, verification, and communication rather than proceeding linearly from question to theorem.

Process 8.4.1. *Mathematical Research Cycle*
For a proposed mathematical problem, maintain the following revisable cycle.

(i) *Question*: state the objects, scope, current assumptions, and a precise target that can be proved or refuted.
(ii) *Literature*: record definitions, earlier results, counterexamples, nearby formulations, and current open status.
(iii) *Exploration*: compute examples, boundary cases, and nonexamples while recording the tested domain.
(iv) *Conjecture*: state the strongest precise claim supported by exploration and include every suspected hypothesis.
(v) *Attack*: search independently for a proof and a counterexample; record failed routes and new obstructions.
(vi) *Revision*: weaken, strengthen, split, or reframe the conjecture when an example or proof obligation demands it.
(vii) *Verification*: check every proof dependency, compare with prior results, and seek independent criticism.
(viii) *Communication*: state novelty accurately, write a complete proof, cite provenance, and record limitations.

MIT's project laboratory similarly presents mathematical discovery through data generation, conjecture, experiment, proof or counterexample, and writing (MIT OpenCourseWare, 2013).

Process 8.4.2. *Research Claim Ledger*
Maintain one auditable row per substantive claim.

(i) *Claim*: record the exact wording and scope.
(ii) *Status*: record every applicable status: proved, conjectured, computed, observed, reproduced, replicated, or interpreted.
(iii) *Support*: record its evidence, dependencies, source locator, and unresolved checks.
(iv) *Revision*: update the row whenever a hypothesis, dataset, code revision, or conclusion changes.

The ledger prevents an exploratory observation from silently becoming a theorem or empirical conclusion.

Convention 8.4.3. *Reproducibility, Replicability, and Generalizability*
Adopt the National Academies' 2019 terminology (National Academies of Sciences, Engineering, and Medicine, 2019).

(i) *Reproducibility*: consistent computational results from the same data, code, methods, and analysis conditions.
(ii) *Replicability*: consistent results from a new study addressing the same question with newly obtained data.
(iii) *Generalizability*: applicability of a result to contexts or populations beyond those directly studied.

These are distinct evidential targets: a reproducible computation need not replicate on new data or generalize to a new setting.

Principle 8.4.4. *Research Integrity and Stewardship*
Maintain research records that permit scrutiny, correction, and appropriate reuse. Report methods and findings honestly; preserve accurate records; credit contributions and prior work; disclose conflicts; respect confidentiality, consent, licenses, and governing rules; and correct the record when an error is found. These duties reflect the honesty, accountability, fairness, and stewardship principles of the Singapore Statement (Second World Conference on Research Integrity, 2010).

Warning 8.4.5. *Novelty and Negative Results*
Novelty does not imply truth, and publication does not certify correctness. Search for prior and concurrent work before claiming priority, and report a failed proof, null result, or nonreplication with its actual protocol and uncertainty. A negative outcome may diagnose a false conjecture, an inadequate method, or a boundary of generality; the evidence must distinguish these possibilities.

8.5 Machine Learning and AI Research

Machine-learning and AI conclusions draw on statistical, computational, system, and social evidence; the study design must identify the authority supporting each conclusion.

Process 8.5.1. *Machine-Learning and AI Study Protocol*
Specify an empirical study before interpreting its scores.

(i) *Question*: state the population, task, context of use, intervention or comparison, and claimed outcome.
(ii) *Claim type*: classify each target as theoretical, empirical, causal, computational, system, or normative.
(iii) *Data*: record provenance, version, license, collection, consent or access status, labels, exclusions, and preprocessing.
(iv) *Evaluation boundary*: protect test data from training, model selection, prompt design, preprocessing, and human iteration.
(v) *Comparators*: choose relevant baselines, ablations, and resource-matched alternatives before inspecting final results.
(vi) *Protocol*: fix splits, metrics, hyperparameter selection, seeds, stopping rules, hardware, software, and compute budget.
(vii) *Uncertainty*: repeat stochastic runs and report how intervals, variation, or significance measures are calculated.
(viii) *Stress tests*: examine subgroups, shift, robustness, failure modes, sensitivity, and plausible misuse within scope.
(ix) *Artifacts*: preserve code, data handles, checkpoints, configurations, logs, and command-to-result mappings.
(x) *Report*: separate observed results from interpretation and state limitations, costs, risks, and unsupported generalizations.

The 2026 NeurIPS checklist and its reproducibility program emphasize assumptions, complete proofs, experimental detail, uncertainty, artifacts, ethics, and limitations (Neural Information Processing Systems Foundation, 2026; Pineau et al., 2021).

Process 8.5.2. *Dataset and Model Documentation*
Publish documentation alongside every durable ML artifact.

(i) *Dataset*: record motivation, version, provenance, composition, collection, preprocessing, labeling, license, intended uses, restrictions, and maintenance.
(ii) *Model*: record identity, version, intended and excluded uses, training data, evaluation protocol, subgroup results, and limitations.
(iii) *System*: record interfaces, human roles, deployment assumptions, monitoring, update policy, safeguards, and rollback conditions.

Dataset datasheets and model cards provide complementary documentation patterns for provenance, intended use, evaluation, and limitations (Gebru et al., 2021; Mitchell et al., 2019).

Principle 8.5.3. *Contextual AI Risk Assessment*
Accuracy alone is not a complete system claim. For intended context, select and justify tests for the following applicable characteristics.

(i) validity and reliability;
(ii) safety;
(iii) security and resilience;
(iv) accountability and transparency;
(v) explainability and interpretability;
(vi) privacy;
(vii) harmful-bias management.

These characteristics can conflict and require documented tradeoffs.
his versioned vocabulary follows the voluntary NIST AI RMF 1.0 (Tabassi, 2023).

Warning 8.5.4. *Adaptive Evaluation and Leakage*
Any choice influenced by protected evaluation data makes the final score adaptive. Repeated leaderboard queries, test-set debugging, manual example selection, and unreported prompt tuning can leak evaluation information.
Reserve a final assessment boundary; otherwise disclose the adaptation and narrow the claim.

Warning 8.5.5. *Benchmark Overclaiming*
A higher score supports a claim only under the reported dataset, metric, resources, selection procedure, and uncertainty.
It does not establish practical usefulness, causal benefit, robustness, fairness, safety, or superiority in another operating environment without matching evidence.

8.6 Reading and Synthesizing Research Papers

Choose reading depth according to the intended task: triage, comprehension, verification, reproduction, or synthesis.

Process 8.6.1. *Three-Pass Paper Reading*
Adapt the three-pass method of Keshav (2007) to the paper's evidence type and record the output of each completed pass.

(i) *Triage*: inspect the title, abstract, introduction, headings, conclusion, figures, and references. Record the paper's category, context, central claimed contribution, apparent assumptions, and relevance to the intended task.
(ii) *Comprehension*: read the body carefully, map each central claim to its stated assumptions and evidence, inspect figures and tables, and identify unfamiliar prerequisites or missing details.
(iii) *Reconstruction*: independently rebuild each decisive proof, derivation, algorithm, or experiment far enough to identify hidden assumptions, fragile steps, and reproducibility barriers.

Stop after the earliest pass whose recorded output resolves the intended task.
If a missing prerequisite prevents the next pass, identify and acquire it before resuming.

Process 8.6.2. *Paper Claim–Evidence Ledger*
Create one entry for each central claim and record its locator, exact scope, assumptions, evidence type, dependencies, result, uncertainty, and limitations. For a mathematical paper, reconstruct the definitions, hypotheses, cited dependencies, and proof obligations. For an empirical paper, reconstruct the sample, protocol, comparator, metric, variability, and analysis. For a systems paper, reconstruct the boundary, workload, implementation, platform, and failure model. After comparing the claim with that record, classify it as supported, partially supported, unsupported, or not assessed. Reputation and venue are metadata rather than claim-level evidence.

Process 8.6.3. *Literature Search and Synthesis*
Build a claim-centered literature map rather than a sequence of paper summaries.

(i) *Seed*: start from a precise research question, corresponding keywords, a recent survey, and several directly relevant papers.
(ii) *Backward search*: follow repeated foundational citations to original results, data, or methods.
(iii) *Forward search*: locate corrections, replications, extensions, and critiques that cite each key work.

(iv) *Cluster*: group papers by question, assumptions, method, evidence, and operating context rather than by author.
(v) *Compare*: normalize terminology and record agreements, contradictions, gaps, and incomparable protocols claim by claim.
(vi) *Saturate*: record the search date, sources, and inclusion boundary. Stop when another complete search and citation-tracing pass changes neither the paper clusters nor the identified agreements, contradictions, and gaps.

Keshav's survey procedure likewise expands seed papers through repeated authors, shared references, recent proceedings (Keshav, 2007).

Warning 8.6.4. *Version and Source Status*
Before treating a paper as evidence, check its version, venue, peer-review status, corrections, retractions, supplements, artifact links, and conflicts of interest. Cite the version examined and, when available, the original source for a result or dataset. Preprint and peer-review status affect provenance and scrutiny, but neither status establishes or refutes the paper's claims.

Principle 8.6.5. *Read Against the Claim*
For each central claim, compare its scope in the title, abstract, or conclusion with the assumptions and evidence in the body. Record what was established, under which assumptions, by which evidence, with what uncertainty, and within which population, system, or operating boundary. State the synthesized conclusion no more broadly than this comparison supports.

Part II
Structural Linear Algebra

1 Vector Spaces and Linear Structure

1.1 Vector Spaces

Vector spaces encode addition and scalar multiplication. Subspaces, spans, bases, dimension, and coordinates describe how linear structure is generated and measured.

Definition 1.1.1. *Vector Space*
Let $\mathbb{F}$ be a field. A vector space over $\mathbb{F}$ is a set $\mathcal{V}$ with the following structure.
The operations are $+\colon \mathcal{V}\times\mathcal{V}\to\mathcal{V}$ and scalar multiplication $\mathbb{F}\times\mathcal{V}\to\mathcal{V}$. The scalar action is written $(a,\mathbf{v})\mapsto a\mathbf{v}$, and the axioms are:

(i) $(\forall\,\mathbf{u},\mathbf{v}\in\mathcal{V})\;\mathbf{u}+\mathbf{v}=\mathbf{v}+\mathbf{u}$;
(ii) $(\forall\,\mathbf{u},\mathbf{v},\mathbf{w}\in\mathcal{V})\;(\mathbf{u}+\mathbf{v})+\mathbf{w}=\mathbf{u}+(\mathbf{v}+\mathbf{w})$;
(iii) an element $\mathbf{0}\in\mathcal{V}$ satisfies $(\forall\,\mathbf{v}\in\mathcal{V})\;\mathbf{0}+\mathbf{v}=\mathbf{v}$;
(iv) $(\forall\,\mathbf{v}\in\mathcal{V})(\exists\,\mathbf{w}\in\mathcal{V})\;\mathbf{v}+\mathbf{w}=\mathbf{0}$;
(v) $(\forall\,\mathbf{v}\in\mathcal{V})\;1\mathbf{v}=\mathbf{v}$;
(vi) $(\forall\,a,b\in\mathbb{F})(\forall\,\mathbf{v}\in\mathcal{V})\;(ab)\mathbf{v}=a(b\mathbf{v})$;
(vii) $(\forall\,a\in\mathbb{F})(\forall\,\mathbf{u},\mathbf{v}\in\mathcal{V})\;a(\mathbf{u}+\mathbf{v})=a\mathbf{u}+a\mathbf{v}$;
(viii) $(\forall\,a,b\in\mathbb{F})(\forall\,\mathbf{v}\in\mathcal{V})\;(a+b)\mathbf{v}=a\mathbf{v}+b\mathbf{v}$.

If $\mathcal{V}=\{\mathbf{0}\}$, then $\mathcal{V}$ is a *zero vector space*; otherwise $\mathcal{V}$ is a *nonzero vector space*.

Theorem 1.1.2. *Basic Consequences of Vector Space Axioms*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$. Then:

(i) the additive identity is unique;
(ii) each $\mathbf{v}\in\mathcal{V}$ has a unique additive inverse, denoted $-\mathbf{v}$;
(iii) $(\forall\,\mathbf{v}\in\mathcal{V})\;0\mathbf{v}=\mathbf{0}$;
(iv) $(\forall\,a\in\mathbb{F})\;a\mathbf{0}=\mathbf{0}$;
(v) $(\forall\,a\in\mathbb{F})(\forall\,\mathbf{v}\in\mathcal{V})\;[a\mathbf{v}=\mathbf{0}\iff(a=0\vee\mathbf{v}=\mathbf{0})]$.

Proof.

(i) If $\mathbf{0}$ and $\mathbf{0}'$ are additive identities, then $\mathbf{0}=\mathbf{0}+\mathbf{0}'=\mathbf{0}'$.
(ii) If $\mathbf{w},\mathbf{w}'$ are additive inverses of $\mathbf{v}$, then $\mathbf{w}=\mathbf{w}+\mathbf{0}=\mathbf{w}+(\mathbf{v}+\mathbf{w}')=(\mathbf{w}+\mathbf{v})+\mathbf{w}'=\mathbf{0}+\mathbf{w}'=\mathbf{w}'$.
(iii) $0\mathbf{v}=(0+0)\mathbf{v}=0\mathbf{v}+0\mathbf{v}$; after adding $-(0\mathbf{v})$ to both sides, $0\mathbf{v}=\mathbf{0}$.
(iv) $a\mathbf{0}=a(\mathbf{0}+\mathbf{0})=a\mathbf{0}+a\mathbf{0}$; after adding $-(a\mathbf{0})$ to both sides, $a\mathbf{0}=\mathbf{0}$.
(v) ($\Rightarrow$) Suppose $a\mathbf{v}=\mathbf{0}$. If $a=0$, then $a=0\vee\mathbf{v}=\mathbf{0}$. If $a\neq0$, then $\mathbf{v}=1\mathbf{v}=(a^{-1}a)\mathbf{v}=a^{-1}(a\mathbf{v})=a^{-1}\mathbf{0}=\mathbf{0}$ by (iv).
(v) ($\Leftarrow$) If $a=0$ or $\mathbf{v}=\mathbf{0}$, then the conclusion follows from (iii) or (iv).

Structural Commentary: The proof derives cancellation, zero actions, and inverse uniqueness from the axioms.
Key Insight: Zero and inverse behavior is forced by the axioms. □

Corollary 1.1.3. *Scalar Multiplication by -1 Is Negation*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$. Then $(\forall\,\mathbf{v}\in\mathcal{V})\;(-1)\mathbf{v}=-\mathbf{v}$.

Proof. For $\mathbf{v}\in\mathcal{V}$, $\mathbf{v}+(-1)\mathbf{v}=1\mathbf{v}+(-1)\mathbf{v}=(1-1)\mathbf{v}=0\mathbf{v}$.
By Theorem 1.1.2, $\mathbf{v}+(-1)\mathbf{v}=\mathbf{0}$ and additive inverses are unique, so $(-1)\mathbf{v}=-\mathbf{v}$.
Structural Commentary: The proof identifies $(-1)\mathbf{v}$ as the unique additive inverse.
Key Insight: Negation is scalar action by -1. □

Example 1.1.4. *Function-Space Model*
Let $\mathbb{F}$ be a field and let X be a set. Set $\mathbb{F}^X:=\{f:X\to\mathbb{F}\}$. For $f,g\in\mathbb{F}^X$ and $a\in\mathbb{F}$, define $f+g$ and af pointwise.
Thus $(f+g)(x)=f(x)+g(x)$ and $(af)(x)=af(x)$ for $x\in X$. Then $\mathbb{F}^X$ is an $\mathbb{F}$-vector space.
Evaluating each axiom at $x\in X$ reduces it to the corresponding field identity, and $\mathbf{0}$ is the constant 0 function.
Key Insight: Pointwise operations inherit linear structure from the scalar field.

1.2 Subspaces and Spans

Definition 1.2.1. *Subspace*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$.
A *subspace* of $\mathcal{V}$ is a subset $\mathcal{U}\subseteq\mathcal{V}$ that is an $\mathbb{F}$-vector space under the inherited operations; write $\mathcal{U}\leq\mathcal{V}$.

Theorem 1.2.2. *Subspace Test*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$ and let $\emptyset\neq\mathcal{U}\subseteq\mathcal{V}$. Then $\mathcal{U}\leq\mathcal{V}\iff(\forall\,\mathbf{u},\mathbf{v}\in\mathcal{U})(\forall\,c\in\mathbb{F})\;c\mathbf{u}+\mathbf{v}\in\mathcal{U}$.

Proof.

($\Rightarrow$) $(\forall\,\mathbf{u},\mathbf{v}\in\mathcal{U})(\forall\,c\in\mathbb{F})\;c\mathbf{u}+\mathbf{v}\in\mathcal{U}$ by inherited scalar and additive closure.
($\Leftarrow$) Let C denote the stated closure condition, and choose $\mathbf{u}_0\in\mathcal{U}$. The identity $\mathbf{0}=(-1)\mathbf{u}_0+\mathbf{u}_0\in\mathcal{U}$ holds by C and Corollary 1.1.3.
$(\forall\,\mathbf{u}\in\mathcal{U})\;-\mathbf{u}=(-1)\mathbf{u}+\mathbf{0}\in\mathcal{U}$ by C and Corollary 1.1.3. $(\forall\,\mathbf{u}\in\mathcal{U})(\forall\,c\in\mathbb{F})\;c\mathbf{u}=c\mathbf{u}+\mathbf{0}\in\mathcal{U}$ by C.
$(\forall\,\mathbf{u},\mathbf{v}\in\mathcal{U})\;\mathbf{u}+\mathbf{v}=1\mathbf{u}+\mathbf{v}\in\mathcal{U}$ by C. The remaining vector-space axioms are inherited from $\mathcal{V}$, so $\mathcal{U}\leq\mathcal{V}$.

Structural Commentary: Nonemptiness supplies a zero; the single closure condition supplies inverses, scalar multiples, and sums.
Key Insight: One affine-looking closure test captures all subspace closure. □

Proposition 1.2.3. *Intersections of Subspaces*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$, let $\emptyset\neq I$, and let $\{\mathcal{U}_i\}_{i\in I}$ be a family of subspaces of $\mathcal{V}$. Then $\bigcap_{i\in I}\mathcal{U}_i\leq\mathcal{V}$.

Proof. Set $M := \bigcap_{i\in I} \mathcal{U}_i$. Then $\mathbf{0} \in M$ by $(\forall\, i \in I)\, \mathbf{0} \in \mathcal{U}_i$, so $M \neq \emptyset$.
$(\forall\, \mathbf{u}, \mathbf{v} \in M)(\forall\, c \in \mathbb{F})(\forall\, i \in I)\, c\mathbf{u} + \mathbf{v} \in \mathcal{U}_i$ by the definition of M and $\mathcal{U}_i \leq \mathcal{V}$.
Hence $(\forall\, \mathbf{u}, \mathbf{v} \in M)(\forall\, c \in \mathbb{F})\, c\mathbf{u} + \mathbf{v} \in M$, and $M \leq \mathcal{V}$ by Theorem 1.2.2.
Structural Commentary: The proof verifies nonemptiness and closure pointwise across the indexed family.
Key Insight: Shared closure survives intersection. □

Definition 1.2.4. *Lists, Linear Combinations, and Span*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$.

(i) For $m \in \mathbb{N}_0$, a *list* in $\mathcal{V}$ is $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_m)$; the case $m = 0$ is the empty list $()$.

(ii) For $m \in \mathbb{N}_0$, $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_m)$, and $(a_1, \ldots, a_m) \in \mathbb{F}^m$, a *linear combination* of β is $\sum_{j=1}^{m} a_j \mathbf{v}_j$.
The case $m = 0$ is the empty linear combination, whose value is $\mathbf{0}$.

(iii) For $E \subseteq \mathcal{V}$, its *span* is the set of all finite linear combinations of entries from E.
Precisely, $\operatorname{span}(E) := \left\{ \sum_{j=1}^{m} a_j \mathbf{v}_j : m \in \mathbb{N}_0,\ (a_1, \ldots, a_m) \in \mathbb{F}^m,\ (\mathbf{v}_1, \ldots, \mathbf{v}_m) \in E^m \right\}$; hence $\operatorname{span}(\emptyset) = \{\mathbf{0}\}$.

(iv) For $m \in \mathbb{N}_0$ and $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_m)$, define $\operatorname{span}(\beta) := \operatorname{span}(\{\mathbf{v}_j : 1 \leq j \leq m\})$. For the empty list, $\operatorname{span}(()) = \{\mathbf{0}\}$.

(v) $E \subseteq \mathcal{V}$ *spans* $\mathcal{V}$ iff $\operatorname{span}(E) = \mathcal{V}$. A list β *spans* $\mathcal{V}$ iff $\operatorname{span}(\beta) = \mathcal{V}$.

Theorem 1.2.5. *Span is the Smallest Containing Subspace*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$ and let $E \subseteq \mathcal{V}$. Then:

(i) $\operatorname{span}(E) \leq \mathcal{V}$;
(ii) $E \subseteq \operatorname{span}(E)$;
(iii) $(\forall\, \mathcal{U} \leq \mathcal{V})\, [E \subseteq \mathcal{U} \Rightarrow \operatorname{span}(E) \subseteq \mathcal{U}]$.

Proof.

(i) The empty combination has value $\mathbf{0}$, so $\mathbf{0} \in \operatorname{span}(E)$. Let $\mathbf{x}, \mathbf{y} \in \operatorname{span}(E)$ and $c \in \mathbb{F}$.
Choose $m, n \in \mathbb{N}_0$ and finite linear-combination representations from E, $\mathbf{x} = \sum_{j=1}^{m} a_j \mathbf{e}_j$ and $\mathbf{y} = \sum_{k=1}^{n} b_k \mathbf{f}_k$.
Then $c\mathbf{x} + \mathbf{y} = \sum_{j=1}^{m} (ca_j)\mathbf{e}_j + \sum_{k=1}^{n} b_k \mathbf{f}_k \in \operatorname{span}(E)$ by concatenating the two lists. Thus $\operatorname{span}(E) \leq \mathcal{V}$ by Theorem 1.2.2.

(ii) $(\forall\, \mathbf{v} \in E)\, \mathbf{v} = 1\mathbf{v} \in \operatorname{span}(E)$, so $E \subseteq \operatorname{span}(E)$.

(iii) Let $\mathcal{U} \leq \mathcal{V}$ and $E \subseteq \mathcal{U}$. Set $P(m) := [(\forall\, (a_1, \ldots, a_m) \in \mathbb{F}^m)(\forall\, (\mathbf{e}_1, \ldots, \mathbf{e}_m) \in E^m)\ \sum_{j=1}^{m} a_j \mathbf{e}_j \in \mathcal{U}]$.
The base case $P(0)$ holds by $\mathbf{0} \in \mathcal{U}$. Assume $m \in \mathbb{N}_0$, $P(m)$, $(a_1, \ldots, a_{m+1}) \in \mathbb{F}^{m+1}$, and $(\mathbf{e}_1, \ldots, \mathbf{e}_{m+1}) \in E^{m+1}$.
Set $\mathbf{s} := \sum_{j=1}^{m} a_j \mathbf{e}_j$. Then $\mathbf{s} \in \mathcal{U}$ by $P(m)$. $a_{m+1}\mathbf{e}_{m+1} \in \mathcal{U}$ by $E \subseteq \mathcal{U}$ and scalar closure in $\mathcal{U}$.
Hence $\sum_{j=1}^{m+1} a_j \mathbf{e}_j = \mathbf{s} + a_{m+1}\mathbf{e}_{m+1} \in \mathcal{U}$ by additive closure, so $P(m+1)$.
$(\forall\, m \in \mathbb{N}_0)\, P(m)$ by induction. Hence $\operatorname{span}(E) \subseteq \mathcal{U}$ by the definition of span.

Structural Commentary: The proof verifies closure, generator inclusion, and minimality in statement order.
Key Insight: Finite linear combinations are exactly the closure forced by E. □

Proposition 1.2.6. *Monotonicity of Span*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$, and let $\mathcal{U}, \mathcal{W} \subseteq \mathcal{V}$. Then $\mathcal{U} \subseteq \mathcal{W} \Rightarrow \operatorname{span}(\mathcal{U}) \subseteq \operatorname{span}(\mathcal{W})$.

Proof. Assume $\mathcal{U} \subseteq \mathcal{W}$. Then $\operatorname{span}(\mathcal{W}) \leq \mathcal{V}$ and $\mathcal{W} \subseteq \operatorname{span}(\mathcal{W})$ by Theorem 1.2.5(i)–(ii).
Thus $\mathcal{U} \subseteq \operatorname{span}(\mathcal{W})$, and $\operatorname{span}(\mathcal{U}) \subseteq \operatorname{span}(\mathcal{W})$ by Theorem 1.2.5(iii).
Structural Commentary: The proof compares both generating sets inside the same containing subspace.
Key Insight: Minimality converts generator inclusion into span inclusion. □

Computation Method 1.2.7. *Subspace and Span Diagnostic*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$ and let $S \subseteq \mathcal{V}$. Return the output matching the task:

(i) *Subspace certificate*: establish $S \neq \emptyset$ and $(\forall\, \mathbf{u}, \mathbf{v} \in S)(\forall\, c \in \mathbb{F})\, c\mathbf{u} + \mathbf{v} \in S$. Then $S \leq \mathcal{V}$ by Theorem 1.2.2.

(ii) *Failure certificate*: if $S = \emptyset$, then $S \not\leq \mathcal{V}$. Otherwise exhibit $\mathbf{u}, \mathbf{v} \in S$ and $c \in \mathbb{F}$ with $c\mathbf{u} + \mathbf{v} \notin S$.
Then $S \not\leq \mathcal{V}$ by Theorem 1.2.2. The condition $\mathbf{0} \in S$ alone is insufficient.

(iii) *Generated subspace*: return $\operatorname{span}(S)$, the set of all finite linear combinations from S.
Precisely, $\operatorname{span}(S) = \left\{ \sum_{i=1}^{n} a_i \mathbf{s}_i : n \in \mathbb{N}_0,\ (a_1, \ldots, a_n) \in \mathbb{F}^n,\ (\mathbf{s}_1, \ldots, \mathbf{s}_n) \in S^n \right\}$, with the empty sum $\mathbf{0}$ at $n = 0$.

1.3 Linear Independence and Bases

Throughout this subsection, let $\mathcal{V}$ be a vector space over $\mathbb{F}$.

Definition 1.3.1. *Linear Independence, Bases, and Finite-Dimensionality*

(i) A nonempty finite list $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_m)$ in $\mathcal{V}$ is *linearly independent* iff $(\forall\, (a_1, \ldots, a_m) \in \mathbb{F}^m)\, [\sum_{j=1}^{m} a_j \mathbf{v}_j = \mathbf{0} \Rightarrow a_1 = \cdots = a_m = 0]$.
The empty list is linearly independent. A finite list that is not linearly independent is *linearly dependent*.

(ii) A list β is a *basis* of $\mathcal{V}$ iff β is linearly independent and $\operatorname{span}(\beta) = \mathcal{V}$.

(iii) $\mathcal{V}$ is *finite-dimensional* iff $(\exists\, m \in \mathbb{N}_0)(\exists\, \beta \in \mathcal{V}^m)\ \operatorname{span}(\beta) = \mathcal{V}$. Otherwise $\mathcal{V}$ is *infinite-dimensional*.

Proposition 1.3.2. *Unique Coefficients for Independent Lists*
Let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_m)$ be linearly independent in $\mathcal{V}$, $\mathbf{a} := (a_1, \ldots, a_m) \in \mathbb{F}^m$, $\mathbf{b} := (b_1, \ldots, b_m) \in \mathbb{F}^m$; $\sum_{j=1}^{m} a_j \mathbf{v}_j = \sum_{j=1}^{m} b_j \mathbf{v}_j$ iff $\mathbf{a} = \mathbf{b}$.

Proof.

($\Rightarrow$) $\sum_{j=1}^{m}(a_j - b_j)\mathbf{v}_j = \mathbf{0}$ by subtracting the two sums. Hence $(\forall\, j \in \{1,\dots,m\})\, a_j - b_j = 0$ by linear independence of β, so $\mathbf{a} = \mathbf{b}$.

($\Leftarrow$) The two sums are equal by equality of the coefficient tuples.

Structural Commentary: Subtracting two representations converts coefficient comparison into the defining zero-relation test.
Key Insight: Independence detects equality coefficient by coefficient. □

Proposition 1.3.3. *Unique Coordinate Representation*

Let $\beta = (\mathbf{v}_1,\dots,\mathbf{v}_n)$ be a finite list in $\mathcal{V}$. Then β is a basis of $\mathcal{V}$ iff $(\forall\, \mathbf{v} \in \mathcal{V})(\exists!\,(a_1,\dots,a_n) \in \mathbb{F}^n)\, \mathbf{v} = \sum_{j=1}^{n} a_j\mathbf{v}_j$.

Proof.

($\Rightarrow$) Every $\mathbf{v} \in \mathcal{V}$ has a coefficient tuple by $\operatorname{span}(\beta) = \mathcal{V}$, and that tuple is unique by Proposition 1.3.2.

($\Leftarrow$) $\operatorname{span}(\beta) = \mathcal{V}$ by the existence clause. If $\sum_{j=1}^{n} a_j\mathbf{v}_j = \mathbf{0}$, then $\sum_{j=1}^{n} a_j\mathbf{v}_j = \sum_{j=1}^{n} 0\mathbf{v}_j$, so $(\forall\, j \in \{1,\dots,n\})\, a_j = 0$ by the uniqueness clause. Thus β is linearly independent and hence a basis.

Structural Commentary: Spanning supplies coordinate tuples, while independence separates any two such tuples.
Key Insight: A basis is precisely a list with universal and unique coordinates. □

Proposition 1.3.4. *Appending to a Dependent List*

Let $\beta = (\mathbf{v}_1,\dots,\mathbf{v}_m)$ be linearly dependent in $\mathcal{V}$. Then $(\forall\, \mathbf{v} \in \mathcal{V})\,(\mathbf{v}_1,\dots,\mathbf{v}_m,\mathbf{v})$ is linearly dependent.

Proof. Choose $(a_1,\dots,a_m) \in \mathbb{F}^m$ such that $\sum_{j=1}^{m} a_j\mathbf{v}_j = \mathbf{0}$ and $(\exists\, j \in \{1,\dots,m\})\, a_j \neq 0$ by dependence of β.

For $\mathbf{v} \in \mathcal{V}$, $\sum_{j=1}^{m} a_j\mathbf{v}_j + 0\mathbf{v} = \mathbf{0}$ is a nontrivial relation on $(\beta, \mathbf{v})$.

Structural Commentary: The original relation is embedded into the longer coefficient tuple by assigning zero to the appended entry.
Key Insight: An existing dependence relation survives every append. □

Definition 1.3.5. *Omitting a Vector from a List*

Let $\beta = (\mathbf{v}_1,\dots,\mathbf{v}_m)$ be a nonempty list in $\mathcal{V}$. For $j \in \{1,\dots,m\}$, write $\beta_{\widehat{j}} := (\mathbf{v}_1,\dots,\widehat{\mathbf{v}_j},\dots,\mathbf{v}_m)$; if $m = 1$, then $\beta_{\widehat{1}} = ()$.

Proposition 1.3.6. *Omitting from an Independent List*

If $\beta = (\mathbf{v}_1,\dots,\mathbf{v}_m)$ is a nonempty linearly independent list, then $(\forall\, j \in \{1,\dots,m\})$ $\beta_{\widehat{j}}$ is linearly independent.

Proof. Fix $j \in \{1,\dots,m\}$, and let $(a_i)_{i\neq j}$ satisfy $\sum_{i\neq j} a_i\mathbf{v}_i = \mathbf{0}$. Set $a_j := 0$.

Then $\sum_{i=1}^{m} a_i\mathbf{v}_i = \mathbf{0}$, so $(\forall\, i \in \{1,\dots,m\})\, a_i = 0$ by independence of β. Hence every coefficient in the original relation is zero.

Structural Commentary: Padding a sublist relation with a zero coefficient turns it into a relation on the original list.
Key Insight: Deletion cannot introduce a new cancellation. □

Proposition 1.3.7. *Adjoining and Removing Vectors from Lists*

Let $\beta = (\mathbf{v}_1,\dots,\mathbf{v}_m)$ be a list in $\mathcal{V}$, and write $(\beta, \mathbf{v}) := (\mathbf{v}_1,\dots,\mathbf{v}_m,\mathbf{v})$.

(i) If β is linearly independent and $\mathbf{v} \notin \operatorname{span}(\beta)$, then $(\beta, \mathbf{v})$ is linearly independent.

(ii) If $(a_1,\dots,a_m) \in \mathbb{F}^m$, $\sum_{i=1}^{m} a_i\mathbf{v}_i = \mathbf{0}$, and $j \in \{1,\dots,m\}$ satisfies $a_j \neq 0$, then $\operatorname{span}(\beta_{\widehat{j}}) = \operatorname{span}(\beta)$.
Hence $\operatorname{span}(\beta) = \mathcal{V}$ implies $\operatorname{span}(\beta_{\widehat{j}}) = \mathcal{V}$.

Proof.

(i) Let $\sum_{i=1}^{m} a_i\mathbf{v}_i + a\mathbf{v} = \mathbf{0}$. If $a \neq 0$, then $\mathbf{v} = -a^{-1}\sum_{i=1}^{m} a_i\mathbf{v}_i \in \operatorname{span}(\beta)$, contrary to hypothesis.
Hence $a = 0$, and then $(\forall\, i \in \{1,\dots,m\})\, a_i = 0$ by independence of β.

(ii) $\mathbf{v}_j = -a_j^{-1}\sum_{i\neq j} a_i\mathbf{v}_i \in \operatorname{span}(\beta_{\widehat{j}})$ by $a_j \neq 0$ and the stated relation.
Thus every vector of β lies in $\operatorname{span}(\beta_{\widehat{j}})$, so $\operatorname{span}(\beta) \subseteq \operatorname{span}(\beta_{\widehat{j}})$. The reverse inclusion is immediate because $\beta_{\widehat{j}}$ is a sublist of β.

Structural Commentary: The first argument isolates the appended coefficient; the second solves for a nonzero-coefficient entry.
Key Insight: Append outside the current span, or delete an entry already controlled by the others. □

Theorem 1.3.8. *Basis Characterizations*

Let $\beta = (\mathbf{v}_1,\dots,\mathbf{v}_n)$ be a finite list in $\mathcal{V}$. Then the following are equivalent:

(i) β is a basis of $\mathcal{V}$;

(ii) $(\forall\, \mathbf{x} \in \mathcal{V})(\exists!\,(a_1,\dots,a_n) \in \mathbb{F}^n)\, \mathbf{x} = \sum_{j=1}^{n} a_j\mathbf{v}_j$;

(iii) $\operatorname{span}(\beta) = \mathcal{V}$, and no proper sublist of β spans $\mathcal{V}$;

(iv) β is linearly independent, and $(\forall\, \mathbf{x} \in \mathcal{V})$ $(\beta, \mathbf{x})$ is linearly dependent.

Proof.

(*i*) $\Rightarrow$ (*ii*) by Proposition 1.3.3.

(*ii*) $\Rightarrow$ (*iii*). The equality $\operatorname{span}(\beta) = \mathcal{V}$ holds by the existence clause.
Suppose a proper sublist γ of β spans $\mathcal{V}$, and choose an occurrence $\mathbf{v}_j$ omitted from γ.
A representation of $\mathbf{v}_j$ by γ extends to a β-coefficient tuple whose jth entry is 0, whereas the standard coefficient tuple for $\mathbf{v}_j$ has jth entry 1. This contradicts the uniqueness clause.

(*iii*) $\Rightarrow$ (*iv*). If β were linearly dependent, choose a nontrivial relation $\sum_{j=1}^{n} a_j \mathbf{v}_j = \mathbf{0}$ and an index j with $a_j \neq 0$.
Then $\beta_{\widehat{j}}$ would span $\mathcal{V}$ by Proposition 1.3.7(ii), contrary to minimality. Hence β is linearly independent.
For $\mathbf{x} \in \mathcal{V}$, choose $\mathbf{x} = \sum_{j=1}^{n} a_j \mathbf{v}_j$ by $\operatorname{span}(\beta) = \mathcal{V}$. Then $(a_1, \dots, a_n, -1)$ is a nonzero relation tuple for $(\beta, \mathbf{x})$.

(*iv*) $\Rightarrow$ (*i*). If $\operatorname{span}(\beta) \neq \mathcal{V}$, choose $\mathbf{x} \in \mathcal{V} \setminus \operatorname{span}(\beta)$. Then $(\beta, \mathbf{x})$ is linearly independent by Proposition 1.3.7(i), contrary to (iv). Thus $\operatorname{span}(\beta) = \mathcal{V}$, and β is a basis by the independence clause in (iv).

Structural Commentary: The implication cycle passes through unique coordinates, minimal spanning, and maximal independence.
Key Insight: A basis is both an irredundant spanning list and an independence-maximal list. □

Lemma 1.3.9. *Replacement Lemma*
Let $\mathcal{V} \neq \{\mathbf{0}\}$, let $\beta = (\mathbf{u}_1, \dots, \mathbf{u}_r)$ span $\mathcal{V}$, and let $\mathbf{0} \neq \mathbf{v} = \sum_{i=1}^{r} c_i \mathbf{u}_i$. For $j \in \{1, \dots, r\}$, set $\beta_{j \leftarrow \mathbf{v}} := (\mathbf{u}_1, \dots, \mathbf{u}_{j-1}, \mathbf{v}, \mathbf{u}_{j+1}, \dots, \mathbf{u}_r)$.

(i) $(\exists\, j \in \{1, \dots, r\})\, c_j \neq 0$.
(ii) If $c_j \neq 0$, then $\operatorname{span}(\beta_{j \leftarrow \mathbf{v}}) = \mathcal{V}$.
(iii) If $c_j \neq 0$ and β is a basis, then $\beta_{j \leftarrow \mathbf{v}}$ is a basis.
(iv) If $r \geq 2$, β is a basis, $k \in \{1, \dots, r-1\}$, and $\mathbf{v} \notin \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$, then $(\exists\, j \in \{k+1, \dots, r\})$ $\beta_{j \leftarrow \mathbf{v}}$ is a basis.

Proof.

(i) If $(\forall\, j \in \{1, \dots, r\})\, c_j = 0$, then $\mathbf{v} = \sum_{i=1}^{r} c_i \mathbf{u}_i = \mathbf{0}$, contrary to hypothesis.

(ii) Assume $c_j \neq 0$. Then $\mathbf{u}_j = c_j^{-1} \left(\mathbf{v} - \sum_{i \neq j} c_i \mathbf{u}_i \right) \in \operatorname{span}(\beta_{j \leftarrow \mathbf{v}})$, so $\operatorname{span}(\beta) \subseteq \operatorname{span}(\beta_{j \leftarrow \mathbf{v}})$.
Conversely, $\mathbf{v} \in \operatorname{span}(\beta)$, so $\operatorname{span}(\beta_{j \leftarrow \mathbf{v}}) \subseteq \operatorname{span}(\beta)$. Hence $\operatorname{span}(\beta_{j \leftarrow \mathbf{v}}) = \mathcal{V}$.

(iii) Assume $c_j \neq 0$ and β is a basis. Let $\sum_{i<j} b_i \mathbf{u}_i + a\mathbf{v} + \sum_{i>j} b_i \mathbf{u}_i = \mathbf{0}$. Then $\sum_{i \neq j} (b_i + a c_i) \mathbf{u}_i + a c_j \mathbf{u}_j = \mathbf{0}$ by substituting $\mathbf{v} = \sum_{i=1}^{r} c_i \mathbf{u}_i$.
Thus $a c_j = 0$ and $(\forall\, i \neq j)\, b_i + a c_i = 0$ by independence of β. Hence $a = 0$ by $c_j \neq 0$, and then $(\forall\, i \neq j)\, b_i = 0$.
Therefore $\beta_{j \leftarrow \mathbf{v}}$ is linearly independent; it spans $\mathcal{V}$ by (ii), so it is a basis.

(iv) If $(\forall\, j \in \{k+1, \dots, r\})\, c_j = 0$, then $\mathbf{v} = \sum_{i=1}^{k} c_i \mathbf{u}_i \in \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$, contrary to hypothesis.

(v) Choose $j \in \{k+1, \dots, r\}$ with $c_j \neq 0$. Then $\beta_{j \leftarrow \mathbf{v}}$ is a basis by (iii).

Structural Commentary: Solving for a nonzero-coefficient entry preserves span; comparing coefficients preserves independence.
Key Insight: A vector may replace precisely an entry on which its expansion genuinely depends. □

Lemma 1.3.10. *Linear Dependence Lemma*
Let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_m)$ be linearly dependent with $\mathbf{v}_1 \neq \mathbf{0}$. Then $(\exists\, j \in \{2, \dots, m\})\, [\mathbf{v}_j \in \operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_{j-1}) \wedge \operatorname{span}(\beta_{\widehat{j}}) = \operatorname{span}(\beta)]$.

Proof.

(i) *Terminal coefficient*: Choose a nontrivial relation $\sum_{i=1}^{m} a_i \mathbf{v}_i = \mathbf{0}$, and set $j := \max\{i : a_i \neq 0\}$.
The equality $j = 1$ would imply $\mathbf{v}_1 = \mathbf{0}$ by $a_1 \mathbf{v}_1 = \mathbf{0}$ and $a_1 \neq 0$, contrary to hypothesis. Hence $j \in \{2, \dots, m\}$.

(ii) *Earlier-span representation*: $(\forall\, i > j)\, a_i = 0$ by the choice of j, and therefore $\mathbf{v}_j = -a_j^{-1} \sum_{i=1}^{j-1} a_i \mathbf{v}_i \in \operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_{j-1})$.

(iii) *Span preservation*: This representation rewrites every linear combination of β without $\mathbf{v}_j$, so $\operatorname{span}(\beta) \subseteq \operatorname{span}(\beta_{\widehat{j}})$.
The reverse inclusion holds because $\beta_{\widehat{j}}$ is a sublist of β. Hence $\operatorname{span}(\beta_{\widehat{j}}) = \operatorname{span}(\beta)$.

Structural Commentary: The last nonzero relation coefficient identifies a later vector in the earlier span that can be removed.
Key Insight: Choose the final active coefficient to preserve both order and span. □

Theorem 1.3.11. *Independent Lists Are No Longer Than Spanning Lists*
If $\mathcal{V}$ is finite-dimensional, $\alpha = (\mathbf{u}_1, \dots, \mathbf{u}_m)$ is linearly independent, and $\gamma = (\mathbf{w}_1, \dots, \mathbf{w}_n)$ spans $\mathcal{V}$, then $m \leq n$.

Proof.

(i) *Contradictory regime*: Suppose $m > n$. Then $n \geq 1$: if $n = 0$, then $\mathbf{u}_1 \in \mathcal{V} = \operatorname{span}(\gamma) = \{\mathbf{0}\}$, contrary to independence of α.

(ii) *Successive replacement*: Construct spanning lists γ_k of length n with designated occurrences of $\mathbf{u}_1, \dots, \mathbf{u}_k$ for $0 \leq k \leq n$.
Set $\gamma_0 := \gamma$. Suppose $k < n$ and γ_k has been constructed. Then $\mathbf{u}_{k+1} \notin \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$ by independence of α.
Expand $\mathbf{u}_{k+1}$ in the spanning list γ_k. Some coefficient at a nondesignated position is nonzero; otherwise the expansion would place $\mathbf{u}_{k+1}$ in $\operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$. The vector $\mathbf{u}_{k+1}$ is nonzero by independence of α. Replace the identified position by $\mathbf{u}_{k+1}$.
The resulting list γ_{k+1} spans $\mathcal{V}$ by Lemma 1.3.9(ii), has length n, and retains every earlier designated occurrence.

(iii) *Terminal list*: The designated occurrences of $\mathbf{u}_1, \dots, \mathbf{u}_n$ occupy all n positions of γ_n. Hence $\operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_n) = \operatorname{span}(\gamma_n) = \mathcal{V}$.

(iv) *Contradiction*: Since $m > n$, $\mathbf{u}_{n+1} \in \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_n)$ by the terminal equality, contrary to independence of α.

Structural Commentary: Each replacement reserves one independent vector while keeping the spanning-list length and span fixed.
Key Insight: After all spanning positions are reserved, no further independent direction can remain. □

Theorem 1.3.12. *Reducing Spanning Lists*
If $\mathcal{V}$ is finite-dimensional, then every spanning list in $\mathcal{V}$ contains a basis sublist.

Proof. Let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ be a spanning list of $\mathcal{V}$. If β is independent, it is a basis. Otherwise remove one vector without changing span: omit $\mathbf{v}_1$ if $\mathbf{v}_1 = \mathbf{0}$; if $\mathbf{v}_1 \neq \mathbf{0}$, remove a suitable $\mathbf{v}_j$ by Lemma 1.3.10. The resulting sublist still spans $\mathcal{V}$ and has length one less. Repeating at most n times reaches a spanning independent sublist, hence a basis.
Structural Commentary: Each deletion shortens the list without changing span, so finite descent reaches an independent sublist.
Key Insight: Repeatedly remove a certified redundancy until only a basis remains. □

Theorem 1.3.13. *Extending Independent Lists*
If $\mathcal{V}$ is finite-dimensional, then every linearly independent list in $\mathcal{V}$ extends to a basis of $\mathcal{V}$.

Proof.

(i) *Setup*: Let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_m)$ be linearly independent in $\mathcal{V}$, and choose a finite spanning list $(\mathbf{w}_1, \dots, \mathbf{w}_n)$ of $\mathcal{V}$.
(ii) *Construction*: Starting from $\delta_0 := \beta$, inspect $\mathbf{w}_1, \dots, \mathbf{w}_n$ in order
At stage j, append $\mathbf{w}_j$ exactly when $\mathbf{w}_j \notin \operatorname{span}(\delta_{j-1})$, and call the resulting list δ_j.
Every δ_j is linearly independent by induction using Proposition 1.3.7(i) at each append.
(iii) *Verification*: $(\forall\, j \in \{1, \dots, n\})\ \mathbf{w}_j \in \operatorname{span}(\delta_n)$ because each $\mathbf{w}_j$ was either already spanned when inspected or appended, and subsequent stages only append. Thus $\operatorname{span}(\mathbf{w}_1, \dots, \mathbf{w}_n) \subseteq \operatorname{span}(\delta_n)$ by Theorem 1.2.5(iii).
Hence $\operatorname{span}(\delta_n) = \mathcal{V}$, and the independent list δ_n is a basis extending β.

Structural Commentary: The finite scan preserves independence while absorbing each chosen spanning generator.
Key Insight: Append exactly the generators not already controlled by the current span. □

Corollary 1.3.14. *Bases and Subspaces in Finite Dimension*
If $\mathcal{V}$ is finite-dimensional, then:

(i) $\mathcal{V}$ has a basis;
(ii) $(\forall \mathcal{U} \leq \mathcal{V})$ $\mathcal{U}$ is finite-dimensional.

Proof. Choose a finite spanning list $\gamma = (\mathbf{w}_1, \dots, \mathbf{w}_n)$ of $\mathcal{V}$.

(i) A basis of $\mathcal{V}$ is contained in γ by Theorem 1.3.12.
(ii) Fix $\mathcal{U} \leq \mathcal{V}$, and set $\beta_0 := ()$. Whenever $\operatorname{span}(\beta_k) \neq \mathcal{U}$, choose $\mathbf{u}_{k+1} \in \mathcal{U} \setminus \operatorname{span}(\beta_k)$ and set $\beta_{k+1} := (\beta_k, \mathbf{u}_{k+1})$.
Every constructed list is linearly independent by induction using Proposition 1.3.7(i).
The construction cannot reach β_{n+1} by Theorem 1.3.11, because γ is a spanning list of length n.
Hence it stops at some $k \leq n$ with $\operatorname{span}(\beta_k) = \mathcal{U}$. Thus β_k is a finite basis of $\mathcal{U}$, so $\mathcal{U}$ is finite-dimensional.

Structural Commentary: Basis reduction handles $\mathcal{V}$; the ambient length bound forces every subspace construction to terminate.
Key Insight: Ambient finite spanning length bounds the size of every independent subspace list. □

Definition 1.3.15. *Independent Sets and Hamel Bases*
A subset $I \subseteq \mathcal{V}$ is *linearly independent* iff every finite list of distinct vectors in I is linearly independent.
A subset $\mathcal{B} \subseteq \mathcal{V}$ is a *Hamel basis* of $\mathcal{V}$ iff $\mathcal{B}$ is linearly independent and $\operatorname{span}(\mathcal{B}) = \mathcal{V}$.
For $a : \mathcal{B} \to \mathbb{F}$, define $\operatorname{supp}_{\mathcal{B}}(a) := \{\mathbf{b} \in \mathcal{B} : a(\mathbf{b}) \neq 0\}$. A *finite $\mathcal{B}$-expansion* of $\mathbf{v} \in \mathcal{V}$ is a function $a : \mathcal{B} \to \mathbb{F}$ with finite support such that $\mathbf{v} = \sum_{\mathbf{b} \in \operatorname{supp}_{\mathcal{B}}(a)} a(\mathbf{b})\mathbf{b}$. For a finite Hamel basis, any ordering of $\mathcal{B}$ is an ordered basis.

Proposition 1.3.16. *Hamel Coordinate Representation*
If $\mathcal{B}$ is a Hamel basis of $\mathcal{V}$, then every $\mathbf{v} \in \mathcal{V}$ has a unique finite $\mathcal{B}$-expansion.

Proof. Fix $\mathbf{v} \in \mathcal{V}$. Choose $m \in \mathbb{N}_0$, $(c_1, \dots, c_m) \in \mathbb{F}^m$, and $(\mathbf{b}_1, \dots, \mathbf{b}_m) \in \mathcal{B}^m$ such that $\mathbf{v} = \sum_{j=1}^{m} c_j \mathbf{b}_j$ by $\operatorname{span}(\mathcal{B}) = \mathcal{V}$.
For $\mathbf{b} \in \mathcal{B}$, set $J_{\mathbf{b}} := \{j \in \{1, \dots, m\} : \mathbf{b}_j = \mathbf{b}\}$, and define $a : \mathcal{B} \to \mathbb{F}$ by $a(\mathbf{b}) := \sum_{j \in J_{\mathbf{b}}} c_j$.
Then $\operatorname{supp}_{\mathcal{B}}(a) \subseteq \{\mathbf{b}_1, \dots, \mathbf{b}_m\}$, and $\mathbf{v} = \sum_{\mathbf{b} \in \operatorname{supp}_{\mathcal{B}}(a)} a(\mathbf{b})\mathbf{b}$ by regrouping equal entries. Hence a is a finite $\mathcal{B}$-expansion of $\mathbf{v}$.
For uniqueness, let $a, a' : \mathcal{B} \to \mathbb{F}$ be finite $\mathcal{B}$-expansions of $\mathbf{v}$, and set $F := \operatorname{supp}_{\mathcal{B}}(a) \cup \operatorname{supp}_{\mathcal{B}}(a')$.
Then F is finite and $\sum_{\mathbf{b} \in F} (a(\mathbf{b}) - a'(\mathbf{b}))\mathbf{b} = \mathbf{0}$. Thus $(\forall\, \mathbf{b} \in F)\, a(\mathbf{b}) = a'(\mathbf{b})$ by independence of $\mathcal{B}$. Both vanish on $\mathcal{B} \setminus F$, so $a = a'$.
Structural Commentary: Existence consolidates repeated generators; uniqueness compares their combined finite support.
Key Insight: Hamel coordinates are ordinary independent-list coefficients indexed by finite support. □

Theorem 1.3.17. *Hamel Basis Extension*
Assume Zorn's lemma. Then:

(i) if $I \subseteq S \subseteq \mathcal{V}$, I is linearly independent, and $\operatorname{span}(S) = \mathcal{V}$, then $(\exists\, \mathcal{B})\, [I \subseteq \mathcal{B} \subseteq S \wedge \mathcal{B}$ is a Hamel basis of $\mathcal{V}]$;
(ii) $\mathcal{V}$ has a Hamel basis;
(iii) every linearly independent subset of $\mathcal{V}$ extends to a Hamel basis of $\mathcal{V}$;
(iv) every spanning subset of $\mathcal{V}$ contains a Hamel basis of $\mathcal{V}$.

Proof.

(i) Let $\mathscr{P} := \{E : I \subseteq E \subseteq S,\ E \text{ is linearly independent}\}$, ordered by inclusion.
Then $I \in \mathscr{P}$. Let $\mathcal{C} \subseteq \mathscr{P}$ be a nonempty chain, and set $U := \bigcup_{E \in \mathcal{C}} E$. Then $I \subseteq U \subseteq S$.
Let $m \in \mathbb{N}$, and consider a relation $\sum_{k=1}^{m} a_k \mathbf{u}_k = \mathbf{0}$ among distinct vectors of U.
Choose $E_1, \dots, E_m \in \mathcal{C}$ such that $(\forall\, k \in \{1, \dots, m\})\, \mathbf{u}_k \in E_k$.
Some $E_* \in \mathcal{C}$ contains $E_1 \cup \cdots \cup E_m$ by finite induction on the chain order.
Thus $(\forall\, k \in \{1, \dots, m\})\, a_k = 0$ by independence of E_*, so $U \in \mathscr{P}$.
Hence every nonempty chain has an upper bound in $\mathscr{P}$; the empty chain is bounded by I.
Choose a maximal $\mathcal{B} \in \mathscr{P}$ by Zorn's lemma. Suppose $s \in S \setminus \operatorname{span}(\mathcal{B})$.
In a finite relation among distinct vectors of $\mathcal{B} \cup \{s\}$, a nonzero coefficient of s would imply $s \in \operatorname{span}(\mathcal{B})$, while a zero coefficient leaves a relation in $\mathcal{B}$. Hence $\mathcal{B} \cup \{s\}$ is linearly independent, contrary to maximality of $\mathcal{B}$.
Therefore $S \subseteq \operatorname{span}(\mathcal{B})$, so $\operatorname{span}(\mathcal{B}) = \mathcal{V}$ by $\operatorname{span}(S) = \mathcal{V}$. Thus $I \subseteq \mathcal{B} \subseteq S$, and $\mathcal{B}$ is a Hamel basis.
(ii) $\mathcal{V}$ has a Hamel basis by (i) with the linearly independent set $I = \emptyset$ and the spanning set $S = \mathcal{V}$.
(iii) Every prescribed linearly independent subset extends to a Hamel basis by (i) with $S = \mathcal{V}$.
(iv) Every prescribed spanning subset contains a Hamel basis by (i) with $I = \emptyset$.

Structural Commentary: Chain unions preserve finite independence, and maximality rules out every unspanned element of S.
Key Insight: Finitary independence is stable under chain unions, so Zorn maximality forces a Hamel basis. □

1.4 Dimension and Coordinates

Throughout this subsection, let $\mathcal{V}$ be a vector space over $\mathbb{F}$.

Theorem 1.4.1. *Basis Length Is Well-Defined*
If $\mathcal{V}$ is finite-dimensional and β_1, β_2 are bases of $\mathcal{V}$ of lengths m, n, respectively, then $m = n$.

Proof. The inequality $m \leq n$ holds by Theorem 1.3.11, with β_1 independent and β_2 spanning.
After interchanging the bases, $n \leq m$ holds by the same theorem. Hence $m = n$.
Structural Commentary: Using both basis roles proves the opposite length inequalities.
Key Insight: Symmetric comparison makes basis length intrinsic. □

Definition 1.4.2. *Dimension of a Finite-Dimensional Space*
Assume $\mathcal{V}$ is finite-dimensional. Choose a basis $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ by Corollary 1.3.14, and define $\dim(\mathcal{V}) := n$.
This value is independent of β by Theorem 1.4.1, and $\mathcal{V}$ is called *n-dimensional*. Since $()$ is a basis of $\{\mathbf{0}\}$, $\dim(\{\mathbf{0}\}) = 0$.

Proposition 1.4.3. *Subspace Dimension Criterion*
Let $\mathcal{V}$ be finite-dimensional and let $\mathcal{U} \leq \mathcal{V}$. Then:
(i) $\dim(\mathcal{U}) \leq \dim(\mathcal{V})$;
(ii) $\dim(\mathcal{U}) = \dim(\mathcal{V})$ *iff* $\mathcal{U} = \mathcal{V}$.

Proof. Choose a basis $\delta = (\mathbf{u}_1, \ldots, \mathbf{u}_m)$ of $\mathcal{U}$ and a basis $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ of $\mathcal{V}$ by Corollary 1.3.14.
(*i*) The list δ is independent in $\mathcal{V}$, while β spans $\mathcal{V}$. Hence $m \leq n$ by Theorem 1.3.11, so $\dim(\mathcal{U}) \leq \dim(\mathcal{V})$.
(*ii*) ($\Rightarrow$) Suppose $\dim(\mathcal{U}) = \dim(\mathcal{V})$. Then $m = n$. Extend δ to a basis of $\mathcal{V}$ by Theorem 1.3.13.
The extension adds no entry because its length is n by Theorem 1.4.1. Thus $\mathcal{U} = \operatorname{span}(\delta) = \mathcal{V}$.
(*ii*) ($\Leftarrow$) If $\mathcal{U} = \mathcal{V}$, then δ is a basis of $\mathcal{V}$, so $m = n$ by Theorem 1.4.1. Hence $\dim(\mathcal{U}) = \dim(\mathcal{V})$.
Structural Commentary: Length comparison proves the bound; basis extension tests equality against a new ambient direction.
Key Insight: A subspace of full ambient dimension cannot be proper. □

Proposition 1.4.4. *Full-Dimension Basis Criteria*
Let $\mathcal{V}$ be finite-dimensional and set $n := \dim(\mathcal{V})$. Then:
(i) if γ is a spanning list in $\mathcal{V}$ of length n, then γ is a basis;
(ii) if α is a linearly independent list in $\mathcal{V}$ of length n, then α is a basis.

Proof.
(*i*) A basis sublist β of γ exists by Theorem 1.3.12. Its length is n by Definition 1.4.2 and Theorem 1.4.1.
Since γ also has length n, the sublist β equals γ. Hence γ is a basis.
(*ii*) Extend α to a basis β of $\mathcal{V}$ by Theorem 1.3.13. The length of β is n by Definition 1.4.2.
Hence the extension adds no entry to the length-n list α. Hence $\alpha = \beta$ is a basis.
Structural Commentary: At full length, basis reduction cannot delete and basis extension cannot append.
Key Insight: At the ambient dimension, either half of the basis condition forces the other. □

Theorem 1.4.5. *Dimension as Basis Cardinality*
Assume the Choice Principle 6.1.2. If $\mathcal{B}$ and $\mathcal{C}$ are Hamel bases of $\mathcal{V}$, then $|\mathcal{B}| = |\mathcal{C}|$.

Proof.
(i) *Finite case*: Assume $|\mathcal{B}| = n \in \mathbb{N}_0$, and order $\mathcal{B}$ as a spanning list β. Then $\mathcal{V}$ is finite-dimensional.
The set $\mathcal{C}$ cannot contain $n+1$ distinct vectors by Theorem 1.3.11, because they would form an independent list longer than β.
Thus $\mathcal{C}$ is finite; otherwise finite recursion would select such vectors. If γ orders $\mathcal{C}$ and has length k, then $k = n$ by Theorem 1.4.1, and $|\mathcal{C}| = k = n$ by Proposition 6.3.15(i). Interchanging the bases handles finite $\mathcal{C}$.
(ii) *Support incidence*: Assume $\mathcal{B}$ and $\mathcal{C}$ are infinite. For $\mathbf{c} \in \mathcal{C}$, let $a_{\mathbf{c}} : \mathcal{B} \to \mathbb{F}$ be its unique finite $\mathcal{B}$-expansion by Proposition 1.3.16, and set $S_{\mathbf{c}} := \operatorname{supp}_{\mathcal{B}}(a_{\mathbf{c}})$. Fix $\mathbf{b} \in \mathcal{B}$ and write $\mathbf{b} = \sum_{j=1}^{m} d_j \mathbf{c}_j$ with $\mathbf{c}_j \in \mathcal{C}$.
If $\mathbf{b} \notin \bigcup_{\mathbf{c} \in \mathcal{C}} S_{\mathbf{c}}$, then substituting the $\mathcal{B}$-expansions makes the coefficient at $\mathbf{b}$ equal to $\sum_{j=1}^{m} d_j a_{\mathbf{c}_j}(\mathbf{b}) = 0$, whereas the standard expansion of $\mathbf{b}$ has coefficient 1. This discrepancy is impossible by uniqueness in Proposition 1.3.16.
Hence $(\forall\, \mathbf{b} \in \mathcal{B})(\exists\, \mathbf{c} \in \mathcal{C})\, \mathbf{b} \in S_{\mathbf{c}}$. Set $D := \{(\mathbf{c}, \mathbf{b}) \in \mathcal{C} \times \mathcal{B} : \mathbf{b} \in S_{\mathbf{c}}\}$.
(iii) *Cardinal comparison*: Choose $(\mathbf{c}_{\mathbf{b}})_{\mathbf{b} \in \mathcal{B}}$ such that $(\forall\, \mathbf{b} \in \mathcal{B})\, [\mathbf{c}_{\mathbf{b}} \in \mathcal{C} \wedge \mathbf{b} \in S_{\mathbf{c}_{\mathbf{b}}}]$ by Principle 6.1.2.
Then $\mathbf{b} \mapsto (\mathbf{c}_{\mathbf{b}}, \mathbf{b})$ injects $\mathcal{B}$ into D. Fix a well-order of $\mathcal{B}$ by Principle 6.3.2(iv), let $p_{\mathbf{c}}(\mathbf{b}) \in \mathbb{N}$ be position of $\mathbf{b}$ in the induced ordering of the finite set $S_{\mathbf{c}}$. The map $(\mathbf{c}, \mathbf{b}) \mapsto (\mathbf{c}, p_{\mathbf{c}}(\mathbf{b}))$ injects D into $\mathcal{C} \times \mathbb{N}$. Hence $|\mathcal{B}| \leq |D| \leq |\mathcal{C} \times \mathbb{N}|$ by Proposition 6.5.2(i).
By Proposition 6.5.2(iv) and Proposition 6.3.15(iii), $|\mathcal{C} \times \mathbb{N}| = |\mathcal{C}|\, \aleph_0$.
Since $\mathcal{C}$ is infinite, $\aleph_0 \leq |\mathcal{C}|$ by Proposition 6.3.15(iv), so $|\mathcal{C}|\, \aleph_0 = |\mathcal{C}|$ by Theorem 6.6.3(ii). Therefore $|\mathcal{B}| \leq |\mathcal{C}|$.
(iv) *Symmetry*: Interchanging $\mathcal{B}$ and $\mathcal{C}$ proves $|\mathcal{C}| \leq |\mathcal{B}|$. These inequalities correspond to injections in both directions by Proposition 6.5.2(i), so $\mathcal{B} \sim_{\#} \mathcal{C}$ by Theorem 6.2.3. Hence $|\mathcal{B}| = |\mathcal{C}|$ by Proposition 6.3.14(ii).
Structural Commentary: Finite supports form an incidence relation that choice and well-ordering encode by cardinal injections.
Key Insight: Record each support occurrence by one basis vector and one finite position. □

Definition 1.4.6. *Hamel Dimension*
Assume Zorn's lemma and the Choice Principle 6.1.2. Choose a Hamel basis $\mathcal{B}$ of $\mathcal{V}$ by Theorem 1.3.17, and define $\dim(\mathcal{V}) := |\mathcal{B}|$.
The value is independent of $\mathcal{B}$ by Theorem 1.4.5. If $\mathcal{V}$ has a finite ordered basis of length n, its underlying set is a Hamel basis of cardinality n by Proposition 6.3.15(i); hence this definition extends Definition 1.4.2.

1.5 Linear Maps and Operators

Linear maps preserve vector-space operations. Pointwise operations and composition form their coordinate-free algebra, while basis values determine finite-dimensional maps.

Throughout this subsection, $\mathcal{U}, \mathcal{V}, \mathcal{W}$ are vector spaces over the same fixed field $\mathbb{F}$.

Definition 1.5.1. *Linear Map*
A function $T : \mathcal{V} \to \mathcal{W}$ is *linear* iff $(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})(\forall\, a, b \in \mathbb{F})\, T(a\mathbf{u} + b\mathbf{v}) = aT\mathbf{u} + bT\mathbf{v}$.
The collection of linear maps from $\mathcal{V}$ to $\mathcal{W}$ is denoted $\mathcal{L}(\mathcal{V}, \mathcal{W})$. Write $\mathcal{L}(\mathcal{V}) := \mathcal{L}(\mathcal{V}, \mathcal{V})$; its elements are *operators* on $\mathcal{V}$.

Definition 1.5.2. *Zero and Identity Maps*
The *zero map* from $\mathcal{V}$ to $\mathcal{W}$ is $0_{\mathcal{V},\mathcal{W}} : \mathcal{V} \to \mathcal{W}$ satisfying $(\forall\, \mathbf{v} \in \mathcal{V})\, 0_{\mathcal{V},\mathcal{W}}\mathbf{v} = \mathbf{0}_{\mathcal{W}}$.
The *identity map* on $\mathcal{V}$ is $I_{\mathcal{V}} : \mathcal{V} \to \mathcal{V}$ satisfying $(\forall\, \mathbf{v} \in \mathcal{V})\, I_{\mathcal{V}}\mathbf{v} = \mathbf{v}$.

Proposition 1.5.3. *Linear Maps Send Zero to Zero*
If $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, then $T\mathbf{0}_{\mathcal{V}} = \mathbf{0}_{\mathcal{W}}$.

Proof. By linearity, $T\mathbf{0}_{\mathcal{V}} = T(\mathbf{0}_{\mathcal{V}} + \mathbf{0}_{\mathcal{V}}) = T\mathbf{0}_{\mathcal{V}} + T\mathbf{0}_{\mathcal{V}}$. Hence $T\mathbf{0}_{\mathcal{V}} = \mathbf{0}_{\mathcal{W}}$ by cancellation.
Structural Commentary: Additivity converts zero preservation into a cancellation identity.
Key Insight: The additive identity is fixed by every linear map. □

Definition 1.5.4. *Operations on Linear Maps*
For $S, T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ and $a \in \mathbb{F}$, define pointwise $(S + T)\mathbf{v} := S\mathbf{v} + T\mathbf{v}$ and $(aT)\mathbf{v} := a(T\mathbf{v})$ for $\mathbf{v} \in \mathcal{V}$.

Proposition 1.5.5. *Zero, Identity, and the Linear-Map Space*
(i) $0_{\mathcal{V},\mathcal{W}} \in \mathcal{L}(\mathcal{V}, \mathcal{W})$.
(ii) $I_{\mathcal{V}} \in \mathcal{L}(\mathcal{V})$.
(iii) The operations above make $\mathcal{L}(\mathcal{V}, \mathcal{W})$ a vector space over $\mathbb{F}$.

Proof.
(i) For $a, b \in \mathbb{F}$ and $\mathbf{u}, \mathbf{v} \in \mathcal{V}$, $0_{\mathcal{V},\mathcal{W}}(a\mathbf{u} + b\mathbf{v}) = \mathbf{0}_{\mathcal{W}} = a(0_{\mathcal{V},\mathcal{W}}\mathbf{u}) + b(0_{\mathcal{V},\mathcal{W}}\mathbf{v})$ by Theorem 1.1.2(iv). Hence $0_{\mathcal{V},\mathcal{W}} \in \mathcal{L}(\mathcal{V}, \mathcal{W})$.
(ii) For $a, b \in \mathbb{F}$ and $\mathbf{u}, \mathbf{v} \in \mathcal{V}$, $I_{\mathcal{V}}(a\mathbf{u} + b\mathbf{v}) = a\mathbf{u} + b\mathbf{v} = aI_{\mathcal{V}}\mathbf{u} + bI_{\mathcal{V}}\mathbf{v}$, so $I_{\mathcal{V}} \in \mathcal{L}(\mathcal{V})$.
(iii) For $S, T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ and $a, b \in \mathbb{F}$, set $A := aS + bT$. For $c, d \in \mathbb{F}$, $\mathbf{u}, \mathbf{v} \in \mathcal{V}$, $A(c\mathbf{u} + d\mathbf{v}) = a(cS\mathbf{u} + dS\mathbf{v}) + b(cT\mathbf{u} + dT\mathbf{v}) = cA\mathbf{u} + dA\mathbf{v}$, so $A \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Hence $\mathcal{L}(\mathcal{V}, \mathcal{W})$ is closed under addition and scalar multiplication.
For $\mathbf{v} \in \mathcal{V}$, $(T + 0_{\mathcal{V},\mathcal{W}})\mathbf{v} = T\mathbf{v} = (0_{\mathcal{V},\mathcal{W}} + T)\mathbf{v}$, and $(T + (-1)T)\mathbf{v} = \mathbf{0}_{\mathcal{W}}$ by Corollary 1.1.3.
Thus $T + 0_{\mathcal{V},\mathcal{W}} = T = 0_{\mathcal{V},\mathcal{W}} + T$ and $T + (-1)T = 0_{\mathcal{V},\mathcal{W}}$ by Assumption 3.1.2.
The remaining axioms hold pointwise in $\mathcal{W}$ and hence for the maps by Assumption 3.1.2.
Structural Commentary: Closure is algebraic; function extensionality lifts codomain axioms pointwise.
Key Insight: Function spaces inherit vector-space structure from their codomain. □

Definition 1.5.6. *Product of Linear Maps*
For $T \in \mathcal{L}(\mathcal{U}, \mathcal{V})$ and $S \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, define their *product* as the function $ST : \mathcal{U} \to \mathcal{W}$ satisfying $(\forall\, \mathbf{u} \in \mathcal{U})\, (ST)\mathbf{u} = S(T\mathbf{u})$.

Proposition 1.5.7. *Algebra of Linear Map Products*
Let $T \in \mathcal{L}(\mathcal{U}, \mathcal{V})$ and $S \in \mathcal{L}(\mathcal{V}, \mathcal{W})$.
(i) $ST \in \mathcal{L}(\mathcal{U}, \mathcal{W})$.
(ii) If $\mathcal{X}$ is a vector space over $\mathbb{F}$ and $R \in \mathcal{L}(\mathcal{W}, \mathcal{X})$, then $(RS)T = R(ST)$.
(iii) $TI_{\mathcal{U}} = T = I_{\mathcal{V}}T$.
(iv) If $S_1, S_2 \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, then $(S_1 + S_2)T = S_1T + S_2T$.
(v) If $T_1, T_2 \in \mathcal{L}(\mathcal{U}, \mathcal{V})$, then $S(T_1 + T_2) = ST_1 + ST_2$.

Proof.
(i) For $\mathbf{u}, \mathbf{x} \in \mathcal{U}$ and $a, b \in \mathbb{F}$, $(ST)(a\mathbf{u} + b\mathbf{x}) = S(aT\mathbf{u} + bT\mathbf{x}) = aS(T\mathbf{u}) + bS(T\mathbf{x}) = a(ST)\mathbf{u} + b(ST)\mathbf{x}$, so $ST \in \mathcal{L}(\mathcal{U}, \mathcal{W})$.
(ii) For $\mathbf{u} \in \mathcal{U}$, $((RS)T)\mathbf{u} = R(S(T\mathbf{u})) = (R(ST))\mathbf{u}$. Hence $(RS)T = R(ST)$ by Assumption 3.1.2.
(iii) For $\mathbf{u} \in \mathcal{U}$, $(TI_{\mathcal{U}})\mathbf{u} = T\mathbf{u} = (I_{\mathcal{V}}T)\mathbf{u}$. Hence $TI_{\mathcal{U}} = T = I_{\mathcal{V}}T$ by Assumption 3.1.2.
(iv) For $\mathbf{u} \in \mathcal{U}$, $((S_1 + S_2)T)\mathbf{u} = S_1(T\mathbf{u}) + S_2(T\mathbf{u}) = (S_1T + S_2T)\mathbf{u}$. Hence $(S_1 + S_2)T = S_1T + S_2T$ by Assumption 3.1.2.
(v) For $\mathbf{u} \in \mathcal{U}$, $(S(T_1 + T_2))\mathbf{u} = S(T_1\mathbf{u} + T_2\mathbf{u}) = S(T_1\mathbf{u}) + S(T_2\mathbf{u}) = (ST_1 + ST_2)\mathbf{u}$.
Hence $S(T_1 + T_2) = ST_1 + ST_2$ by Assumption 3.1.2.
Structural Commentary: Pointwise evaluation reduces composition identities to codomain equalities.
Key Insight: Composition and pointwise addition form the algebra of linear maps. □

Proposition 1.5.8. *Linear Maps Are Determined by a Finite Basis*
If $(\mathbf{v}_1, \ldots, \mathbf{v}_n)$ is a basis of $\mathcal{V}$ and $\mathbf{w}_1, \ldots, \mathbf{w}_n \in \mathcal{W}$, then $(\exists!\, T \in \mathcal{L}(\mathcal{V}, \mathcal{W}))(\forall\, j \in \{1, \ldots, n\})\, T(\mathbf{v}_j) = \mathbf{w}_j$.

Proof. By Proposition 1.3.3, each $\mathbf{v} \in \mathcal{V}$ has a unique expression $\mathbf{v} = \sum_{j=1}^{n} a_j\mathbf{v}_j$. Define $T(\mathbf{v}) := \sum_{j=1}^{n} a_j\mathbf{w}_j$.
The map T is well-defined by coordinate uniqueness, and $(\forall\, j \in \{1, \ldots, n\})\, T\mathbf{v}_j = \mathbf{w}_j$ by the standard coordinate tuples.
For $\mathbf{x} = \sum_{j=1}^{n} a_j\mathbf{v}_j$, $\mathbf{y} = \sum_{j=1}^{n} b_j\mathbf{v}_j$, and $c, d \in \mathbb{F}$, $c\mathbf{x} + d\mathbf{y} = \sum_{j=1}^{n} (ca_j + db_j)\mathbf{v}_j$, so $T(c\mathbf{x} + d\mathbf{y}) = cT\mathbf{x} + dT\mathbf{y}$. Thus $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$.
For $A \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ with the prescribed basis values, $A\mathbf{v} = \sum_{j=1}^{n} a_jA\mathbf{v}_j = \sum_{j=1}^{n} a_j\mathbf{w}_j = T\mathbf{v}$ for $\mathbf{v} \in \mathcal{V}$. Hence $A = T$ by Assumption 3.1.2.
Structural Commentary: Coordinate uniqueness supports construction; function extensionality completes uniqueness.
Key Insight: Arbitrary basis images extend to exactly one linear map. □

Principle 1.5.9. *Coordinate-Free Principle*
By Proposition 1.5.8, basis images determine a linear map before coordinates encode it.
This viewpoint organizes finite-dimensional representations but does not make the map depend on the chosen basis.

1.6 Kernels, Ranges, and Map Properties

Throughout this subsection, $\mathcal{U}, \mathcal{V}, \mathcal{W}$ are vector spaces over the same fixed field $\mathbb{F}$.

Definition 1.6.1. *Kernel and Range of a Linear Map*
For $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, define its *kernel*, or *nullspace*, by $\ker(T) := \{\mathbf{v} \in \mathcal{V} : T\mathbf{v} = \mathbf{0}_{\mathcal{W}}\}$ and its range by $\text{range}(T) := \{T\mathbf{v} : \mathbf{v} \in \mathcal{V}\}$.

Proposition 1.6.2. *Injectivity and the Kernel*
A linear map $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ is injective iff $\ker(T) = \{\mathbf{0}_{\mathcal{V}}\}$.

Proof.
($\Rightarrow$) Suppose T is injective. For $\mathbf{v} \in \ker(T)$, $T\mathbf{v} = \mathbf{0}_{\mathcal{W}} = T\mathbf{0}_{\mathcal{V}}$ by Proposition 1.5.3, so $\mathbf{v} = \mathbf{0}_{\mathcal{V}}$ by injectivity.
Moreover, $\mathbf{0}_{\mathcal{V}} \in \ker(T)$ by the displayed equality; hence $\ker(T) = \{\mathbf{0}_{\mathcal{V}}\}$.
($\Leftarrow$) Suppose $\ker(T) = \{\mathbf{0}_{\mathcal{V}}\}$. For $\mathbf{v}, \mathbf{w} \in \mathcal{V}$ with $T\mathbf{v} = T\mathbf{w}$, $T(\mathbf{v} - \mathbf{w}) = \mathbf{0}_{\mathcal{W}}$ by linearity, so $\mathbf{v} - \mathbf{w} \in \ker(T)$ and $\mathbf{v} = \mathbf{w}$.
Structural Commentary: The forward direction compares kernel vectors with zero; the reverse moves equal images into the kernel.
Key Insight: Differences convert image collisions into kernel vectors. □

Proposition 1.6.3. *Kernel and Range Are Subspaces*
If $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, then:
(i) $\ker(T)$ is a subspace of $\mathcal{V}$.
(ii) $\text{range}(T)$ is a subspace of $\mathcal{W}$.

Proof.
(i) The kernel contains $\mathbf{0}_{\mathcal{V}}$ by Proposition 1.5.3. For $\mathbf{u}, \mathbf{v} \in \ker(T)$ and $a \in \mathbb{F}$, $T(a\mathbf{u} + \mathbf{v}) = aT\mathbf{u} + T\mathbf{v} = \mathbf{0}_{\mathcal{W}}$, so $a\mathbf{u} + \mathbf{v} \in \ker(T)$. Therefore $\ker(T) \leq \mathcal{V}$ by Theorem 1.2.2.
(ii) The range contains $\mathbf{0}_{\mathcal{W}} = T\mathbf{0}_{\mathcal{V}}$ by Proposition 1.5.3. For $T\mathbf{u}, T\mathbf{v} \in \text{range}(T)$ and $a \in \mathbb{F}$, $aT\mathbf{u} + T\mathbf{v} = T(a\mathbf{u} + \mathbf{v}) \in \text{range}(T)$. Therefore $\text{range}(T) \leq \mathcal{W}$ by Theorem 1.2.2.
Structural Commentary: Each proof verifies nonemptiness and linear-combination closure before invoking the subspace test.
Key Insight: Linearity stabilizes the zero fiber and the image. □

Definition 1.6.4. *Invertible Linear Map and Isomorphism*
A linear map $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ is *invertible* iff $(\exists\, S \in \mathcal{L}(\mathcal{W}, \mathcal{V}))\,[ST = I_{\mathcal{V}} \wedge TS = I_{\mathcal{W}}]$.
Such an S is an *inverse* of T. An invertible linear map is an *isomorphism*; if an isomorphism $\mathcal{V} \to \mathcal{W}$ exists, write $\mathcal{V} \cong \mathcal{W}$.

Proposition 1.6.5. *Inverse Is Unique*
If $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ is invertible, then $(\exists!\, S \in \mathcal{L}(\mathcal{W}, \mathcal{V}))\,[ST = I_{\mathcal{V}} \wedge TS = I_{\mathcal{W}}]$. Denote this map by T^{-1}.

Proof. An inverse exists by invertibility of T. Suppose $S_1, S_2 \in \mathcal{L}(\mathcal{W}, \mathcal{V})$ satisfy $S_1T = I_{\mathcal{V}} = S_2T$ and $TS_1 = I_{\mathcal{W}} = TS_2$.
Then $S_1 = S_1I_{\mathcal{W}} = S_1(TS_2) = (S_1T)S_2 = I_{\mathcal{V}}S_2 = S_2$ by Proposition 1.5.7(ii)–(iii) and the candidate inverse identities.
Structural Commentary: Existence is definitional; associativity compares any two inverse candidates.
Key Insight: A two-sided inverse has no freedom. □

Proposition 1.6.6. *Inverse of a Product Reverses Order*
Let $T \in \mathcal{L}(\mathcal{U}, \mathcal{V})$ and $S \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ be invertible.
(i) ST is invertible.
(ii) $(ST)^{-1} = T^{-1}S^{-1}$.

Proof.
(i) Set $R := T^{-1}S^{-1}$. Then $R \in \mathcal{L}(\mathcal{W}, \mathcal{U})$ by Proposition 1.5.7(i).
The identity $R(ST) = T^{-1}(S^{-1}S)T = T^{-1}T = I_{\mathcal{U}}$ holds by Proposition 1.5.7(ii)–(iii) and the inverse identities.
Similarly, $(ST)R = S(TT^{-1})S^{-1} = SS^{-1} = I_{\mathcal{W}}$ by Proposition 1.5.7(ii)–(iii) and the inverse identities. Hence ST is invertible.
(ii) Since R is a two-sided inverse of ST, $(ST)^{-1} = T^{-1}S^{-1}$ by Proposition 1.6.5.
Structural Commentary: The reversed product is checked against both inverse identities, then identified by uniqueness.
Key Insight: Composition order reverses under inversion. □

Proposition 1.6.7. *Invertibility and Bijectivity*
For $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, the map T is invertible iff it is both injective and surjective.

Proof.
($\Rightarrow$) Let $S = T^{-1}$. If $\mathbf{v}, \mathbf{w} \in \mathcal{V}$ and $T\mathbf{v} = T\mathbf{w}$, then $\mathbf{v} = (ST)\mathbf{v} = S(T\mathbf{v}) = S(T\mathbf{w}) = (ST)\mathbf{w} = \mathbf{w}$, so T is injective.
If $\mathbf{y} \in \mathcal{W}$, then $\mathbf{y} = (TS)\mathbf{y} = T(S\mathbf{y})$, so T is surjective.
($\Leftarrow$) Suppose T is injective and surjective. For $\mathbf{y} \in \mathcal{W}$, a unique $\mathbf{v} \in \mathcal{V}$ satisfies $T\mathbf{v} = \mathbf{y}$ by surjectivity and injectivity; define $S\mathbf{y} := \mathbf{v}$.
For $a, b \in \mathbb{F}$ and $\mathbf{y}_1, \mathbf{y}_2 \in \mathcal{W}$, $S(a\mathbf{y}_1 + b\mathbf{y}_2) = aS\mathbf{y}_1 + bS\mathbf{y}_2$ by injectivity because both sides have T-image $a\mathbf{y}_1 + b\mathbf{y}_2$.
Hence $S \in \mathcal{L}(\mathcal{W}, \mathcal{V})$. By construction, $(\forall\, \mathbf{y} \in \mathcal{W})\,(TS)\mathbf{y} = \mathbf{y}$, so $TS = I_{\mathcal{W}}$ by Assumption 3.1.2.
For $\mathbf{v} \in \mathcal{V}$, $T((ST)\mathbf{v}) = T\mathbf{v}$, whence $(ST)\mathbf{v} = \mathbf{v}$ by injectivity. Therefore $ST = I_{\mathcal{V}}$ by Assumption 3.1.2, and T is invertible.
Structural Commentary: Surjectivity constructs the reverse map; injectivity makes it linear and enforces both inverse identities.
Key Insight: Unique preimages turn a bijection into a linear inverse. □

Definition 1.6.8. *Morphism Terminology for Linear Maps*
Within vector spaces, the following terminology applies to $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$:
(i) T is a *homomorphism*.
(ii) T is an *endomorphism* iff $\mathcal{V} = \mathcal{W}$.
(iii) T is a *monomorphism*, or *embedding*, iff T is injective; equivalently, $\ker(T) = \{\mathbf{0}_{\mathcal{V}}\}$ by Proposition 1.6.2.
(iv) T is an *epimorphism* iff T is surjective, equivalently $\text{range}(T) = \mathcal{W}$.
(v) T is an *isomorphism* iff T is invertible; equivalently, T is injective and surjective by Proposition 1.6.7.
(vi) T is an *automorphism* iff $\mathcal{V} = \mathcal{W}$ and T is invertible.

1.7 Rank-Nullity and Dimension Criteria

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$.

Theorem 1.7.1. *Range from Basis Images*
Let $\mathcal{V}$ be finite-dimensional with basis $(\mathbf{v}_1, \dots, \mathbf{v}_n)$, and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Then:

(i) $\operatorname{range}(T) = \operatorname{span}(T\mathbf{v}_1, \dots, T\mathbf{v}_n)$.
(ii) $\operatorname{range}(T)$ *is finite-dimensional.*
(iii) $\dim(\operatorname{range}(T)) \leq n$.

Proof.

(i) ($\Rightarrow$) For $\mathbf{y} \in \operatorname{range}(T)$, choose $\mathbf{v} \in \mathcal{V}$ with $\mathbf{y} = T\mathbf{v}$ and write $\mathbf{v} = \sum_{j=1}^{n} c_j \mathbf{v}_j$.

Then $\mathbf{y} = \sum_{j=1}^{n} c_j T\mathbf{v}_j$ by linearity, so $\operatorname{range}(T) \subseteq \operatorname{span}(T\mathbf{v}_1, \dots, T\mathbf{v}_n)$.

(i) ($\Leftarrow$) $\sum_{j=1}^{n} a_j T\mathbf{v}_j = T(\sum_{j=1}^{n} a_j \mathbf{v}_j) \in \operatorname{range}(T)$ for $a_1, \dots, a_n \in \mathbb{F}$, so the reverse inclusion holds.

(ii) The finite list in (i) spans $\operatorname{range}(T)$, so the range is finite-dimensional.

(i) A basis sublist of the list in (i) exists by Theorem 1.3.12. Its length is at most n, and therefore $\dim(\operatorname{range}(T)) \leq n$.

Structural Commentary: Two inclusions identify the range; basis reduction then converts its generating list into a dimension bound.
Key Insight: A linear map transports every basis expansion to its image. □

Definition 1.7.2. *Rank and Nullity*
Let $\mathcal{V}$ be finite-dimensional and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Define $\operatorname{rank}(T) := \dim(\operatorname{range}(T))$ and $\operatorname{nullity}(T) := \dim(\ker(T))$.
The rank is finite by Theorem 1.7.1(ii); the nullity is finite by Proposition 1.6.3 and Corollary 1.3.14.

Theorem 1.7.3. *Rank-Nullity Theorem*
If $\mathcal{V}$ is finite-dimensional and $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, then:

(i) $\operatorname{range}(T)$ *is finite-dimensional.*
(ii) $\dim(\mathcal{V}) = \operatorname{nullity}(T) + \operatorname{rank}(T)$.

Proof. The kernel has a basis $(\mathbf{u}_1, \dots, \mathbf{u}_m)$ by Proposition 1.6.3 and Corollary 1.3.14.
Extend it to a basis $(\mathbf{u}_1, \dots, \mathbf{u}_m, \mathbf{w}_1, \dots, \mathbf{w}_r)$ of $\mathcal{V}$ by Theorem 1.3.13.
For $\mathbf{v} = \sum_{i=1}^{m} a_i \mathbf{u}_i + \sum_{j=1}^{r} b_j \mathbf{w}_j$, $T\mathbf{v} = \sum_{j=1}^{r} b_j T\mathbf{w}_j$ by linearity, so $(T\mathbf{w}_1, \dots, T\mathbf{w}_r)$ spans $\operatorname{range}(T)$.
If $\sum_{j=1}^{r} c_j T\mathbf{w}_j = \mathbf{0}_{\mathcal{W}}$, then $\mathbf{x} := \sum_{j=1}^{r} c_j \mathbf{w}_j \in \ker(T) = \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_m)$.
Thus $\mathbf{x}$ also has an extended-basis representation with every $\mathbf{w}_j$-coefficient zero, so $c_1 = \cdots = c_r = 0$ by Proposition 1.3.3.
Hence $(T\mathbf{w}_1, \dots, T\mathbf{w}_r)$ is a basis of $\operatorname{range}(T)$.

(i) The basis $(T\mathbf{w}_1, \dots, T\mathbf{w}_r)$ is finite, so $\operatorname{range}(T)$ is finite-dimensional.

(ii) The three bases have lengths m, r, and $m + r$, respectively. Hence $\operatorname{nullity}(T) = m$, $\operatorname{rank}(T) = r$, and $\dim(\mathcal{V}) = m + r$.

Structural Commentary: Extending a kernel basis produces complementary vectors whose images form a basis of the range.
Key Insight: Every domain basis direction is either killed or detected. □

Corollary 1.7.4. *Maps to Smaller Spaces Are Not Injective*
If finite-dimensional vector spaces $\mathcal{V}$ and $\mathcal{W}$ satisfy $\dim(\mathcal{V}) > \dim(\mathcal{W})$, then no $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ is injective.

Proof. Fix $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. By Proposition 1.6.3 and Proposition 1.4.3, $\operatorname{rank}(T) \leq \dim(\mathcal{W})$.
By Theorem 1.7.3, $\operatorname{nullity}(T) = \dim(\mathcal{V}) - \operatorname{rank}(T) \geq \dim(\mathcal{V}) - \dim(\mathcal{W}) > 0$.
Thus $\ker(T) \neq \{\mathbf{0}_{\mathcal{V}}\}$, so T is not injective by Proposition 1.6.2.
Structural Commentary: The range bound feeds rank-nullity, forcing a nontrivial kernel.
Key Insight: Excess domain dimension must collapse. □

Corollary 1.7.5. *Maps to Larger Spaces Are Not Surjective*
If finite-dimensional vector spaces $\mathcal{V}$ and $\mathcal{W}$ satisfy $\dim(\mathcal{V}) < \dim(\mathcal{W})$, then no $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ is surjective.

Proof. Fix $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. By Theorem 1.7.3, $\operatorname{rank}(T) = \dim(\mathcal{V}) - \operatorname{nullity}(T) \leq \dim(\mathcal{V}) < \dim(\mathcal{W})$. Since $\operatorname{range}(T) \leq \mathcal{W}$ by Proposition 1.6.3, $\operatorname{range}(T) \neq \mathcal{W}$ by Proposition 1.4.3. Hence T is not surjective.
Structural Commentary: Rank-nullity bounds the range below the codomain dimension.
Key Insight: A smaller domain cannot cover a larger codomain. □

Corollary 1.7.6. *Equal-Dimension Kernel-Range Criterion*
Let $\mathcal{V}$ and $\mathcal{W}$ be finite-dimensional vector spaces with $\dim(\mathcal{V}) = \dim(\mathcal{W})$, and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Then:

(i) $\ker(T) = \{\mathbf{0}_{\mathcal{V}}\}$ *iff* $\operatorname{range}(T) = \mathcal{W}$.
(ii) T *is injective iff T is surjective.*

Proof.

(i) ($\Rightarrow$) If $\ker(T) = \{\mathbf{0}_{\mathcal{V}}\}$, then $\operatorname{nullity}(T) = 0$ and $\operatorname{rank}(T) = \dim(\mathcal{V}) = \dim(\mathcal{W})$ by Theorem 1.7.3.
Since $\operatorname{range}(T) \leq \mathcal{W}$ by Proposition 1.6.3, $\operatorname{range}(T) = \mathcal{W}$ by Proposition 1.4.3.

(i) ($\Leftarrow$) If $\operatorname{range}(T) = \mathcal{W}$, then $\operatorname{rank}(T) = \dim(\mathcal{W}) = \dim(\mathcal{V})$ and $\operatorname{nullity}(T) = 0$ by Theorem 1.7.3.
The zero subspace and $\ker(T)$ both have dimension zero, so they are equal by Proposition 1.4.3.

(ii) ($\Rightarrow$) If T is injective, then $\ker(T) = \{\mathbf{0}_{\mathcal{V}}\}$ by Proposition 1.6.2. By (i), $\operatorname{range}(T) = \mathcal{W}$, so T is surjective.

(ii) ($\Leftarrow$) If T is surjective, then $\operatorname{range}(T) = \mathcal{W}$. By (i), $\ker(T) = \{\mathbf{0}_{\mathcal{V}}\}$, so T is injective by Proposition 1.6.2.

Structural Commentary: Rank-nullity exchanges kernel loss with range deficit; the kernel criterion translates this to maps.
Key Insight: Equal dimensions leave no room for one-sided failure. □

Theorem 1.7.7. *Finite-Dimensional Invertibility Criteria*
If $\mathcal{V}$ is finite-dimensional and $T \in \mathcal{L}(\mathcal{V})$, then the following are equivalent:

(i) T *is invertible;*
(ii) T *is injective;*
(iii) T *is surjective.*

Proof.

$(i) \Rightarrow (ii)$ The map T is injective by Proposition 1.6.7.
$(ii) \Rightarrow (iii)$ The map T is surjective by Corollary 1.7.6, applied with the same domain and codomain.
$(iii) \Rightarrow (i)$ The map T is injective by Corollary 1.7.6, hence bijective and therefore invertible by Proposition 1.6.7.

Structural Commentary: Bijectivity supplies the outer implications; equal dimension links injectivity and surjectivity.
Key Insight: A nonzero kernel is the sole finite-dimensional obstruction to operator invertibility. □

Proposition 1.7.8. *Isomorphisms Preserve Bases*
Let $T : \mathcal{V} \to \mathcal{W}$ be an isomorphism and let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ be a finite list in $\mathcal{V}$. Set $T\beta = (T\mathbf{v}_1, \dots, T\mathbf{v}_n)$. The following are equivalent:

(i) β *is a basis of* $\mathcal{V}$.
(ii) $T\beta$ *is a basis of* $\mathcal{W}$.

Proof. The map T is injective and surjective by Proposition 1.6.7.

$(i) \Rightarrow (ii)$ For $\mathbf{w} \in \mathcal{W}$, choose $\mathbf{v} \in \mathcal{V}$ with $\mathbf{w} = T\mathbf{v}$ and write $\mathbf{v} = \sum_{j=1}^{n} a_j \mathbf{v}_j$. Then $\mathbf{w} = \sum_{j=1}^{n} a_j T\mathbf{v}_j$ by linearity, so $T\beta$ spans $\mathcal{W}$.
If $\sum_{j=1}^{n} a_j T\mathbf{v}_j = \mathbf{0}_{\mathcal{W}}$, then $T(\sum_{j=1}^{n} a_j \mathbf{v}_j) = \sum_{j=1}^{n} a_j T\mathbf{v}_j = \mathbf{0}_{\mathcal{W}} = T\mathbf{0}_{\mathcal{V}}$ by linearity and Proposition 1.5.3.
Injectivity and independence of β imply $a_1 = \cdots = a_n = 0$. Hence $T\beta$ is a basis of $\mathcal{W}$.
$(ii) \Rightarrow (i)$ For $\mathbf{v} \in \mathcal{V}$, write $T\mathbf{v} = \sum_{j=1}^{n} a_j T\mathbf{v}_j = T(\sum_{j=1}^{n} a_j \mathbf{v}_j)$ by linearity. By injectivity, $\mathbf{v} = \sum_{j=1}^{n} a_j \mathbf{v}_j$, so β spans $\mathcal{V}$.
If $\sum_{j=1}^{n} a_j \mathbf{v}_j = \mathbf{0}_{\mathcal{V}}$, then $\sum_{j=1}^{n} a_j T\mathbf{v}_j = \mathbf{0}_{\mathcal{W}}$ by linearity and Proposition 1.5.3.
Independence of $T\beta$ implies $a_1 = \cdots = a_n = 0$. Hence β is a basis of $\mathcal{V}$.

Structural Commentary: Surjectivity transports spanning representations; injectivity preserves and reflects linear relations.
Key Insight: Isomorphisms preserve both halves of the basis condition. □

Theorem 1.7.9. *Isomorphism and Dimension*
Finite-dimensional vector spaces $\mathcal{V}$ and $\mathcal{W}$ are isomorphic iff $\dim(\mathcal{V}) = \dim(\mathcal{W})$.

Proof.

$(\Rightarrow)$ Let $T : \mathcal{V} \to \mathcal{W}$ be an isomorphism. Choose a basis $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ of $\mathcal{V}$ by Corollary 1.3.14.
Then $T\beta$ is a basis of $\mathcal{W}$ by Proposition 1.7.8, so $\dim(\mathcal{V}) = n = \dim(\mathcal{W})$.
$(\Leftarrow)$ Suppose $\dim(\mathcal{V}) = \dim(\mathcal{W}) = n$, and choose bases $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ and $\gamma = (\mathbf{w}_1, \dots, \mathbf{w}_n)$ by Corollary 1.3.14.
Choose $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ satisfying $(\forall\, j \in \{1, \dots, n\})\, T\mathbf{v}_j = \mathbf{w}_j$ by Proposition 1.5.8. By Theorem 1.7.1(i), $\operatorname{range}(T) = \operatorname{span}(\gamma) = \mathcal{W}$.
or $\mathbf{v} = \sum_{j=1}^{n} a_j \mathbf{v}_j \in \ker(T)$, $\mathbf{0}_{\mathcal{W}} = T\mathbf{v} = \sum_{j=1}^{n} a_j \mathbf{w}_j$, so $a_1 = \cdots = a_n = 0$ by independence of γ.
Thus $\ker(T) = \{\mathbf{0}_{\mathcal{V}}\}$, and T is injective by Proposition 1.6.2.
It is surjective by its range identity, hence invertible by Proposition 1.6.7 and therefore an isomorphism.

Structural Commentary: The forward direction transports a basis; the reverse prescribes an isomorphism on matching bases.
Key Insight: Dimension counts the coordinates preserved by an isomorphism. □

2 Direct Sums, Quotients, and Decomposition

2.1 Sums and Direct Sums

Sums combine subspaces inside a common ambient space, while products and external sums assemble separate spaces. Directness records when these decompositions are unique.

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$.

Definition 2.1.1. *Sums of Subspaces*
Let $m \in \mathbb{N}$ and let $\mathcal{U}_1, \dots, \mathcal{U}_m \leq \mathcal{V}$.

(i) Their *sum* is $\mathcal{U}_1 + \cdots + \mathcal{U}_m := \left\{ \sum_{j=1}^{m} \mathbf{u}_j : (\forall\, j \in \{1, \dots, m\})\, \mathbf{u}_j \in \mathcal{U}_j \right\}$.
(ii) For $\mathcal{U}, \mathcal{W} \leq \mathcal{V}$, $\mathcal{U} + \mathcal{W} = \{\mathbf{u} + \mathbf{w} : \mathbf{u} \in \mathcal{U},\ \mathbf{w} \in \mathcal{W}\}$.
(iii) The sum is *direct* iff $(\forall\, \mathbf{v} \in \mathcal{U}_1 + \cdots + \mathcal{U}_m)(\exists!\, (\mathbf{u}_1, \dots, \mathbf{u}_m) \in \mathcal{U}_1 \times \cdots \times \mathcal{U}_m)\, \mathbf{v} = \sum_{j=1}^{m} \mathbf{u}_j$. A direct sum is denoted $\mathcal{U}_1 \oplus \cdots \oplus \mathcal{U}_m$.

Proposition 2.1.2. *Sum of Subspaces Is the Smallest Containing Subspace*
Let $m \in \mathbb{N}$, let $\mathcal{U}_1, \dots, \mathcal{U}_m \leq \mathcal{V}$, and set $S := \sum_{j=1}^{m} \mathcal{U}_j$.

(i) $S \leq \mathcal{V}$, $(\forall\, j \in \{1, \dots, m\})\, \mathcal{U}_j \subseteq S$, *and* $(\forall\, \mathcal{W} \leq \mathcal{V})[(\forall\, j \in \{1, \dots, m\})\, \mathcal{U}_j \subseteq \mathcal{W} \Rightarrow S \subseteq \mathcal{W}]$.
(ii) $S = \operatorname{span}(\bigcup_{j=1}^{m} \mathcal{U}_j)$.

Proof.

(i) $(\forall\, j \in \{1,\dots,m\})\, \mathbf{0}_{\mathcal{V}} \in \mathcal{U}_j$, so $\mathbf{0}_{\mathcal{V}} \in S$. Let $\mathbf{x}, \mathbf{y} \in S$ and $c \in \mathbb{F}$.

Choose $(\mathbf{u}_1,\dots,\mathbf{u}_m), (\mathbf{v}_1,\dots,\mathbf{v}_m) \in \mathcal{U}_1 \times \cdots \times \mathcal{U}_m$ with $\mathbf{x} = \sum_{j=1}^{m} \mathbf{u}_j$ and $\mathbf{y} = \sum_{j=1}^{m} \mathbf{v}_j$.

Then $c\mathbf{x} + \mathbf{y} = \sum_{j=1}^{m} (c\mathbf{u}_j + \mathbf{v}_j) \in S$ by $(\forall\, j \in \{1,\dots,m\})\, c\mathbf{u}_j + \mathbf{v}_j \in \mathcal{U}_j$. Hence $S \leq \mathcal{V}$ by Theorem 1.2.2.

For $j \in \{1,\dots,m\}$ and $\mathbf{u} \in \mathcal{U}_j$, the sum with jth term $\mathbf{u}$ and all other terms $\mathbf{0}_{\mathcal{V}}$ belongs to S, so $\mathcal{U}_j \subseteq S$.
If $\mathcal{W} \leq \mathcal{V}$ and $(\forall\, j \in \{1,\dots,m\})\, \mathcal{U}_j \subseteq \mathcal{W}$, then each defining finite sum for S belongs to $\mathcal{W}$ by additive closure; hence $S \subseteq \mathcal{W}$.

(ii) Set $E := \bigcup_{j=1}^{m} \mathcal{U}_j$. Then $\operatorname{span}(E) \subseteq S$ by Theorem 1.2.5(iii) and part (i).

The inclusions $E \subseteq \operatorname{span}(E) \leq \mathcal{V}$ hold by Theorem 1.2.5(i)–(ii), so $S \subseteq \operatorname{span}(E)$ by part (i). Thus $S = \operatorname{span}(E)$.

Structural Commentary: Closure and minimality establish the sum; span minimality identifies the same subspace.
Key Insight: Both constructions are forced by the same generators. □

Perspective 2.1.3. *Sum Is Not Union*
Proposition 2.1.2 identifies $\mathcal{U} + \mathcal{W}$ with the linear closure of $\mathcal{U} \cup \mathcal{W}$. The union itself contains only vectors already in one summand.
If neither summand contains the other, choose $\mathbf{u} \in \mathcal{U} \setminus \mathcal{W}$ and $\mathbf{w} \in \mathcal{W} \setminus \mathcal{U}$.
Then $\mathbf{u} + \mathbf{w} \notin \mathcal{U} \cup \mathcal{W}$, since membership in either summand would place the other chosen vector there.
Thus the sum supplies exactly the mixed vectors missing from the union.

Theorem 2.1.4. *Finite Unions of Proper Subspaces*

Let $n \in \mathbb{N}$ and let $\mathcal{V} \neq \{\mathbf{0}_{\mathcal{V}}\}$ be over an infinite field $\mathbb{F}$. If $\mathcal{U}_1,\dots,\mathcal{U}_n \subsetneq \mathcal{V}$ are subspaces, then $\mathcal{V} \neq \bigcup_{j=1}^{n} \mathcal{U}_j$.

Proof.

(i) *Minimal cover*: Assume $\mathcal{V} = \bigcup_{j=1}^{n} \mathcal{U}_j$. Choose a minimal subcover $\mathcal{W}_1,\dots,\mathcal{W}_k$ and set $K := \{1,\dots,k\}$.

Then $(\forall\, i \in K)\, \mathcal{W}_i \not\subseteq \bigcup_{j \in K\setminus\{i\}} \mathcal{W}_j$ by minimality. The case $k = 1$ contradicts $\mathcal{W}_1 \subsetneq \mathcal{V}$; hence $k \geq 2$.

(ii) *Affine line*: Choose $\mathbf{w} \in \mathcal{W}_1 \setminus \bigcup_{j=2}^{k} \mathcal{W}_j$ and $\mathbf{v} \in \mathcal{V} \setminus \mathcal{W}_1$. Since $k \geq 2$ and $\mathbf{0}_{\mathcal{V}} \in \mathcal{W}_2$, $\mathbf{w} \neq \mathbf{0}_{\mathcal{V}}$. Set $A := \{\mathbf{v} + r\mathbf{w} : r \in \mathbb{F}\}$.

The parametrization $r \mapsto \mathbf{v} + r\mathbf{w}$ is injective, so A is infinite by the infinitude of $\mathbb{F}$.

(iii) *Intersections*: If $\mathbf{v} + r\mathbf{w} \in \mathcal{W}_1$, then $\mathbf{v} = (\mathbf{v} + r\mathbf{w}) - r\mathbf{w} \in \mathcal{W}_1$, a contradiction; hence $A \cap \mathcal{W}_1 = \emptyset$.
For $j \in \{2,\dots,k\}$, if $r_1 \neq r_2$ and $\mathbf{v} + r_1\mathbf{w}, \mathbf{v} + r_2\mathbf{w} \in \mathcal{W}_j$, then $(r_1 - r_2)\mathbf{w} \in \mathcal{W}_j$, so $\mathbf{w} \in \mathcal{W}_j$, a contradiction. Thus $|A \cap \mathcal{W}_j| \leq 1$.

(iv) *Contradiction*: The set $A \cap \bigcup_{j=1}^{k} \mathcal{W}_j$ is finite by part (iii), whereas $A \subseteq \mathcal{V} = \bigcup_{j=1}^{k} \mathcal{W}_j$ would make it equal to the infinite set A.

Therefore the assumed cover does not exist.

Structural Commentary: A minimal cover selects a direction whose affine line meets every summand finitely.
Key Insight: An infinite affine line defeats a finite cover. □

Definition 2.1.5. *Subspace Poset, Meet, and Join*

(i) The *subspace poset* is $\operatorname{Sub}(\mathcal{V}) := \{\mathcal{U} \subseteq \mathcal{V} : \mathcal{U} \leq \mathcal{V}\}$, ordered by inclusion.
(ii) For $\{\mathcal{U}_i\}_{i\in I} \subseteq \operatorname{Sub}(\mathcal{V})$, its *meet* is $\bigwedge_{i\in I} \mathcal{U}_i := \bigcap_{i\in I} \mathcal{U}_i$.
(iii) For $\{\mathcal{U}_i\}_{i\in I} \subseteq \operatorname{Sub}(\mathcal{V})$, its *join* is $\bigvee_{i\in I} \mathcal{U}_i := \sum_{i\in I} \mathcal{U}_i := \operatorname{span}(\bigcup_{i\in I} \mathcal{U}_i)$.
(iv) The empty meet is $\mathcal{V}$, and the empty join is $\{\mathbf{0}_{\mathcal{V}}\}$.

Proposition 2.1.6. *Subspace Meet and Join*
Let $\{\mathcal{U}_i\}_{i\in I} \subseteq \operatorname{Sub}(\mathcal{V})$.

(i) $\bigwedge_{i\in I} \mathcal{U}_i = \inf\{\mathcal{U}_i : i \in I\}$.

(ii) $\bigvee_{i\in I} \mathcal{U}_i = \sup\{\mathcal{U}_i : i \in I\}$.

(iii) $\bigvee_{i\in I} \mathcal{U}_i = \left\{ \sum_{i\in F} \mathbf{u}_i : F \subseteq I,\ |F| < \infty,\ (\forall\, i \in F)\, \mathbf{u}_i \in \mathcal{U}_i \right\}$, *where the empty sum is* $\mathbf{0}_{\mathcal{V}}$.

Proof.

(i) If $I = \emptyset$, the empty meet is $\mathcal{V}$, the greatest lower bound of the empty family. Assume $I \neq \emptyset$ and set $M := \bigcap_{i\in I} \mathcal{U}_i$.

Then $M \leq \mathcal{V}$ by Proposition 1.2.3, $(\forall\, i \in I)\, M \subseteq \mathcal{U}_i$, and $(\forall \mathcal{W} \leq \mathcal{V})[(\forall\, i \in I)\, \mathcal{W} \subseteq \mathcal{U}_i \Rightarrow \mathcal{W} \subseteq M]$. Hence $M = \inf\{\mathcal{U}_i : i \in I\}$.

(ii) Set $J := \operatorname{span}(\bigcup_{i\in I} \mathcal{U}_i)$. Then $J \leq \mathcal{V}$ and $(\forall\, i \in I)\, \mathcal{U}_i \subseteq J$ by Theorem 1.2.5(i)–(ii).

If $\mathcal{W} \leq \mathcal{V}$ and $(\forall\, i \in I)\, \mathcal{U}_i \subseteq \mathcal{W}$, then $\bigcup_{i\in I} \mathcal{U}_i \subseteq \mathcal{W}$, so $J \subseteq \mathcal{W}$ by Theorem 1.2.5(iii).

Thus J is the least upper bound, including $J = \{\mathbf{0}_{\mathcal{V}}\}$ when $I = \emptyset$.

(iii) Every stated finite sum is a linear combination of vectors in $\bigcup_{i\in I} \mathcal{U}_i$, so it belongs to J.

Conversely, each $\mathbf{x} \in J$ is a finite linear combination of vectors from that union.
Group terms assigned to the same index; linear closure of $\mathcal{U}_i$ replaces each nonempty group by one vector in $\mathcal{U}_i$.
The empty combination represents $\mathbf{0}_{\mathcal{V}}$, so the displayed representation set equals J.

Structural Commentary: Order bounds identify meet and join; grouping span terms establishes finite representation.
Key Insight: Intersection preserves constraints; span combines directions. □

Theorem 2.1.7. *Subspace Lattice*
The poset $\mathrm{Sub}(\mathcal{V})$ *has the following properties.*

(i) It is a complete lattice. For $\{\mathcal{U}_i\}_{i\in I} \subseteq \mathrm{Sub}(\mathcal{V})$, $\bot = \{\mathbf{0}_\mathcal{V}\}$, $\top = \mathcal{V}$, $\bigwedge_{i\in I} \mathcal{U}_i = \bigcap_{i\in I} \mathcal{U}_i$, *and* $\bigvee_{i\in I} \mathcal{U}_i = \sum_{i\in I} \mathcal{U}_i = \mathrm{span}(\bigcup_{i\in I} \mathcal{U}_i)$.

(ii) It is modular: $(\forall \mathcal{U},\mathcal{S},\mathcal{T} \leq \mathcal{V})[\mathcal{U} \leq \mathcal{S} \Rightarrow \mathcal{S} \cap (\mathcal{T}+\mathcal{U}) = (\mathcal{S}\cap\mathcal{T})+\mathcal{U}]$.

Proof.

(i) The arbitrary meet and join formulas hold by Proposition 2.1.6(i)–(ii).
The empty formulas identify $\top = \mathcal{V}$ and $\bot = \{\mathbf{0}_\mathcal{V}\}$, so $\mathrm{Sub}(\mathcal{V})$ is complete.

(ii) Let $\mathcal{U} \leq \mathcal{S}$. If $\mathbf{x} \in (\mathcal{S}\cap\mathcal{T})+\mathcal{U}$, write $\mathbf{x} = \mathbf{y}+\mathbf{u}$ with $\mathbf{y} \in \mathcal{S}\cap\mathcal{T}$ and $\mathbf{u} \in \mathcal{U}$. Then $\mathbf{x} \in \mathcal{S}\cap(\mathcal{T}+\mathcal{U})$.
Conversely, if $\mathbf{x} \in \mathcal{S}\cap(\mathcal{T}+\mathcal{U})$, write $\mathbf{x} = \mathbf{t}+\mathbf{u}$ with $\mathbf{t} \in \mathcal{T}$ and $\mathbf{u} \in \mathcal{U}$. Then $\mathbf{t} = \mathbf{x}-\mathbf{u} \in \mathcal{S}\cap\mathcal{T}$ by $\mathbf{x},\mathbf{u} \in \mathcal{S}$, so $\mathbf{x} \in (\mathcal{S}\cap\mathcal{T})+\mathcal{U}$.

Structural Commentary: Completeness follows from the bound formulas; two inclusions establish modularity.
Key Insight: A contained summand survives intersection unchanged. □

Proposition 2.1.8. *Two-Subspace Directness Criterion*
Let $\mathcal{U}$ *and* $\mathcal{W}$ *be subspaces of* $\mathcal{V}$. *Then* $\mathcal{U}+\mathcal{W}$ *is direct iff* $\mathcal{U}\cap\mathcal{W} = \{\mathbf{0}_\mathcal{V}\}$.

Proof.

(⇒) Assume $\mathcal{U}+\mathcal{W}$ is direct. For $\mathbf{x} \in \mathcal{U}\cap\mathcal{W}$, directness of $\mathbf{x} = \mathbf{x}+\mathbf{0}_\mathcal{V} = \mathbf{0}_\mathcal{V}+\mathbf{x}$ forces $\mathbf{x} = \mathbf{0}_\mathcal{V}$. Hence $\mathcal{U}\cap\mathcal{W} = \{\mathbf{0}_\mathcal{V}\}$.

(⇐) Assume $\mathcal{U}\cap\mathcal{W} = \{\mathbf{0}_\mathcal{V}\}$ and let $\mathbf{u}_1+\mathbf{w}_1 = \mathbf{u}_2+\mathbf{w}_2$, where $\mathbf{u}_1,\mathbf{u}_2 \in \mathcal{U}$ and $\mathbf{w}_1,\mathbf{w}_2 \in \mathcal{W}$.
Then $\mathbf{u}_1-\mathbf{u}_2 = \mathbf{w}_2-\mathbf{w}_1 \in \mathcal{U}\cap\mathcal{W}$, so $\mathbf{u}_1 = \mathbf{u}_2$ and $\mathbf{w}_1 = \mathbf{w}_2$.
Every vector in the sum has a decomposition by its definition; therefore the sum is direct.

Structural Commentary: The two directions translate decomposition equality into intersection and back.
Key Insight: Trivial intersection prevents cross-summand cancellation. □

Perspective 2.1.9. *Sums Always Exist; Directness Is Extra*
For $\mathcal{U},\mathcal{W} \leq \mathcal{V}$, the sum $\mathcal{U}+\mathcal{W}$ exists as the smallest subspace containing both by Proposition 2.1.2.
The notation $\mathcal{U}\oplus\mathcal{W}$ records the additional equivalent conditions in Proposition 2.1.8: $\mathcal{U}\cap\mathcal{W} = \{\mathbf{0}_\mathcal{V}\}$ and uniqueness of $\mathbf{u}+\mathbf{w}$.
Thus $+$ records generation, whereas $\oplus$ records generation without ambiguity; this comparison is not proof authority.

Proposition 2.1.10. *Equivalent Conditions for a Direct Sum*
For $m \in \mathbb{N}$ *and subspaces* $\mathcal{U}_1,\ldots,\mathcal{U}_m \leq \mathcal{V}$, *the following are equivalent:*

(i) $\mathcal{V} = \mathcal{U}_1 \oplus \cdots \oplus \mathcal{U}_m$;

(ii) $(\forall\, \mathbf{v} \in \mathcal{V})(\exists!\, (\mathbf{u}_1,\ldots,\mathbf{u}_m) \in \mathcal{U}_1\times\cdots\times\mathcal{U}_m)\, \mathbf{v} = \sum_{j=1}^{m} \mathbf{u}_j$;

(iii) $\mathcal{V} = \sum_{j=1}^{m} \mathcal{U}_j$ *and* $(\forall\, (\mathbf{u}_1,\ldots,\mathbf{u}_m) \in \mathcal{U}_1\times\cdots\times\mathcal{U}_m)[\sum_{j=1}^{m} \mathbf{u}_j = \mathbf{0}_\mathcal{V} \Rightarrow (\forall\, j \in \{1,\ldots,m\})\, \mathbf{u}_j = \mathbf{0}_\mathcal{V}]$.

Proof.

(i) ⇒ *(ii)* Condition (i) asserts that the sum equals $\mathcal{V}$ and that its decompositions are unique, which is condition (ii).

(ii) ⇒ *(iii)* Existence in (ii) implies $\mathcal{V} = \sum_{j=1}^{m} \mathcal{U}_j$.

If $\sum_{j=1}^{m} \mathbf{u}_j = \mathbf{0}_\mathcal{V}$, uniqueness identifies this representation with $\sum_{j=1}^{m} \mathbf{0}_\mathcal{V}$, so $(\forall\, j \in \{1,\ldots,m\})\, \mathbf{u}_j = \mathbf{0}_\mathcal{V}$.

(iii) ⇒ *(i)* The equality in (iii) supplies a decomposition of every $\mathbf{v} \in \mathcal{V}$. If $\sum_{j=1}^{m} \mathbf{u}_j = \sum_{j=1}^{m} \mathbf{w}_j$, then $\sum_{j=1}^{m} (\mathbf{u}_j-\mathbf{w}_j) = \mathbf{0}_\mathcal{V}$.

Hence $(\forall\, j \in \{1,\ldots,m\})\, \mathbf{u}_j = \mathbf{w}_j$ by the zero-relation condition, so the sum is direct and equals $\mathcal{V}$.

Structural Commentary: The implication cycle separates existence of decompositions from the zero-relation obstruction.
Key Insight: Uniqueness is equivalent to trivial zero relations. □

Definition 2.1.11. *Product of Vector Spaces*
Let $m \in \mathbb{N}$ and let $\mathcal{V}_1,\ldots,\mathcal{V}_m$ be $\mathbb{F}$-vector spaces.

(i) Their *product* is $\mathcal{V}_1\times\cdots\times\mathcal{V}_m := \{(\mathbf{v}_1,\ldots,\mathbf{v}_m) : (\forall\, j \in \{1,\ldots,m\})\, \mathbf{v}_j \in \mathcal{V}_j\}$.
(ii) Addition is $(\mathbf{u}_1,\ldots,\mathbf{u}_m)+(\mathbf{v}_1,\ldots,\mathbf{v}_m) := (\mathbf{u}_1+\mathbf{v}_1,\ldots,\mathbf{u}_m+\mathbf{v}_m)$.
(iii) Scalar multiplication is $a(\mathbf{v}_1,\ldots,\mathbf{v}_m) := (a\mathbf{v}_1,\ldots,a\mathbf{v}_m)$ for $a \in \mathbb{F}$.

Proposition 2.1.12. *Products Are Vector Spaces*
If $m \in \mathbb{N}$ *and* $\mathcal{V}_1,\ldots,\mathcal{V}_m$ *are vector spaces over* $\mathbb{F}$, *then* $\mathcal{V}_1\times\cdots\times\mathcal{V}_m$ *is a vector space under componentwise operations.*

Proof. Set $P := \mathcal{V}_1\times\cdots\times\mathcal{V}_m$ and let $\mathbf{0}_j$ be the zero vector of $\mathcal{V}_j$. The operations are closed on P by componentwise closure.
The tuple $(\mathbf{0}_1,\ldots,\mathbf{0}_m)$ is an additive identity, and $(-\mathbf{v}_1,\ldots,-\mathbf{v}_m)$ is the additive inverse of $(\mathbf{v}_1,\ldots,\mathbf{v}_m)$.
For arbitrary tuples $\mathbf{u},\mathbf{v},\mathbf{w} \in P$, scalars $a,b \in \mathbb{F}$, and $j \in \{1,\ldots,m\}$, the jth coordinates on both sides of each commutativity, associativity, scalar-identity, scalar-associativity, and distributivity axiom are equal by the corresponding axiom in $\mathcal{V}_j$.
Coordinatewise equality proves each tuple identity, so P is an $\mathbb{F}$-vector space.
Structural Commentary: Closure, identities, and all algebraic laws are verified coordinatewise.
Key Insight: Tuple equality reduces every axiom to its components. □

Theorem 2.1.13. *Dimension of a Product*
Let $m \in \mathbb{N}$ *and let* $\mathcal{V}_1,\ldots,\mathcal{V}_m$ *be finite-dimensional* $\mathbb{F}$*-vector spaces.*
Then $P := \mathcal{V}_1\times\cdots\times\mathcal{V}_m$ *is finite-dimensional and* $\dim(P) = \sum_{j=1}^{m} \dim(\mathcal{V}_j)$.

Proof. For $j \in \{1,\dots,m\}$, let $(\mathbf{v}_{j,1},\dots,\mathbf{v}_{j,n_j})$ be a basis of $\mathcal{V}_j$.
For $j \in \{1,\dots,m\}$ and $k \in \{1,\dots,n_j\}$, let $\mathbf{e}_{j,k} \in P$ have jth component $\mathbf{v}_{j,k}$ and zero in every other component.
The list of all $\mathbf{e}_{j,k}$ spans P because each component has an expansion in its chosen basis.
If $\sum_{j=1}^{m}\sum_{k=1}^{n_j} a_{j,k}\mathbf{e}_{j,k} = \mathbf{0}$, then $(\forall\, j \in \{1,\dots,m\})\ \sum_{k=1}^{n_j} a_{j,k}\mathbf{v}_{j,k} = \mathbf{0}_{\mathcal{V}_j}$.
Hence $(\forall\, j \in \{1,\dots,m\})(\forall\, k \in \{1,\dots,n_j\})\, a_{j,k} = 0$ by linear independence of each factor basis.
Thus the list is a basis, and its length $\sum_{j=1}^{m} n_j = \sum_{j=1}^{m} \dim(\mathcal{V}_j)$ proves the formula.
Structural Commentary: Embedded factor bases span componentwise and are independent componentwise.
Key Insight: Each factor contributes its own coordinate directions. □

Definition 2.1.14. *Graph of a Function*
For $T : \mathcal{V} \to \mathcal{W}$, its *graph* is $\operatorname{graph}(T) := \{(\mathbf{v}, T\mathbf{v}) : \mathbf{v} \in \mathcal{V}\} \subseteq \mathcal{V} \times \mathcal{W}$.

Proposition 2.1.15. *Linearity and Graphs*
A function $T : \mathcal{V} \to \mathcal{W}$ is linear iff $\operatorname{graph}(T) \leq \mathcal{V} \times \mathcal{W}$.

Proof.
(⇒) Assume T is linear. Then $(\mathbf{0}_{\mathcal{V}}, \mathbf{0}_{\mathcal{W}}) \in \operatorname{graph}(T)$ by Proposition 1.5.3.
For $(\mathbf{u}, T\mathbf{u}), (\mathbf{v}, T\mathbf{v}) \in \operatorname{graph}(T)$ and $a, b \in \mathbb{F}$, $a(\mathbf{u}, T\mathbf{u}) + b(\mathbf{v}, T\mathbf{v}) = (a\mathbf{u} + b\mathbf{v}, T(a\mathbf{u} + b\mathbf{v})) \in \operatorname{graph}(T)$ by linearity.
Hence $\operatorname{graph}(T) \leq \mathcal{V} \times \mathcal{W}$ by Theorem 1.2.2.
(⇐) Assume $\operatorname{graph}(T) \leq \mathcal{V} \times \mathcal{W}$. For $\mathbf{u}, \mathbf{v} \in \mathcal{V}$ and $a, b \in \mathbb{F}$, $(a\mathbf{u} + b\mathbf{v}, aT\mathbf{u} + bT\mathbf{v}) = a(\mathbf{u}, T\mathbf{u}) + b(\mathbf{v}, T\mathbf{v}) \in \operatorname{graph}(T)$.
Membership in the graph forces $T(a\mathbf{u} + b\mathbf{v}) = aT\mathbf{u} + bT\mathbf{v}$, so T is linear.
Structural Commentary: Each direction translates the linear-combination law into graph closure.
Key Insight: Graph closure is the linearity identity in product form. □

Definition 2.1.16. *External Product*
Let $\{\mathcal{V}_i : i \in I\}$ be $\mathbb{F}$-vector spaces.
(i) The *external direct product* is $\prod_{i\in I} \mathcal{V}_i := \{(\mathbf{v}_i)_{i\in I} : (\forall i \in I)\, \mathbf{v}_i \in \mathcal{V}_i\}$.
(ii) Addition is defined by $(\forall\, i \in I)\, (\mathbf{u} + \mathbf{v})_i := \mathbf{u}_i + \mathbf{v}_i$.
(iii) Scalar multiplication is defined by $(\forall\, i \in I)\, (a\mathbf{v})_i := a\mathbf{v}_i$ for $a \in \mathbb{F}$.

Definition 2.1.17. *Support and Finite Sums of a Family*
Let I be an index set, and let $\mathcal{X}_i$ be a vector space with zero vector $\mathbf{0}_i$ for $i \in I$.
(i) The *support* of $\mathbf{x} = (\mathbf{x}_i)_{i\in I} \in \prod_{i\in I} \mathcal{X}_i$ is $\operatorname{supp}(\mathbf{x}) := \{i \in I : \mathbf{x}_i \neq \mathbf{0}_i\}$.
(ii) The family $\mathbf{x}$ is *finitely supported* iff $|\operatorname{supp}(\mathbf{x})| < \infty$.
(iii) If $(\forall\, i \in I)\, \mathcal{X}_i \leq \mathcal{V}$ and $\mathbf{x}$ is finitely supported, its *finite sum* is $\sum_{i\in I} \mathbf{x}_i := \sum_{i\in\operatorname{supp}(\mathbf{x})} \mathbf{x}_i$; the empty sum is $\mathbf{0}_{\mathcal{V}}$.

Definition 2.1.18. *External Direct Sum*
Let $\{\mathcal{V}_i : i \in I\}$ be $\mathbb{F}$-vector spaces. The *external direct sum* is $\bigoplus_{i\in I}^{\text{ext}} \mathcal{V}_i := \{\mathbf{v} \in \prod_{i\in I} \mathcal{V}_i : |\operatorname{supp}(\mathbf{v})| < \infty\}$.

Proposition 2.1.19. *External Sums Are Finite-Support Products*
Let $\{\mathcal{V}_i\}_{i\in I}$ be $\mathbb{F}$-vector spaces and set $P := \prod_{i\in I} \mathcal{V}_i$ and $S := \bigoplus_{i\in I}^{\text{ext}} \mathcal{V}_i$.
(i) P is an $\mathbb{F}$-vector space under componentwise operations.
(ii) $S \leq P$.
(iii) If $|I| < \infty$, then $S = P$.

Proof.
(i) Componentwise closure keeps addition and scalar multiplication in P.
The family $(\mathbf{0}_i)_{i\in I}$ is its zero, and $(-\mathbf{v}_i)_{i\in I}$ is the inverse of $\mathbf{v}$. For arbitrary elements, scalars, and $i \in I$, the relevant identity at coordinate i holds by the corresponding identity in $\mathcal{V}_i$; coordinatewise equality proves the identity in P.
(ii) The zero family has empty support. For $\mathbf{u}, \mathbf{v} \in S$ and $a \in \mathbb{F}$, $\operatorname{supp}(a\mathbf{u} + \mathbf{v}) \subseteq \operatorname{supp}(\mathbf{u}) \cup \operatorname{supp}(\mathbf{v})$, a finite set.
Hence $a\mathbf{u} + \mathbf{v} \in S$, so $S \leq P$ by Theorem 1.2.2.
(iii) If $|I| < \infty$ and $\mathbf{v} \in P$, then $\operatorname{supp}(\mathbf{v}) \subseteq I$ is finite. Thus $P \subseteq S$, while $S \subseteq P$ by construction, so $S = P$.
Structural Commentary: Coordinatewise axioms build the product; support containment proves the remaining claims.
Key Insight: Finite linear combinations preserve finite support. □

Definition 2.1.20. *Finitely Nonzero Sequence Space*
The *finitely nonzero sequence space* is $\mathbb{F}^{(\mathbb{N})} := \bigoplus_{j\in\mathbb{N}}^{\text{ext}} \mathbb{F} = \{(x_j)_{j\in\mathbb{N}} \in \mathbb{F}^{\mathbb{N}} : |\{j \in \mathbb{N} : x_j \neq 0\}| < \infty\}$, with componentwise operations.

Proposition 2.1.21. *Finitely Nonzero Sequences Form a Vector Space*
The set $\mathbb{F}^{(\mathbb{N})}$ is a vector space over $\mathbb{F}$ under componentwise addition and scalar multiplication.

Proof. The space $\mathbb{F}^{(\mathbb{N})}$ is the external direct sum of the constant family $\mathcal{V}_j = \mathbb{F}$ by its definition, so it is a subspace of the product $\mathbb{F}^{\mathbb{N}}$ by Proposition 2.1.19(ii). Hence it is an $\mathbb{F}$-vector space under the inherited componentwise operations.
Structural Commentary: The result specializes the external direct-sum subspace construction to a constant countable family.
Key Insight: Finitely supported sequences are a canonical external sum. □

Set $\operatorname{Seq}(\mathbb{F}) := \mathbb{F}^{\mathbb{N}}$. Then $\mathbb{F}^{(\mathbb{N})} \leq \operatorname{Seq}(\mathbb{F})$ by Proposition 2.1.21.

Definition 2.1.22. *Internal Direct Sum of a Family*

For $\{\mathcal{U}_i\}_{i\in I} \subseteq \mathrm{Sub}(\mathcal{V})$, the internal sum $S := \sum_{i\in I} \mathcal{U}_i$ is *direct* iff $(\forall\, \mathbf{v} \in S)(\exists!\, \mathbf{u} \in \bigoplus_{i\in I}^{\text{ext}} \mathcal{U}_i)\, \mathbf{v} = \sum_{i\in I} \mathbf{u}_i$.
A direct internal sum is denoted $\bigoplus_{i\in I} \mathcal{U}_i$; the equality $\mathcal{V} = \bigoplus_{i\in I} \mathcal{U}_i$ additionally asserts $\mathcal{V} = S$.

Proposition 2.1.23. *Family Direct-Sum Criterion*
For $\{\mathcal{U}_i\}_{i\in I} \subseteq \mathrm{Sub}(\mathcal{V})$, the following are equivalent:

(i) $\sum_{i\in I} \mathcal{U}_i$ *is direct;*
(ii) $(\forall\, F \subseteq I)[|F| < \infty \Rightarrow (\forall\, (\mathbf{u}_i)_{i\in F} \in \prod_{i\in F} \mathcal{U}_i)(\sum_{i\in F} \mathbf{u}_i = \mathbf{0}_{\mathcal{V}} \Rightarrow (\forall\, i \in F)\, \mathbf{u}_i = \mathbf{0}_{\mathcal{V}})]$;
(iii) $(\forall\, i \in I)\mathcal{U}_i \cap \sum_{j\in I\setminus\{i\}} \mathcal{U}_j = \{\mathbf{0}_{\mathcal{V}}\}$.

Proof.

(i) $\Rightarrow$ *(ii)* Let $F \subseteq I$ be finite and let $(\mathbf{u}_i)_{i\in F} \in \prod_{i\in F} \mathcal{U}_i$ satisfy $\sum_{i\in F} \mathbf{u}_i = \mathbf{0}_{\mathcal{V}}$. Extend this family by zero outside F.
Directness identifies the resulting decomposition with the all-zero decomposition, so $(\forall\, i \in F)\, \mathbf{u}_i = \mathbf{0}_{\mathcal{V}}$.
(ii) $\Rightarrow$ *(iii)* Fix $i \in I$ and let $\mathbf{x} \in \mathcal{U}_i \cap \sum_{j\in I\setminus\{i\}} \mathcal{U}_j$.
Then $\mathbf{x} = \sum_{j\in F} \mathbf{u}_j$ for a finite $F \subseteq I \setminus \{i\}$ with $(\forall\, j \in F)\, \mathbf{u}_j \in \mathcal{U}_j$ by Proposition 2.1.6(iii).
The relation on $F \cup \{i\}$ with ith term $\mathbf{x}$ and jth term $-\mathbf{u}_j$ is zero. It is trivial by (ii), so $\mathbf{x} = \mathbf{0}_{\mathcal{V}}$.
(iii) $\Rightarrow$ *(i)* Let $F \subseteq I$ be finite and suppose $\sum_{i\in F} \mathbf{u}_i = \mathbf{0}_{\mathcal{V}}$ with $(\forall\, i \in F)\, \mathbf{u}_i \in \mathcal{U}_i$.
For $k \in F$, $\mathbf{u}_k = -\sum_{i\in F\setminus\{k\}} \mathbf{u}_i \in \mathcal{U}_k \cap \sum_{j\in I\setminus\{k\}} \mathcal{U}_j = \{\mathbf{0}_{\mathcal{V}}\}$ by (iii), so every finite zero relation is trivial.
Each vector in the sum has a finite decomposition by Proposition 2.1.6(iii).
The difference of two decompositions is a finite zero relation, so they coincide and the sum is direct.

Structural Commentary: The cycle converts unique decompositions into zero relations and collective intersection tests.
Key Insight: Directness forbids cancellation across distinct summands. □

Proposition 2.1.24. *Direct Sum Map*

Let $m \in \mathbb{N}$ and let $\mathcal{U}_1, \ldots, \mathcal{U}_m \leq \mathcal{V}$. Define $\Gamma : \prod_{j=1}^{m} \mathcal{U}_j \to \sum_{j=1}^{m} \mathcal{U}_j$ by $\Gamma((\mathbf{u}_j)_{j=1}^{m}) := \sum_{j=1}^{m} \mathbf{u}_j$. The following hold:

(i) $\Gamma \in \mathcal{L}(\mathcal{U}_1 \times \cdots \times \mathcal{U}_m, \mathcal{U}_1 + \cdots + \mathcal{U}_m)$;
(ii) $\mathcal{U}_1 + \cdots + \mathcal{U}_m$ *is direct iff* Γ *is injective.*

Proof.

(i) For $\mathbf{u}, \mathbf{v} \in \mathcal{U}_1 \times \cdots \times \mathcal{U}_m$ and $a, b \in \mathbb{F}$, $\Gamma(a\mathbf{u} + b\mathbf{v}) = \sum_{j=1}^{m} (a\mathbf{u}_j + b\mathbf{v}_j) = a\Gamma(\mathbf{u}) + b\Gamma(\mathbf{v})$. Hence Γ is linear.
(ii) $(\Rightarrow)$ Assume sum is direct. If $\Gamma(\mathbf{u}) = \Gamma(\mathbf{v})$, then $\mathbf{u}$ and $\mathbf{v}$ are decompositions of same vector, so $\mathbf{u} = \mathbf{v}$ by directness. QED.
(ii) $(\Leftarrow)$ Assume Γ is injective. If $\sum_{j=1}^{m} \mathbf{u}_j = \sum_{j=1}^{m} \mathbf{v}_j$, then $\Gamma(\mathbf{u}) = \Gamma(\mathbf{v})$, so $\mathbf{u} = \mathbf{v}$ by injectivity.
Thus every vector in the sum has a unique decomposition, and the sum is direct.

Structural Commentary: Linearity is coordinatewise; injectivity translates equality of sums into equality of decompositions.
Key Insight: Directness is injectivity of the addition map. □

2.2 Quotient Spaces

Quotients collapse a prescribed subspace while retaining the linear structure that is independent of the collapsed directions.
Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$.

Definition 2.2.1. *Affine Subset Parallel to a Subspace*
Let $\mathcal{U} \leq \mathcal{V}$. For $\mathbf{v} \in \mathcal{V}$, the subset $\mathbf{v} + \mathcal{U} := \{\mathbf{v} + \mathbf{u} : \mathbf{u} \in \mathcal{U}\}$ is the *affine subset* through $\mathbf{v}$ parallel to $\mathcal{U}$.

Proposition 2.2.2. *Parallel Affine Subsets Are Equal or Disjoint*
Let $\mathcal{U} \leq \mathcal{V}$ and $\mathbf{v}, \mathbf{w} \in \mathcal{V}$. The following conditions are equivalent:

(i) $\mathbf{v} - \mathbf{w} \in \mathcal{U}$;
(ii) $\mathbf{v} + \mathcal{U} = \mathbf{w} + \mathcal{U}$;
(iii) $(\mathbf{v} + \mathcal{U}) \cap (\mathbf{w} + \mathcal{U}) \neq \emptyset$.

Proof.

(i) $\Rightarrow$ *(ii)* Suppose $\mathbf{v} - \mathbf{w} \in \mathcal{U}$. For $\mathbf{u} \in \mathcal{U}$, $\mathbf{v} + \mathbf{u} = \mathbf{w} + ((\mathbf{v} - \mathbf{w}) + \mathbf{u}) \in \mathbf{w} + \mathcal{U}$, so $\mathbf{v} + \mathcal{U} \subseteq \mathbf{w} + \mathcal{U}$.
Since $\mathbf{w} - \mathbf{v} = -(\mathbf{v} - \mathbf{w}) \in \mathcal{U}$, exchanging $\mathbf{v}$ and $\mathbf{w}$ establishes the reverse inclusion.
(ii) $\Rightarrow$ *(iii)* If $\mathbf{v} + \mathcal{U} = \mathbf{w} + \mathcal{U}$, then $\mathbf{v} \in (\mathbf{v} + \mathcal{U}) \cap (\mathbf{w} + \mathcal{U})$.
(iii) $\Rightarrow$ *(i)* Choose $\mathbf{x} \in (\mathbf{v} + \mathcal{U}) \cap (\mathbf{w} + \mathcal{U})$ and $\mathbf{u}_1, \mathbf{u}_2 \in \mathcal{U}$ with $\mathbf{x} = \mathbf{v} + \mathbf{u}_1 = \mathbf{w} + \mathbf{u}_2$. Then $\mathbf{v} - \mathbf{w} = \mathbf{u}_2 - \mathbf{u}_1 \in \mathcal{U}$.

Structural Commentary: A cyclic implication proof connects differences, equality, and intersection.
Key Insight: A common point exposes the difference of representatives. □

Definition 2.2.3. *Underlying Quotient Set*
For $\mathcal{U} \leq \mathcal{V}$, the *quotient set* is $\mathcal{V}/\mathcal{U} := \{\mathbf{v} + \mathcal{U} : \mathbf{v} \in \mathcal{V}\}$.

Proposition 2.2.4. *Quotient Relation Is a Linear Congruence*
Let $\mathcal{U} \leq \mathcal{V}$ and define a relation on $\mathcal{V}$ by $\mathbf{v} \equiv_{\mathcal{U}} \mathbf{w} \iff \mathbf{v} - \mathbf{w} \in \mathcal{U}$.

(i) $(\forall\, \mathbf{v} \in \mathcal{V})\, \mathbf{v} \equiv_{\mathcal{U}} \mathbf{v}$.
(ii) $(\forall\, \mathbf{v}, \mathbf{w} \in \mathcal{V})[\mathbf{v} \equiv_{\mathcal{U}} \mathbf{w} \Rightarrow \mathbf{w} \equiv_{\mathcal{U}} \mathbf{v}]$.

(iii) $(\forall\, \mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathcal{V})[(\mathbf{u} \equiv_{\mathcal{U}} \mathbf{v} \wedge \mathbf{v} \equiv_{\mathcal{U}} \mathbf{w}) \Rightarrow \mathbf{u} \equiv_{\mathcal{U}} \mathbf{w}]$.
(iv) $(\forall\, a, b \in \mathbb{F})(\forall\, \mathbf{v}_1, \mathbf{v}_2, \mathbf{w}_1, \mathbf{w}_2 \in \mathcal{V})[(\mathbf{v}_1 \equiv_{\mathcal{U}} \mathbf{v}_2 \wedge \mathbf{w}_1 \equiv_{\mathcal{U}} \mathbf{w}_2) \Rightarrow a\mathbf{v}_1 + b\mathbf{w}_1 \equiv_{\mathcal{U}} a\mathbf{v}_2 + b\mathbf{w}_2]$.
Thus $\equiv_{\mathcal{U}}$ is an equivalence relation compatible with linear combinations.

Proof.
(i) For $\mathbf{v} \in \mathcal{V}$, $\mathbf{v} - \mathbf{v} = \mathbf{0} \in \mathcal{U}$.
(ii) If $\mathbf{v} - \mathbf{w} \in \mathcal{U}$, then $\mathbf{w} - \mathbf{v} = -(\mathbf{v} - \mathbf{w}) \in \mathcal{U}$.
(iii) If $\mathbf{u} - \mathbf{v}, \mathbf{v} - \mathbf{w} \in \mathcal{U}$, then $\mathbf{u} - \mathbf{w} = (\mathbf{u} - \mathbf{v}) + (\mathbf{v} - \mathbf{w}) \in \mathcal{U}$.
(iv) If $\mathbf{v}_1 - \mathbf{v}_2, \mathbf{w}_1 - \mathbf{w}_2 \in \mathcal{U}$, then $(a\mathbf{v}_1 + b\mathbf{w}_1) - (a\mathbf{v}_2 + b\mathbf{w}_2) = a(\mathbf{v}_1 - \mathbf{v}_2) + b(\mathbf{w}_1 - \mathbf{w}_2) \in \mathcal{U}$ for $a, b \in \mathbb{F}$.
Structural Commentary: The four items verify the equivalence axioms and linear compatibility.
Key Insight: Linear combinations preserve differences lying in the subspace. □

Perspective 2.2.5. *Cosets as Equivalence Classes*
The equivalence class of $\mathbf{v}$ under $\equiv_{\mathcal{U}}$ is $\mathbf{v} + \mathcal{U}$ by Proposition 2.2.2. Hence the quotient set in Definition 2.2.3 is the abstract quotient set from Definition 5.2.5. It remembers a vector only up to addition by an element of $\mathcal{U}$.

Proposition 2.2.6. *Quotient-Space Structure*
Let $\mathcal{U} \leq \mathcal{V}$. For $\mathbf{v}, \mathbf{w} \in \mathcal{V}$ and $a \in \mathbb{F}$, set $(\mathbf{v} + \mathcal{U}) + (\mathbf{w} + \mathcal{U}) := (\mathbf{v} + \mathbf{w}) + \mathcal{U}$ and $a(\mathbf{v} + \mathcal{U}) := a\mathbf{v} + \mathcal{U}$.
(i) These operations are independent of the chosen representatives.
(ii) With these operations, $\mathcal{V}/\mathcal{U}$ is a vector space, called the quotient space of $\mathcal{V}$ by $\mathcal{U}$.

Proof.
(i) Suppose $\mathbf{v} + \mathcal{U} = \mathbf{v}' + \mathcal{U}$ and $\mathbf{w} + \mathcal{U} = \mathbf{w}' + \mathcal{U}$. Then $\mathbf{v} - \mathbf{v}', \mathbf{w} - \mathbf{w}' \in \mathcal{U}$ by Proposition 2.2.2.
Hence $(\mathbf{v} + \mathbf{w}) - (\mathbf{v}' + \mathbf{w}') \in \mathcal{U}$ by Proposition 2.2.4(iv), and $a\mathbf{v} - a\mathbf{v}' = a(\mathbf{v} - \mathbf{v}') \in \mathcal{U}$.
The resulting sum and scalar-multiple cosets are equal by Proposition 2.2.2.
(ii) Write $[\mathbf{v}] := \mathbf{v} + \mathcal{U}$. For $\mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathcal{V}$ and $a, b \in \mathbb{F}$, $([\mathbf{u}] + [\mathbf{v}]) + [\mathbf{w}] = [\mathbf{u} + \mathbf{v} + \mathbf{w}] = [\mathbf{u}] + ([\mathbf{v}] + [\mathbf{w}])$, $[\mathbf{v}] + [\mathbf{w}] = [\mathbf{w}] + [\mathbf{v}]$, $[\mathbf{0}] = \mathcal{U}$ is an additive identity, and $[-\mathbf{v}]$ is the additive inverse of $[\mathbf{v}]$.
The scalar identities $1[\mathbf{v}] = [\mathbf{v}]$, $a(b[\mathbf{v}]) = (ab)[\mathbf{v}]$, $a([\mathbf{v}] + [\mathbf{w}]) = a[\mathbf{v}] + a[\mathbf{w}]$, and $(a + b)[\mathbf{v}] = a[\mathbf{v}] + b[\mathbf{v}]$ hold by the vector-space identities in $\mathcal{V}$. Thus all vector-space axioms hold.
Structural Commentary: Representative independence precedes direct verification of the vector-space axioms.
Key Insight: Coset arithmetic inherits every identity from representatives. □

Definition 2.2.7. *Quotient Map*
For $\mathcal{U} \leq \mathcal{V}$, the *quotient map* is $\pi : \mathcal{V} \to \mathcal{V}/\mathcal{U}$ defined by $\pi(\mathbf{v}) := \mathbf{v} + \mathcal{U}$.

Proposition 2.2.8. *Properties of the Quotient Map*
Let $\mathcal{U} \leq \mathcal{V}$ and define $\pi : \mathcal{V} \to \mathcal{V}/\mathcal{U}$ by $\pi(\mathbf{v}) = \mathbf{v} + \mathcal{U}$.
(i) π is linear.
(ii) π is surjective.
(iii) $\ker(\pi) = \mathcal{U}$.

Proof.
(i) For $\mathbf{v}, \mathbf{w} \in \mathcal{V}$ and $a, b \in \mathbb{F}$, $\pi(a\mathbf{v} + b\mathbf{w}) = (a\mathbf{v} + b\mathbf{w}) + \mathcal{U} = a\pi(\mathbf{v}) + b\pi(\mathbf{w})$.
(ii) If $\mathbf{x} \in \mathcal{V}/\mathcal{U}$, choose $\mathbf{v} \in \mathcal{V}$ with $\mathbf{x} = \mathbf{v} + \mathcal{U} = \pi(\mathbf{v})$ by the definition of $\mathcal{V}/\mathcal{U}$.
(iii) For $\mathbf{v} \in \mathcal{V}$, $\pi(\mathbf{v}) = \mathcal{U} \iff \mathbf{v} \in \mathcal{U}$ by Proposition 2.2.2. Therefore $\ker(\pi) = \mathcal{U}$.
Structural Commentary: The proof verifies linearity, surjectivity, and the kernel in statement order.
Key Insight: The zero coset is exactly the collapsed subspace. □

Theorem 2.2.9. *Dimension of a Quotient*
Let $\mathcal{V}$ be finite-dimensional and $\mathcal{U} \leq \mathcal{V}$.
(i) $\mathcal{V}/\mathcal{U}$ is finite-dimensional.
(ii) $\dim(\mathcal{V}/\mathcal{U}) = \dim(\mathcal{V}) - \dim(\mathcal{U})$.

Proof. Let $\pi : \mathcal{V} \to \mathcal{V}/\mathcal{U}$ be the quotient map. Its range is $\mathcal{V}/\mathcal{U}$ and its kernel is $\mathcal{U}$ by Proposition 2.2.8(ii)–(iii).
(i) The range $\mathcal{V}/\mathcal{U}$ is finite-dimensional by Theorem 1.7.3(i).
(ii) The formula in (ii) holds by Theorem 1.7.3(ii) with $\ker(\pi) = \mathcal{U}$ and $\operatorname{range}(\pi) = \mathcal{V}/\mathcal{U}$.
Structural Commentary: Quotient-map properties followed by rank-nullity handle finiteness and dimension.
Key Insight: Quotient dimension is the rank of the quotient map. □

Theorem 2.2.10. *Subspace Correspondence for Quotients*
Let $\mathcal{U} \leq \mathcal{V}$, let $\pi : \mathcal{V} \to \mathcal{V}/\mathcal{U}$ be the quotient map, and set $\mathfrak{A} := \{\mathcal{T} \leq \mathcal{V} : \mathcal{U} \leq \mathcal{T}\}$ and $\mathfrak{B} := \{\mathcal{Y} : \mathcal{Y} \leq \mathcal{V}/\mathcal{U}\}$. For $\mathcal{T} \in \mathfrak{A}$ and $\mathcal{Y} \in \mathfrak{B}$, set $\Phi(\mathcal{T}) := \mathcal{T}/\mathcal{U} = \pi(\mathcal{T})$ and $\Psi(\mathcal{Y}) := \pi^{-1}(\mathcal{Y})$.
(i) $\Phi : \mathfrak{A} \to \mathfrak{B}$ and $\Psi : \mathfrak{B} \to \mathfrak{A}$ are well-defined.
(ii) Φ and Ψ are inverse bijections: $\Psi\Phi = I_{\mathfrak{A}}$ and $\Phi\Psi = I_{\mathfrak{B}}$.
(iii) Both maps preserve inclusion.

Proof.
(i) Let $\mathcal{T} \in \mathfrak{A}$. The set $\mathcal{T}/\mathcal{U}$ contains $\mathcal{U} = \mathbf{0} + \mathcal{U}$, and $a(\mathbf{t}_1 + \mathcal{U}) + b(\mathbf{t}_2 + \mathcal{U}) = (a\mathbf{t}_1 + b\mathbf{t}_2) + \mathcal{U} \in \mathcal{T}/\mathcal{U}$ for $\mathbf{t}_1, \mathbf{t}_2 \in \mathcal{T}$ and $a, b \in \mathbb{F}$.
Hence $\Phi(\mathcal{T}) \leq \mathcal{V}/\mathcal{U}$ by Theorem 1.2.2. Let $\mathcal{Y} \in \mathfrak{B}$. The set $\pi^{-1}(\mathcal{Y})$ contains $\mathbf{0}_{\mathcal{V}}$, and $\pi(a\mathbf{v} + b\mathbf{w}) = a\pi(\mathbf{v}) + b\pi(\mathbf{w}) \in \mathcal{Y}$ for $\mathbf{v}, \mathbf{w} \in \pi^{-1}(\mathcal{Y})$ and $a, b \in \mathbb{F}$; hence $\pi^{-1}(\mathcal{Y}) \leq \mathcal{V}$ by Theorem 1.2.2. Moreover, $\mathcal{U} = \ker(\pi) \subseteq \pi^{-1}(\mathcal{Y})$ by Proposition 2.2.8(iii).
(ii) Let $\mathcal{T} \in \mathfrak{A}$. For $\mathbf{t} \in \mathcal{T}$, $\pi(\mathbf{t}) \in \pi(\mathcal{T})$, so $\mathcal{T} \subseteq \pi^{-1}(\pi(\mathcal{T}))$. If $\mathbf{v} \in \pi^{-1}(\pi(\mathcal{T}))$, choose $\mathbf{t} \in \mathcal{T}$ with $\mathbf{v} + \mathcal{U} = \mathbf{t} + \mathcal{U}$.
Then $\mathbf{v} - \mathbf{t} \in \mathcal{U} \subseteq \mathcal{T}$ by Proposition 2.2.2, so $\mathbf{v} \in \mathcal{T}$. Thus $\Psi(\Phi(\mathcal{T})) = \mathcal{T}$. Let $\mathcal{Y} \in \mathfrak{B}$.
If $\mathbf{v} \in \pi^{-1}(\mathcal{Y})$, then $\pi(\mathbf{v}) \in \mathcal{Y}$, so $\pi(\pi^{-1}(\mathcal{Y})) \subseteq \mathcal{Y}$. If $\mathbf{y} \in \mathcal{Y}$, choose $\mathbf{v} \in \mathcal{V}$ with $\pi(\mathbf{v}) = \mathbf{y}$ by Proposition 2.2.8(ii).
Then $\mathbf{v} \in \pi^{-1}(\mathcal{Y})$, so $\mathbf{y} \in \pi(\pi^{-1}(\mathcal{Y}))$. Therefore $\Phi(\Psi(\mathcal{Y})) = \mathcal{Y}$.

(iii) If $\mathcal{T}_1 \subseteq \mathcal{T}_2$ in $\mathfrak{A}$, then $\pi(\mathcal{T}_1) \subseteq \pi(\mathcal{T}_2)$. If $\mathcal{Y}_1 \subseteq \mathcal{Y}_2$ in $\mathfrak{B}$, then $\pi^{-1}(\mathcal{Y}_1) \subseteq \pi^{-1}(\mathcal{Y}_2)$.

Structural Commentary: Well-defined assignments, inverse identities, and monotonicity establish the correspondence.
Key Insight: Images and preimages undo the quotient construction exactly. □

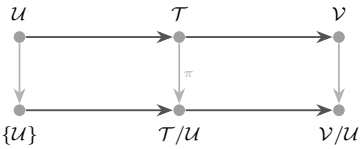

Figure 10: Intermediate subspaces above $\mathcal{U}$ correspond to subspaces of the quotient; horizontal arrows denote inclusions and vertical arrows denote quotient images.

Figure 10 illustrates Theorem 2.2.10: $\mathcal{U} \subseteq \mathcal{T} \subseteq \mathcal{V}$ descends to $\{\mathcal{U}\} \subseteq \mathcal{T}/\mathcal{U} \subseteq \mathcal{V}/\mathcal{U}$, while inverse images recover the original subspaces. The theorem, rather than the diagram, owns the correspondence.

Theorem 2.2.11. *Universal Property of the Quotient Map*
Let $\mathcal{U} \leq \mathcal{V}$, let $\pi : \mathcal{V} \to \mathcal{V}/\mathcal{U}$ be the quotient map, and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ satisfy $\mathcal{U} \leq \ker(T)$.

(i) $(\exists!\, \overline{T} \in \mathcal{L}(\mathcal{V}/\mathcal{U}, \mathcal{W}))[\overline{T}\pi = T \wedge (\forall\, \mathbf{v} \in \mathcal{V})\, \overline{T}(\mathbf{v}+\mathcal{U}) = T\mathbf{v}]$.
(ii) The map $\overline{T}$ from (i) satisfies $\ker(\overline{T}) = \ker(T)/\mathcal{U}$.
(iii) The map $\overline{T}$ from (i) satisfies $\operatorname{range}(\overline{T}) = \operatorname{range}(T)$.

Proof.

(i) Define $\overline{T}(\mathbf{v}+\mathcal{U}) := T\mathbf{v}$. If $\mathbf{v}+\mathcal{U} = \mathbf{w}+\mathcal{U}$, then $\mathbf{v}-\mathbf{w} \in \mathcal{U} \leq \ker(T)$ by Proposition 2.2.2, so $T\mathbf{v} - T\mathbf{w} = T(\mathbf{v}-\mathbf{w}) = \mathbf{0}$. Hence $\overline{T}$ is well-defined. For $a, b \in \mathbb{F}$ and $\mathbf{v}, \mathbf{w} \in \mathcal{V}$, $\overline{T}(a(\mathbf{v}+\mathcal{U}) + b(\mathbf{w}+\mathcal{U})) = T(a\mathbf{v}+b\mathbf{w}) = aT\mathbf{v} + bT\mathbf{w}$, so $\overline{T}$ is linear. Also, $(\overline{T}\pi)(\mathbf{v}) = \overline{T}(\mathbf{v}+\mathcal{U}) = T\mathbf{v}$ for $\mathbf{v} \in \mathcal{V}$, so $\overline{T}\pi = T$. If $S \in \mathcal{L}(\mathcal{V}/\mathcal{U}, \mathcal{W})$ satisfies $S\pi = T$, then $(\forall\, \mathbf{v} \in \mathcal{V})\, S(\mathbf{v}+\mathcal{U}) = S\pi(\mathbf{v}) = T\mathbf{v} = \overline{T}(\mathbf{v}+\mathcal{U})$. Since $\mathcal{V}/\mathcal{U} = \{\mathbf{v}+\mathcal{U} : \mathbf{v} \in \mathcal{V}\}$, $S = \overline{T}$.
(ii) For $\mathbf{v} \in \mathcal{V}$, $\mathbf{v}+\mathcal{U} \in \ker(\overline{T}) \iff T\mathbf{v} = \mathbf{0} \iff \mathbf{v} \in \ker(T)$. Hence $\ker(\overline{T}) = \{\mathbf{v}+\mathcal{U} : \mathbf{v} \in \ker(T)\} = \ker(T)/\mathcal{U}$.
(iii) The equality $\operatorname{range}(\overline{T}) = \{\overline{T}(\mathbf{v}+\mathcal{U}) : \mathbf{v} \in \mathcal{V}\} = \{T\mathbf{v} : \mathbf{v} \in \mathcal{V}\} = \operatorname{range}(T)$ is immediate from the defining formula.

Structural Commentary: Construction establishes factorisation; set calculations identify kernel and range.
Key Insight: Killing $\mathcal{U}$ is precisely the condition for descent. □

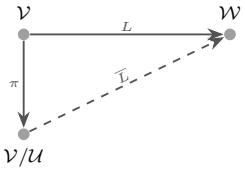

Figure 11: If $\mathcal{U} \subseteq \ker(L)$, the map L factors uniquely through the quotient map π; the dashed arrow is the induced map $\overline{L}$.

Figure 11 depicts Theorem 2.2.11, using L in place of T: collapsing $\mathcal{U}$ first does not change a map that already vanishes on $\mathcal{U}$. The theorem, rather than the diagram, owns existence and uniqueness.

Theorem 2.2.12. *Quotient by the Kernel*
Let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ and define $\widetilde{T}(\mathbf{v} + \ker(T)) := T\mathbf{v}$.

(i) The assignment defines a well-defined linear map $\widetilde{T} : \mathcal{V}/\ker(T) \to \mathcal{W}$.
(ii) $\widetilde{T}$ is injective.
(iii) $\operatorname{range}(\widetilde{T}) = \operatorname{range}(T)$.
(iv) The codomain restriction $\widehat{T} : \mathcal{V}/\ker(T) \to \operatorname{range}(T)$ is an isomorphism; hence $\mathcal{V}/\ker(T) \cong \operatorname{range}(T)$.

Proof.

(i) The claimed well-defined linear map exists by Theorem 2.2.11(i) with $\mathcal{U} = \ker(T)$.
(ii) The identity $\ker(\widetilde{T}) = \ker(T)/\ker(T) = \{\ker(T)\}$ holds by Theorem 2.2.11(ii). Thus $\widetilde{T}$ is injective by Proposition 1.6.2.
(iii) The range identity holds by Theorem 2.2.11(iii).
(iv) The codomain restriction $\widehat{T}$ is linear and injective by parts (i)–(ii), and it is surjective by part (iii). Therefore $\widehat{T}$ is invertible by Proposition 1.6.7, and $\mathcal{V}/\ker(T) \cong \operatorname{range}(T)$.

Structural Commentary: The universal property constructs the map; kernel and range identities produce the isomorphism.
Key Insight: Removing the kernel makes the induced map injective. □

Theorem 2.2.13. *Second Isomorphism Theorem*
If $\mathcal{S}, \mathcal{T} \leq \mathcal{V}$, then $\mathcal{S}/(\mathcal{S} \cap \mathcal{T}) \cong (\mathcal{S}+\mathcal{T})/\mathcal{T}$.

Proof.

(i) *Construction*: The sum $\mathcal{S}+\mathcal{T}$ is a subspace containing $\mathcal{T}$ by Proposition 2.1.2(i). Define $L : \mathcal{S} \to (\mathcal{S}+\mathcal{T})/\mathcal{T}$ by $L\mathbf{s} := \mathbf{s}+\mathcal{T}$. For $\mathbf{s}, \mathbf{r} \in \mathcal{S}$ and $a, b \in \mathbb{F}$, $L(a\mathbf{s}+b\mathbf{r}) = (a\mathbf{s}+b\mathbf{r}) + \mathcal{T} = aL\mathbf{s} + bL\mathbf{r}$, so L is linear.
(ii) *Kernel*: For $\mathbf{s} \in \mathcal{S}$, $L\mathbf{s} = \mathcal{T} \iff \mathbf{s} \in \mathcal{T}$ by Proposition 2.2.2. Hence $\ker(L) = \mathcal{S} \cap \mathcal{T}$.
(iii) *Surjectivity*: Each coset equals $(\mathbf{s}+\mathbf{t}) + \mathcal{T} = \mathbf{s} + \mathcal{T} = L\mathbf{s}$ for suitable $\mathbf{s} \in \mathcal{S}$ and $\mathbf{t} \in \mathcal{T}$; hence L is surjective.
(iv) *Conclusion*: The equality $\operatorname{range}(L) = (\mathcal{S}+\mathcal{T})/\mathcal{T}$ holds by part (iii). Therefore $\mathcal{S}/(\mathcal{S} \cap \mathcal{T}) \cong (\mathcal{S}+\mathcal{T})/\mathcal{T}$ by Theorem 2.2.12 with the linearity and kernel identity from parts (i)–(ii).

Structural Commentary: Construction, kernel, surjectivity, and the first isomorphism theorem form four operative stages.
Key Insight: The target forgets exactly $\mathcal{S} \cap \mathcal{T}$. □

Theorem 2.2.14. *Third Isomorphism Theorem*
If $\mathcal{U} \leq \mathcal{T} \leq \mathcal{V}$, then $(\mathcal{V}/\mathcal{U})/(\mathcal{T}/\mathcal{U}) \cong \mathcal{V}/\mathcal{T}$.

Proof.

(i) *Construction*: The inclusion $\mathcal{T}/\mathcal{U} \leq \mathcal{V}/\mathcal{U}$ holds by Theorem 2.2.10(i). Define $L : \mathcal{V}/\mathcal{U} \to \mathcal{V}/\mathcal{T}$ by $L(\mathbf{v}+\mathcal{U}) := \mathbf{v}+\mathcal{T}$.
(ii) *Well-Definedness and Linearity*: If $\mathbf{v}+\mathcal{U} = \mathbf{w}+\mathcal{U}$, then $\mathbf{v}-\mathbf{w} \in \mathcal{U} \subseteq \mathcal{T}$ by Proposition 2.2.2, so $\mathbf{v}+\mathcal{T} = \mathbf{w}+\mathcal{T}$ by the same proposition. For $a, b \in \mathbb{F}$, $L(a(\mathbf{v}+\mathcal{U}) + b(\mathbf{w}+\mathcal{U})) = (a\mathbf{v}+b\mathbf{w})+\mathcal{T} = aL(\mathbf{v}+\mathcal{U}) + bL(\mathbf{w}+\mathcal{U})$.
(iii) *Kernel and Range*: For $\mathbf{v} \in \mathcal{V}$, $L(\mathbf{v}+\mathcal{U}) = \mathcal{T} \iff \mathbf{v} \in \mathcal{T}$ by Proposition 2.2.2; hence $\ker(L) = \mathcal{T}/\mathcal{U}$.
Every $\mathbf{v}+\mathcal{T} \in \mathcal{V}/\mathcal{T}$ equals $L(\mathbf{v}+\mathcal{U})$, so L is surjective.
(iv) *Conclusion*: The equality $\operatorname{range}(L) = \mathcal{V}/\mathcal{T}$ holds by part (iii).
Therefore $(\mathcal{V}/\mathcal{U})/(\mathcal{T}/\mathcal{U}) \cong \mathcal{V}/\mathcal{T}$ by Theorem 2.2.12 with the linearity and kernel identity from parts (ii)–(iii).

Structural Commentary: Construction, kernel computation, and the first isomorphism theorem identify the iterated quotient.
Key Insight: The nested collapse has kernel $\mathcal{T}/\mathcal{U}$. □

Quotient spaces retain precisely the structure invariant under translation by a chosen subspace. Their correspondence, universal property, and isomorphism theorems formalise which data survive that collapse.

2.3 Decomposition and Complementation

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$. Dimension counts first detect directness; complements then realize quotients as concrete subspaces.

Theorem 2.3.1. *Dimension Formula for a Sum*
If $\mathcal{U}, \mathcal{W} \leq \mathcal{V}$ are finite-dimensional, then $\dim(\mathcal{U}+\mathcal{W}) = \dim(\mathcal{U}) + \dim(\mathcal{W}) - \dim(\mathcal{U} \cap \mathcal{W})$.

Proof. The subspace $\mathcal{U} \cap \mathcal{W}$ is finite-dimensional by Proposition 1.4.3. Choose basis $\epsilon = (\mathbf{e}_1, \ldots, \mathbf{e}_r)$ of intersection by Corollary 1.3.14.
Extend ϵ to bases $\beta_{\mathcal{U}} = (\mathbf{e}_1, \ldots, \mathbf{e}_r, \mathbf{u}_1, \ldots, \mathbf{u}_p)$ of $\mathcal{U}$ and $\beta_{\mathcal{W}} = (\mathbf{e}_1, \ldots, \mathbf{e}_r, \mathbf{w}_1, \ldots, \mathbf{w}_q)$ of $\mathcal{W}$ by Theorem 1.3.13.
Set $\gamma := (\mathbf{e}_1, \ldots, \mathbf{e}_r, \mathbf{u}_1, \ldots, \mathbf{u}_p, \mathbf{w}_1, \ldots, \mathbf{w}_q)$. The list γ spans $\mathcal{U}+\mathcal{W}$.
Suppose $\sum_{i=1}^{r} a_i\mathbf{e}_i + \sum_{j=1}^{p} b_j\mathbf{u}_j + \sum_{k=1}^{q} c_k\mathbf{w}_k = \mathbf{0}$. Then $\sum_{i=1}^{r} a_i\mathbf{e}_i + \sum_{j=1}^{p} b_j\mathbf{u}_j = -\sum_{k=1}^{q} c_k\mathbf{w}_k \in \mathcal{U} \cap \mathcal{W}$.
Its representation in $\beta_{\mathcal{U}}$ therefore has $b_1 = \cdots = b_p = 0$.
The remaining relation belongs to $\beta_{\mathcal{W}}$, so $a_1 = \cdots = a_r = c_1 = \cdots = c_q = 0$.
Thus γ is a basis of $\mathcal{U}+\mathcal{W}$, and $\dim(\mathcal{U}+\mathcal{W}) = r+p+q = (r+p)+(r+q)-r$.
Structural Commentary: An intersection basis is extended twice; concatenation then separates shared from new directions.
Key Insight: Subtract the dimension counted in both summands. □

Corollary 2.3.2. *Dimension of a Direct Sum*
If $\mathcal{U}, \mathcal{W} \leq \mathcal{V}$ are finite-dimensional and $\mathcal{U} \cap \mathcal{W} = \{\mathbf{0}\}$, then $\dim(\mathcal{U} \oplus \mathcal{W}) = \dim(\mathcal{U}) + \dim(\mathcal{W})$.

Proof. The sum is direct by Proposition 2.1.8. Since $\dim(\mathcal{U} \cap \mathcal{W}) = 0$, the asserted equality holds by Theorem 2.3.1.
Structural Commentary: The directness criterion removes the intersection term from the sum formula.
Key Insight: Trivial overlap makes dimensions additive. □

Corollary 2.3.3. *Large Subspaces Must Intersect*
Let $\mathcal{U}, \mathcal{W} \leq \mathcal{V}$, where $\mathcal{V}$ is finite-dimensional, and let $k \in \mathbb{N}$.

(i) If $\dim(\mathcal{U}) + \dim(\mathcal{W}) > \dim(\mathcal{V})$, then $\mathcal{U} \cap \mathcal{W}$ contains a nonzero vector.
(ii) If $\dim(\mathcal{U}) + \dim(\mathcal{W}) \geq \dim(\mathcal{V}) + k$, then $\mathcal{U} \cap \mathcal{W}$ contains k linearly independent vectors.

Proof. The inequality $\dim(\mathcal{U}+\mathcal{W}) \leq \dim(\mathcal{V})$ holds by Proposition 1.4.3.
Hence $\dim(\mathcal{U} \cap \mathcal{W}) = \dim(\mathcal{U}) + \dim(\mathcal{W}) - \dim(\mathcal{U}+\mathcal{W}) \geq \dim(\mathcal{U}) + \dim(\mathcal{W}) - \dim(\mathcal{V})$ by Theorem 2.3.1.

(i) Under strict inequality, $\dim(\mathcal{U} \cap \mathcal{W}) \geq 1$. Choose basis of intersection by Corollary 1.3.14; any one of its vectors is nonzero.
(ii) Under second inequality, $\dim(\mathcal{U} \cap \mathcal{W}) \geq k$.
A basis of the intersection exists by Corollary 1.3.14, and any k of its vectors are linearly independent.

Structural Commentary: The sum formula converts excess ambient dimension into a lower bound on overlap.
Key Insight: Excess dimension must reappear in the intersection. □

Theorem 2.3.4. *Direct Sums and Dimension*
Let $m \in \mathbb{N}$, $\mathcal{V}$ be finite-dimensional, $\mathcal{U}_1, \ldots, \mathcal{U}_m \leq \mathcal{V}$. For $1 \leq j \leq m$, let β_j be an ordered basis of $\mathcal{U}_j$, $\beta = (\beta_1, \ldots, \beta_m)$ be their concatenation.

(i) The sum $\mathcal{U}_1 + \cdots + \mathcal{U}_m$ is direct iff $\dim(\mathcal{U}_1 + \cdots + \mathcal{U}_m) = \sum_{j=1}^{m} \dim(\mathcal{U}_j)$.
(ii) If the sum is direct, then β is an ordered basis of $\mathcal{U}_1 \oplus \cdots \oplus \mathcal{U}_m$.

Proof. The list β spans $\mathcal{U}_1 + \cdots + \mathcal{U}_m$ and has length $\sum_{j=1}^{m} \dim(\mathcal{U}_j)$.

(i) ($\Rightarrow$) Suppose the sum is direct. A linear relation among the vectors of β determines vectors $\mathbf{u}_j \in \mathcal{U}_j$ satisfying $\sum_{j=1}^{m} \mathbf{u}_j = \mathbf{0}$.
Every $\mathbf{u}_j$ is zero by Proposition 2.1.23, and then every coefficient is zero by the independence of β_j.
Thus β is a basis, and its length proves the dimension equality.
(i) ($\Leftarrow$) Suppose dimension equality holds. The spanning list β has length $\dim(\mathcal{U}_1 + \cdots + \mathcal{U}_m)$, so it is a basis by Proposition 1.4.4.
If $\sum_{j=1}^{m} \mathbf{u}_j = \mathbf{0}$ with $\mathbf{u}_j \in \mathcal{U}_j$, expanding each $\mathbf{u}_j$ in β_j produces a relation in β.
Its coefficients, and hence every $\mathbf{u}_j$, are zero. The sum is therefore direct by Proposition 2.1.23.

(*ii*) Under directness, the linear-independence argument in the forward direction of part (i) applies to β.
Since β already spans the sum, it is an ordered basis of $\mathcal{U}_1 \oplus \cdots \oplus \mathcal{U}_m$.

Structural Commentary: Concatenation converts directness into independence and dimension equality into full basis length.
Key Insight: Dimensions add exactly when concatenation has no redundancy. □

Definition 2.3.5. *Basis Adapted to a Direct Sum*
Let $m \in \mathbb{N}$, let $\mathcal{V} = \mathcal{U}_1 \oplus \cdots \oplus \mathcal{U}_m$ be finite-dimensional, and let β be an ordered basis of $\mathcal{V}$.
The basis β is *adapted to the direct-sum decomposition* iff there are ordered bases β_j of $\mathcal{U}_j$ such that $\beta = (\beta_1, \ldots, \beta_m)$.

Proposition 2.3.6. *Complements Exist in Finite Dimensions*
If $\mathcal{V}$ is finite-dimensional and $\mathcal{U} \leq \mathcal{V}$, then $(\exists\, \mathcal{W} \leq \mathcal{V})\, \mathcal{V} = \mathcal{U} \oplus \mathcal{W}$.

Proof. Choose a basis $(\mathbf{u}_1, \ldots, \mathbf{u}_m)$ of $\mathcal{U}$ by Corollary 1.3.14, and extend it to a basis $(\mathbf{u}_1, \ldots, \mathbf{u}_m, \mathbf{w}_1, \ldots, \mathbf{w}_n)$ of $\mathcal{V}$ by Theorem 1.3.13.
Set $\mathcal{W} := \operatorname{span}(\mathbf{w}_1, \ldots, \mathbf{w}_n)$. The extended basis spans $\mathcal{V}$, so $\mathcal{V} = \mathcal{U} + \mathcal{W}$.
If $\mathbf{x} \in \mathcal{U} \cap \mathcal{W}$, subtracting its two representations produces a relation in the extended basis.
Linear independence forces every coefficient to vanish, so $\mathbf{x} = \mathbf{0}$. Therefore $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$ by Proposition 2.1.8.
Structural Commentary: Basis extension isolates the old directions from the newly appended directions.
Key Insight: The appended basis vectors span a complement. □

Theorem 2.3.7. *Complements Exist*
Assume Zorn's lemma. If $\mathcal{U} \leq \mathcal{V}$, then $(\exists\, \mathcal{W} \leq \mathcal{V})\, \mathcal{V} = \mathcal{U} \oplus \mathcal{W}$.

Proof. Choose a Hamel basis $\mathcal{B}_\mathcal{U}$ of $\mathcal{U}$ and extend it to a Hamel basis $\mathcal{B}$ of $\mathcal{V}$ by Theorem 1.3.17. Set $\mathcal{C} := \mathcal{B} \setminus \mathcal{B}_\mathcal{U}$ and $\mathcal{W} := \operatorname{span}(\mathcal{C})$.
Every finite $\mathcal{B}$-expansion separates into terms indexed by $\mathcal{B}_\mathcal{U}$ and terms indexed by $\mathcal{C}$, so $\mathcal{V} = \mathcal{U} + \mathcal{W}$.
If $\mathbf{x} \in \mathcal{U} \cap \mathcal{W}$, then $\mathbf{x}$ has one $\mathcal{B}$-expansion supported in $\mathcal{B}_\mathcal{U}$ and another supported in the disjoint set $\mathcal{C}$.
These expansions agree by Proposition 1.3.16, so both have empty support and $\mathbf{x} = \mathbf{0}$. Therefore $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$ by Proposition 2.1.8.
Structural Commentary: Hamel basis extension partitions all coordinates into subspace and complementary supports.
Key Insight: Disjoint coordinate supports produce a complement. □

Proposition 2.3.8. *Rank-Nullity as a Complement Isomorphism*
Let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ and suppose $\mathcal{V} = \ker(T) \oplus \mathcal{M}$.

(i) The restriction $T|_\mathcal{M} : \mathcal{M} \to \operatorname{range}(T)$ is an isomorphism.
(ii) If $\mathcal{V}$ is finite-dimensional, then $\dim(\mathcal{V}) = \dim(\ker(T)) + \dim(\operatorname{range}(T))$.

Proof.

(i) The restriction is linear and $\ker(T|_\mathcal{M}) = \mathcal{M} \cap \ker(T) = \{\mathbf{0}\}$, so it is injective by Proposition 1.6.2.
If $T\mathbf{v} \in \operatorname{range}(T)$, write $\mathbf{v} = \mathbf{k} + \mathbf{m}$ with $\mathbf{k} \in \ker(T)$ and $\mathbf{m} \in \mathcal{M}$. Then $T\mathbf{v} = T\mathbf{m}$, so the restriction is surjective onto $\operatorname{range}(T)$.
It is therefore an isomorphism by Proposition 1.6.7.

(ii) Suppose $\mathcal{V}$ is finite-dimensional. The subspaces $\ker(T)$ and $\mathcal{M}$ are finite-dimensional by Proposition 1.4.3, and $\operatorname{range}(T)$ is finite-dimensional by Theorem 1.7.1. Thus $\dim(\mathcal{V}) = \dim(\ker(T)) + \dim(\mathcal{M})$ by Corollary 2.3.2, while $\dim(\mathcal{M}) = \dim(\operatorname{range}(T))$ by part (i) and Theorem 1.7.9. Substitution proves the formula.

Structural Commentary: The restriction removes precisely the invisible kernel directions before dimensions are counted.
Key Insight: A kernel complement models the range exactly. □

Proposition 2.3.9. *One-Sided Inverses Split in Finite Dimensions*
Let $\mathcal{V}$ and $\mathcal{W}$ be finite-dimensional, and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$.

(i) If T is injective, then $(\exists\, L \in \mathcal{L}(\mathcal{W}, \mathcal{V}))\, LT = I_\mathcal{V}$.
(ii) If T is surjective, then $(\exists\, R \in \mathcal{L}(\mathcal{W}, \mathcal{V}))\, TR = I_\mathcal{W}$.

Proof.

(i) Suppose T is injective. Choose $\mathcal{H} \leq \mathcal{W}$ with $\mathcal{W} = \operatorname{range}(T) \oplus \mathcal{H}$ by Proposition 2.3.6.
For the unique decomposition $\mathbf{w} = T\mathbf{v} + \mathbf{h}$, define $L\mathbf{w} := \mathbf{v}$.
This is well-defined: directness determines $T\mathbf{v}$ and $\mathbf{h}$, while injectivity determines $\mathbf{v}$.
If $\mathbf{w}_i = T\mathbf{v}_i + \mathbf{h}_i$ for $i = 1, 2$ and $a, b \in \mathbb{F}$, then $L(a\mathbf{w}_1 + b\mathbf{w}_2) = L(T(a\mathbf{v}_1 + b\mathbf{v}_2) + (a\mathbf{h}_1 + b\mathbf{h}_2)) = a\mathbf{v}_1 + b\mathbf{v}_2 = aL\mathbf{w}_1 + bL\mathbf{w}_2$.
Hence L is linear, and $LT\mathbf{v} = \mathbf{v}$ for every $\mathbf{v} \in \mathcal{V}$.

(ii) Suppose T is surjective. Choose $\mathcal{H} \leq \mathcal{V}$ with $\mathcal{V} = \ker(T) \oplus \mathcal{H}$ by Proposition 2.3.6.
Since $\operatorname{range}(T) = \mathcal{W}$, the restriction $T|_\mathcal{H} : \mathcal{H} \to \mathcal{W}$ is an isomorphism by Proposition 2.3.8(i).
Let $R := (T|_\mathcal{H})^{-1}$, regarded as a linear map from $\mathcal{W}$ to $\mathcal{V}$. Then $TR = I_\mathcal{W}$.

Structural Commentary: A range complement extends a left inverse; a kernel complement supports a right inverse.
Key Insight: Complements turn injectivity or surjectivity into a splitting. □

Proposition 2.3.10. *Quotient by a Complemented Subspace*
Let $\mathcal{U}, \mathcal{W} \leq \mathcal{V}$ with $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$. Then the map $J : \mathcal{W} \to \mathcal{V}/\mathcal{U}$ defined by $J(\mathbf{w}) := \mathbf{w} + \mathcal{U}$ is an isomorphism.
Consequently, every complement of $\mathcal{U}$ is isomorphic to $\mathcal{V}/\mathcal{U}$.

Proof.

(i) *Linearity*: For $a, b \in \mathbb{F}$, $\mathbf{w}_1, \mathbf{w}_2 \in \mathcal{W}$, equality $J(a\mathbf{w}_1 + b\mathbf{w}_2) = aJ(\mathbf{w}_1) + bJ(\mathbf{w}_2)$ holds by Proposition 2.2.6. Thus J is linear.

(ii) *Injectivity*: The equivalence $J(\mathbf{w}) = \mathcal{U} \Leftrightarrow \mathbf{w} \in \mathcal{U}$ holds by Proposition 2.2.2.
Hence $\ker(J) = \mathcal{U} \cap \mathcal{W} = \{\mathbf{0}\}$, and J is injective by Proposition 1.6.2.

(iii) *Surjectivity*: Let $\mathbf{v} + \mathcal{U} \in \mathcal{V}/\mathcal{U}$. Write $\mathbf{v} = \mathbf{u} + \mathbf{w}$ with $\mathbf{u} \in \mathcal{U}$ and $\mathbf{w} \in \mathcal{W}$.
Then $\mathbf{v} + \mathcal{U} = \mathbf{w} + \mathcal{U} = J(\mathbf{w})$ by Proposition 2.2.2, so J is surjective.

(iv) *Conclusion*: The map J is an isomorphism by Proposition 1.6.7.
Since $\mathcal{W}$ was an arbitrary complement of $\mathcal{U}$, this proves the consequent.

Structural Commentary: The proof checks that each coset has exactly one representative in the complement.
Key Insight: A complement is a concrete model of the quotient. □

Definition 2.3.11. *Codimension*
If $\mathcal{U} \leq \mathcal{V}$ and $\mathcal{V}/\mathcal{U}$ is finite-dimensional, then the *codimension of $\mathcal{U}$ in $\mathcal{V}$* is $\operatorname{codim}_{\mathcal{V}}(\mathcal{U}) := \dim(\mathcal{V}/\mathcal{U})$.

If $\mathcal{V}$ is finite-dimensional, then $\operatorname{codim}_{\mathcal{V}}(\mathcal{U}) = \dim(\mathcal{V}) - \dim(\mathcal{U})$ by Theorem 2.2.9. If $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$ and $\mathcal{V}/\mathcal{U}$ is finite-dimensional, then $\mathcal{W} \cong \mathcal{V}/\mathcal{U}$ by Proposition 2.3.10, so $\operatorname{codim}_{\mathcal{V}}(\mathcal{U}) = \dim(\mathcal{W})$ by Proposition 1.7.8.

Perspective 2.3.12. *Quotients Split over Fields*
In finite dimensions, a complement $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$ exists by Proposition 2.3.6, and $\mathcal{V}/\mathcal{U} \cong \mathcal{W}$ by Proposition 2.3.10.
Thus the quotient forgets the $\mathcal{U}$-component and retains the complementary coordinate.

Proposition 2.3.13. *Quotient of a Direct Sum*
If $\mathcal{V} = \mathcal{V}_1 \oplus \mathcal{V}_2$ and $\mathcal{U}_j \leq \mathcal{V}_j$ for $j = 1, 2$, then $\mathcal{V}/(\mathcal{U}_1 \oplus \mathcal{U}_2) \cong (\mathcal{V}_1/\mathcal{U}_1) \times (\mathcal{V}_2/\mathcal{U}_2)$.

Proof.
(i) *Denominator*: Since $\mathcal{U}_1 \cap \mathcal{U}_2 \subseteq \mathcal{V}_1 \cap \mathcal{V}_2 = \{\mathbf{0}\}$, the sum $\mathcal{U}_1 + \mathcal{U}_2$ is direct by Proposition 2.1.8.
(ii) *Construction*: For the unique decomposition $\mathbf{v} = \mathbf{v}_1 + \mathbf{v}_2$, define $\Phi : \mathcal{V} \to (\mathcal{V}_1/\mathcal{U}_1) \times (\mathcal{V}_2/\mathcal{U}_2)$ by $\Phi(\mathbf{v}_1 + \mathbf{v}_2) := (\mathbf{v}_1 + \mathcal{U}_1, \mathbf{v}_2 + \mathcal{U}_2)$. Componentwise quotient operations show that Φ is linear by Proposition 2.2.6.
(iii) *Range and kernel*: Every pair $(\mathbf{x}_1 + \mathcal{U}_1, \mathbf{x}_2 + \mathcal{U}_2)$ equals $\Phi(\mathbf{x}_1 + \mathbf{x}_2)$, so Φ is surjective.
Moreover, $\Phi(\mathbf{v}_1 + \mathbf{v}_2) = (\mathcal{U}_1, \mathcal{U}_2)$ iff $\mathbf{v}_j \in \mathcal{U}_j$ for $j = 1, 2$ by Proposition 2.2.2. Hence $\ker(\Phi) = \mathcal{U}_1 \oplus \mathcal{U}_2$.
(iv) *Conclusion*: The claimed isomorphism holds by Theorem 2.2.12, because $\operatorname{range}(\Phi)$ is the whole product.
Structural Commentary: Direct-sum coordinates define the map; its componentwise kernel identifies the quotient.
Key Insight: Quotienting a direct sum acts coordinatewise. □

Perspective 2.3.14. *Quotients Depend on the Embedding*
A complement realizes a quotient, but the result depends on how the subspace is embedded.
Let $\mathcal{V}$ have countable basis $(\mathbf{e}_n)_{n\geq 1}$ and set $\mathcal{S} := \operatorname{span}(\mathbf{e}_n : n \geq 2)$.
The forward shift $F : \mathcal{V} \to \mathcal{S}$ defined by $F(\mathbf{e}_n) = \mathbf{e}_{n+1}$ is an isomorphism: unique finite basis expansions make it linear, and the backward shift $\mathbf{e}_{n+1} \mapsto \mathbf{e}_n$ is its inverse. Thus $\mathcal{S} \cong \mathcal{V}$.
Nevertheless, $\mathcal{V} = \mathcal{V} \oplus \{\mathbf{0}\}$ and $\mathcal{V} = \mathcal{S} \oplus \mathbb{F}\mathbf{e}_1$, so $\mathcal{V}/\mathcal{V} \cong \{\mathbf{0}\}$ while $\mathcal{V}/\mathcal{S} \cong \mathbb{F}\mathbf{e}_1$ by Proposition 2.3.10.
Hence isomorphic subspaces can have nonisomorphic quotients when embedded differently.

2.4 Algebraic Projections and Resolutions

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$. Projections encode direct-sum coordinates as operators, while resolutions package finite decompositions into mutually annihilating idempotents.

Definition 2.4.1. *Projection Along a Complement*
(i) An operator $P \in \mathcal{L}(\mathcal{V})$ is an *algebraic projection*, or *idempotent operator*, iff $P^2 = P$.
(ii) If $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$, the *projection onto $\mathcal{U}$ along $\mathcal{W}$* is the map $\rho_{\mathcal{U},\mathcal{W}} : \mathcal{V} \to \mathcal{V}$ defined by $(\forall\, (\mathbf{u}, \mathbf{w}) \in \mathcal{U} \times \mathcal{W})\, \rho_{\mathcal{U},\mathcal{W}}(\mathbf{u} + \mathbf{w}) := \mathbf{u}$.

Proposition 2.4.2. *Algebraic Projections and Direct-Sum Splittings*
The following hold.
(i) For $P \in \mathcal{L}(\mathcal{V})$, $P^2 = P$ iff $\mathcal{V} = \operatorname{range}(P) \oplus \ker(P)$ and $P = \rho_{\operatorname{range}(P),\ker(P)}$.
(ii) If $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$, then $\rho_{\mathcal{U},\mathcal{W}} \in \mathcal{L}(\mathcal{V})$ and $\rho_{\mathcal{U},\mathcal{W}}^2 = \rho_{\mathcal{U},\mathcal{W}}$.
(iii) If $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$, then $\operatorname{range}(\rho_{\mathcal{U},\mathcal{W}}) = \mathcal{U}$ and $\ker(\rho_{\mathcal{U},\mathcal{W}}) = \mathcal{W}$.

Proof.
(i) ($\Rightarrow$) Suppose $P^2 = P$. For $\mathbf{v} \in \mathcal{V}$, $\mathbf{v} = P\mathbf{v} + (\mathbf{v} - P\mathbf{v})$, where $P\mathbf{v} \in \operatorname{range}(P)$ and $\mathbf{v} - P\mathbf{v} \in \ker(P)$.
If $\mathbf{x} \in \operatorname{range}(P) \cap \ker(P)$, choose $\mathbf{y} \in \mathcal{V}$ with $\mathbf{x} = P\mathbf{y}$. Then $\mathbf{x} = P^2\mathbf{y} = P\mathbf{x} = \mathbf{0}$, so the sum is direct by Proposition 2.1.8.
The displayed decomposition satisfies $(\forall\, \mathbf{v} \in \mathcal{V})\, \rho_{\operatorname{range}(P),\ker(P)}\mathbf{v} = P\mathbf{v}$; hence $P = \rho_{\operatorname{range}(P),\ker(P)}$.
(i) ($\Leftarrow$) Suppose $\mathcal{V} = \operatorname{range}(P) \oplus \ker(P)$ and $P = \rho_{\operatorname{range}(P),\ker(P)}$.
If $\mathbf{v} = \mathbf{x} + \mathbf{y}$ with $\mathbf{x} \in \operatorname{range}(P)$ and $\mathbf{y} \in \ker(P)$, then $P^2\mathbf{v} = P\mathbf{x} = \mathbf{x} = P\mathbf{v}$; hence $P^2 = P$.
(ii) Set $R := \rho_{\mathcal{U},\mathcal{W}}$ and write $\mathbf{v}_j = \mathbf{u}_j + \mathbf{w}_j$ with $(\mathbf{u}_j, \mathbf{w}_j) \in \mathcal{U} \times \mathcal{W}$ for $j = 1, 2$.
For $a, b \in \mathbb{F}$, $R(a\mathbf{v}_1 + b\mathbf{v}_2) = a\mathbf{u}_1 + b\mathbf{u}_2 = aR\mathbf{v}_1 + bR\mathbf{v}_2$ by uniqueness of direct-sum decompositions, so R is linear.
Also $R^2(\mathbf{u} + \mathbf{w}) = R\mathbf{u} = \mathbf{u} = R(\mathbf{u} + \mathbf{w})$, so R is idempotent.
(iii) The inclusion $\operatorname{range}(\rho_{\mathcal{U},\mathcal{W}}) \subseteq \mathcal{U}$ holds by the defining formula, while $\rho_{\mathcal{U},\mathcal{W}}\mathbf{u} = \mathbf{u}$ for $\mathbf{u} \in \mathcal{U}$; hence the range is $\mathcal{U}$.
For $\mathbf{v} = \mathbf{u} + \mathbf{w}$, $\rho_{\mathcal{U},\mathcal{W}}\mathbf{v} = \mathbf{0}$ iff $\mathbf{u} = \mathbf{0}$ iff $\mathbf{v} \in \mathcal{W}$, so the kernel is $\mathcal{W}$.
Structural Commentary: Decomposition handles characterization; coordinates verify linearity, idempotence, range, and kernel.
Key Insight: Every idempotent keeps its range and kills its kernel. □

Proposition 2.4.3. *Complementary Algebraic Projections*
If $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$, then the following hold.
(i) $\rho_{\mathcal{U},\mathcal{W}} + \rho_{\mathcal{W},\mathcal{U}} = I_{\mathcal{V}}$.
(ii) $\rho_{\mathcal{U},\mathcal{W}}\rho_{\mathcal{W},\mathcal{U}} = \rho_{\mathcal{W},\mathcal{U}}\rho_{\mathcal{U},\mathcal{W}} = 0$.

Proof. Let $\mathbf{v} = \mathbf{u} + \mathbf{w}$ with $(\mathbf{u}, \mathbf{w}) \in \mathcal{U} \times \mathcal{W}$.
(i) $(\rho_{\mathcal{U},\mathcal{W}} + \rho_{\mathcal{W},\mathcal{U}})\mathbf{v} = \mathbf{u} + \mathbf{w} = \mathbf{v}$. Since this equality holds on $\mathcal{V}$, the sum is $I_{\mathcal{V}}$.
(ii) $\rho_{\mathcal{U},\mathcal{W}}\rho_{\mathcal{W},\mathcal{U}}\mathbf{v} = \rho_{\mathcal{U},\mathcal{W}}\mathbf{w} = \mathbf{0}$ and $\rho_{\mathcal{W},\mathcal{U}}\rho_{\mathcal{U},\mathcal{W}}\mathbf{v} = \rho_{\mathcal{W},\mathcal{U}}\mathbf{u} = \mathbf{0}$. Since both equalities hold on $\mathcal{V}$, both products are zero.
Structural Commentary: The two coordinate projections are evaluated on the same unique decomposition.
Key Insight: Complementary projections partition identity and annihilate each other. □

Definition 2.4.4. *Algebraic Orthogonality and Resolutions*
(i) Algebraic projections $\rho, \sigma \in \mathcal{L}(\mathcal{V})$ are *algebraically orthogonal*, written $\rho \perp \sigma$, iff $\rho\sigma = \sigma\rho = 0$.
(ii) A *resolution of identity* on $\mathcal{V}$ is a finite family of algebraic projections $(\rho_i)_{i=1}^k$ such that $k \in \mathbb{N}$,

$$(\forall\, i, j \in \{1, \ldots, k\})(i \neq j \Rightarrow \rho_i \perp \rho_j), \text{ and } \sum_{i=1}^{k} \rho_i = I_{\mathcal{V}}.$$

Theorem 2.4.5. *Resolution Ranges Form a Direct Sum*
Let $(\rho_i)_{i=1}^k$ be a resolution of identity on $\mathcal{V}$, and set $\mathcal{R}_i := \operatorname{range}(\rho_i)$ for $i \in \{1,\dots,k\}$. Then the following hold.

(i) $\mathcal{V} = \bigoplus_{i=1}^{k} \mathcal{R}_i$.

(ii) $(\forall\, i \in \{1,\dots,k\})\ \ker(\rho_i) = \bigoplus_{j\in\{1,\dots,k\}\setminus\{i\}} \mathcal{R}_j$.

Proof.

(i) For $\mathbf{v} \in \mathcal{V}$, $\mathbf{v} = \sum_{i=1}^{k} \rho_i \mathbf{v} \in \sum_{i=1}^{k} \mathcal{R}_i$. Suppose $\sum_{i=1}^{k} \mathbf{x}_i = \mathbf{0}$ with $\mathbf{x}_i \in \mathcal{R}_i$.
For $m \in \{1,\dots,k\}$, idempotence and algebraic orthogonality imply $\rho_m \mathbf{x}_m = \mathbf{x}_m$ and $(\forall\, i \in \{1,\dots,k\} \setminus \{m\})\ \rho_m \mathbf{x}_i = \mathbf{0}$.
Hence $\mathbf{x}_m = \rho_m \sum_{i=1}^{k} \mathbf{x}_i = \mathbf{0}$. The sum is direct by Proposition 2.1.23.

(ii) By part (i), write $\mathbf{v} = \sum_{j=1}^{k} \mathbf{x}_j$ uniquely with $\mathbf{x}_j \in \mathcal{R}_j$. The equality $\rho_i \mathbf{v} = \mathbf{x}_i$ holds by idempotence and algebraic orthogonality.
Hence $\mathbf{v} \in \ker(\rho_i)$ iff $\mathbf{x}_i = \mathbf{0}$. These are exactly the vectors in $\bigoplus_{j\in\{1,\dots,k\}\setminus\{i\}} \mathcal{R}_j$.

Structural Commentary: The identity establishes spanning; orthogonal idempotents isolate each component and identify every kernel.
Key Insight: Mutually annihilating projections recover unique direct-sum coordinates. □

Theorem 2.4.6. *Direct Sums Give Resolutions*
Let $k \in \mathbb{N}$, set $K := \{1,\dots,k\}$, and suppose $\mathcal{V} = \bigoplus_{i\in K} \mathcal{U}_i$. For $i \in K$, set $\rho_i := \rho_{\mathcal{U}_i, \sum_{j\in K\setminus\{i\}} \mathcal{U}_j}$. Then $(\rho_i)_{i\in K}$ is a resolution of identity.

Proof. For $i \in K$, set $\mathcal{W}_i := \sum_{j\in K\setminus\{i\}} \mathcal{U}_j$. Then $\mathcal{U}_i \cap \mathcal{W}_i = \{\mathbf{0}\}$ by Proposition 2.1.23(iii), while $\mathcal{V} = \mathcal{U}_i + \mathcal{W}_i$ by the assumed sum.
Hence $\mathcal{V} = \mathcal{U}_i \oplus \mathcal{W}_i$ by Proposition 2.1.8, and ρ_i is an algebraic projection by Proposition 2.4.2(ii).
For the unique decomposition $\mathbf{v} = \sum_{i\in K} \mathbf{u}_i$, $\rho_i \mathbf{v} = \mathbf{u}_i$; hence $(\sum_{i\in K} \rho_i)\mathbf{v} = \mathbf{v}$. This pointwise identity proves $\sum_{i\in K} \rho_i = I_{\mathcal{V}}$.
If $i \neq j$, then $\rho_i \rho_j \mathbf{v} = \rho_i \mathbf{u}_j = \mathbf{0}$ and $\rho_j \rho_i \mathbf{v} = \rho_j \mathbf{u}_i = \mathbf{0}$. Thus $\rho_i \perp \rho_j$, and the family is a resolution of identity.
Structural Commentary: Direct-sum uniqueness defines coordinate projections; pointwise identities verify the resolution conditions.
Key Insight: Coordinate projections isolate summands and reconstruct every vector. □

Theorem 2.4.7. *Algebra of Projections*
Let $\rho, \sigma \in \mathcal{L}(\mathcal{V})$ be algebraic projections, and assume $2 \neq 0$ in $\mathbb{F}$.

(i) The operator $\rho + \sigma$ is an algebraic projection iff $\rho \perp \sigma$.
Under these conditions, $\operatorname{range}(\rho+\sigma) = \operatorname{range}(\rho) \oplus \operatorname{range}(\sigma)$ *and* $\ker(\rho+\sigma) = \ker(\rho) \cap \ker(\sigma)$.

(ii) The operator $\rho - \sigma$ is an algebraic projection iff $\rho\sigma = \sigma\rho = \sigma$.
Under these conditions, $\operatorname{range}(\rho-\sigma) = \operatorname{range}(\rho) \cap \ker(\sigma)$ *and* $\ker(\rho-\sigma) = \ker(\rho) \oplus \operatorname{range}(\sigma)$.

(iii) If $\rho\sigma = \sigma\rho$, then $\rho\sigma$ is an algebraic projection, $\operatorname{range}(\rho\sigma) = \operatorname{range}(\rho) \cap \operatorname{range}(\sigma)$, *and* $\ker(\rho\sigma) = \ker(\rho) + \ker(\sigma)$.

Proof.

(i) ($\Rightarrow$) Set $A := \rho\sigma$, $B := \sigma\rho$, and $C := \rho\sigma\rho$. The identity $(\rho+\sigma)^2 = \rho+\sigma$ is equivalent to $A + B = 0$.
Then $A + C = \rho(A+B) = 0$ and $C + B = (A+B)\rho = 0$, so $A = B$ and $2A = 0$.
The scalar 2 is invertible by $2 \neq 0$ in the field $\mathbb{F}$; hence $A = B = 0$ and $\rho \perp \sigma$.

(i) ($\Leftarrow$) Suppose $\rho \perp \sigma$. Then $(\rho+\sigma)^2 = \rho+\sigma$, so the sum is an algebraic projection.
Its range is contained in $\operatorname{range}(\rho) + \operatorname{range}(\sigma)$, while $(\rho+\sigma)(\mathbf{x}+\mathbf{y}) = \mathbf{x}+\mathbf{y}$ for $(\mathbf{x},\mathbf{y}) \in \operatorname{range}(\rho) \times \operatorname{range}(\sigma)$.
If $\mathbf{z} \in \operatorname{range}(\rho) \cap \operatorname{range}(\sigma)$ and $\mathbf{z} = \sigma\mathbf{w}$, then $\mathbf{z} = \rho\mathbf{z} = \rho\sigma\mathbf{w} = \mathbf{0}$; hence the range sum is direct by Proposition 2.1.8.
$(\rho+\sigma)\mathbf{v} = \mathbf{0} \Rightarrow \rho\mathbf{v} = \rho(\rho+\sigma)\mathbf{v} = \mathbf{0}$ and $\sigma\mathbf{v} = \sigma(\rho+\sigma)\mathbf{v} = \mathbf{0}$. Reverse implication is immediate. Thus $\ker(\rho+\sigma) = \ker(\rho) \cap \ker(\sigma)$.

(ii) ($\Rightarrow$) Suppose $Q := \rho - \sigma$ is algebraic projection. Then $(I_{\mathcal{V}} - Q)^2 = I_{\mathcal{V}} - Q$ and $(I_{\mathcal{V}} - \rho)^2 = I_{\mathcal{V}} - \rho$ hold by $Q^2 = Q$ and $\rho^2 = \rho$.
Since $I_{\mathcal{V}} - Q = (I_{\mathcal{V}} - \rho) + \sigma$, $(I_{\mathcal{V}} - \rho) \perp \sigma$ by part (i). Therefore $(I_{\mathcal{V}} - \rho)\sigma = \sigma(I_{\mathcal{V}} - \rho) = 0$, which is equivalent to $\rho\sigma = \sigma\rho = \sigma$.

(ii) ($\Leftarrow$) Suppose $\rho\sigma = \sigma\rho = \sigma$ and set $Q := \rho - \sigma$. The operator $I_{\mathcal{V}} - \rho$ is an algebraic projection and is algebraically orthogonal to σ, so $I_{\mathcal{V}} - Q = (I_{\mathcal{V}} - \rho) + \sigma$ is an algebraic projection by part (i). Since $I_{\mathcal{V}} - Q$ is idempotent, $Q^2 = (I_{\mathcal{V}} - (I_{\mathcal{V}} - Q))^2 = I_{\mathcal{V}} - (I_{\mathcal{V}} - Q) = Q$.
Since $\rho Q = Q$ and $\sigma Q = 0$, $\operatorname{range}(Q) \subseteq \operatorname{range}(\rho) \cap \ker(\sigma)$; the reverse inclusion holds because $Q\mathbf{x} = \mathbf{x}$ when $\rho\mathbf{x} = \mathbf{x}$ and $\sigma\mathbf{x} = \mathbf{0}$.
The operator Q kills both $\ker(\rho)$ and $\operatorname{range}(\sigma)$. Their intersection is trivial: if $\mathbf{z} = \sigma\mathbf{w} \in \ker(\rho)$, then $\mathbf{z} = \rho\sigma\mathbf{w} = \rho\mathbf{z} = \mathbf{0}$.
Their sum is direct by Proposition 2.1.8, and $\ker(\rho) \oplus \operatorname{range}(\sigma) \subseteq \ker(Q)$ because Q kills both summands.
Conversely, if $\mathbf{v} \in \ker(Q)$, then $\rho\mathbf{v} = \sigma\mathbf{v}$ and $\mathbf{v} = (\mathbf{v} - \rho\mathbf{v}) + \sigma\mathbf{v} \in \ker(\rho) \oplus \operatorname{range}(\sigma)$. Hence $\ker(Q) = \ker(\rho) \oplus \operatorname{range}(\sigma)$.

(iii) Suppose $\rho\sigma = \sigma\rho$. Then $(\rho\sigma)^2 = \rho^2\sigma^2 = \rho\sigma$, so $\rho\sigma$ is an algebraic projection.
If $\mathbf{x} = \rho\sigma\mathbf{y}$, then $\rho\mathbf{x} = \mathbf{x} = \sigma\mathbf{x}$; conversely, $\rho\mathbf{x} = \mathbf{x} = \sigma\mathbf{x}$ implies $\mathbf{x} = \rho\sigma\mathbf{x}$. Thus $\operatorname{range}(\rho\sigma) = \operatorname{range}(\rho) \cap \operatorname{range}(\sigma)$.
If $\mathbf{x} \in \ker(\rho)$, then $\rho\sigma\mathbf{x} = \sigma\rho\mathbf{x} = \mathbf{0}$; if $\mathbf{x} \in \ker(\sigma)$, then $\rho\sigma\mathbf{x} = \mathbf{0}$. Hence $\ker(\rho) + \ker(\sigma) \subseteq \ker(\rho\sigma)$.
If $\rho\sigma\mathbf{v} = \mathbf{0}$, then $\mathbf{v} = (\mathbf{v} - \sigma\mathbf{v}) + \sigma\mathbf{v}$ with $\mathbf{v} - \sigma\mathbf{v} \in \ker(\sigma)$ and $\sigma\mathbf{v} \in \ker(\rho)$; hence $\ker(\rho\sigma) = \ker(\rho) + \ker(\sigma)$.

Structural Commentary: Expanding idempotence isolates cross terms; fixed and killed subspaces determine each range and kernel.
Key Insight: Commuting idempotents encode intersections and sums. □

3 Matrix Representations, Change of Basis, Block Matrices, and Operations

3.1 Matrix Algebra and Linear Systems

Throughout this subsection, all matrices are over the same fixed field $\mathbb{F}$, and every size parameter is a positive integer.

Definition 3.1.1. *Matrices and Matrix Operations*

(i) *Matrix space and equality*: $\operatorname{Mat}(m,n,\mathbb{F}) := \{[A_{j,k}]_{1\le j\le m,\ 1\le k\le n} : A_{j,k} \in \mathbb{F}\}$.
For A, C in this space, $(A = C) \iff (\forall\, j \in \{1,\dots,m\})(\forall\, k \in \{1,\dots,n\})\ A_{j,k} = C_{j,k}$.

(ii) *Entries, rows, and columns*: if $A = [A_{j,k}] \in \operatorname{Mat}(m,n,\mathbb{F})$, then $A_{j,k}$ is its (j,k)-entry, $A_{j,\cdot}$ is row j, and $A_{\cdot,k}$ is column k.

(iii) *Transpose*: for $A \in \operatorname{Mat}(m,n,\mathbb{F})$, the transpose $A^t \in \operatorname{Mat}(n,m,\mathbb{F})$ satisfies $(\forall\, j \in \{1,\dots,m\})(\forall\, k \in \{1,\dots,n\})\ (A^t)_{k,j} := A_{j,k}$.

(iv) *Main diagonal and diagonal matrix*: if $A = [A_{j,k}] \in \mathrm{Mat}(m,n,\mathbb{F})$ and $r = \min(m,n)$, its main diagonal is $(A_{1,1},\dots,A_{r,r})$. For $\lambda_1,\dots,\lambda_n \in \mathbb{F}$, $\mathrm{diag}(\lambda_1,\dots,\lambda_n) \in \mathrm{Mat}(n,n,\mathbb{F})$ has (j,j)-entry λ_j and all off-diagonal entries zero.
(v) *Symmetry*: a matrix $A \in \mathrm{Mat}(n,n,\mathbb{F})$ is symmetric iff $A^t = A$, and skew-symmetric iff $A^t = -A$.
(vi) *Triangularity*: a matrix $A \in \mathrm{Mat}(n,n,\mathbb{F})$ is upper triangular iff $(\forall\, j,k \in \{1,\dots,n\})(j > k \Rightarrow A_{j,k} = 0)$. Lower triangular iff $(\forall\, j,k \in \{1,\dots,n\})(j < k \Rightarrow A_{j,k} = 0)$. Diagonal iff $(\forall\, j,k \in \{1,\dots,n\})(j \neq k \Rightarrow A_{j,k} = 0)$.
(vii) *Linear operations*: for $A, C \in \mathrm{Mat}(m,n,\mathbb{F})$ and $a \in \mathbb{F}$, $(A+C)_{j,k} := A_{j,k} + C_{j,k}$ and $(aA)_{j,k} := aA_{j,k}$ for admissible j,k.
(viii) *Row-column pairing*: if $r_1,\dots,r_n,c_1,\dots,c_n \in \mathbb{F}$, $\mathbf{r} = (r_1,\dots,r_n)$, and $\mathbf{c} = (c_1,\dots,c_n)^t$, then $\mathbf{rc} := \sum_{s=1}^{n} r_s c_s$.
(ix) *Matrix product*: for $A \in \mathrm{Mat}(m,n,\mathbb{F})$ and $B \in \mathrm{Mat}(n,p,\mathbb{F})$, the product $AB \in \mathrm{Mat}(m,p,\mathbb{F})$ satisfies $(\forall\, j \in \{1,\dots,m\})(\forall\, k \in \{1,\dots,p\})\,(AB)_{j,k} := \sum_{s=1}^{n} A_{j,s}B_{s,k}$.
(x) *Matrix-vector product*: identify $\mathbf{x} = (x_1,\dots,x_n)^t \in \mathbb{F}^n$ with its column matrix. For $A \in \mathrm{Mat}(m,n,\mathbb{F})$, define $A\mathbf{x} \in \mathbb{F}^m$ by $(\forall\, j \in \{1,\dots,m\})\,(A\mathbf{x})_j := \sum_{k=1}^{n} A_{j,k}x_k$.
(xi) *Matrix units*: for $j \in \{1,\dots,m\}$ and $k \in \{1,\dots,n\}$, $E_{j,k} \in \mathrm{Mat}(m,n,\mathbb{F})$ has (j,k)-entry 1 and all other entries zero.
(xii) *Identity and inverse*: $I_n := \mathrm{diag}(1,\dots,1) = [\delta_{j,k}] \in \mathrm{Mat}(n,n,\mathbb{F})$, where $\delta_{j,k} = 1$ iff $j = k$. A matrix $B \in \mathrm{Mat}(n,n,\mathbb{F})$ is a two-sided inverse of $A \in \mathrm{Mat}(n,n,\mathbb{F})$ iff $AB = I_n = BA$; the matrix A is invertible iff it has a two-sided inverse.

Proposition 3.1.2. *Basic Matrix Product Laws*
Let $A, A' \in \mathrm{Mat}(m,n,\mathbb{F})$, $B, B' \in \mathrm{Mat}(n,p,\mathbb{F})$, $C \in \mathrm{Mat}(p,q,\mathbb{F})$, and $a \in \mathbb{F}$. Then:
(i) $(AB)C = A(BC)$;
(ii) $I_m A = A = AI_n$;
(iii) $(A+A')B = AB + A'B$ *and* $A(B+B') = AB + AB'$;
(iv) $(aA)B = a(AB) = A(aB)$.

Proof.
(i) For admissible j,k, $((AB)C)_{j,k} = \sum_{s=1}^{p}\sum_{r=1}^{n} A_{j,r}B_{r,s}C_{s,k} = \sum_{r=1}^{n}\sum_{s=1}^{p} A_{j,r}B_{r,s}C_{s,k} = (A(BC))_{j,k}$ by finite distributivity. Thus $(AB)C = A(BC)$ by entrywise equality.
(ii) For admissible j,k, $(I_m A)_{j,k} = \sum_{r=1}^{m} \delta_{j,r}A_{r,k} = A_{j,k} = \sum_{r=1}^{n} A_{j,r}\delta_{r,k} = (AI_n)_{j,k}$. Hence $I_m A = A = AI_n$.
(iii) For admissible j,k, finite distributivity implies $((A+A')B)_{j,k} = \sum_{r=1}^{n}(A_{j,r}+A'_{j,r})B_{r,k} = (AB+A'B)_{j,k}$. Also implies $(A(B+B'))_{j,k} = \sum_{r=1}^{n} A_{j,r}(B_{r,k}+B'_{r,k}) = (AB+AB')_{j,k}$. Entrywise equality proves both laws.
(iv) For admissible j,k, $((aA)B)_{j,k} = a\sum_{r=1}^{n} A_{j,r}B_{r,k} = (a(AB))_{j,k} = (A(aB))_{j,k}$; hence the matrices are equal.

Structural Commentary: Each law reduces to corresponding identities among finite scalar sums.
Key Insight: Entrywise equality transfers field arithmetic to compatible matrices. □

Lemma 3.1.3. *Uniqueness of Two-Sided Inverses*
Let $A, B, C \in \mathrm{Mat}(n,n,\mathbb{F})$. If $AB = I_n$ and $BC = I_n$, then $A = C$.

Proof. By Proposition 3.1.2 and the hypotheses, $A = AI_n = A(BC) = (AB)C = I_n C = C$.
Structural Commentary: A common middle inverse forces the left and right inverses to coincide.
Key Insight: Associativity turns $AB = I_n = BC$ into $A = C$. □

Definition 3.1.4. *Inverse Matrix Notation*
If $A \in \mathrm{Mat}(n,n,\mathbb{F})$ is invertible, its unique two-sided inverse by Lemma 3.1.3 is denoted A^{-1}.
The set of invertible matrices in $\mathrm{Mat}(n,n,\mathbb{F})$ is denoted $\mathrm{Mat}(n,n,\mathbb{F})^{\times}$.

Proposition 3.1.5. *Matrix Spaces*
For $m,n \in \mathbb{Z}_{>0}$, the following hold.
(i) The entrywise operations make $\mathrm{Mat}(m,n,\mathbb{F})$ *a vector space over* $\mathbb{F}$.
(ii) The family $(E_{j,k})_{1\le j\le m,\ 1\le k\le n}$ *is a basis; hence* $\dim(\mathrm{Mat}(m,n,\mathbb{F})) = mn$.

Proof.
(i) The zero matrix and entrywise negatives supply the additive identity and inverses. Each remaining vector-space axiom holds in every entry by the corresponding field law, so it holds by matrix equality.
(ii) Every $A = [A_{j,k}]$ has the expansion $A = \sum_{j=1}^{m}\sum_{k=1}^{n} A_{j,k}E_{j,k}$. If $\sum_{j=1}^{m}\sum_{k=1}^{n} c_{j,k}E_{j,k} = 0$, then its (j,k)-entry is $c_{j,k} = 0$. Hence the family spans and is linearly independent. Its mn members form a basis, so the stated dimension is mn.

Structural Commentary: Entrywise field laws establish the space, and matrix units establish its basis.
Key Insight: Each matrix unit isolates one independent scalar coordinate. □

Proposition 3.1.6. *Matrix Product Entries Are Row Times Column*
If $A \in \mathrm{Mat}(m,n,\mathbb{F})$ and $B \in \mathrm{Mat}(n,p,\mathbb{F})$, then $(\forall\, j \in \{1,\dots,m\})(\forall\, k \in \{1,\dots,p\})\,(AB)_{j,k} = A_{j,\cdot}B_{\cdot,k}$.

Proof. Both sides equal $\sum_{r=1}^{n} A_{j,r}B_{r,k}$ by the definitions of matrix multiplication and row-column pairing.
Structural Commentary: Matrix multiplication is assembled entry-by-entry from row-column pairings.
Key Insight: Each entry of AB sees one row of A and one column of B. □

Definition 3.1.7. *Map Induced by a Matrix*
For $A \in \mathrm{Mat}(m,n,\mathbb{F})$, the *map induced by A* is $T_A : \mathbb{F}^n \to \mathbb{F}^m$ defined by $T_A(\mathbf{x}) = A\mathbf{x}$.

Proposition 3.1.8. *Matrix-Induced Maps Are Linear*
If $A \in \mathrm{Mat}(m,n,\mathbb{F})$, then $T_A : \mathbb{F}^n \to \mathbb{F}^m$ is linear.

Proof. For $\mathbf{x},\mathbf{y} \in \mathbb{F}^n$, $a,b \in \mathbb{F}$, and $j \in \{1,\dots,m\}$, $(T_A(a\mathbf{x}+b\mathbf{y}))_j = \sum_{k=1}^{n} A_{j,k}(ax_k + by_k) = a(T_A\mathbf{x})_j + b(T_A\mathbf{y})_j$.
Coordinatewise equality proves $T_A(a\mathbf{x}+b\mathbf{y}) = aT_A\mathbf{x} + bT_A\mathbf{y}$.
Structural Commentary: Matrix-vector multiplication preserves linear combinations.
Key Insight: Every matrix defines a canonical linear map between coordinate spaces. □

Proposition 3.1.9. *Matrix-Vector Products as Column Combinations*
If $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_n] \in \mathrm{Mat}(m,n,\mathbb{F})$ and $\mathbf{x} = (x_1,\dots,x_n)^t \in \mathbb{F}^n$, then $A\mathbf{x} = \sum_{k=1}^{n} x_k\mathbf{a}_k$.

Proof. For $j \in \{1,\dots,m\}$, both vectors have jth entry $\sum_{k=1}^{n} A_{j,k}x_k$.
Structural Commentary: Multiplying by a column selects a linear combination of the columns of A.
Key Insight: The coordinates of $\mathbf{x}$ are precisely the column coefficients. □

Proposition 3.1.10. *Matrix Products by Columns*
If $A \in \mathrm{Mat}(m,r,\mathbb{F})$ and $B = [\mathbf{b}_1 \ \cdots \ \mathbf{b}_n] \in \mathrm{Mat}(r,n,\mathbb{F})$, then $AB = [A\mathbf{b}_1 \ \cdots \ A\mathbf{b}_n]$.

Proof. For $j \in \{1,\dots,m\}$ and $k \in \{1,\dots,n\}$, the jth entries of the kth column of AB and of $A\mathbf{b}_k$ both equal $\sum_{\ell=1}^{r} A_{j,\ell}B_{\ell,k}$.
Structural Commentary: Matrix products apply A to columns of B.
Key Insight: The columns of AB are obtained by applying A to the columns of B. □

Proposition 3.1.11. *Matrix Products as Sums of Outer Products*
Let $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_r] \in \mathrm{Mat}(m,r,\mathbb{F})$ and $B \in \mathrm{Mat}(r,n,\mathbb{F})$. If the ℓth row of B is $\mathbf{b}_\ell^t$ with $\mathbf{b}_\ell \in \mathbb{F}^n$, then $AB = \sum_{\ell=1}^{r} \mathbf{a}_\ell\mathbf{b}_\ell^t$.

Proof. For admissible j,k, the (j,k)-entry of $\mathbf{a}_\ell\mathbf{b}_\ell^t$ is $A_{j,\ell}B_{\ell,k}$, so the corresponding entry of the stated sum is $\sum_{\ell=1}^{r} A_{j,\ell}B_{\ell,k} = (AB)_{j,k}$.
Structural Commentary: Column-row products decompose a matrix product into single column-row pieces.
Key Insight: Each shared index ℓ contributes one outer product. □

Definition 3.1.12. *Column Space, Matrix Rank, and Nullity*
Let $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_n] \in \mathrm{Mat}(m,n,\mathbb{F})$.
(i) $\mathrm{col}(A) := \mathrm{span}(\mathbf{a}_1,\dots,\mathbf{a}_n) \subseteq \mathbb{F}^m$, and $\mathrm{row}(A) := \mathrm{col}(A^t) \subseteq \mathbb{F}^n$.
(ii) $\ker(A) := \{\mathbf{x} \in \mathbb{F}^n : A\mathbf{x} = \mathbf{0}\}$ is the *nullspace*, and $\mathrm{nullity}(A) := \dim(\ker(A))$.
(iii) $\mathrm{rank}(A) := \dim(\mathrm{col}(A))$ is the column rank, while $\dim(\mathrm{row}(A))$ is the row rank.
(iv) The matrix A has *full rank* iff $\mathrm{rank}(A) = \min(m,n)$, *full column rank* iff $\mathrm{rank}(A) = n$, and *full row rank* iff $\mathrm{rank}(A) = m$.
$\mathrm{range}(T_A) = \mathrm{col}(A)$ and $\mathrm{range}(T_{A^t}) = \mathrm{row}(A)$ by Proposition 3.1.9, while $\ker(T_A) = \ker(A)$ by definition.
These three sets are subspaces by Proposition 3.1.8 and Proposition 1.6.3, so the stated dimensions are defined.

Proposition 3.1.13. *Solvability and Complete Solution Sets*
Let $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_n] \in \mathrm{Mat}(m,n,\mathbb{F})$ and $\mathbf{b} \in \mathbb{F}^m$. Then:
(i) The system $A\mathbf{x} = \mathbf{b}$ with $\mathbf{x} \in \mathbb{F}^n$ is solvable iff $\mathbf{b} \in \mathrm{col}(A)$.
(ii) If $A\mathbf{x}_p = \mathbf{b}$, its solution set is $\mathbf{x}_p + \ker(A) = \{\mathbf{x}_p + \mathbf{x}_0 : \mathbf{x}_0 \in \ker(A)\}$.

Proof.

(i) ($\Rightarrow$) If $A\mathbf{x} = \mathbf{b}$ for $\mathbf{x} = (x_1,\dots,x_n)^t$, then $\mathbf{b} = A\mathbf{x} = \sum_{j=1}^{n} x_j\mathbf{a}_j \in \mathrm{col}(A)$ by Proposition 3.1.9.

(i) ($\Leftarrow$) If $\mathbf{b} \in \mathrm{col}(A)$, then $(\exists\, x_1,\dots,x_n \in \mathbb{F})\, \mathbf{b} = \sum_{j=1}^{n} x_j\mathbf{a}_j$. For $\mathbf{x} = (x_1,\dots,x_n)^t$, $A\mathbf{x} = \mathbf{b}$ by Proposition 3.1.9.

(ii) If $A\mathbf{x}_p = \mathbf{b}$, then $(\forall\, \mathbf{x} \in \mathbb{F}^n)\, A\mathbf{x} = \mathbf{b} \iff A(\mathbf{x}-\mathbf{x}_p) = \mathbf{0} \iff \mathbf{x}-\mathbf{x}_p \in \ker(A) \iff \mathbf{x} \in \mathbf{x}_p + \ker(A)$ by Proposition 3.1.8.

Structural Commentary: Column expansion proves existence, while subtraction identifies the complete affine fiber.
Key Insight: Column space decides existence; kernel decides nonuniqueness. □

Proposition 3.1.14. *Elementary Transpose Rules*
Let $A, C \in \mathrm{Mat}(m,n,\mathbb{F})$ and $a \in \mathbb{F}$. Then:
(i) $(A^t)^t = A$;
(ii) $(A+C)^t = A^t + C^t$ and $(aA)^t = aA^t$;
(iii) $I_n^t = I_n$.

Proof.

(i) For admissible j,k, $((A^t)^t)_{j,k} = (A^t)_{k,j} = A_{j,k}$.
(ii) For admissible j,k, $((A+C)^t)_{j,k} = A_{k,j} + C_{k,j} = (A^t + C^t)_{j,k}$ and $((aA)^t)_{j,k} = aA_{k,j} = (aA^t)_{j,k}$.
(iii) For $j,k \in \{1,\dots,n\}$, $(I_n^t)_{j,k} = \delta_{k,j} = \delta_{j,k} = (I_n)_{j,k}$.

Structural Commentary: Each identity follows by swapping the two entry indices.
Key Insight: Transposition preserves entrywise operations and reverses index order. □

Example 3.1.15. *Symmetric and Skew-Symmetric Decomposition*
Assume $2 \neq 0$ in $\mathbb{F}$ and set $M := \mathrm{Mat}(n, n, \mathbb{F})$. Define $\mathrm{Sym}_n(\mathbb{F}) := \{A \in M : A^t = A\}$ and $\mathrm{Skew}_n(\mathbb{F}) := \{A \in M : A^t = -A\}$.
The map $\tau : M \to M$, $\tau(A) := A^t$, is linear by Proposition 3.1.14(ii). Thus $\tau - I_M, \tau + I_M \in \mathcal{L}(M)$ by Proposition 1.5.5.
Since $\mathrm{Sym}_n(\mathbb{F}) = \ker(\tau - I_M)$ and $\mathrm{Skew}_n(\mathbb{F}) = \ker(\tau + I_M)$, both are subspaces of M by Proposition 1.6.3(i).
For $A \in M$, set $S_A := \frac{1}{2}(A + A^t)$ and $K_A := \frac{1}{2}(A - A^t)$. Then $S_A^t = S_A$, $K_A^t = -K_A$, and $A = S_A + K_A$ by Proposition 3.1.14.
Hence $M = \mathrm{Sym}_n(\mathbb{F}) + \mathrm{Skew}_n(\mathbb{F})$. If $A \in \mathrm{Sym}_n(\mathbb{F}) \cap \mathrm{Skew}_n(\mathbb{F})$, then $A = A^t = -A$ and $2A = 0$, whence $A = 0$ because $2 \neq 0$ is invertible in $\mathbb{F}$. Therefore $M = \mathrm{Sym}_n(\mathbb{F}) \oplus \mathrm{Skew}_n(\mathbb{F})$ by Proposition 2.1.8.
Structural Commentary: Transpose splits a matrix into its even and odd parts.
Key Insight: The directness of the split uses the ability to divide by 2.

Proposition 3.1.16. *Transpose Reverses Products*
If $A \in \mathrm{Mat}(m, n, \mathbb{F})$ and $B \in \mathrm{Mat}(n, p, \mathbb{F})$, then $(AB)^t = B^t A^t$.

Proof. For $j \in \{1, \ldots, p\}$ and $k \in \{1, \ldots, m\}$, $((AB)^t)_{j,k} = (AB)_{k,j} = \sum_{\ell=1}^{n} A_{k,\ell} B_{\ell,j}$.
The same sum equals $\sum_{\ell=1}^{n} (B^t)_{j,\ell} (A^t)_{\ell,k} = (B^t A^t)_{j,k}$, so the matrices are equal.
Structural Commentary: Transposition swaps the order of composition encoded by matrix multiplication.
Key Insight: Rows become columns, so the product order reverses. □

Corollary 3.1.17. *Matrix Inverses and Transposes Reverse Products*
Let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$ be invertible. Then:
(i) AB is invertible and $(AB)^{-1} = B^{-1}A^{-1}$;
(ii) A^t is invertible and $(A^t)^{-1} = (A^{-1})^t$.

Proof.
(i) For $D := B^{-1}A^{-1}$, $D(AB) = I_n = (AB)D$ by Proposition 3.1.2 and the inverse equations; hence $(AB)^{-1} = D$.
(ii) For $C := (A^{-1})^t$, $CA^t = I_n = A^t C$ by Proposition 3.1.16 and Proposition 3.1.14(iii); hence $(A^t)^{-1} = C$.
Structural Commentary: Each claim verifies the two inverse equations after reversing multiplication order.
Key Insight: Both inversion and transposition reverse products. □

3.2 Coordinates and Matrix Representations

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$.

Definition 3.2.1. *Coordinate Vector*
Let $n \geq 1$, let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ be a basis of a vector space $\mathcal{V}$, and let $\mathbf{v} \in \mathcal{V}$. By Proposition 1.3.3, $(\exists!\, (c_1, \ldots, c_n) \in \mathbb{F}^n)\, \mathbf{v} = \sum_{j=1}^{n} c_j \mathbf{v}_j$.
For this tuple, the *β-coordinate vector* of $\mathbf{v}$ is $[\mathbf{v}]_\beta := (c_1, \ldots, c_n)^t \in \mathbb{F}^n$.
The function $[\cdot]_\beta : \mathcal{V} \to \mathbb{F}^n$ is the *β-coordinate map*. The order of the list β fixes the order of the coordinates.

Proposition 3.2.2. *Coordinate Maps Are Isomorphisms*
Let $n \geq 1$, and let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ be a basis of a vector space $\mathcal{V}$. The coordinate map $[\cdot]_\beta : \mathcal{V} \to \mathbb{F}^n$ has the following properties:
(i) It is linear.
(ii) It is injective.
(iii) It is surjective and hence an isomorphism.

Proof.
(i) Let $\mathbf{u}, \mathbf{v} \in \mathcal{V}$ and $c, d \in \mathbb{F}$, and write $[\mathbf{u}]_\beta = (a_1, \ldots, a_n)^t$ and $[\mathbf{v}]_\beta = (b_1, \ldots, b_n)^t$.
Then $[c\mathbf{u} + d\mathbf{v}]_\beta = (ca_1 + db_1, \ldots, ca_n + db_n)^t = c[\mathbf{u}]_\beta + d[\mathbf{v}]_\beta$, so $[\cdot]_\beta$ is linear.
(ii) If $[\mathbf{u}]_\beta = [\mathbf{v}]_\beta$, then $\mathbf{u}$ and $\mathbf{v}$ have the same coefficients in β, so $\mathbf{u} = \mathbf{v}$ by Proposition 1.3.3. Thus $[\cdot]_\beta$ is injective.
(iii) For $(c_1, \ldots, c_n)^t \in \mathbb{F}^n$, set $\mathbf{v} := \sum_{j=1}^{n} c_j \mathbf{v}_j$. Then $[\mathbf{v}]_\beta = (c_1, \ldots, c_n)^t$, so $[\cdot]_\beta$ is surjective.
It is therefore an isomorphism by Proposition 1.6.7.
Structural Commentary: The three checks compare vectors with their unique coefficient tuples.
Key Insight: An ordered basis identifies the vector space with its coordinate space without losing linear structure. □

Definition 3.2.3. *Matrix Representation*
Let $n, m \geq 1$, let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ be a basis of $\mathcal{V}$, and let $\gamma = (\mathbf{w}_1, \ldots, \mathbf{w}_m)$ be a basis of $\mathcal{W}$.
For $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, the *matrix of T from β-coordinates to γ-coordinates* is $[T]_{\gamma \leftarrow \beta} := \big[[T(\mathbf{v}_1)]_\gamma \ \cdots \ [T(\mathbf{v}_n)]_\gamma\big] \in \mathrm{Mat}(m, n, \mathbb{F})$.
Thus its jth column is the uniquely determined coordinate vector $[T(\mathbf{v}_j)]_\gamma$.

Proposition 3.2.4. *Matrices Respect Linear Combinations of Maps*
Let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ be a basis of $\mathcal{V}$, and let $\gamma = (\mathbf{w}_1, \ldots, \mathbf{w}_m)$ be a basis of $\mathcal{W}$.
If $S, T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ and $a \in \mathbb{F}$, then $[aS + T]_{\gamma \leftarrow \beta} = a[S]_{\gamma \leftarrow \beta} + [T]_{\gamma \leftarrow \beta}$.

Proof. By Proposition 1.5.5, $aS + T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. For $j \in \{1, \ldots, n\}$, $[(aS + T)\mathbf{v}_j]_\gamma = [aS\mathbf{v}_j + T\mathbf{v}_j]_\gamma = a[S\mathbf{v}_j]_\gamma + [T\mathbf{v}_j]_\gamma$ by Proposition 3.2.2(i). These are the respective jth columns of the two matrices, so the matrices are equal.
Structural Commentary: The proof compares the coordinate images of each domain basis vector.
Key Insight: Taking a matrix representation preserves the vector-space operations on linear maps. □

Proposition 3.2.5. *Matrix Representation Acts on Coordinates*
Let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ be a basis of $\mathcal{V}$, let $\gamma = (\mathbf{w}_1, \ldots, \mathbf{w}_m)$ be a basis of $\mathcal{W}$, and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Then $(\forall\, \mathbf{v} \in \mathcal{V})\, [T(\mathbf{v})]_\gamma = [T]_{\gamma \leftarrow \beta} [\mathbf{v}]_\beta$.

Proof. Let $\mathbf{v} \in \mathcal{V}$, and write $[\mathbf{v}]_\beta = (a_1, \ldots, a_n)^t$, so $\mathbf{v} = \sum_{j=1}^{n} a_j \mathbf{v}_j$. By linearity of T and Proposition 3.2.2(i), $[T(\mathbf{v})]_\gamma = \sum_{j=1}^{n} a_j [T(\mathbf{v}_j)]_\gamma$.
The summands are the columns of $[T]_{\gamma \leftarrow \beta}$, and this sum equals $[T]_{\gamma \leftarrow \beta} [\mathbf{v}]_\beta$ by Proposition 3.1.9.
Structural Commentary: The proof expands a vector in the domain basis and tracks that expansion through T.
Key Insight: Applying a linear map becomes matrix multiplication after both bases are fixed. □

3.3 Matrix-Induced Maps and Rank

Throughout this subsection, all matrices are over the same fixed field $\mathbb{F}$, and every matrix size is a positive integer.

Corollary 3.3.1. *Matrix Rank-Nullity*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$. Then:
(i) $\dim(\ker(A)) + \dim(\mathrm{col}(A)) = n$; *equivalently,* $\mathrm{nullity}(A) + \mathrm{rank}(A) = n$.
(ii) If $m = n$, then $\ker(A) = \{\mathbf{0}\}$ iff $\mathrm{col}(A) = \mathbb{F}^n$.

Proof.
(i) Write $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_n]$. The map $T_A : \mathbb{F}^n \to \mathbb{F}^m$ is linear by Proposition 3.1.8.
For $\mathbf{x} = (x_1, \ldots, x_n)^t$, $T_A\mathbf{x} = A\mathbf{x} = \sum_{j=1}^{n} x_j\mathbf{a}_j$ by Proposition 3.1.9.
Hence $\mathrm{range}(T_A) = \mathrm{col}(A)$, while $\ker(T_A) = \ker(A)$ holds by $T_A\mathbf{x} = A\mathbf{x}$; $\dim(\ker(A)) + \dim(\mathrm{col}(A)) = n$ by Theorem 1.7.3(ii).
The equivalent identity is the same equality under $\mathrm{nullity}(A) = \dim(\ker(A))$ and $\mathrm{rank}(A) = \dim(\mathrm{col}(A))$.
(ii) ($\Rightarrow$) Suppose $m = n$ and $\ker(A) = \{\mathbf{0}\}$. Then $\dim(\mathrm{col}(A)) = n = \dim(\mathbb{F}^n)$ by part (i).
Since $\mathrm{col}(A) \subseteq \mathbb{F}^n$, $\mathrm{col}(A) = \mathbb{F}^n$ by Proposition 1.4.3(ii).
(ii) ($\Leftarrow$) Suppose $m = n$ and $\mathrm{col}(A) = \mathbb{F}^n$. Then $\dim(\ker(A)) = 0$ by part (i).
The zero subspace and $\ker(A)$ have the same dimension, so $\ker(A) = \{\mathbf{0}\}$ by Proposition 1.4.3(ii).
Structural Commentary: Rank-nullity transfers through the induced map; the square case compares full-dimensional subspaces.
Key Insight: A matrix inherits rank-nullity from its coordinate-space map. □

Theorem 3.3.2. *Row Rank Equals Column Rank*
For $A \in \mathrm{Mat}(m,n,\mathbb{F})$, $\dim(\mathrm{row}(A)) = \dim(\mathrm{col}(A))$. Equivalently, $\mathrm{rank}(A^t) = \mathrm{rank}(A)$.

Proof. Let $C = [\mathbf{c}_1 \ \cdots \ \mathbf{c}_q] \in \mathrm{Mat}(p,q,\mathbb{F})$ be arbitrary, and set $s := \mathrm{rank}(C)$.
If $s = 0$, then $\dim(\mathrm{col}(C)) = 0 = \dim(\{\mathbf{0}\})$, so $\mathrm{col}(C) = \{\mathbf{0}\}$ by Proposition 1.4.3(ii). Hence $C = 0$ and $\mathrm{rank}(C^t) = 0$.
Suppose $s > 0$. A basis sublist $(\mathbf{c}_{j_1}, \ldots, \mathbf{c}_{j_s})$ of the columns exists by Theorem 1.3.12; set $B := [\mathbf{c}_{j_1} \ \cdots \ \mathbf{c}_{j_s}] \in \mathrm{Mat}(p,s,\mathbb{F})$.
The relation $(\forall\, k \in \{1,\ldots,q\})(\exists!\, \mathbf{x}_k \in \mathbb{F}^s)\, \mathbf{c}_k = B\mathbf{x}_k$ holds by Proposition 1.3.3.
Set $X := [\mathbf{x}_1 \ \cdots \ \mathbf{x}_q] \in \mathrm{Mat}(s,q,\mathbb{F})$. Then $C = BX$ by Proposition 3.1.10, and $C^t = X^tB^t$ by Proposition 3.1.16.
Each column of C^t lies in the span of the s columns of X^t by Proposition 3.1.10 and Proposition 3.1.9.
Hence $\mathrm{col}(C^t)$ has a basis of at most s members by Theorem 1.3.12, and $\mathrm{rank}(C^t) \le s = \mathrm{rank}(C)$.
Thus $\mathrm{rank}(C^t) \le \mathrm{rank}(C)$ for the arbitrary matrix C above. For $C = A$, $\mathrm{rank}(A^t) \le \mathrm{rank}(A)$.
For $C = A^t$, $\mathrm{rank}(A) \le \mathrm{rank}(A^t)$ because $(A^t)^t = A$ by Proposition 3.1.14(i).
Structural Commentary: A column-basis factorization proves one rank inequality; transposition supplies the reverse inequality.
Key Insight: Transposition preserves the number of independent matrix directions. □

Perspective 3.3.3. *Row and Column Spaces Have Different Hosts*
For $A \in \mathrm{Mat}(m,n,\mathbb{F})$, $\mathrm{row}(A) = \mathrm{col}(A^t) \subseteq \mathbb{F}^n$ and $\mathrm{col}(A) \subseteq \mathbb{F}^m$.
When $m \neq n$, Theorem 3.3.2 identifies their dimensions, not the subspaces in their different ambient spaces.

Theorem 3.3.4. *Four Fundamental Matrix Subspaces*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ and let $r := \mathrm{rank}(A)$. Then:
(i) $\mathrm{row}(A), \ker(A) \subseteq \mathbb{F}^n$ *and* $\mathrm{col}(A), \ker(A^t) \subseteq \mathbb{F}^m$.
(ii) $\dim(\mathrm{col}(A)) = \dim(\mathrm{row}(A)) = r$, $\dim(\ker(A)) = n - r$, *and* $\dim(\ker(A^t)) = m - r$.

Proof.
(i) The row and column inclusions hold by their entry lengths, while the kernel inclusions hold by the domains of T_A and T_{A^t}.
(ii) The equality $\dim(\mathrm{col}(A)) = r$ holds by the definition of rank, and $\dim(\mathrm{row}(A)) = r = \mathrm{rank}(A^t)$ by Theorem 3.3.2.
Hence $\dim(\ker(A)) = n - r$ and $\dim(\ker(A^t)) = m - r$ by Corollary 3.3.1(i) for A and A^t, respectively.
Structural Commentary: Ambient sizes place the subspaces; row-column equality and rank-nullity determine their dimensions.
Key Insight: One rank parameter controls both image and kernel dimensions. □

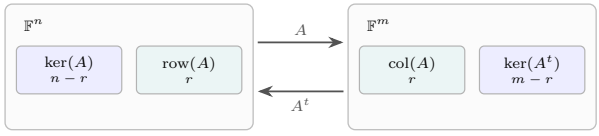

Figure 12: Hosts and dimensions of the four fundamental subspaces, with arrows for $A : \mathbb{F}^n \to \mathbb{F}^m$ and $A^t : \mathbb{F}^m \to \mathbb{F}^n$.

Figure 12 illustrates Theorem 3.3.4. Its boxes encode only ambient hosts and dimensions, not direct sums or orthogonality.

Corollary 3.3.5. *Homogeneous Systems with More Variables Than Equations*
If $A \in \mathrm{Mat}(m,n,\mathbb{F})$ with $n > m$, then $(\exists\, \mathbf{x} \in \mathbb{F}^n \setminus \{\mathbf{0}\})\, A\mathbf{x} = \mathbf{0}$.

Proof. The map $T_A : \mathbb{F}^n \to \mathbb{F}^m$ is linear by Proposition 3.1.8 and is not injective by Corollary 1.7.4.
Thus $\ker(T_A) \neq \{\mathbf{0}\}$ by Proposition 1.6.2. Choose $\mathbf{x} \in \ker(T_A) \setminus \{\mathbf{0}\}$. Then $A\mathbf{x} = T_A\mathbf{x} = \mathbf{0}$.
Structural Commentary: The dimension obstruction transfers from the induced map to the homogeneous system.
Key Insight: More variables force a nontrivial nullspace. □

Corollary 3.3.6. *Inhomogeneous Systems with More Equations Than Variables*
If $A \in \mathrm{Mat}(m,n,\mathbb{F})$ with $m > n$, then $(\exists\, \mathbf{b} \in \mathbb{F}^m)(\forall\, \mathbf{x} \in \mathbb{F}^n)\, A\mathbf{x} \neq \mathbf{b}$.

Proof. The map $T_A : \mathbb{F}^n \to \mathbb{F}^m$ is linear by Proposition 3.1.8 and is not surjective by Corollary 1.7.5.
Choose $\mathbf{b} \in \mathbb{F}^m \setminus \mathrm{range}(T_A)$. Then $(\forall\, \mathbf{x} \in \mathbb{F}^n)\, A\mathbf{x} = T_A\mathbf{x} \neq \mathbf{b}$.
Structural Commentary: The dimension obstruction leaves a right-hand side outside the induced map's range.
Key Insight: More equations force an unreachable right-hand side. □

3.4 Invertibility and the Matrix-Map Dictionary

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$, and every matrix size is a positive integer.

Theorem 3.4.1. *Columns of an Invertible Matrix Form a Basis*
Let $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_n] \in \mathrm{Mat}(n, n, \mathbb{F})$ *be invertible. Then* $(\mathbf{a}_1, \ldots, \mathbf{a}_n)$ *is a basis of* $\mathbb{F}^n$.

Proof. Fix $\mathbf{y} \in \mathbb{F}^n$ and set $\mathbf{x} = (x_1, \ldots, x_n)^t := A^{-1}\mathbf{y}$.
Then $\mathbf{y} = I_n\mathbf{y} = (AA^{-1})\mathbf{y} = A\mathbf{x} = \sum_{j=1}^{n} x_j\mathbf{a}_j$ by Proposition 3.1.2, the inverse relation $AA^{-1} = I_n$, and Proposition 3.1.9.
If $\mathbf{c} = (c_1, \ldots, c_n)^t$ satisfies $\mathbf{y} = \sum_{j=1}^{n} c_j\mathbf{a}_j = A\mathbf{c}$, then $\mathbf{c} = I_n\mathbf{c} = (A^{-1}A)\mathbf{c} = A^{-1}\mathbf{y} = \mathbf{x}$ by Proposition 3.1.2 and $A^{-1}A = I_n$.
Hence $(\forall\, \mathbf{y} \in \mathbb{F}^n)(\exists!\, \mathbf{x} \in \mathbb{F}^n)\, \mathbf{y} = \sum_{j=1}^{n} x_j\mathbf{a}_j$, so $(\mathbf{a}_1, \ldots, \mathbf{a}_n)$ is a basis by Proposition 1.3.3.
Structural Commentary: The inverse constructs the unique coefficient column required by the basis criterion.
Key Insight: Invertibility turns matrix multiplication into unique coordinate representation. □

Theorem 3.4.2. *One-Sided Inverses of Square Matrices*
Let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$. *If* $AB = I_n$, *then* $BA = I_n$.

Proof. The induced map $T_B : \mathbb{F}^n \to \mathbb{F}^n$ is linear by Proposition 3.1.8.
If $\mathbf{x} \in \ker(T_B)$, then $B\mathbf{x} = \mathbf{0}$ and $\mathbf{x} = I_n\mathbf{x} = (AB)\mathbf{x} = A(B\mathbf{x}) = \mathbf{0}$ by Proposition 3.1.2; hence T_B is injective by Proposition 1.6.2.
It is surjective by Theorem 1.7.7, $(ii) \Rightarrow (iii)$. Fix $\mathbf{y} \in \mathbb{F}^n$ and choose $\mathbf{x} \in \mathbb{F}^n$ satisfying $\mathbf{y} = B\mathbf{x}$.
Then $BA\mathbf{y} = BA(B\mathbf{x}) = B((AB)\mathbf{x}) = B\mathbf{x} = \mathbf{y}$ by Proposition 3.1.2.
Substituting the columns of I_n for $\mathbf{y}$, $BA = I_n$ by Proposition 3.1.10 and Proposition 3.1.2.
Structural Commentary: Kernel triviality and equal dimension convert a left inverse into the missing right inverse.
Key Insight: Surjectivity lets the known inverse relation reach every vector. □

Motivation 3.4.3. *Coordinate Encoding*
Fixing bases encodes a linear map by a matrix. The next results verify composition compatibility and exact matrix recovery.

Proposition 3.4.4. *Composition and Matrix Multiplication*
Let $\alpha = (\mathbf{u}_1, \ldots, \mathbf{u}_\ell)$, $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$, *and* $\delta = (\mathbf{w}_1, \ldots, \mathbf{w}_m)$ *be bases of* $\mathcal{U}$, $\mathcal{V}$, *and* $\mathcal{W}$, *respectively.*
If $T \in \mathcal{L}(\mathcal{U}, \mathcal{V})$ *and* $S \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, *then* $[ST]_{\delta\leftarrow\alpha} = [S]_{\delta\leftarrow\beta}[T]_{\beta\leftarrow\alpha}$.

Proof. $ST \in \mathcal{L}(\mathcal{U}, \mathcal{W})$ by Proposition 1.5.7(i). Fix $j \in \{1, \ldots, \ell\}$.
Then $[(ST)\mathbf{u}_j]_\delta = [S(T\mathbf{u}_j)]_\delta = [S]_{\delta\leftarrow\beta}[T\mathbf{u}_j]_\beta$ by Proposition 3.2.5, with input $T\mathbf{u}_j$.
The first and last terms are jth columns of $[ST]_{\delta\leftarrow\alpha}$ and $[S]_{\delta\leftarrow\beta}[T]_{\beta\leftarrow\alpha}$, respectively, by Definition 3.2.3 and Proposition 3.1.10.
Since j was arbitrary, the matrices are equal by Definition 3.1.1(i).
Structural Commentary: Comparing basis-vector images identifies the corresponding columns of the composition and product matrices.
Key Insight: Composition order becomes matrix multiplication order. □

Theorem 3.4.5. *Linear Maps and Matrices Are the Same Data*
Let $\dim(\mathcal{V}) = n \geq 1$ *and* $\dim(\mathcal{W}) = m \geq 1$, *and fix bases* $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ *and* $\gamma = (\mathbf{w}_1, \ldots, \mathbf{w}_m)$.
Define $\Phi : \mathcal{L}(\mathcal{V}, \mathcal{W}) \to \mathrm{Mat}(m, n, \mathbb{F})$ *by* $\Phi(T) := [T]_{\gamma\leftarrow\beta}$. *Then:*

(i) Φ *is an isomorphism.*
(ii) $\dim(\mathcal{L}(\mathcal{V}, \mathcal{W})) = mn$.

Proof.

(i) Both spaces are vector spaces by Proposition 1.5.5 and Proposition 3.1.5(i), and Φ is linear by Proposition 3.2.4.
Suppose $\Phi(S) = \Phi(T)$. Then $(\forall\, j \in \{1, \ldots, n\})\, [S\mathbf{v}_j]_\gamma = [T\mathbf{v}_j]_\gamma$ by Definition 3.2.3, so $(\forall\, j \in \{1, \ldots, n\})\, S\mathbf{v}_j = T\mathbf{v}_j$ by Proposition 3.2.2(ii). Hence $S = T$ by Proposition 1.5.8, and Φ is injective.
Fix $A = [a_{i,j}] \in \mathrm{Mat}(m, n, \mathbb{F})$ and set $\mathbf{z}_j := \sum_{i=1}^{m} a_{i,j}\mathbf{w}_i$ $(j \in \{1, \ldots, n\})$.
The relation $(\exists!\, R \in \mathcal{L}(\mathcal{V}, \mathcal{W}))(\forall\, j \in \{1, \ldots, n\})\, R\mathbf{v}_j = \mathbf{z}_j$ holds by Proposition 1.5.8; fix this R.
Then $(\forall\, j \in \{1, \ldots, n\})\, [R\mathbf{v}_j]_\gamma = (a_{1,j}, \ldots, a_{m,j})^t$ by Definition 3.2.1, so $\Phi(R) = A$ by Definition 3.2.3.
Thus Φ is surjective and therefore an isomorphism by Proposition 1.6.7.

(ii) The matrix units form a basis of $\mathrm{Mat}(m, n, \mathbb{F})$ with mn members by Proposition 3.1.5(ii).
Their inverse images under Φ form a basis of $\mathcal{L}(\mathcal{V}, \mathcal{W})$ by part (i) and Proposition 1.7.8. Hence $\dim(\mathcal{L}(\mathcal{V}, \mathcal{W})) = mn$.

Structural Commentary: Basis images establish the isomorphism; transporting matrix units determines the dimension.
Key Insight: A matrix records exactly the images of a domain basis. □

Perspective 3.4.6. *Finite-Support Coordinate Model*
Proposition 3.2.2 and Theorem 3.4.5 identify finite-dimensional spaces and their maps with coordinate columns and matrices after bases are chosen. Definition 2.1.20 supplies the countable finite-support model $\mathbb{F}^{(\mathbb{N})}$; the analogy stops before infinite linear combinations.

3.5 Change of Basis and Coordinate Transformations

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$.

Definition 3.5.1. *Change-of-Basis Matrix*
Let $n \geq 1$, and let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ and $\gamma = (\mathbf{w}_1, \ldots, \mathbf{w}_n)$ be bases of the same vector space $\mathcal{V}$.
The *change-of-basis matrix from β-coordinates to γ-coordinates* is $C_{\gamma\leftarrow\beta} := [I_\mathcal{V}]_{\gamma\leftarrow\beta} \in \mathrm{Mat}(n, n, \mathbb{F})$.
The identity $(\forall\, \mathbf{v} \in \mathcal{V})\, [\mathbf{v}]_\gamma = C_{\gamma\leftarrow\beta}[\mathbf{v}]_\beta$ holds by Proposition 3.2.5, with $T = I_\mathcal{V}$.

Figure 13: Direction of the coordinate rewrite implemented by $C_{\gamma\leftarrow\beta}$.

Figure 13 depicts $C_{\gamma\leftarrow\beta}$ carrying $[\mathbf{v}]_\beta$ to $[\mathbf{v}]_\gamma$; Definition 3.5.1 owns the exact identity.

Theorem 3.5.2. *Change-of-Basis Matrices*
Let $\mathcal{V}$ be n-dimensional, where $n \geq 1$, and let β be a basis of $\mathcal{V}$.

(i) If γ is a basis of $\mathcal{V}$, then $C_{\gamma\leftarrow\beta}$ is invertible with $(C_{\gamma\leftarrow\beta})^{-1} = C_{\beta\leftarrow\gamma}$.
(ii) If $S \in \mathrm{Mat}(n, n, \mathbb{F})$ is invertible, then $S = C_{\gamma\leftarrow\beta}$ for a basis γ of $\mathcal{V}$.

Proof.

(i) The identity $[I_\mathcal{V}]_{\beta\leftarrow\beta} = I_n = [I_\mathcal{V}]_{\gamma\leftarrow\gamma}$ holds by Definition 3.2.1 and Definition 3.2.3.
Hence $C_{\beta\leftarrow\gamma}C_{\gamma\leftarrow\beta} = [I_\mathcal{V} I_\mathcal{V}]_{\beta\leftarrow\beta} = I_n$ and $C_{\gamma\leftarrow\beta}C_{\beta\leftarrow\gamma} = [I_\mathcal{V} I_\mathcal{V}]_{\gamma\leftarrow\gamma} = I_n$ by Definition 3.5.1 and Proposition 3.4.4.
Thus $C_{\gamma\leftarrow\beta}$ is invertible with inverse $C_{\beta\leftarrow\gamma}$.
(ii) Write $S^{-1} = [\mathbf{s}_1 \ \cdots \ \mathbf{s}_n]$. The relation $(\forall j \in \{1, \ldots, n\})(\exists!\, \mathbf{w}_j \in \mathcal{V})\, [\mathbf{w}_j]_\beta = \mathbf{s}_j$ holds by Proposition 3.2.2(ii),(iii).
Set $\gamma := (\mathbf{w}_1, \ldots, \mathbf{w}_n)$. The matrix S^{-1} is invertible with inverse S, so $(\mathbf{s}_1, \ldots, \mathbf{s}_n)$ is a basis of $\mathbb{F}^n$ by Theorem 3.4.1.
The map $[\cdot]_\beta^{-1} : \mathbb{F}^n \to \mathcal{V}$ is an isomorphism by Proposition 3.2.2(iii), so γ is a basis of $\mathcal{V}$ by Proposition 1.7.8.
The relation $(\forall j \in \{1, \ldots, n\})\, (C_{\beta\leftarrow\gamma})_{\cdot,j} = [\mathbf{w}_j]_\beta = \mathbf{s}_j$ holds by Definition 3.5.1 and Definition 3.2.3; hence $C_{\beta\leftarrow\gamma} = S^{-1}$ by Definition 3.1.1(i). Therefore $C_{\gamma\leftarrow\beta} = S$ by part (i) and Lemma 3.1.3.

Structural Commentary: Composition proves reciprocity; inverse-coordinate columns realize an arbitrary invertible matrix.
Key Insight: Coordinate isomorphisms transport bases in both directions. □

Theorem 3.5.3. *Change of Bases for a Linear Map*
Let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ and $\beta' = (\mathbf{v}'_1, \ldots, \mathbf{v}'_n)$ be bases of $\mathcal{V}$, and let $\gamma = (\mathbf{w}_1, \ldots, \mathbf{w}_m)$ and $\gamma' = (\mathbf{w}'_1, \ldots, \mathbf{w}'_m)$ be bases of $\mathcal{W}$, where $n, m \geq 1$. Then $[T]_{\gamma'\leftarrow\beta'} = C_{\gamma'\leftarrow\gamma}[T]_{\gamma\leftarrow\beta}C_{\beta\leftarrow\beta'}$.

Proof. $T = I_\mathcal{W} T I_\mathcal{V}$ by Proposition 1.5.7(ii),(iii). Hence $[T]_{\gamma'\leftarrow\beta'} = [I_\mathcal{W} T I_\mathcal{V}]_{\gamma'\leftarrow\beta'} = [I_\mathcal{W}]_{\gamma'\leftarrow\gamma}[T]_{\gamma\leftarrow\beta}[I_\mathcal{V}]_{\beta\leftarrow\beta'}$ by Proposition 3.4.4 twice. The outer matrices are $C_{\gamma'\leftarrow\gamma}$ and $C_{\beta\leftarrow\beta'}$ by Definition 3.5.1.
Structural Commentary: Identity maps insert the codomain and domain coordinate transitions around the fixed representation.
Key Insight: Output coordinates transform on the left; input coordinates transform on the right. □

3.6 Rank and Invertibility Consequences

Throughout this subsection, all matrices are over the same fixed field $\mathbb{F}$, and every matrix size is a positive integer.

Corollary 3.6.1. *Basis Columns Form an Invertible Matrix*
Let $n \geq 1$. If $(\mathbf{a}_1, \ldots, \mathbf{a}_n)$ is a basis of $\mathbb{F}^n$, then $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_n] \in \mathrm{Mat}(n, n, \mathbb{F})$ is invertible.

Proof. Let $\epsilon = (\mathbf{e}_1, \ldots, \mathbf{e}_n)$ be the ordered list of columns of I_n, and set $\alpha := (\mathbf{a}_1, \ldots, \mathbf{a}_n)$.
The matrix I_n is invertible with inverse I_n by Proposition 3.1.2(ii), so ϵ is a basis of $\mathbb{F}^n$ by Theorem 3.4.1.
The relation $(\forall j \in \{1, \ldots, n\})\, [\mathbf{a}_j]_\epsilon = \mathbf{a}_j$ holds by Definition 3.2.1, Proposition 3.1.9, and $I_n \mathbf{a}_j = \mathbf{a}_j$.
Thus $C_{\epsilon\leftarrow\alpha} = A$ by Definition 3.5.1 and Definition 3.2.3, and A is invertible by Theorem 3.5.2(i).
Structural Commentary: Standard coordinates identify the column matrix with a change-of-basis matrix.
Key Insight: A basis-to-basis coordinate rewrite is invertible. □

Corollary 3.6.2. *Invertibility and Full Rank*
Let $n \geq 1$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$. Then A is invertible $\iff \mathrm{rank}(A) = n$.

Proof.

($\Rightarrow$) Suppose A is invertible. Its columns form basis of $\mathbb{F}^n$ by Theorem 3.4.1; hence $\mathrm{col}(A) = \mathbb{F}^n$, $\mathrm{rank}(A) = n$ by Definition 3.1.12.
($\Leftarrow$) Suppose $\mathrm{rank}(A) = n$. Then $\dim(\mathrm{col}(A)) = n = \dim(\mathbb{F}^n)$ by Definition 3.1.12, so $\mathrm{col}(A) = \mathbb{F}^n$ by Proposition 1.4.3(ii).
The n columns of A therefore form a basis of $\mathbb{F}^n$ by Proposition 1.4.4(i), and A is invertible by Corollary 3.6.1.

Structural Commentary: One direction reads rank from basis columns; the converse upgrades full dimension to a basis.
Key Insight: Square-matrix invertibility is equivalent to full column rank. □

Corollary 3.6.3. *Square Matrix Algebraic Invertibility Dictionary*
Let $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_n] \in \mathrm{Mat}(n, n, \mathbb{F})$. The following are equivalent:

(i) A is invertible;
(ii) $\mathbf{a}_1, \ldots, \mathbf{a}_n$ form a basis of $\mathbb{F}^n$;
(iii) $\mathbf{a}_1, \ldots, \mathbf{a}_n$ are linearly independent;
(iv) $\mathbf{a}_1, \ldots, \mathbf{a}_n$ span $\mathbb{F}^n$;
(v) for every $\mathbf{b} \in \mathbb{F}^n$, the system $A\mathbf{x} = \mathbf{b}$ has a unique solution;
(vi) the homogeneous system $A\mathbf{x} = \mathbf{0}$ has only the zero solution.

Proof.

(i) $\Rightarrow$ *(ii)* By Theorem 3.4.1, the columns of an invertible matrix form a basis.
(ii) $\Rightarrow$ *(iii)* A basis is linearly independent.
(iii) $\Rightarrow$ *(iv)* In $\mathbb{F}^n$, n linearly independent vectors form a basis, hence span.
(iv) $\Rightarrow$ *(v)* In $\mathbb{F}^n$, n spanning vectors form a basis, so every $\mathbf{b}$ has unique coordinates $\mathbf{x}$ in $A\mathbf{x} = \mathbf{b}$.
(v) $\Rightarrow$ *(vi)* Apply (v) to $\mathbf{b} = \mathbf{0}$; since $\mathbf{x} = \mathbf{0}$ is a solution, it is the only one.
(vi) $\Rightarrow$ *(i)* Condition (vi) says the columns are independent.
Hence they form a basis of $\mathbb{F}^n$, and Corollary 3.6.1 gives invertibility.

Structural Commentary: Square invertibility is column basishood.
Key Insight: Invertible columns give unique coordinates. □

Corollary 3.6.4. *Transpose Preserves Invertibility*
Let $n \geq 1$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$. Then A is invertible $\iff$ A^t is invertible.

Proof.
($\Rightarrow$) Suppose A is invertible. Then $\mathrm{rank}(A) = n$ by Corollary 3.6.2, and $\mathrm{rank}(A^t) = \mathrm{rank}(A) = n$ by Theorem 3.3.2. Hence A^t is invertible by Corollary 3.6.2.
($\Leftarrow$) Suppose A^t is invertible. The matrix $(A^t)^t$ is invertible by the forward direction with A^t in place of A. Since $(A^t)^t = A$ by Proposition 3.1.14(i), A is invertible.

Structural Commentary: Rank invariance proves the forward direction; double transposition reverses it.
Key Insight: Transposition preserves full rank. □

Theorem 3.6.5. *Completing a Full-Column-Rank Matrix*
Let $1 \leq n < m$ and $X \in \mathrm{Mat}(m, n, \mathbb{F})$. If $\mathrm{rank}(X) = n$, then $(\exists\, X' \in \mathrm{Mat}(m, m-n, \mathbb{F}))$ $[\,X\ X'\,] \in \mathrm{Mat}(m, m, \mathbb{F})^{\times}$.

Proof. Write $X = [\mathbf{x}_1\ \cdots\ \mathbf{x}_n]$. Then $\dim(\mathrm{col}(X)) = n$ by Definition 3.1.12. The columns form a spanning list of length n in $\mathrm{col}(X)$. Hence they form a basis of $\mathrm{col}(X)$ by Proposition 1.4.4(i) and are linearly independent in $\mathbb{F}^m$.
Extend them to a basis $(\mathbf{x}_1, \ldots, \mathbf{x}_m)$ of $\mathbb{F}^m$ by Theorem 1.3.13, and set $X' := [\mathbf{x}_{n+1}\ \cdots\ \mathbf{x}_m] \in \mathrm{Mat}(m, m-n, \mathbb{F})$.
The matrix $[\,X\ X'\,]$ is invertible by Corollary 3.6.1.
Structural Commentary: Column rank identifies an independent list; basis extension supplies the missing columns.
Key Insight: Full-column-rank matrices are initial blocks of invertible matrices. □

Theorem 3.6.6. *Full-Rank Products Preserve Rank*
Let $A \in \mathrm{Mat}(m, n, \mathbb{F})$. Then:
(i) If $X \in \mathrm{Mat}(p, m, \mathbb{F})$ and $Y \in \mathrm{Mat}(n, q, \mathbb{F})$ satisfy $\mathrm{rank}(X) = m$ and $\mathrm{rank}(Y) = n$, then $\mathrm{rank}(XAY) = \mathrm{rank}(A)$.
(ii) If $P \in \mathrm{Mat}(m, m, \mathbb{F})$ and $Q \in \mathrm{Mat}(n, n, \mathbb{F})$ are invertible, then $\mathrm{rank}(PAQ) = \mathrm{rank}(A)$.

Proof.
(i) The equality $\dim(\ker(X)) = 0$ holds by Corollary 3.3.1(i), so $\ker(X) = \{\mathbf{0}\}$ by Proposition 1.4.3(ii). Hence $\ker(XA) = \{\mathbf{z} \in \mathbb{F}^n : X(A\mathbf{z}) = \mathbf{0}\} = \{\mathbf{z} \in \mathbb{F}^n : A\mathbf{z} = \mathbf{0}\} = \ker(A)$, and $\mathrm{rank}(XA) = \mathrm{rank}(A)$ by Corollary 3.3.1(i). Since $\mathrm{rank}(Y^t) = \mathrm{rank}(Y) = n$ by Theorem 3.3.2, the equality $\mathrm{rank}(Y^t A^t) = \mathrm{rank}(A^t)$ holds by the preceding kernel argument with (X, A) replaced by (Y^t, A^t). The identity $(AY)^t = Y^t A^t$ holds by Proposition 3.1.16. Hence $\mathrm{rank}(AY) = \mathrm{rank}(Y^t A^t) = \mathrm{rank}(A^t) = \mathrm{rank}(A)$ by Theorem 3.3.2 and the preceding equality. Finally, $\mathrm{rank}(XAY) = \mathrm{rank}(AY) = \mathrm{rank}(A)$ by the preceding kernel argument with A replaced by AY.
(ii) Set $X = P$ and $Y = Q$. Then $\mathrm{rank}(P) = m$ and $\mathrm{rank}(Q) = n$ by Corollary 3.6.2, so $\mathrm{rank}(PAQ) = \mathrm{rank}(A)$ by part (i).

Structural Commentary: Kernel preservation handles left factors; transposition converts right factors to the same argument.
Key Insight: Full column and row rank prevent dimensional collapse. □

3.7 Block Matrix Algebra

Throughout this subsection, all vector spaces and matrices are over the same fixed field $\mathbb{F}$, and every matrix size is a positive integer.

Definition 3.7.1. *Block Partitions and Conformality*
Let $r, s \geq 1$, let $m_1, \ldots, m_r$ and $n_1, \ldots, n_s$ be positive integers, and let $A \in \mathrm{Mat}\left(\sum_{i=1}^{r} m_i, \sum_{j=1}^{s} n_j, \mathbb{F}\right)$.
An *$r \times s$ block partition* $A = [A_{ij}]$ groups consecutive rows according to $(m_1, \ldots, m_r)$ and consecutive columns according to $(n_1, \ldots, n_s)$, so $(\forall\, i \in \{1, \ldots, r\})(\forall\, j \in \{1, \ldots, s\})\ A_{ij} \in \mathrm{Mat}(m_i, n_j, \mathbb{F})$. The submatrices A_{ij} are the *blocks*.
(i) Two $r \times s$ block partitions $A = [A_{ij}]$ and $C = [C_{ij}]$ are *conformal for addition* if corresponding blocks have the same size.
(ii) An $r \times s$ block partition $A = [A_{ik}]$ and an $s \times t$ block partition $B = [B_{kj}]$, where $t \geq 1$, are *conformal for multiplication* if $\exists\, p_1, \ldots, p_t \in \mathbb{Z}_{>0}$ such that $A_{ik} \in \mathrm{Mat}(m_i, n_k, \mathbb{F})$ and $B_{kj} \in \mathrm{Mat}(n_k, p_j, \mathbb{F})$ $\forall i \in \{1, \ldots, r\}$, $k \in \{1, \ldots, s\}$, $j \in \{1, \ldots, t\}$.

Definition 3.7.2. *Block Matrix of a Linear Map*
Suppose $\mathcal{V} = \mathcal{U}_1 \oplus \mathcal{U}_2$ and $\mathcal{W} = \mathcal{Z}_1 \oplus \mathcal{Z}_2$, where $\dim(\mathcal{U}_j) = n_j \geq 1$ and $\dim(\mathcal{Z}_i) = m_i \geq 1$ for $i, j \in \{1, 2\}$. Choose ordered bases α_j of $\mathcal{U}_j$ and β_i of $\mathcal{Z}_i$. By Definition 2.3.5, $\alpha = (\alpha_1, \alpha_2)$ and $\beta = (\beta_1, \beta_2)$ are bases of $\mathcal{V}$ and $\mathcal{W}$ adapted to the decompositions.
For $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, its representation matrix has conformal partition $[T]_{\beta \leftarrow \alpha} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$, where $A_{ij} \in \mathrm{Mat}(m_i, n_j, \mathbb{F})$ for $i, j \in \{1, 2\}$.
The jth block column contains coordinate columns of images of basis α_j, while the ith block row retains their β_i-coordinate entries.

Proposition 3.7.3. *Block Matrix Arithmetic*
The following identities hold.
(i) If $A = [A_{ij}]$ and $C = [C_{ij}]$ are conformal $r \times s$ block partitions, then $A + C = [A_{ij} + C_{ij}]$.
In particular, conformal 2×2 partitions satisfy $A + C = \begin{bmatrix} A_{11}+C_{11} & A_{12}+C_{12} \\ A_{21}+C_{21} & A_{22}+C_{22} \end{bmatrix}$.
(ii) If $A = [A_{ik}]$ and $B = [B_{kj}]$ are conformal for multiplication, then $(AB)_{ij} = \sum_{k=1}^{s} A_{ik} B_{kj}$ for every admissible i, j.
In particular, conformal 2×2 partitions satisfy $AB = \begin{bmatrix} A_{11}B_{11}+A_{12}B_{21} & A_{11}B_{12}+A_{12}B_{22} \\ A_{21}B_{11}+A_{22}B_{21} & A_{21}B_{12}+A_{22}B_{22} \end{bmatrix}$.

Proof.
(i) By Definition 3.1.1, matrix addition is entrywise. Because conformality assigns the same entry positions to corresponding blocks, addition may be performed blockwise, so $A + C = [A_{ij} + C_{ij}]$. The case $r = s = 2$ is the stated specialization.
(ii) By Proposition 3.1.6, each entry of AB is the row-column sum over the shared index. Group that index into the s consecutive intervals determined by the common block sizes. The contribution from the kth interval is the corresponding entry of $A_{ik}B_{kj}$.
Therefore $(AB)_{ij} = \sum_{k=1}^{s} A_{ik} B_{kj}$. The case of two block rows and two block columns is the stated specialization.

Structural Commentary: Addition is entrywise; multiplication groups the shared index.
Key Insight: Block arithmetic is ordinary matrix arithmetic performed at a coarser scale. □

Proposition 3.7.4. *Stacks Intersect Kernels, Concatenations Sum Columns*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$, $B \in \mathrm{Mat}(p,n,\mathbb{F})$, $C \in \mathrm{Mat}(m,r,\mathbb{F})$, and $D \in \mathrm{Mat}(m,s,\mathbb{F})$. Then:

(i) $\ker\left(\left[\begin{smallmatrix} A \\ B \end{smallmatrix}\right]\right) = \ker(A) \cap \ker(B)$.
(ii) $\mathrm{col}([\,C\ D\,]) = \mathrm{col}(C) + \mathrm{col}(D)$.

Proof.

(i) By Proposition 3.7.3, $\left[\begin{smallmatrix} A \\ B \end{smallmatrix}\right]\mathbf{x} = \left[\begin{smallmatrix} A\mathbf{x} \\ B\mathbf{x} \end{smallmatrix}\right]$ for every $\mathbf{x} \in \mathbb{F}^n$.
By Definition 3.1.12, $\mathbf{x} \in \ker\left(\left[\begin{smallmatrix} A \\ B \end{smallmatrix}\right]\right)$ if and only if $A\mathbf{x} = \mathbf{0}$ and $B\mathbf{x} = \mathbf{0}$, which is equivalent to $\mathbf{x} \in \ker(A) \cap \ker(B)$.
(ii) By Proposition 3.7.3, $[\,C\ D\,]\left[\begin{smallmatrix} \mathbf{u} \\ \mathbf{v} \end{smallmatrix}\right] = C\mathbf{u} + D\mathbf{v}$ for every $\mathbf{u} \in \mathbb{F}^r$ and $\mathbf{v} \in \mathbb{F}^s$.
By Definition 3.1.12, $\mathrm{col}([\,C\ D\,]) = \{C\mathbf{u} + D\mathbf{v} : \mathbf{u} \in \mathbb{F}^r,\ \mathbf{v} \in \mathbb{F}^s\} = \mathrm{col}(C) + \mathrm{col}(D)$.

Structural Commentary: The kernel and column-space definitions translate both block actions.
Key Insight: Vertical blocks intersect kernels; horizontal blocks add column spaces. □

Proposition 3.7.5. *Block Centrosymmetry and Commutation*
Let $n \geq 1$, let $A, B, C, D \in \mathrm{Mat}(n,n,\mathbb{F})$, and set $M = \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right]$ and $L_{2n} = \left[\begin{smallmatrix} 0 & I_n \\ I_n & 0 \end{smallmatrix}\right]$ in $\mathrm{Mat}(2n,2n,\mathbb{F})$.
Then M has block centrosymmetric form, meaning $A = D$ and $B = C$, if and only if $L_{2n}M = ML_{2n}$.

Proof. By Proposition 3.7.3, $L_{2n}M = \left[\begin{smallmatrix} C & D \\ A & B \end{smallmatrix}\right]$ and $ML_{2n} = \left[\begin{smallmatrix} B & A \\ D & C \end{smallmatrix}\right]$.
(⇒) If M has block centrosymmetric form, then $A = D$ and $B = C$, so the two block products agree. Therefore $L_{2n}M = ML_{2n}$.
(⇐) If $L_{2n}M = ML_{2n}$, then corresponding blocks are equal by Definition 3.1.1.
Thus $C = B$ and $D = A$, so M has block centrosymmetric form.

Structural Commentary: Explicit block multiplication reduces commutation with L_{2n} to equality of opposite blocks.
Key Insight: The exchange matrix detects block centrosymmetry. □

Definition 3.7.6. *Direct Sum of Matrices*
For $A \in \mathrm{Mat}(m,n,\mathbb{F})$ and $B \in \mathrm{Mat}(p,q,\mathbb{F})$, the *direct sum* of A and B is $A \oplus B := \left[\begin{smallmatrix} A & 0 \\ 0 & B \end{smallmatrix}\right] \in \mathrm{Mat}(m+p, n+q, \mathbb{F})$, where the upper-right and lower-left zero blocks have sizes $m \times q$ and $p \times n$, respectively.

3.8 Matrix Operations and Identities

Throughout this subsection, all matrices are over the same fixed field $\mathbb{F}$, and every matrix size is a positive integer.

Definition 3.8.1. *Trace and Determinant of a Matrix*
Let $n \geq 1$ and $A = [a_{jk}] \in \mathrm{Mat}(n,n,\mathbb{F})$.

(i) The *trace* of A is $\mathrm{tr}(A) := \sum_{j=1}^{n} a_{jj}$.

(ii) The *determinant* of A is $\det A := \sum_{\sigma \in \mathfrak{S}_n} \mathrm{sign}(\sigma) \prod_{j=1}^{n} a_{\sigma(j),j}$.

Theorem 3.8.2. *Basic Determinant Laws*
Let $n \geq 1$ and $A, B \in \mathrm{Mat}(n,n,\mathbb{F})$.

(i) $\det I_n = 1$.
(ii) For fixed $k \in \{1,\dots,n\}$ and $(A_{\cdot,j})_{j \neq k}$, the map $\mathbf{x} \mapsto \det(A_{\cdot,1},\dots,\mathbf{x},\dots,A_{\cdot,n})$ is linear.
(iii) Swapping two columns negates the determinant.
(iv) If two columns of A are equal, then $\det A = 0$.
(v) If A is triangular, then $\det A = \prod_{j=1}^{n} a_{jj}$.
(vi) $\det(AB) = \det(A)\det(B)$.
(vii) A is invertible if and only if $\det A \neq 0$.
(viii) If A is invertible, then $\det(A^{-1}) = (\det A)^{-1}$.
(ix) $\det(A^t) = \det(A)$.

Proof.

(i) In the permutation formula for I_n, only the identity permutation has a nonzero product, and its contribution is 1.
(ii) For $k \in \{1,\dots,n\}$, $\det(A_{\cdot,1},\dots,\mathbf{x},\dots,A_{\cdot,n}) = \sum_{\sigma \in \mathfrak{S}_n} \mathrm{sign}(\sigma) x_{\sigma(k)} \prod_{\ell \neq k} a_{\sigma(\ell),\ell}$, which is linear in $\mathbf{x}$.
(iii) Let τ transpose columns p and q, and let $B_{\cdot,j} = A_{\cdot,\tau(j)}$. Then $\det B = -\det A$ by reindexing the determinant sum with $\rho = \sigma \circ \tau$, because $\mathrm{sign}(\rho \circ \tau) = -\mathrm{sign}(\rho)$.
(iv) If columns p and q are equal, pair the term indexed by σ with the term indexed by $\sigma \circ (p\ q)$. Their products agree and their signs are opposite, so every pair sums to zero, including when $\mathrm{char}(\mathbb{F}) = 2$.
(v) Suppose A is upper triangular. A nonzero term satisfies $(\forall j \in \{1,\dots,n\})\, \sigma(j) \leq j$, hence $\sigma = \mathrm{id}$ and $\det A = \prod_{j=1}^{n} a_{jj}$. The lower-triangular case is analogous with $(\forall j \in \{1,\dots,n\})\, \sigma(j) \geq j$.
(vi) Let F be alternating and multilinear in its n column arguments. Standard-basis expansion produces terms indexed by $(i_1,\dots,i_n) \in \{1,\dots,n\}^n$; repeated indices vanish by alternation.
The surviving tuples are permutations, and $F(\mathbf{e}_{\sigma(1)},\dots,\mathbf{e}_{\sigma(n)}) = \mathrm{sign}(\sigma)F(I_n)$ by alternation. Hence $F(A_{\cdot,1},\dots,A_{\cdot,n}) = F(I_n)\det A$.
For fixed A, $H(B) := \det(AB)$ is alternating and multilinear in the columns of B, with $H(I_n) = \det A$. Thus $\det(AB) = H(B) = H(I_n)\det B = \det(A)\det(B)$.
(vii) (⇒) If A is invertible, then $\det A \neq 0$ because $1 = \det(AA^{-1}) = \det(A)\det(A^{-1})$ by parts (i) and (vi).
(vii) (⇐) If A were singular, one column would be a linear combination of the others, and $\det A = 0$ by parts (ii) and (iv), contrary to $\det A \neq 0$. Thus A is invertible.
(viii) If A is invertible, then $\det(A^{-1}) = (\det A)^{-1}$ by $1 = \det(AA^{-1}) = \det(A)\det(A^{-1})$ from parts (i), (vi), and (vii).

(ix) $\det(A^t) = \sum_{\sigma\in\mathfrak{S}_n} \operatorname{sign}(\sigma) \prod_{j=1}^{n} a_{j,\sigma(j)} = \sum_{\tau\in\mathfrak{S}_n} \operatorname{sign}(\tau) \prod_{j=1}^{n} a_{\tau(j),j} = \det A$ by reindexing with $\tau = \sigma^{-1}$.

Structural Commentary: The permutation formula establishes alternation and triangularity before multiplicativity and invertibility.
Key Insight: Alternating multilinearity reduces every column expansion to signed basis permutations. □

Lemma 3.8.3. *Identity Blocks Do Not Change Determinant*
Let $m \geq 1$, $n \geq 0$, and $A \in \operatorname{Mat}(m, m, \mathbb{F})$.

(i) $\det(I_n \oplus A) = \det A$;
(ii) $\det(A \oplus I_n) = \det A$.

Proof.

(i) If $n = 0$, the identity holds by the empty identity-block convention. If $n \geq 1$, every nonzero permutation term fixes $\{1, \ldots, n\}$ pointwise; relabeling the remaining indices produces exactly the determinant expansion of A.
(ii) If $n = 0$, the identity again holds by convention. If $n \geq 1$, every nonzero term fixes the last n indices pointwise, and the remaining sum is $\det A$.

Structural Commentary: Each block position reduces the permutation sum to the indices occupied by A.
Key Insight: An identity block forces its coordinates to remain fixed. □

Theorem 3.8.4. *Determinant of an Upper Block-Triangular Matrix*
Let $r, s \geq 1$, $A \in \operatorname{Mat}(r, r, \mathbb{F})$, $B \in \operatorname{Mat}(r, s, \mathbb{F})$, and $D \in \operatorname{Mat}(s, s, \mathbb{F})$.
Then $\det \left(\begin{smallmatrix} A & B \\ 0 & D \end{smallmatrix}\right) = \det(A)\det(D)$.

Proof. $\left(\begin{smallmatrix} A & B \\ 0 & D \end{smallmatrix}\right) = \left(\begin{smallmatrix} I_r & 0 \\ 0 & D \end{smallmatrix}\right) \left(\begin{smallmatrix} I_r & B \\ 0 & I_s \end{smallmatrix}\right) \left(\begin{smallmatrix} A & 0 \\ 0 & I_s \end{smallmatrix}\right)$.
The outer determinants are $\det D$ and $\det A$ by Lemma 3.8.3; the middle determinant is 1 by Theorem 3.8.2(v).
The formula follows by Theorem 3.8.2(vi).
Structural Commentary: A three-factor decomposition isolates the two diagonal-block determinants.
Key Insight: The off-diagonal block lies in a unit upper-triangular factor. □

Definition 3.8.5. *Polynomial Evaluation on a Square Matrix*
Let $n \geq 1$ and $A \in \operatorname{Mat}(n, n, \mathbb{F})$. Define $A^0 := I_n$ and $(\forall\, j \in \mathbb{Z}_{\geq 0})\, A^{j+1} := A^j A$.
For $p(z) = \sum_{j=0}^{d} c_j z^j \in \mathbb{F}[z]$, where $d \geq 0$, the *evaluation of p at A* is $p(A) := \sum_{j=0}^{d} c_j A^j \in \operatorname{Mat}(n, n, \mathbb{F})$.

Proposition 3.8.6. *Algebra of Matrix Direct Sums*

(i) If $A, C \in \operatorname{Mat}(m, n, \mathbb{F})$, $B, D \in \operatorname{Mat}(r, s, \mathbb{F})$, and $a, b \in \mathbb{F}$, then $a(A \oplus B) + b(C \oplus D) = (aA + bC) \oplus (aB + bD)$.
(ii) If $A \in \operatorname{Mat}(m, n, \mathbb{F})$, $C \in \operatorname{Mat}(n, \ell, \mathbb{F})$, $B \in \operatorname{Mat}(r, s, \mathbb{F})$, and $D \in \operatorname{Mat}(s, t, \mathbb{F})$, then $(A \oplus B)(C \oplus D) = AC \oplus BD$.
(iii) If $A \in \operatorname{Mat}(m, m, \mathbb{F})$, $B \in \operatorname{Mat}(n, n, \mathbb{F})$, and $k \in \mathbb{Z}_{>0}$, then $(A \oplus B)^k = A^k \oplus B^k$.
(iv) If $A \in \operatorname{Mat}(m, m, \mathbb{F})$, $B \in \operatorname{Mat}(n, n, \mathbb{F})$, and $p \in \mathbb{F}[z]$, then $p(A \oplus B) = p(A) \oplus p(B)$.

Proof.

(i) By Definition 3.7.6, Definition 3.1.1, and Proposition 3.7.3, $a(A \oplus B) + b(C \oplus D) = \left[\begin{smallmatrix} aA+bC & 0 \\ 0 & aB+bD \end{smallmatrix}\right] = (aA + bC) \oplus (aB + bD)$.
(ii) By Definition 3.7.6 and Proposition 3.7.3, $(A \oplus B)(C \oplus D) = \left[\begin{smallmatrix} AC & 0 \\ 0 & BD \end{smallmatrix}\right] = AC \oplus BD$.
(iii) Set $P_k := ((A \oplus B)^k = A^k \oplus B^k)$. By Definition 3.8.5 and Proposition 3.1.2, P_1 holds.
If P_k holds, then $(A \oplus B)^{k+1} = (A \oplus B)^k (A \oplus B) = (A^k \oplus B^k)(A \oplus B) = A^{k+1} \oplus B^{k+1}$ by the recurrence defining powers, the induction hypothesis, and (ii). Therefore $(\forall\, k \in \mathbb{Z}_{>0})\, P_k$ by Theorem 2.6.2.
(iv) Write $p(z) = \sum_{j=0}^{d} c_j z^j$. The identity $(A \oplus B)^j = A^j \oplus B^j$ holds for $j = 0$ by Definition 3.8.5, Definition 3.7.6, for $j \geq 1$ by (iii).
By (i), scalar multiples, finite sums of these direct sums are componentwise. Hence $p(A \oplus B) = p(A) \oplus p(B)$ by Definition 3.8.5.

Structural Commentary: Block formulas extend by induction and linearity.
Key Insight: Direct-sum blocks evolve independently under matrix algebra. □

Proposition 3.8.7. *Diagonal Multiplication Scales Rows and Columns*
Let $A = [a_{ij}] \in \operatorname{Mat}(m, n, \mathbb{F})$, let $\lambda_1, \ldots, \lambda_n, \mu_1, \ldots, \mu_m \in \mathbb{F}$, and set $\Lambda := \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$ and $M := \operatorname{diag}(\mu_1, \ldots, \mu_m)$. Then:

(i) $A\Lambda = [\lambda_j a_{ij}]$; right multiplication by Λ scales column j by λ_j.
(ii) $MA = [\mu_i a_{ij}]$; left multiplication by M scales row i by μ_i.

Proof.

(i) For admissible i, j, $(A\Lambda)_{ij} = \sum_{r=1}^{n} a_{ir}\Lambda_{rj} = a_{ij}\lambda_j = \lambda_j a_{ij}$ by Definition 3.1.1 and commutativity in $\mathbb{F}$.
(ii) For admissible i, j, $(MA)_{ij} = \sum_{r=1}^{m} M_{ir} a_{rj} = \mu_i a_{ij}$ by Definition 3.1.1.

Structural Commentary: Diagonal sparsity isolates one summand in each entry formula.
Key Insight: The multiplication side determines whether rows or columns are scaled. □

Proposition 3.8.8. *Inverse of an Upper Block-Triangular Matrix*
Let $Y \in \operatorname{Mat}(m, m, \mathbb{F})$ and $Z \in \operatorname{Mat}(n, n, \mathbb{F})$ be invertible, and let $X \in \operatorname{Mat}(m, n, \mathbb{F})$.
Then $\left[\begin{smallmatrix} Y & X \\ 0 & Z \end{smallmatrix}\right]^{-1} = \left[\begin{smallmatrix} Y^{-1} & -Y^{-1}XZ^{-1} \\ 0 & Z^{-1} \end{smallmatrix}\right] \in \operatorname{Mat}(m+n, m+n, \mathbb{F})$, *where each lower-left zero block has size $n \times m$.*

Proof. Set $M := \left[\begin{smallmatrix} Y & X \\ 0 & Z \end{smallmatrix}\right]$ and $N := \left[\begin{smallmatrix} Y^{-1} & -Y^{-1}XZ^{-1} \\ 0 & Z^{-1} \end{smallmatrix}\right]$.
By Proposition 3.7.3 and Proposition 3.1.2, $MN = \left[\begin{smallmatrix} I_m & -XZ^{-1}+XZ^{-1} \\ 0 & I_n \end{smallmatrix}\right] = I_{m+n}$ and $NM = \left[\begin{smallmatrix} I_m & Y^{-1}X-Y^{-1}X \\ 0 & I_n \end{smallmatrix}\right] = I_{m+n}$.
Thus $N = M^{-1}$ by Definition 3.1.1 and Lemma 3.1.3.
Structural Commentary: Two block products verify both inverse identities.
Key Insight: The off-diagonal correction cancels the coupling block. □

Theorem 3.8.9. *Inverse of an Upper Triangular Matrix*
Let $n \geq 1$ and let $A = [a_{ij}] \in \mathrm{Mat}(n, n, \mathbb{F})$ be upper triangular with $(\forall\, i \in \{1, \dots, n\})\, a_{ii} \neq 0$. Then:
(i) A is invertible.
(ii) A^{-1} is upper triangular.
(iii) The diagonal of A^{-1} is $(a_{11}^{-1}, \dots, a_{nn}^{-1})$.

Proof. Let P_n denote the conjunction of (i)–(iii) in size n under the stated hypotheses.
For $n = 1$, $A^{-1} = [a_{11}^{-1}]$ by $[a_{11}][a_{11}^{-1}] = I_1 = [a_{11}^{-1}][a_{11}]$, Definition 3.1.1, Lemma 3.1.3.
This inverse is upper triangular with diagonal (a_{11}^{-1}), so P_1 holds. Suppose $n > 1$ and P_{n-1} holds.
Write $A = \left[\begin{smallmatrix} B & \mathbf{x} \\ 0 & a_{nn} \end{smallmatrix}\right]$, where $B \in \mathrm{Mat}(n-1, n-1, \mathbb{F})$ is upper triangular with nonzero diagonal and $\mathbf{x} \in \mathbb{F}^{n-1}$.
(i) The blocks B, $[a_{nn}]$ invertible by induction hypothesis, Definition 3.1.1, respectively. Hence A invertible by Proposition 3.8.8.
(ii) The matrix B^{-1} is upper triangular by the induction hypothesis.
By Proposition 3.8.8, $A^{-1} = \left[\begin{smallmatrix} B^{-1} & -B^{-1}\mathbf{x}a_{nn}^{-1} \\ 0 & a_{nn}^{-1} \end{smallmatrix}\right]$, which is upper triangular by Definition 3.1.1.
(iii) By the induction hypothesis, the diagonal of B^{-1} is $(a_{11}^{-1}, \dots, a_{n-1,n-1}^{-1})$.
By the block formula in (ii), the diagonal of A^{-1} is $(a_{11}^{-1}, \dots, a_{n-1,n-1}^{-1}, a_{nn}^{-1})$.
Thus P_n holds, so $(\forall\, n \in \mathbb{Z}_{>0})\, P_n$ by Theorem 2.6.2.
Structural Commentary: Induction transfers all three claims through the block inverse formula.
Key Insight: Triangular inversion reduces dimension while preserving the zero pattern. □

4 Duality and Multilinear Structure

4.1 Dual Spaces and Dual Bases

Duality studies vectors through scalar-valued tests. This subsection develops algebraic duals, dual bases, coordinate functionals, separation by functionals, and their dimension consequences.

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$.

Definition 4.1.1. *Linear Functional and Dual Space*
(i) A *linear functional* on $\mathcal{V}$ is an element $\varphi \in \mathcal{L}(\mathcal{V}, \mathbb{F})$.
(ii) The *algebraic dual space* of $\mathcal{V}$ is $\mathcal{V}' := \mathcal{L}(\mathcal{V}, \mathbb{F})$.

Pointwise addition and scalar multiplication make $\mathcal{V}'$ a vector space over $\mathbb{F}$ by Proposition 1.5.5.

Example 4.1.2. *Evaluation and Integral Functionals*
(i) Define $\mathrm{ev}_0 : \mathbb{F}[x] \to \mathbb{F}$ by $\mathrm{ev}_0(p) := p(0)$.
The identity $(\forall\, \alpha, \beta \in \mathbb{F})(\forall\, p, q \in \mathbb{F}[x])\ \mathrm{ev}_0(\alpha p + \beta q) = \alpha\, \mathrm{ev}_0(p) + \beta\, \mathrm{ev}_0(q)$ proves $\mathrm{ev}_0 \in \mathcal{V}'$ for $\mathcal{V} = \mathbb{F}[x]$.
(ii) For $\mathbb{F} = \mathbb{R}$, let $C[a, b]$ be the real vector space of continuous functions on $[a, b]$ and define $I : C[a, b] \to \mathbb{R}$ by $I(f) := \int_a^b f(x)\, dx$.
By linearity of the integral, $(\forall\, \alpha, \beta \in \mathbb{R})(\forall\, f, g \in C[a, b])\, I(\alpha f + \beta g) = \alpha I(f) + \beta I(g)$, so $I \in C[a, b]'$.

Definition 4.1.3. *Dual Basis*
Let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ be an ordered basis of $\mathcal{V}$, where $n \in \mathbb{N}_0$.
Its *dual basis* is the list $\beta' = (\varphi_1, \dots, \varphi_n)$ in $\mathcal{V}'$ characterized by $(\forall\, j, k \in \{1, \dots, n\})\, \varphi_j(\mathbf{v}_k) = \delta_{j,k}$.
If $n \geq 1$, each φ_j exists uniquely by Proposition 1.5.8; if $n = 0$, then $\beta' := ()$.

Theorem 4.1.4. *Dual Basis and Dimension of the Dual Space*
Let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ be a basis of the finite-dimensional space $\mathcal{V}$, and let $\beta' = (\varphi_1, \dots, \varphi_n)$ be its dual basis. Then:
(i) β' is a basis of $\mathcal{V}'$;
(ii) $\dim(\mathcal{V}') = \dim(\mathcal{V})$.

Proof.
(i) If $n = 0$, then $\mathcal{V} = \{\mathbf{0}\}$, and $\mathcal{V}' = \{0\}$ by Proposition 1.5.3; thus $()$ is a basis of $\mathcal{V}'$.
Suppose $n \geq 1$. If $\sum_{j=1}^{n} a_j \varphi_j = 0$, then $(\forall\, k \in \{1, \dots, n\})\, a_k = \sum_{j=1}^{n} a_j \varphi_j(\mathbf{v}_k) = 0$, so β' is linearly independent.
For $\varphi \in \mathcal{V}'$ and $\mathbf{v} = \sum_{k=1}^{n} c_k \mathbf{v}_k$, one has $\big(\sum_{j=1}^{n} \varphi(\mathbf{v}_j)\varphi_j\big)(\mathbf{v}) = \sum_{j=1}^{n} \varphi(\mathbf{v}_j) c_j = \varphi(\mathbf{v})$ by Definition 4.1.3.
Hence $\varphi = \sum_{j=1}^{n} \varphi(\mathbf{v}_j)\varphi_j$ by Assumption 3.1.2, and β' spans $\mathcal{V}'$.
(ii) Both bases have length n by (i), so $\dim(\mathcal{V}') = n = \dim(\mathcal{V})$ by Definition 1.4.2.
Structural Commentary: Evaluation on the original basis proves independence and reconstructs every functional.
Key Insight: Basis values are precisely the coordinates of a functional. □

Proposition 4.1.5. *Coordinate Functionals for a Hamel Basis*
Let $\mathcal{B} = \{\mathbf{b}_i\}_{i \in I}$ be Hamel basis of $\mathcal{V}$. For $\mathbf{v} \in \mathcal{V}$, let $a_{\mathbf{v}} : I \to \mathbb{F}$ be unique finitely supported function satisfying $\mathbf{v} = \sum_{j \in \mathrm{supp}(a_{\mathbf{v}})} a_{\mathbf{v}}(j)\mathbf{b}_j$, and define $\varepsilon_i(\mathbf{v}) := a_{\mathbf{v}}(i)$ for $i \in I$. Then:
(i) $(\forall\, i \in I)\, \varepsilon_i \in \mathcal{V}'$;

(ii) $\{\varepsilon_i\}_{i\in I}$ *is linearly independent;*
(iii) $\operatorname{span}\{\varepsilon_i : i \in I\} = \mathcal{V}'$ *iff* $|I| < \infty$*;*
(iv) $|I| < \infty$ *iff* $\mathcal{V}$ *is finite-dimensional.*

Proof.

(i) For $\alpha, \beta \in \mathbb{F}$ and $\mathbf{v}, \mathbf{w} \in \mathcal{V}$, the identity $a_{\alpha\mathbf{v}+\beta\mathbf{w}} = \alpha a_{\mathbf{v}} + \beta a_{\mathbf{w}}$ holds by uniqueness in Proposition 1.3.16.
Hence $(\forall\, i \in I)\, \varepsilon_i(\alpha\mathbf{v} + \beta\mathbf{w}) = \alpha\varepsilon_i(\mathbf{v}) + \beta\varepsilon_i(\mathbf{w})$, so $(\forall\, i \in I)\, \varepsilon_i \in \mathcal{V}'$ by Definition 4.1.1.

(ii) If $i_1, \dots, i_N \in I$ are distinct and $\sum_{r=1}^{N} c_r \varepsilon_{i_r} = 0$, then $(\forall\, s \in \{1, \dots, N\})\, c_s = \sum_{r=1}^{N} c_r \varepsilon_{i_r}(\mathbf{b}_{i_s}) = 0$.
Thus every finite relation is trivial, so $\{\varepsilon_i\}_{i\in I}$ is linearly independent.

(iii) $(\Rightarrow)$ Suppose $\operatorname{span}\{\varepsilon_i : i \in I\} = \mathcal{V}'$ and I is infinite. Define $\varphi(\mathbf{v}) := \sum_{j \in \operatorname{supp}(a_{\mathbf{v}})} a_{\mathbf{v}}(j)$.
By coordinate uniqueness, $(\forall\, \alpha, \beta \in \mathbb{F})(\forall\, \mathbf{v}, \mathbf{w} \in \mathcal{V})\, \varphi(\alpha\mathbf{v} + \beta\mathbf{w}) = \alpha\varphi(\mathbf{v}) + \beta\varphi(\mathbf{w})$, so $\varphi \in \mathcal{V}'$
The equality $(\forall\, i \in I)\, \varphi(\mathbf{b}_i) = 1$ holds, whereas every element of $\operatorname{span}\{\varepsilon_i : i \in I\}$ vanishes on all but finitely many $\mathbf{b}_i$.
Thus $\varphi \notin \operatorname{span}\{\varepsilon_i : i \in I\}$, a contradiction, and $|I| < \infty$.

(iii) $(\Leftarrow)$ If I is finite, order $\mathcal{B}$. Then $\{\varepsilon_i\}_{i\in I}$ is its dual basis, so it spans $\mathcal{V}'$ by Theorem 4.1.4(i).

(iv) $(\Rightarrow)$ If I is finite, then any ordering of $\mathcal{B}$ is a finite basis, so $\mathcal{V}$ is finite-dimensional.

(iv) $(\Leftarrow)$ Suppose $\mathcal{V}$ has a spanning list of length n and I is infinite. Choose distinct $i_1, \dots, i_{n+1} \in I$.
The list $(\mathbf{b}_{i_1}, \dots, \mathbf{b}_{i_{n+1}})$ is linearly independent, so $n + 1 \le n$ by Theorem 1.3.11, a contradiction. Hence I is finite.

Structural Commentary: Coefficient uniqueness proves linearity and independence; finite support detects finite-dimensionality.
Key Insight: Finite coordinate support cannot represent a functional nonzero on every basis vector. □

Theorem 4.1.6. *Dimension of the Algebraic Dual*
Assume Zorn's lemma and the Choice Principle 6.1.2, and let $\mathcal{V}$ *be an* $\mathbb{F}$*-vector space. Then:*
(i) $\dim(\mathcal{V}) \le \dim(\mathcal{V}')$*;*
(ii) $\dim(\mathcal{V}) = \dim(\mathcal{V}')$ *iff* $\dim(\mathcal{V}) < \infty$*.*

Proof. Choose a Hamel basis $\mathcal{B} = \{\mathbf{b}_i\}_{i\in I}$ by Theorem 1.3.17(ii), set $\kappa := |I| = \dim(\mathcal{V})$ by Definition 1.4.6, and let $\{\varepsilon_i\}_{i\in I}$ denote the coordinate functionals associated with $\mathcal{B}$.

(i) The family $\{\varepsilon_i\}_{i\in I} \subseteq \mathcal{V}'$ is linearly independent by Proposition 4.1.5(ii).
Extend it to a Hamel basis $\mathcal{D}$ of $\mathcal{V}'$ by Theorem 1.3.17(iii).
The map $i \mapsto \varepsilon_i$ injects I into $\mathcal{D}$, so $\kappa = |I| \le |\mathcal{D}| = \dim(\mathcal{V}')$ by Proposition 6.5.2(i) and Definition 1.4.6.

(ii) $(\Rightarrow)$ Suppose $\dim(\mathcal{V}) = \dim(\mathcal{V}')$. Since $\kappa = \dim(\mathcal{V})$, assume for contradiction that κ is infinite.

(a) *Countable scalar core*: Set $D := \{(m, n) \in \mathbb{Z}^2 : n \cdot 1 \neq 0\}$ and $\mathbb{F}_0 := \{(m \cdot 1)(n \cdot 1)^{-1} : (m, n) \in D\} \subseteq \mathbb{F}$.
The elements $0, 1$ belong to $\mathbb{F}_0$. If $x = (m \cdot 1)(n \cdot 1)^{-1}$ and $y = (r \cdot 1)(s \cdot 1)^{-1}$, then $x - y = ((ms - rn) \cdot 1)((ns) \cdot 1)^{-1}$ and $xy = ((mr) \cdot 1)((ns) \cdot 1)^{-1}$; if $x \neq 0$, then $x^{-1} = (n \cdot 1)(m \cdot 1)^{-1}$.
Thus $\mathbb{F}_0$ is a subfield. The set D is at most countable by Proposition 6.2.10, Corollary 6.2.17(ii), and Proposition 6.2.12(i), so $\mathbb{F}_0$ is at most countable by Proposition 6.2.12(ii). The map $E \mapsto \mathbf{1}_E$ injects $\mathcal{P}(I)$ into $\mathbb{F}_0^I$.
The map $i \mapsto \{i\}$ injects I into $\mathcal{P}(I)$, while $I \not\sim_{\#} \mathcal{P}(I)$ by Theorem 6.4.1.
Hence $\kappa < |\mathcal{P}(I)| \le |\mathbb{F}_0^I|$ by Proposition 6.5.2(i),(ii).

(b) *Core-space dimension*: Suppose $\dim_{\mathbb{F}_0}(\mathbb{F}_0^I) \le \kappa$. Choose a Hamel basis $\mathcal{C}$ of $\mathbb{F}_0^I$ by Theorem 1.3.17(ii).
Since $|\mathcal{C}| = \dim_{\mathbb{F}_0}(\mathbb{F}_0^I) \le \kappa$, an injection $\iota : \mathcal{C} \to \kappa$ exists by Proposition 6.5.2(i).
By Proposition 1.3.16, the increasing list of ι-images of the support, paired with its nonzero coefficients, injectively encodes each $f \in \mathbb{F}_0^I$ in $\bigcup_{n<\omega} \big(\{n\} \times (\kappa \times \mathbb{F}_0)^n\big)$. Since $\mathbb{F}_0$ is at most countable and κ is infinite, each finite power injects into κ, and the tagged union injects into $\omega \times \kappa$, by Proposition 6.3.15(iv) and Theorem 6.6.3(ii).
Therefore $|\mathbb{F}_0^I| \le \kappa$ by Proposition 6.5.2(i), contrary to (a). Thus $\dim_{\mathbb{F}_0}(\mathbb{F}_0^I) > \kappa$.

(c) *Scalar transfer*: Choose an $\mathbb{F}_0$-basis $\mathcal{C}$ of $\mathbb{F}_0^I$ by Theorem 1.3.17(ii). For $\mathbf{v} \in \mathcal{V}$, a unique finitely supported $\mathcal{B}$-coefficient function $a_{\mathbf{v}} : I \to \mathbb{F}$ exists by Proposition 1.3.16. For $g \in \mathcal{C}$, define $\Phi_g : \mathcal{V} \to \mathbb{F}$ by $\Phi_g(\mathbf{v}) := \sum_{i \in \operatorname{supp}(a_{\mathbf{v}})} a_{\mathbf{v}}(i) g(i)$.
The identity $a_{\alpha\mathbf{v}+\beta\mathbf{w}} = \alpha a_{\mathbf{v}} + \beta a_{\mathbf{w}}$ holds by coordinate uniqueness.
Hence $(\forall\, \alpha, \beta \in \mathbb{F})(\forall\, \mathbf{v}, \mathbf{w} \in \mathcal{V})\, \Phi_g(\alpha\mathbf{v} + \beta\mathbf{w}) = \alpha\Phi_g(\mathbf{v}) + \beta\Phi_g(\mathbf{w})$ and $\Phi_g \in \mathcal{V}'$.
Let $N \in \mathbb{N}$, let $g_1, \dots, g_N \in \mathcal{C}$ be distinct, and suppose $\sum_{r=1}^{N} c_r \Phi_{g_r} = 0$.
Equality $(\forall\, i \in I)\, \sum_{r=1}^{N} c_r g_r(i) = 0$ holds by evaluation at $\mathbf{b}_i$. Choose $\mathbb{F}_0$-basis $(e_1, \dots, e_s)$ of $\operatorname{span}_{\mathbb{F}_0}\{c_1, \dots, c_N\}$ by Corollary 1.3.14, and $d_{\ell r} \in \mathbb{F}_0$ satisfying $(\forall\, r \in \{1, \dots, N\})\, c_r = \sum_{\ell=1}^{s} d_{\ell r} e_\ell$. For $i \in I$, $0 = \sum_{r=1}^{N} c_r g_r(i) = \sum_{\ell=1}^{s} e_\ell \big(\sum_{r=1}^{N} d_{\ell r} g_r(i) \big)$.
Hence $(\forall\, \ell \in \{1, \dots, s\})(\forall\, i \in I)\, \sum_{r=1}^{N} d_{\ell r} g_r(i) = 0$ by independence of $(e_1, \dots, e_s)$.
$(\forall\, \ell \in \{1, \dots, s\})\, \sum_{r=1}^{N} d_{\ell r} g_r = 0$ by Assumption 3.1.2, $(\forall\, \ell \in \{1, \dots, s\})(\forall\, r \in \{1, \dots, N\})\, d_{\ell r} = 0$ by independence of $\mathcal{C}$.
Hence $(\forall\, r \in \{1, \dots, N\})\, c_r = 0$, so $g \mapsto \Phi_g$ is injective and $\{\Phi_g : g \in \mathcal{C}\}$ is $\mathbb{F}$-linearly independent.
Extend this set to a Hamel basis $\mathcal{E}$ of $\mathcal{V}'$ by Theorem 1.3.17(iii). By (b), $\dim_{\mathbb{F}}(\mathcal{V}') = |\mathcal{E}| \ge |\mathcal{C}| = \dim_{\mathbb{F}_0}(\mathbb{F}_0^I) > \kappa = \dim_{\mathbb{F}}(\mathcal{V})$ by Proposition 6.5.2(i) and Definition 1.4.6, contrary to the assumed equality.

(ii) $(\Leftarrow)$ If $\dim(\mathcal{V}) < \infty$, then $\dim(\mathcal{V}') = \dim(\mathcal{V})$ by Theorem 4.1.4(ii).

Structural Commentary: A countable scalar core transfers Cantor-sized independence from functions to functionals.
Key Insight: Scalar extension preserves independence of core-field coordinate functions. □

Proposition 4.1.7. *Functionals Separate Points*
Assume Zorn's lemma, and let $\mathcal{V}$ *be a vector space.*
(i) $(\forall\, \mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\})(\exists\, \varphi \in \mathcal{V}')\, \varphi(\mathbf{v}) \neq 0$.
(ii) $(\forall\, \mathbf{v} \in \mathcal{V})\, [\mathbf{v} = \mathbf{0} \iff (\forall\, \varphi \in \mathcal{V}')\, \varphi(\mathbf{v}) = 0]$.

(iii) *If* $\mathcal{U} \leq \mathcal{V}$ *and* $\mathbf{x} \in \mathcal{V} \setminus \mathcal{U}$, *then* $(\exists \varphi \in \mathcal{V}')\,[\varphi|_{\mathcal{U}} = 0 \wedge \varphi(\mathbf{x}) = 1]$.
(iv) *If* $\varphi \in \mathcal{V}'$ *and* $\mathbf{x} \in \mathcal{V}$ *satisfy* $\varphi(\mathbf{x}) \neq 0$, *then* $\mathcal{V} = \operatorname{span}(\mathbf{x}) \oplus \ker(\varphi)$.
(v) *If* $0 \neq \varphi, \psi \in \mathcal{V}'$ *and* $\ker(\varphi) = \ker(\psi)$, *then* $(\exists a \in \mathbb{F} \setminus \{0\})\,\varphi = a\psi$.

Proof.

(*i*) Fix $\mathbf{v} \neq \mathbf{0}$. The set $\{\mathbf{v}\}$ is linearly independent, so it extends to a Hamel basis $\mathcal{B} = \{\mathbf{b}_i\}_{i\in I}$ by Theorem 1.3.17(iii).
Let $\{\varepsilon_i\}_{i\in I}$ denote its coordinate functionals, choose $i_0 \in I$ with $\mathbf{b}_{i_0} = \mathbf{v}$. Then $\varepsilon_{i_0} \in \mathcal{V}'$ by Proposition 4.1.5(i), and $\varepsilon_{i_0}(\mathbf{v}) = 1$.
(*ii*) ($\Rightarrow$) If $\mathbf{v} = \mathbf{0}$, then $(\forall \varphi \in \mathcal{V}')\,\varphi(\mathbf{v}) = 0$ by Proposition 1.5.3.
(*ii*) ($\Leftarrow$) If $\mathbf{v} \neq \mathbf{0}$, then $(\exists \psi \in \mathcal{V}')\,\psi(\mathbf{v}) \neq 0$ by (i), contrary to the assumed vanishing. Hence $\mathbf{v} = \mathbf{0}$.
(*iii*) Choose a Hamel basis $\mathcal{B}_{\mathcal{U}}$ of $\mathcal{U}$ by Theorem 1.3.17(ii).
Since $\mathbf{x} \notin \operatorname{span}(\mathcal{B}_{\mathcal{U}})$, every finite relation on $\mathcal{B}_{\mathcal{U}} \cup \{\mathbf{x}\}$ has zero $\mathbf{x}$-coefficient and is then trivial by independence of $\mathcal{B}_{\mathcal{U}}$.
Thus $\mathcal{B}_{\mathcal{U}} \cup \{\mathbf{x}\}$ is linearly independent and extends to a Hamel basis $\mathcal{B} = \{\mathbf{b}_i\}_{i\in I}$ of $\mathcal{V}$ by Theorem 1.3.17(iii).
Let $\{\varepsilon_i\}_{i\in I}$ denote its coordinate functionals, choose $i_0 \in I$ with $\mathbf{b}_{i_0} = \mathbf{x}$, and set $\varphi := \varepsilon_{i_0}$.
Then $\varphi \in \mathcal{V}'$ by Proposition 4.1.5(i), $\varphi(\mathbf{x}) = 1$, and $\varphi|_{\mathcal{U}} = 0$ by $\mathcal{U} = \operatorname{span}(\mathcal{B}_{\mathcal{U}})$.
(*iv*) If $c\mathbf{x} \in \ker(\varphi)$, then $c\varphi(\mathbf{x}) = 0$, so $c = 0$; hence $\operatorname{span}(\mathbf{x}) \cap \ker(\varphi) = \{\mathbf{0}\}$. For $\mathbf{v} \in \mathcal{V}$, set $c_{\mathbf{v}} := \varphi(\mathbf{v})\varphi(\mathbf{x})^{-1}$.
Then $\mathbf{v} = c_{\mathbf{v}}\mathbf{x} + (\mathbf{v} - c_{\mathbf{v}}\mathbf{x})$, with $\mathbf{v} - c_{\mathbf{v}}\mathbf{x} \in \ker(\varphi)$. Thus $\mathcal{V} = \operatorname{span}(\mathbf{x}) \oplus \ker(\varphi)$ by Proposition 2.1.8.
(*v*) Set $\mathcal{K} := \ker(\varphi) = \ker(\psi)$. Since $\varphi \neq 0$, choose $\mathbf{x} \in \mathcal{V} \setminus \mathcal{K}$, set $a := \varphi(\mathbf{x})\psi(\mathbf{x})^{-1} \neq 0$. The identity $\mathcal{V} = \operatorname{span}(\mathbf{x}) \oplus \mathcal{K}$ holds by (iv).
Fix $\mathbf{v} = c\mathbf{x} + \mathbf{k}$ with $c \in \mathbb{F}$ and $\mathbf{k} \in \mathcal{K}$. Then $\varphi(\mathbf{v}) = c\varphi(\mathbf{x}) = ac\psi(\mathbf{x}) = a\psi(\mathbf{v})$. Hence $\varphi = a\psi$ by Assumption 3.1.2.

Structural Commentary: Basis extension constructs separating coordinates; kernel decomposition then compares nonzero functionals.
Key Insight: One normalized coordinate detects any direction outside a prescribed subspace. □

Corollary 4.1.8. *Kernels of Nonzero Functionals*
If $0 \neq \varphi \in \mathcal{V}'$, *then:*

(i) φ *is surjective;*
(ii) $\mathcal{V}/\ker(\varphi) \cong \mathbb{F}$;
(iii) $\operatorname{codim}_{\mathcal{V}}(\ker(\varphi)) = 1$.

Proof. Choose $\mathbf{x} \in \mathcal{V}$ with $\varphi(\mathbf{x}) \neq 0$.

(i) $(\forall a \in \mathbb{F})\,\varphi(a\varphi(\mathbf{x})^{-1}\mathbf{x}) = a$, so $\operatorname{range}(\varphi) = \mathbb{F}$.
(ii) The isomorphism $\mathcal{V}/\ker(\varphi) \cong \operatorname{range}(\varphi) = \mathbb{F}$ holds by Theorem 2.2.12 and (i).
(iii) Choose an isomorphism $T : \mathcal{V}/\ker(\varphi) \to \mathbb{F}$ by (ii). Since (1) is a basis of $\mathbb{F}$ over itself, $(T^{-1}(1))$ is a basis of $\mathcal{V}/\ker(\varphi)$ by Proposition 1.7.8. Hence $\operatorname{codim}_{\mathcal{V}}(\ker(\varphi)) = \dim(\mathcal{V}/\ker(\varphi)) = 1$ by Definition 2.3.11 and Definition 1.4.2.

Structural Commentary: Surjectivity identifies the quotient with the one-dimensional scalar field.
Key Insight: A nonzero functional removes exactly one scalar direction. □

4.2 Double Duals and Dual Maps

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$.

Definition 4.2.1. *Algebraic Double Dual and Natural Map*

(i) The *algebraic double dual* of $\mathcal{V}$ is $\mathcal{V}'' := (\mathcal{V}')'$.
(ii) The *natural evaluation map* $\Lambda_{\mathcal{V}} : \mathcal{V} \to \mathcal{V}''$ is defined by $(\forall \mathbf{v} \in \mathcal{V})(\forall \varphi \in \mathcal{V}')\,\Lambda_{\mathcal{V}}(\mathbf{v})(\varphi) := \varphi(\mathbf{v})$.
For $\mathbf{v} \in \mathcal{V}$, $(\forall a, b \in \mathbb{F})(\forall \varphi, \psi \in \mathcal{V}')\,\Lambda_{\mathcal{V}}(\mathbf{v})(a\varphi + b\psi) = a\varphi(\mathbf{v}) + b\psi(\mathbf{v})$ by pointwise operations in Proposition 1.5.5, so $\Lambda_{\mathcal{V}}(\mathbf{v}) \in \mathcal{V}''$.
(iii) The space $\mathcal{V}$ is *algebraically reflexive* iff $\Lambda_{\mathcal{V}}$ is surjective.

Theorem 4.2.2. *Algebraic Reflexivity*
Let $\mathcal{V}$ *be a vector space. Claims (iii)–(v) assume Zorn's lemma, and (v) additionally assumes the Choice Principle 6.1.2. Then:*

(i) $\Lambda_{\mathcal{V}} \in \mathcal{L}(\mathcal{V}, \mathcal{V}'')$;
(ii) *if* $\dim(\mathcal{V}) < \infty$, *then* $\Lambda_{\mathcal{V}}$ *is an isomorphism;*
(iii) $\Lambda_{\mathcal{V}}$ *is injective;*
(iv) $\Lambda_{\mathcal{V}}$ *is an isomorphism iff* $\mathcal{V}$ *is algebraically reflexive;*
(v) $\mathcal{V}$ *is algebraically reflexive iff* $\dim(\mathcal{V}) < \infty$.

Proof.

(*i*) For $a, b \in \mathbb{F}$, $\mathbf{u}, \mathbf{v} \in \mathcal{V}$, and $\varphi \in \mathcal{V}'$, one has $\Lambda_{\mathcal{V}}(a\mathbf{u} + b\mathbf{v})(\varphi) = \varphi(a\mathbf{u} + b\mathbf{v}) = \big(a\Lambda_{\mathcal{V}}(\mathbf{u}) + b\Lambda_{\mathcal{V}}(\mathbf{v})\big)(\varphi)$.
Hence $\Lambda_{\mathcal{V}}(a\mathbf{u} + b\mathbf{v}) = a\Lambda_{\mathcal{V}}(\mathbf{u}) + b\Lambda_{\mathcal{V}}(\mathbf{v})$ by Assumption 3.1.2, so $\Lambda_{\mathcal{V}} \in \mathcal{L}(\mathcal{V}, \mathcal{V}'')$.
(*ii*) Suppose $\dim(\mathcal{V}) < \infty$, let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ be a basis, and let $\beta' = (\varphi_1, \ldots, \varphi_n)$ be its dual basis.
If $\mathbf{v} = \sum_{j=1}^{n} c_j \mathbf{v}_j \in \ker(\Lambda_{\mathcal{V}})$, then $(\forall k \in \{1, \ldots, n\})\,c_k = \Lambda_{\mathcal{V}}(\mathbf{v})(\varphi_k) = 0$; hence $\mathbf{v} = \mathbf{0}$, also for $n = 0$. Thus $\Lambda_{\mathcal{V}}$ is injective by Proposition 1.6.2. By Theorem 4.1.4(ii) for $\mathcal{V}$, $\dim(\mathcal{V}') = \dim(\mathcal{V}) < \infty$; by the same theorem for $\mathcal{V}'$, $\dim(\mathcal{V}'') = \dim(\mathcal{V}')$.
Therefore $\Lambda_{\mathcal{V}}$ is surjective by Corollary 1.7.6(ii) and is an isomorphism by Proposition 1.6.7.
(*iii*) Assume Zorn's lemma. By Proposition 1.6.2, it suffices to prove $\ker(\Lambda_{\mathcal{V}}) = \{\mathbf{0}\}$.
If $\mathbf{v} \in \ker(\Lambda_{\mathcal{V}})$, then $(\forall \varphi \in \mathcal{V}')\,\varphi(\mathbf{v}) = 0$, so $\mathbf{v} = \mathbf{0}$ by Proposition 4.1.7(ii).
(*iv*) ($\Rightarrow$) If $\Lambda_{\mathcal{V}}$ is an isomorphism, then it is surjective by Proposition 1.6.7; hence $\mathcal{V}$ is algebraically reflexive by Definition 4.2.1(iii).
(*iv*) ($\Leftarrow$) By Proposition 1.6.7, it suffices to prove that $\Lambda_{\mathcal{V}}$ is bijective. It is surjective by algebraic reflexivity and injective by (iii).
(*v*) ($\Rightarrow$) Suppose $\mathcal{V}$ is algebraically reflexive. Then $\Lambda_{\mathcal{V}}$ is an isomorphism by (iv).
If $\dim(\mathcal{V})$ were infinite, then $\dim(\mathcal{V}) < \dim(\mathcal{V}') < \dim(\mathcal{V}'')$ by Theorem 4.1.6(i),(ii), first for $\mathcal{V}$ and then for $\mathcal{V}'$.
Choose a Hamel basis $\mathcal{B}$ of $\mathcal{V}$ by Theorem 1.3.17(ii). The set $\Lambda_{\mathcal{V}}(\mathcal{B})$ is a Hamel basis of $\mathcal{V}''$ by linearity, injectivity, and surjectivity of $\Lambda_{\mathcal{V}}$: linearity and injectivity preserve finite independence, while linearity and surjectivity preserve spanning.
Thus $\dim(\mathcal{V}) = \dim(\mathcal{V}'')$ by Definition 1.4.6, a contradiction. Hence $\dim(\mathcal{V}) < \infty$.
(*v*) ($\Leftarrow$) If $\dim(\mathcal{V}) < \infty$, then $\Lambda_{\mathcal{V}}$ is surjective by (ii) and Proposition 1.6.7; hence $\mathcal{V}$ is algebraically reflexive by Definition 4.2.1(iii).

Structural Commentary: Evaluation proves linearity, separation proves injectivity, and dual dimensions obstruct infinite reflexivity.
Key Insight: Canonical evaluation is surjective exactly before dual dimension grows. □

Perspective 4.2.3. *Why the Double Dual Is Natural*
An isomorphism $\mathcal{V} \cong \mathcal{V}'$ for finite-dimensional $\mathcal{V}$ generally depends on a chosen basis. In contrast, $\Lambda_{\mathcal{V}} : \mathcal{V} \to \mathcal{V}''$ is defined solely by evaluation and requires no basis.

Definition 4.2.4. *Dual Map*
If $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, its *dual map* is $T' : \mathcal{W}' \to \mathcal{V}'$ defined by $(\forall\, \varphi \in \mathcal{W}')\, T'\varphi := \varphi T$.
The relation $(\forall\, \varphi \in \mathcal{W}')\, \varphi T \in \mathcal{L}(\mathcal{V}, \mathbb{F}) = \mathcal{V}'$ holds by Proposition 1.5.7(i). Equivalently, $(\forall\, \varphi \in \mathcal{W}')(\forall\, \mathbf{v} \in \mathcal{V})\, (T'\varphi)(\mathbf{v}) = \varphi(T\mathbf{v})$.

Proposition 4.2.5. *Dual Maps Are Linear*
If $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, then $T' \in \mathcal{L}(\mathcal{W}', \mathcal{V}')$.

Proof. For $a, b \in \mathbb{F}$, $\varphi, \psi \in \mathcal{W}'$, and $\mathbf{v} \in \mathcal{V}$, one has $\big(T'(a\varphi + b\psi)\big)(\mathbf{v}) = (a\varphi + b\psi)(T\mathbf{v}) = \big(aT'\varphi + bT'\psi\big)(\mathbf{v})$.
Hence $T'(a\varphi + b\psi) = aT'\varphi + bT'\psi$ by Assumption 3.1.2, so $T' \in \mathcal{L}(\mathcal{W}', \mathcal{V}')$ by Definition 1.5.1.
Structural Commentary: Pointwise evaluation reduces linearity of the pullback to linearity of each functional.
Key Insight: Precomposition preserves linear combinations while reversing map direction. □

Theorem 4.2.6. *Algebra of Dual Maps*
(i) If $S, T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ and $a, b \in \mathbb{F}$, then $(aS + bT)' = aS' + bT'$.
(ii) If $T \in \mathcal{L}(\mathcal{U}, \mathcal{V})$ and $S \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, then $(ST)' = T'S'$.
(iii) $(I_{\mathcal{V}})' = I_{\mathcal{V}'}$.

Proof.
(i) For $\varphi \in \mathcal{W}'$ and $\mathbf{v} \in \mathcal{V}$, $\big((aS + bT)'\varphi\big)(\mathbf{v}) = \varphi(aS\mathbf{v} + bT\mathbf{v}) = \big(aS'\varphi + bT'\varphi\big)(\mathbf{v})$.
Hence $(aS + bT)' = aS' + bT'$ by Assumption 3.1.2 on $\mathcal{V}$ and $\mathcal{W}'$.
(ii) For $\varphi \in \mathcal{W}'$ and $\mathbf{u} \in \mathcal{U}$, $\big((ST)'\varphi\big)(\mathbf{u}) = \varphi(S(T\mathbf{u})) = \big(T'(S'\varphi)\big)(\mathbf{u})$. Hence $(ST)' = T'S'$ by Assumption 3.1.2 on $\mathcal{U}$ and $\mathcal{W}'$.
(iii) For $\varphi \in \mathcal{V}'$ and $\mathbf{v} \in \mathcal{V}$, $\big((I_{\mathcal{V}})'\varphi\big)(\mathbf{v}) = \varphi(I_{\mathcal{V}}\mathbf{v}) = \varphi(\mathbf{v})$. Hence $(I_{\mathcal{V}})' = I_{\mathcal{V}'}$ by Assumption 3.1.2 on $\mathcal{V}$ and $\mathcal{V}'$.
Structural Commentary: Function extensionality lifts pointwise linearity, composition, and identity calculations to dual maps.
Key Insight: Precomposition reverses products but preserves linear structure. □

Corollary 4.2.7. *Dual Map of an Inverse*
If $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ is an isomorphism, then:
(i) T' is an isomorphism;
(ii) $(T^{-1})' = (T')^{-1}$.

Proof. Set $S := (T^{-1})'$. Then $S \in \mathcal{L}(\mathcal{V}', \mathcal{W}')$ by Proposition 4.2.5.
(i) By Theorem 4.2.6(ii)–(iii), $T'S = (T^{-1}T)' = (I_{\mathcal{V}})' = I_{\mathcal{V}'}$ and $ST' = (TT^{-1})' = (I_{\mathcal{W}})' = I_{\mathcal{W}'}$.
Thus S is a two-sided inverse of T', and T' is an isomorphism by Definition 1.6.4.
(ii) The identity $S = (T')^{-1}$ holds by Proposition 1.6.5; hence $(T^{-1})' = (T')^{-1}$.
Structural Commentary: Reversed product identities construct the dual inverse; uniqueness identifies it.
Key Insight: Contravariance turns both inverse identities into dual identities. □

Corollary 4.2.8. *Double Dual Maps Identify with Original Maps*
Let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ and set $T'' := (T')'$. Then:
(i) $T''\Lambda_{\mathcal{V}} = \Lambda_{\mathcal{W}} T$;
(ii) if $\dim(\mathcal{V}), \dim(\mathcal{W}) < \infty$, then $T'' = \Lambda_{\mathcal{W}} T \Lambda_{\mathcal{V}}^{-1}$.

Proof. $T' \in \mathcal{L}(\mathcal{W}', \mathcal{V}')$ and $T'' \in \mathcal{L}(\mathcal{V}'', \mathcal{W}'')$ by Proposition 4.2.5, first for T and then for T'.
(i) For $\mathbf{v} \in \mathcal{V}$ and $\psi \in \mathcal{W}'$, $\big(T''\Lambda_{\mathcal{V}}(\mathbf{v})\big)(\psi) = \Lambda_{\mathcal{V}}(\mathbf{v})(T'\psi) = (T'\psi)(\mathbf{v}) = \psi(T\mathbf{v}) = \Lambda_{\mathcal{W}}(T\mathbf{v})(\psi)$.
Hence $T''\Lambda_{\mathcal{V}} = \Lambda_{\mathcal{W}} T$ by Assumption 3.1.2 on $\mathcal{W}'$ and $\mathcal{V}$.
(ii) If $\mathcal{V}$ and $\mathcal{W}$ are finite-dimensional, then $\Lambda_{\mathcal{V}}$ and $\Lambda_{\mathcal{W}}$ are isomorphisms by Theorem 4.2.2(ii).
Thus $T'' = T''I_{\mathcal{V}''} = T''\Lambda_{\mathcal{V}}\Lambda_{\mathcal{V}}^{-1} = \Lambda_{\mathcal{W}} T \Lambda_{\mathcal{V}}^{-1}$ by (i) and Proposition 1.5.7(ii)–(iii).
Structural Commentary: Pointwise evaluation proves naturality; finite reflexivity transports T to its double dual.
Key Insight: Both routes evaluate each functional at the same image vector. □

4.3 Annihilators and Transposes

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$.

Definition 4.3.1. *Annihilator*
If $\mathcal{U} \subseteq \mathcal{V}$, the *annihilator of $\mathcal{U}$ in $\mathcal{V}'$* is $\mathcal{U}^0 := \{\varphi \in \mathcal{V}' : (\forall\, \mathbf{u} \in \mathcal{U})\, \varphi(\mathbf{u}) = 0\}$.
The ambient space $\mathcal{V}$ is understood from context; changing it changes the dual space containing $\mathcal{U}^0$.

Proposition 4.3.2. *Annihilators Are Subspaces*
If $\mathcal{U} \subseteq \mathcal{V}$, then $\mathcal{U}^0$ is a subspace of $\mathcal{V}'$.

Proof. The zero functional belongs to $\mathcal{U}^0$. If $\varphi, \psi \in \mathcal{U}^0$, $a \in \mathbb{F}$, and $\mathbf{u} \in \mathcal{U}$, then $(a\varphi + \psi)(\mathbf{u}) = a\varphi(\mathbf{u}) + \psi(\mathbf{u}) = 0$.
Hence $a\varphi + \psi \in \mathcal{U}^0$, and $\mathcal{U}^0 \leq \mathcal{V}'$ by Theorem 1.2.2.
Structural Commentary: The subspace test reduces closure to the preservation of pointwise vanishing.
Key Insight: Linear combinations preserve every annihilating constraint. □

Theorem 4.3.3. *Dimension of the Annihilator*
Let $\mathcal{V}$ be finite-dimensional and let $\mathcal{U}$ be a subspace of $\mathcal{V}$. Then $\dim(\mathcal{U}) + \dim(\mathcal{U}^0) = \dim(\mathcal{V})$.

Proof. Choose basis $(\mathbf{u}_1,\dots,\mathbf{u}_m)$ of $\mathcal{U}$ by Corollary 1.3.14, extend to basis $\beta=(\mathbf{u}_1,\dots,\mathbf{u}_m,\mathbf{w}_1,\dots,\mathbf{w}_k)$ of $\mathcal{V}$ by Theorem 1.3.13.
Let $\beta'=(\varphi_1,\dots,\varphi_m,\psi_1,\dots,\psi_k)$ be the dual basis.
By Theorem 4.1.4(i) and Definition 4.1.3, every $\varphi\in\mathcal{V}'$ satisfies $\varphi=\sum_{j=1}^{m}\varphi(\mathbf{u}_j)\varphi_j+\sum_{\ell=1}^{k}\varphi(\mathbf{w}_\ell)\psi_\ell$. Thus $\varphi\in\mathcal{U}^0$ implies $\varphi=\sum_{\ell=1}^{k}\varphi(\mathbf{w}_\ell)\psi_\ell$.
Conversely, each ψ_ℓ vanishes on $\mathcal{U}=\operatorname{span}(\mathbf{u}_1,\dots,\mathbf{u}_m)$ by Definition 4.1.3.
Hence $(\psi_1,\dots,\psi_k)$ spans $\mathcal{U}^0$ and is linearly independent as a sublist of β', so it is a basis of $\mathcal{U}^0$.
The adapted and annihilator bases have lengths $m+k$ and k, respectively, so $\dim(\mathcal{U})+\dim(\mathcal{U}^0)=m+k=\dim(\mathcal{V})$.
Structural Commentary: An adapted basis identifies the annihilator with the dual coordinates outside $\mathcal{U}$.
Key Insight: Vanishing deletes precisely the dual coordinates indexed by $\mathcal{U}$. □

Theorem 4.3.4. *Annihilator Lattice Identities*
Let $\mathcal{V}$ be finite-dimensional, and let $\mathcal{S},\mathcal{T}$ be subspaces of $\mathcal{V}$.
(i) $\mathcal{S}\subseteq\mathcal{T}\Rightarrow\mathcal{T}^0\subseteq\mathcal{S}^0$.
(ii) $(\mathcal{S}+\mathcal{T})^0=\mathcal{S}^0\cap\mathcal{T}^0$.
(iii) $(\mathcal{S}\cap\mathcal{T})^0=\mathcal{S}^0+\mathcal{T}^0$.

Proof.
(i) If $\mathcal{S}\subseteq\mathcal{T}$ and $\varphi\in\mathcal{T}^0$, then $(\forall\,\mathbf{s}\in\mathcal{S})\,\varphi(\mathbf{s})=0$, so $\varphi\in\mathcal{S}^0$.
(ii) If $\varphi\in(\mathcal{S}+\mathcal{T})^0$, then $\varphi|_{\mathcal{S}}=0$ and $\varphi|_{\mathcal{T}}=0$, so $\varphi\in\mathcal{S}^0\cap\mathcal{T}^0$.
Conversely, if $\varphi\in\mathcal{S}^0\cap\mathcal{T}^0$, then $(\forall\,\mathbf{s}\in\mathcal{S})(\forall\,\mathbf{t}\in\mathcal{T})\,\varphi(\mathbf{s}+\mathbf{t})=\varphi(\mathbf{s})+\varphi(\mathbf{t})=0$, so $\varphi\in(\mathcal{S}+\mathcal{T})^0$.
(iii) By (i), $\mathcal{S}^0+\mathcal{T}^0\subseteq(\mathcal{S}\cap\mathcal{T})^0$. By (ii) and Theorem 2.3.1, $\dim(\mathcal{S}^0+\mathcal{T}^0)=\dim(\mathcal{S}^0)+\dim(\mathcal{T}^0)-\dim((\mathcal{S}+\mathcal{T})^0)$.
The identity $\dim(\mathcal{S}^0+\mathcal{T}^0)=\dim(\mathcal{V})-\dim(\mathcal{S}\cap\mathcal{T})=\dim((\mathcal{S}\cap\mathcal{T})^0)$ holds by Theorem 4.3.3 and Theorem 2.3.1.
Hence the inclusion is an equality by Proposition 1.4.3.
Structural Commentary: Two direct inclusions establish order reversal and sums; a dimension comparison recovers intersections.
Key Insight: Annihilation reverses the finite-dimensional subspace lattice. □

Theorem 4.3.5. *Double Annihilator*
Let $\dim(\mathcal{V})<\infty$ and $M\subseteq\mathcal{V}$, and set $M^{00}:=(M^0)^0\subseteq\mathcal{V}''$. Then:
(i) $M^{00}=\Lambda_{\mathcal{V}}(\operatorname{span}(M))$;
(ii) if $\mathcal{S}\leq\mathcal{V}$, then $\mathcal{S}^{00}=\Lambda_{\mathcal{V}}(\mathcal{S})$, and the corestriction $\Lambda_{\mathcal{V}}|_{\mathcal{S}}:\mathcal{S}\to\mathcal{S}^{00}$ is an isomorphism.

Proof.
(i) If $\mathbf{v}\in\operatorname{span}(M)$ and $\varphi\in M^0$, then $\Lambda_{\mathcal{V}}(\mathbf{v})(\varphi)=\varphi(\mathbf{v})=0$ by linearity of φ, so $\Lambda_{\mathcal{V}}(\operatorname{span}(M))\subseteq M^{00}$.
For the reverse inclusion, let $\eta\in M^{00}$. The relation $(\exists!\,\mathbf{v}\in\mathcal{V})\,\eta=\Lambda_{\mathcal{V}}(\mathbf{v})$ holds by Theorem 4.2.2(ii); fix this $\mathbf{v}$.
Suppose $\mathbf{v}\notin\operatorname{span}(M)$. Choose a basis $(\mathbf{u}_1,\dots,\mathbf{u}_m)$ of $\operatorname{span}(M)$ by Corollary 1.3.14.
The list $(\mathbf{u}_1,\dots,\mathbf{u}_m,\mathbf{v})$ is linearly independent by Proposition 1.3.7 and extends to a basis of $\mathcal{V}$ by Theorem 1.3.13.
Its dual-basis functional φ corresponding to $\mathbf{v}$ satisfies $\varphi|_{\operatorname{span}(M)}=0$ and $\varphi(\mathbf{v})=1$.
Thus $\varphi\in M^0$ but $\eta(\varphi)=1$, contrary to $\eta\in M^{00}$. Hence $M^{00}\subseteq\Lambda_{\mathcal{V}}(\operatorname{span}(M))$.
(ii) The identity $\mathcal{S}^{00}=\Lambda_{\mathcal{V}}(\mathcal{S})$ holds by (i) with $M=\mathcal{S}$. The corestriction is linear and injective by Theorem 4.2.2(i)–(ii), and it is surjective onto $\mathcal{S}^{00}$. Therefore it is an isomorphism by Proposition 1.6.7.
Structural Commentary: One inclusion extends vanishing; an adapted dual basis separates every vector outside the span.
Key Insight: Double annihilation remembers exactly the generated subspace. □

Theorem 4.3.6. *Direct Sums and Annihilators*
Suppose $\mathcal{V}=\mathcal{S}\oplus\mathcal{T}$, and define $E:\mathcal{T}'\to\mathcal{S}^0$ by $(\forall\,\varphi\in\mathcal{T}')(\forall\,\mathbf{s}\in\mathcal{S})(\forall\,\mathbf{t}\in\mathcal{T})\,(E\varphi)(\mathbf{s}+\mathbf{t}):=\varphi(\mathbf{t})$. Then:
(i) E is an isomorphism;
(ii) $\mathcal{V}'=\mathcal{S}^0\oplus\mathcal{T}^0$.

Proof.
(i) Each $\mathbf{v}\in\mathcal{V}$ has a unique representation $\mathbf{v}=\mathbf{s}+\mathbf{t}$ by Proposition 2.1.8, so E is well-defined.
If $\mathbf{v}_i=\mathbf{s}_i+\mathbf{t}_i$ for $i=1,2$ and $a,b\in\mathbb{F}$, then $(E\varphi)(a\mathbf{v}_1+b\mathbf{v}_2)=\varphi(a\mathbf{t}_1+b\mathbf{t}_2)=a(E\varphi)(\mathbf{v}_1)+b(E\varphi)(\mathbf{v}_2)$, so $E\varphi\in\mathcal{V}'$.
The relation $(\forall\,\mathbf{s}\in\mathcal{S})\,(E\varphi)(\mathbf{s})=0$ places $E\varphi$ in $\mathcal{S}^0$. For $a,b\in\mathbb{F}$ and $\varphi,\psi\in\mathcal{T}'$, the identity $E(a\varphi+b\psi)=aE\varphi+bE\psi$ holds pointwise and hence by Assumption 3.1.2, so $E\in\mathcal{L}(\mathcal{T}',\mathcal{S}^0)$. Define $R:\mathcal{S}^0\to\mathcal{T}'$ by $(\forall\,\eta\in\mathcal{S}^0)\,R\eta:=\eta|_{\mathcal{T}}$.
If $\eta\in\mathcal{S}^0$, $a,b\in\mathbb{F}$, and $\mathbf{t}_1,\mathbf{t}_2\in\mathcal{T}$, then $(R\eta)(a\mathbf{t}_1+b\mathbf{t}_2)=a(R\eta)(\mathbf{t}_1)+b(R\eta)(\mathbf{t}_2)$ by linearity of η, so $R\eta\in\mathcal{T}'$.
For $a,b\in\mathbb{F}$ and $\eta,\zeta\in\mathcal{S}^0$, the identity $R(a\eta+b\zeta)=aR\eta+bR\zeta$ holds pointwise, so $R\in\mathcal{L}(\mathcal{S}^0,\mathcal{T}')$ by Assumption 3.1.2.
The identities $(\forall\,\varphi\in\mathcal{T}')\,RE\varphi=\varphi$ and $(\forall\,\eta\in\mathcal{S}^0)(\forall\,\mathbf{s}\in\mathcal{S})(\forall\,\mathbf{t}\in\mathcal{T})\,(ER\eta)(\mathbf{s}+\mathbf{t})=\eta(\mathbf{t})=\eta(\mathbf{s}+\mathbf{t})$ hold by the definitions of E, R, and $\mathcal{S}^0$. Thus R is a two-sided inverse of E by Assumption 3.1.2, and E is an isomorphism.
(ii) For $\varphi\in\mathcal{V}'$, set $\varphi_{\mathcal{S}}:=\varphi\rho_{\mathcal{S},\mathcal{T}}$ and $\varphi_{\mathcal{T}}:=\varphi\rho_{\mathcal{T},\mathcal{S}}$. These functionals belong to $\mathcal{V}'$ by Proposition 2.4.2(ii) and Proposition 1.5.7(i).
Their respective membership in $\mathcal{T}^0$ and $\mathcal{S}^0$ holds by Proposition 2.4.2(iii).
The identity $\varphi=\varphi_{\mathcal{S}}+\varphi_{\mathcal{T}}$ holds by Proposition 2.4.3(i), so $\mathcal{V}'=\mathcal{S}^0+\mathcal{T}^0$.
If $\eta\in\mathcal{S}^0\cap\mathcal{T}^0$, then $(\forall\,\mathbf{s}\in\mathcal{S})(\forall\,\mathbf{t}\in\mathcal{T})\,\eta(\mathbf{s}+\mathbf{t})=0$, so $\eta=0_{\mathcal{V}'}$ by Assumption 3.1.2. Thus $\mathcal{V}'=\mathcal{S}^0\oplus\mathcal{T}^0$.
Structural Commentary: Extension and restriction identify one annihilator; component functionals split every element of the dual.
Key Insight: Each dual component ignores the opposite primal summand. □

Theorem 4.3.7. *Kernel and Range of the Dual Map*
Let $T\in\mathcal{L}(\mathcal{V},\mathcal{W})$. The following statements hold, with finite-dimensionality of $\mathcal{V}$ and $\mathcal{W}$ required only in (ii)–(iv):
(i) $\ker(T')=(\operatorname{range}(T))^0$;
(ii) $\dim(\ker(T'))=\dim(\ker(T))+\dim(\mathcal{W})-\dim(\mathcal{V})$;
(iii) $\operatorname{range}(T')=(\ker(T))^0$;
(iv) $\dim(\operatorname{range}(T'))=\dim(\operatorname{range}(T))$.

Proof. For (ii)–(iv), assume that $\mathcal{V}$ and $\mathcal{W}$ are finite-dimensional.
(i) For $\varphi\in\mathcal{W}'$, $T'\varphi=0$ iff $(\forall\,\mathbf{v}\in\mathcal{V})\,\varphi(T\mathbf{v})=0$ iff $\varphi\in(\operatorname{range}(T))^0$.
(ii) By (i), Theorem 4.3.3, and Theorem 1.7.3(ii), $\dim(\ker(T'))=\dim(\mathcal{W})-\dim(\operatorname{range}(T))=\dim(\ker(T))+\dim(\mathcal{W})-\dim(\mathcal{V})$.

(iii) If $\varphi = T'\psi$ and $\mathbf{v} \in \ker(T)$, then $\varphi(\mathbf{v}) = \psi(T\mathbf{v}) = 0$, so $\operatorname{range}(T') \subseteq (\ker(T))^0$.
By Theorem 1.7.3(ii), (ii), and Theorem 4.1.4(ii), $\dim(\operatorname{range}(T')) = \dim(\mathcal{W}') - \dim(\ker(T')) = \dim(\mathcal{V}) - \dim(\ker(T))$.
The latter dimension equals $\dim((\ker(T))^0)$ by Theorem 4.3.3, so the inclusion is an equality by Proposition 1.4.3.
(iv) By (iii), Theorem 4.3.3, and Theorem 1.7.3(ii), $\dim(\operatorname{range}(T')) = \dim(\mathcal{V}) - \dim(\ker(T)) = \dim(\operatorname{range}(T))$.

Structural Commentary: A direct kernel identity and finite-dimensional counts determine the dual range and both dimensions.
Key Insight: Pullback exchanges unreachable vectors with annihilating functionals. □

Corollary 4.3.8. *Surjectivity and Dual Injectivity*
Let $\mathcal{V}$ and $\mathcal{W}$ be finite-dimensional, and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Then T is surjective iff T' is injective.

Proof.
($\Rightarrow$) If T is surjective, then $\operatorname{range}(T) = \mathcal{W}$, so $\ker(T') = \mathcal{W}^0 = \{0_{\mathcal{W}'}\}$ by Theorem 4.3.7(i). Hence T' is injective by Proposition 1.6.2.
($\Leftarrow$) If T' is injective, then $(\operatorname{range}(T))^0 = \ker(T') = \{0_{\mathcal{W}'}\}$ by Proposition 1.6.2 and Theorem 4.3.7(i).
Thus $\dim(\operatorname{range}(T)) = \dim(\mathcal{W})$ by Theorem 4.3.3, so $\operatorname{range}(T) = \mathcal{W}$ by Proposition 1.4.3.

Structural Commentary: The dual-kernel identity translates surjectivity into a zero-kernel criterion.
Key Insight: A full range has no nonzero annihilator. □

Corollary 4.3.9. *Injectivity and Dual Surjectivity*
Let $\mathcal{V}$ and $\mathcal{W}$ be finite-dimensional, and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Then T is injective iff T' is surjective.

Proof.
($\Rightarrow$) If T is injective, then T' is surjective by Proposition 1.6.2, Theorem 4.3.7(iii), and Definition 4.3.1.
($\Leftarrow$) If T' is surjective, then $(\ker(T))^0 = \operatorname{range}(T') = \mathcal{V}'$ by Theorem 4.3.7(iii).
Thus $\dim(\ker(T)) = 0$ by Theorem 4.3.3, so $\ker(T) = \{\mathbf{0}_{\mathcal{V}}\}$ by Proposition 1.4.3. Therefore T is injective by Proposition 1.6.2.

Structural Commentary: The dual-range identity converts injectivity into surjectivity of the pullback.
Key Insight: A trivial kernel leaves no functional-extension obstruction. □

Corollary 4.3.10. *Dual of a Quotient as an Annihilator*
Let $\mathcal{V}$ be finite-dimensional, let $\mathcal{U} \leq \mathcal{V}$, and let $\pi : \mathcal{V} \to \mathcal{V}/\mathcal{U}$ be the quotient map. Then:
(i) $\ker(\pi') = \{0_{(\mathcal{V}/\mathcal{U})'}\}$;
(ii) $\operatorname{range}(\pi') = \mathcal{U}^0$;
(iii) the corestriction $\pi' : (\mathcal{V}/\mathcal{U})' \to \mathcal{U}^0$ is an isomorphism, so $(\mathcal{V}/\mathcal{U})' \cong \mathcal{U}^0$.

Proof. The quotient is finite-dimensional by Theorem 2.2.9.
(i) The map π is surjective, so π' is injective by Corollary 4.3.8. Hence $\ker(\pi') = \{0_{(\mathcal{V}/\mathcal{U})'}\}$ by Proposition 1.6.2.
(ii) Since $\ker(\pi) = \mathcal{U}$, $\operatorname{range}(\pi') = (\ker(\pi))^0 = \mathcal{U}^0$ by Theorem 4.3.7(iii).
(iii) By (i)–(ii), the corestriction is a linear bijection and hence an isomorphism by Proposition 1.6.7.

Structural Commentary: Dual kernel and range identities make the quotient pullback a bijection onto the annihilator.
Key Insight: Quotient functionals are exactly functionals vanishing on the collapsed subspace. □

Theorem 4.3.11. *Range Membership Dual Alternative*
Let $\mathcal{V}, \mathcal{W}$ be finite-dimensional, $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, and $\mathbf{w} \in \mathcal{W}$. Exactly one holds:
(i) $\mathbf{w} \in \operatorname{range}(T)$;
(ii) $(\exists\, \psi \in \mathcal{W}')[\psi T = 0 \wedge \psi(\mathbf{w}) \neq 0]$.

Proof.
(i) If (i) and (ii) hold, choose $\mathbf{v} \in \mathcal{V}$ with $\mathbf{w} = T\mathbf{v}$ and $\psi \in \mathcal{W}'$ satisfying (ii).
Then $\psi(\mathbf{w}) = \psi(T\mathbf{v}) = 0$, contrary to $\psi(\mathbf{w}) \neq 0$. Hence (i) and (ii) cannot both hold.
(ii) Suppose (i) fails. The map $\Lambda_{\mathcal{W}}$ is injective by Theorem 4.2.2(ii), so $\Lambda_{\mathcal{W}}(\mathbf{w}) \notin \Lambda_{\mathcal{W}}(\operatorname{range}(T)) = (\operatorname{range}(T))^{00}$ by Theorem 4.3.5(i).
Hence $(\exists\, \psi \in (\operatorname{range}(T))^0)\, \Lambda_{\mathcal{W}}(\mathbf{w})(\psi) \neq 0$ by Definition 4.3.1. For such ψ, one has $\psi(\mathbf{w}) \neq 0$ and $(\forall\, \mathbf{v} \in \mathcal{V})\, (\psi T)(\mathbf{v}) = \psi(T\mathbf{v}) = 0$, so $\psi T = 0$ by Assumption 3.1.2. Thus (ii) holds whenever (i) fails.

Structural Commentary: Direct evaluation proves exclusion; double annihilation constructs every missing-range certificate.
Key Insight: A separating functional certifies every missing range vector. □

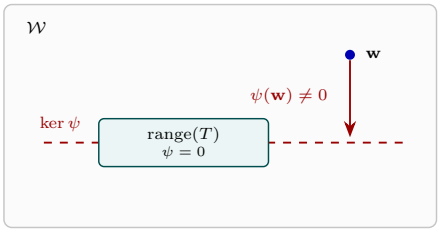

Figure 14: The dual certificate ψ vanishes on $\operatorname{range}(T)$ but detects $\mathbf{w}$ outside that range.

Figure 14 illustrates Theorem 4.3.11: $\operatorname{range}(T) \subseteq \ker(\psi)$ while $\mathbf{w} \notin \ker(\psi)$. It supplies no proof authority.

Proposition 4.3.12. *Standard Coordinate Dual Identification*
For $m \geq 1$, define $\Theta : \mathbb{F}^m \to (\mathbb{F}^m)'$ by $(\forall\, \mathbf{y}, \mathbf{z} \in \mathbb{F}^m)\, \Theta(\mathbf{y})(\mathbf{z}) := \mathbf{y}^t\mathbf{z}$. Then:
(i) Θ is an isomorphism;
(ii) $(\forall\, \psi \in (\mathbb{F}^m)')(\exists!\, \mathbf{y} \in \mathbb{F}^m)(\forall\, \mathbf{z} \in \mathbb{F}^m)\, \psi(\mathbf{z}) = \mathbf{y}^t\mathbf{z}$.

Proof.

(i) For $a, b \in \mathbb{F}$ and $\mathbf{x}, \mathbf{y}, \mathbf{z}, \mathbf{w} \in \mathbb{F}^m$, the identity $\Theta(\mathbf{y})(a\mathbf{z}+b\mathbf{w}) = a\Theta(\mathbf{y})(\mathbf{z})+b\Theta(\mathbf{y})(\mathbf{w})$ holds by Proposition 3.1.2, so $\Theta(\mathbf{y}) \in (\mathbb{F}^m)'$. The identity $\Theta(a\mathbf{x}+b\mathbf{y})(\mathbf{z}) = a\Theta(\mathbf{x})(\mathbf{z}) + b\Theta(\mathbf{y})(\mathbf{z})$ holds by Proposition 3.1.14 and Proposition 3.1.2; hence Θ is linear by Assumption 3.1.2. If $\Theta(\mathbf{y}) = 0$, then $(\forall\, j \in \{1, \dots, m\})\, 0 = \Theta(\mathbf{y})(\mathbf{e}_j) = y_j$, so $\mathbf{y} = \mathbf{0}$ and Θ is injective by Proposition 1.6.2. Since (1) is a basis of $\mathbb{F}$ over itself, $\dim(\mathbb{F}^m) = m = \dim((\mathbb{F}^m)')$ by Theorem 2.1.13 and Theorem 4.1.4(ii). Thus Θ is surjective by Corollary 1.7.6(ii) and is an isomorphism by Proposition 1.6.7.

(ii) Every $\psi \in (\mathbb{F}^m)'$ has a unique preimage $\mathbf{y} \in \mathbb{F}^m$ under Θ by (i), and $\psi(\mathbf{z}) = \Theta(\mathbf{y})(\mathbf{z}) = \mathbf{y}^t\mathbf{z}$ by the defining formula.

Structural Commentary: Matrix identities prove linearity; coordinate evaluations and equal dimensions prove bijectivity.
Key Insight: Every coordinate functional is multiplication by one transposed column. □

Corollary 4.3.13. *Matrix Equation Alternative*
Let $m, n \geq 1$, $A \in \mathrm{Mat}(m, n, \mathbb{F})$, and $\mathbf{b} \in \mathbb{F}^m$. Exactly one holds:

(i) $(\exists\, \mathbf{x} \in \mathbb{F}^n)\, A\mathbf{x} = \mathbf{b}$;
(ii) $(\exists\, \mathbf{y} \in \mathbb{F}^m)[\mathbf{y}^t A = \mathbf{0}^t \wedge \mathbf{y}^t\mathbf{b} \neq 0]$.

Proof. Let $T_A : \mathbb{F}^n \to \mathbb{F}^m$ be the matrix-induced map.
Then $T_A \in \mathcal{L}(\mathbb{F}^n, \mathbb{F}^m)$ by Proposition 3.1.8, and both coordinate spaces are finite-dimensional by Theorem 2.1.13.

(i) The equivalence $\mathbf{b} \in \mathrm{range}(T_A) \iff (\exists\, \mathbf{x} \in \mathbb{F}^n)\, A\mathbf{x} = \mathbf{b}$ holds by $T_A\mathbf{x} = A\mathbf{x}$.

(ii) By Proposition 4.3.12(ii), each $\psi \in (\mathbb{F}^m)'$ has the unique form $\psi(\mathbf{z}) = \mathbf{y}^t\mathbf{z}$. For this $\mathbf{y}$, $\psi T_A = 0$ iff $(\forall\, \mathbf{x} \in \mathbb{F}^n)\, \mathbf{y}^t A\mathbf{x} = 0$ iff $\mathbf{y}^t A = \mathbf{0}^t$ by evaluation on the standard basis of $\mathbb{F}^n$; also, $\psi(\mathbf{b}) \neq 0$ iff $\mathbf{y}^t\mathbf{b} \neq 0$. Exactly one holds by Theorem 4.3.11.

Structural Commentary: Coordinate identification converts the abstract separating functional into a left-null vector.
Key Insight: Left-null vectors are coordinate dual certificates. □

Theorem 4.3.14. *Matrix of the Dual Map Is the Transpose*
Let $\dim(\mathcal{V}) = n \geq 1$ and $\dim(\mathcal{W}) = m \geq 1$, let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, and let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ and $\gamma = (\mathbf{w}_1, \dots, \mathbf{w}_m)$ be bases.
If β' and γ' are the corresponding dual bases, then $[T']_{\beta' \leftarrow \gamma'} = ([T]_{\gamma \leftarrow \beta})^t$.

Proof. Set $A := [T]_{\gamma \leftarrow \beta}$ and $C := [T']_{\beta' \leftarrow \gamma'}$. Write $\beta' = (\varphi_1, \dots, \varphi_n)$ and $\gamma' = (\psi_1, \dots, \psi_m)$. By Definition 3.2.3 and Definition 4.1.3, $(\forall\, k \in \{1, \dots, n\})(\forall\, j \in \{1, \dots, m\})\, C_{k,j} = (T'\psi_j)(\mathbf{v}_k) = \psi_j(T\mathbf{v}_k) = A_{j,k}$, where $T\mathbf{v}_k = \sum_{r=1}^{m} A_{r,k}\mathbf{w}_r$. Hence $C = A^t$.

Structural Commentary: Evaluating dual-basis expansions identifies each dual-matrix entry with the transposed primal entry.
Key Insight: Dual evaluation swaps the row and column indices. □

4.4 Multilinear Structure

Throughout this subsection, all vector spaces are over the same fixed field $\mathbb{F}$.

Definition 4.4.1. *Bilinear Pairings, Matrices, and Induced Functions*

(i) A map $B : \mathcal{V} \times \mathcal{W} \to \mathbb{F}$ is *bilinear* if $(\forall\, a, b \in \mathbb{F})(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})(\forall\, \mathbf{w} \in \mathcal{W})\, B(a\mathbf{u}+b\mathbf{v}, \mathbf{w}) = aB(\mathbf{u}, \mathbf{w}) + bB(\mathbf{v}, \mathbf{w})$, and $(\forall\, a, b \in \mathbb{F})(\forall\, \mathbf{v} \in \mathcal{V})(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{W})\, B(\mathbf{v}, a\mathbf{x}+b\mathbf{y}) = aB(\mathbf{v}, \mathbf{x}) + bB(\mathbf{v}, \mathbf{y})$.

(ii) Suppose $\dim(\mathcal{V}) = m \geq 1$ and $\dim(\mathcal{W}) = n \geq 1$, with ordered bases $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_m)$ and $\gamma = (\mathbf{w}_1, \dots, \mathbf{w}_n)$. The *matrix of B in β, γ* is $[B]_{\beta,\gamma} := [B(\mathbf{v}_i, \mathbf{w}_j)]_{1 \leq i \leq m,\ 1 \leq j \leq n} \in \mathrm{Mat}(m, n, \mathbb{F})$.

(iii) For bilinear B, define Φ_B by $(\forall\, \mathbf{v} \in \mathcal{V})(\forall\, \mathbf{w} \in \mathcal{W})\, (\Phi_B\mathbf{v})(\mathbf{w}) := B(\mathbf{v}, \mathbf{w})$.
Define Ψ_B by $(\forall\, \mathbf{w} \in \mathcal{W})(\forall\, \mathbf{v} \in \mathcal{V})\, (\Psi_B\mathbf{w})(\mathbf{v}) := B(\mathbf{v}, \mathbf{w})$.

Proposition 4.4.2. *Coordinate Evaluation of a Bilinear Pairing*
Let $\dim(\mathcal{V}) = m \geq 1$ and $\dim(\mathcal{W}) = n \geq 1$, let $B : \mathcal{V} \times \mathcal{W} \to \mathbb{F}$ be bilinear.
Let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_m)$ and $\gamma = (\mathbf{w}_1, \dots, \mathbf{w}_n)$ be ordered bases of $\mathcal{V}$ and $\mathcal{W}$, respectively, and set $M := [B]_{\beta,\gamma}$.
For $\mathbf{v} \in \mathcal{V}$ and $\mathbf{w} \in \mathcal{W}$, set $\mathbf{x} := [\mathbf{v}]_\beta$ and $\mathbf{y} := [\mathbf{w}]_\gamma$. Then $B(\mathbf{v}, \mathbf{w}) = \sum_{i=1}^{m}\sum_{j=1}^{n} x_i B(\mathbf{v}_i, \mathbf{w}_j) y_j = \mathbf{x}^t M\mathbf{y}$.

Proof. The identities $\mathbf{v} = \sum_{i=1}^{m} x_i\mathbf{v}_i$ and $\mathbf{w} = \sum_{j=1}^{n} y_j\mathbf{w}_j$ hold by Definition 3.2.1.

Hence $B(\mathbf{v}, \mathbf{w}) = \sum_{i=1}^{m}\sum_{j=1}^{n} x_i y_j B(\mathbf{v}_i, \mathbf{w}_j)$ by Definition 4.4.1(i). The sum equals $\mathbf{x}^t M\mathbf{y}$ by Definition 4.4.1(ii) and Proposition 3.1.6.

Structural Commentary: Two slotwise expansions convert basis coefficients into a matrix product.
Key Insight: A pairing matrix records every basis-vector interaction. □

Proposition 4.4.3. *Bilinear Pairings Linearize through Duals*
Let $B : \mathcal{V} \times \mathcal{W} \to \mathbb{F}$ be bilinear. Then:

(i) *$\Phi_B : \mathcal{V} \to \mathcal{W}'$ and $\Psi_B : \mathcal{W} \to \mathcal{V}'$ are well-defined linear maps;*
(ii) *if $\dim(\mathcal{V}) = m \geq 1$ and $\dim(\mathcal{W}) = n \geq 1$, $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_m)$ and $\gamma = (\mathbf{w}_1, \dots, \mathbf{w}_n)$ are ordered bases of $\mathcal{V}$ and $\mathcal{W}$ with dual bases β', γ', and $M := [B]_{\beta,\gamma}$, then $[\Phi_B]_{\gamma' \leftarrow \beta} = M^t$ and $[\Psi_B]_{\beta' \leftarrow \gamma} = M$.*

Proof.

(i) By Definition 4.4.1(i),(iii), $(\forall\, \mathbf{v} \in \mathcal{V})\, \Phi_B\mathbf{v} \in \mathcal{W}'$ and $(\forall\, \mathbf{w} \in \mathcal{W})\, \Psi_B\mathbf{w} \in \mathcal{V}'$.
For $a, b \in \mathbb{F}$, $\mathbf{u}, \mathbf{v} \in \mathcal{V}$, and $\mathbf{w} \in \mathcal{W}$, $(\Phi_B(a\mathbf{u}+b\mathbf{v}))(\mathbf{w}) = aB(\mathbf{u}, \mathbf{w}) + bB(\mathbf{v}, \mathbf{w}) = (a\Phi_B\mathbf{u} + b\Phi_B\mathbf{v})(\mathbf{w})$.
Hence $\Phi_B(a\mathbf{u}+b\mathbf{v}) = a\Phi_B\mathbf{u} + b\Phi_B\mathbf{v}$ by Assumption 3.1.2. For $\mathbf{x}, \mathbf{y} \in \mathcal{W}$, the identity $\Psi_B(a\mathbf{x}+b\mathbf{y}) = a\Psi_B\mathbf{x} + b\Psi_B\mathbf{y}$ holds by Definition 4.4.1(i) and Assumption 3.1.2. Thus both maps are linear.

(ii) By Definition 3.2.3, 4.1.3, and 4.4.1(ii), $(\forall\, i \in \{1, \dots, m\})(\forall\, j \in \{1, \dots, n\})\, ([\Phi_B]_{\gamma' \leftarrow \beta})_{j,i} = (\Phi_B\mathbf{v}_i)(\mathbf{w}_j) = B(\mathbf{v}_i, \mathbf{w}_j) = M_{i,j}$.
Hence $[\Phi_B]_{\gamma' \leftarrow \beta} = M^t$. Likewise, $(\forall\, i \in \{1, \dots, m\})(\forall\, j \in \{1, \dots, n\})\, ([\Psi_B]_{\beta' \leftarrow \gamma})_{i,j} = (\Psi_B\mathbf{w}_j)(\mathbf{v}_i) = M_{i,j}$ by Definition 3.2.3, 4.1.3, and 4.4.1(ii), so $[\Psi_B]_{\beta' \leftarrow \gamma} = M$.

Structural Commentary: Frozen-slot linearity establishes the maps; dual-basis evaluation identifies their matrices.
Key Insight: Freezing one slot turns bilinearity into dual-valued linearity. □

Definition 4.4.4. *Radicals and Nonsingularity of a Bilinear Pairing*
Let $B : \mathcal{V} \times \mathcal{W} \to \mathbb{F}$ be bilinear.

(i) The *left* and *right radicals* are $\text{rad}_L(B) := \{\mathbf{v} \in \mathcal{V} : (\forall\, \mathbf{w} \in \mathcal{W})\, B(\mathbf{v}, \mathbf{w}) = 0\}$ and $\text{rad}_R(B) := \{\mathbf{w} \in \mathcal{W} : (\forall\, \mathbf{v} \in \mathcal{V})\, B(\mathbf{v}, \mathbf{w}) = 0\}$.
(ii) For $\mathcal{S} \subseteq \mathcal{V}$ and $\mathcal{T} \subseteq \mathcal{W}$, the *right* and *left orthogonals* are $\mathcal{S}^{\perp_R} := \{\mathbf{w} \in \mathcal{W} : (\forall\, \mathbf{s} \in \mathcal{S})\, B(\mathbf{s}, \mathbf{w}) = 0\}$ and ${}^{\perp_L}\mathcal{T} := \{\mathbf{v} \in \mathcal{V} : (\forall\, \mathbf{t} \in \mathcal{T})\, B(\mathbf{v}, \mathbf{t}) = 0\}$.
(iii) B is *left nondegenerate* if $\text{rad}_L(B) = \{\mathbf{0}_\mathcal{V}\}$ and *right nondegenerate* if $\text{rad}_R(B) = \{\mathbf{0}_\mathcal{W}\}$.
(iv) B is *nonsingular* or *perfect* if $\Phi_B : \mathcal{V} \to \mathcal{W}'$ and $\Psi_B : \mathcal{W} \to \mathcal{V}'$ are isomorphisms.

Proposition 4.4.5. *Radicals, Matrices, and Dual Maps*
Let $B : \mathcal{V} \times \mathcal{W} \to \mathbb{F}$ be bilinear. Then:

(i) $\ker(\Phi_B) = \text{rad}_L(B)$ *and* $\ker(\Psi_B) = \text{rad}_R(B)$;
(ii) if $\dim(\mathcal{V}) = m \geq 1$ *and* $\dim(\mathcal{W}) = n \geq 1$, *with ordered bases* β *of* $\mathcal{V}$ *and* γ *of* $\mathcal{W}$ *and with* $M := [B]_{\beta,\gamma}$, *then* $\{[\mathbf{v}]_\beta : \mathbf{v} \in \text{rad}_L(B)\} = \ker(M^t)$ *and* $\{[\mathbf{w}]_\gamma : \mathbf{w} \in \text{rad}_R(B)\} = \ker(M)$;
(iii) under the hypotheses of (ii), $\dim(\text{rad}_L(B)) = m - \text{rank}(M)$ *and* $\dim(\text{rad}_R(B)) = n - \text{rank}(M)$.

Proof.

(i) By Definition 4.4.4(i), 4.4.1(iii), Assumption 3.1.2, $(\forall\, \mathbf{v} \in \mathcal{V})\, \mathbf{v} \in \ker(\Phi_B) \iff (\forall\, \mathbf{w} \in \mathcal{W})\, B(\mathbf{v}, \mathbf{w}) = 0 \iff \mathbf{v} \in \text{rad}_L(B)$.
By Definition 4.4.4(i), 4.4.1(iii), Assumption 3.1.2, $(\forall\, \mathbf{w} \in \mathcal{W})\, \mathbf{w} \in \ker(\Psi_B) \iff (\forall\, \mathbf{v} \in \mathcal{V})\, B(\mathbf{v}, \mathbf{w}) = 0 \iff \mathbf{w} \in \text{rad}_R(B)$
(ii) For $\mathbf{v} \in \mathcal{V}$ and $\mathbf{w} \in \mathcal{W}$, set $\mathbf{x} := [\mathbf{v}]_\beta$ and $\mathbf{y} := [\mathbf{w}]_\gamma$. By Proposition 3.2.5 and 4.4.3(ii), $[\Phi_B\mathbf{v}]_{\gamma'} = M^t\mathbf{x}$ and $[\Psi_B\mathbf{w}]_{\beta'} = M\mathbf{y}$.
Hence $\mathbf{v} \in \text{rad}_L(B) \iff \mathbf{x} \in \ker(M^t)$ and $\mathbf{w} \in \text{rad}_R(B) \iff \mathbf{y} \in \ker(M)$ by (i) and Proposition 3.2.2(ii).
These equivalences prove both coordinate-set identities.
(iii) The coordinate-map restrictions to the two radicals are linear and injective by Proposition 3.2.2(i)–(ii), and they are surjective onto $\ker(M^t)$ and $\ker(M)$ by (ii). Thus their corestrictions are isomorphisms by Proposition 1.6.7, so the radical dimensions equal the corresponding kernel dimensions.
By Corollary 3.3.1(i) and Theorem 3.3.2, $\dim(\ker(M^t)) = m - \text{rank}(M)$ and $\dim(\ker(M)) = n - \text{rank}(M)$.

Structural Commentary: Kernel identities pass through coordinate isomorphisms; rank-nullity then determines both dimensions.
Key Insight: Radicals are the two matrix nullspaces in intrinsic form. □

Proposition 4.4.6. *Square Pairing Nonsingularity Criteria*
Let $B : \mathcal{V} \times \mathcal{W} \to \mathbb{F}$ be bilinear with $\dim(\mathcal{V}) = \dim(\mathcal{W}) = n \geq 1$, *let β and γ be ordered bases of $\mathcal{V}$ and $\mathcal{W}$, respectively.*
Set $M := [B]_{\beta,\gamma}$. The following are equivalent:

(i) B is left nondegenerate;
(ii) B is right nondegenerate;
(iii) M is invertible;
(iv) B is perfect.

Proof.

(i) $\Rightarrow$ *(ii)* If $\text{rad}_L(B) = \{\mathbf{0}_\mathcal{V}\}$, then $\dim(\text{rad}_R(B)) = n - \text{rank}(M) = \dim(\text{rad}_L(B)) = 0$ by Proposition 4.4.5(iii).
Hence $\text{rad}_R(B) = \{\mathbf{0}_\mathcal{W}\}$ by Proposition 1.4.3(ii).
(ii) $\Rightarrow$ *(iii)* If $\text{rad}_R(B) = \{\mathbf{0}_\mathcal{W}\}$, then $0 = \dim(\text{rad}_R(B)) = n - \text{rank}(M)$ by Proposition 4.4.5(iii); M invertible by Corollary 3.6.2.
(iii) $\Rightarrow$ *(iv)* If M is invertible, then $\text{rank}(M) = n$ by Corollary 3.6.2. Hence both radicals have dimension zero by Proposition 4.4.5(iii), so they are zero subspaces by Proposition 1.4.3(ii). Therefore $\ker(\Phi_B) = \{\mathbf{0}_\mathcal{V}\}$ and $\ker(\Psi_B) = \{\mathbf{0}_\mathcal{W}\}$ by Proposition 4.4.5(i). Their domains have dimension n by hypothesis, and their codomains have dimension n by Theorem 4.1.4(ii), so Φ_B and Ψ_B are isomorphisms by Corollary 1.7.6(i), Proposition 1.6.2, and Proposition 1.6.7. Thus B is perfect by Definition 4.4.4(iv).
(iv) $\Rightarrow$ *(i)* If B is perfect, then Φ_B is an isomorphism by Definition 4.4.4(iv) and hence injective by Proposition 1.6.7.
Thus $\ker(\Phi_B) = \{\mathbf{0}_\mathcal{V}\}$ by Proposition 1.6.2, and $\text{rad}_L(B) = \{\mathbf{0}_\mathcal{V}\}$ by Proposition 4.4.5(i).

Structural Commentary: Equal nullities link the radicals; full rank then identifies perfectness.
Key Insight: Square pairings have one shared rank obstruction. □

Corollary 4.4.7. *Perfect Pairings Represent Functionals*
Let $B : \mathcal{V} \times \mathcal{W} \to \mathbb{F}$ be perfect. Then:

(i) $(\forall\, \psi \in \mathcal{W}')(\exists!\, \mathbf{v} \in \mathcal{V})(\forall\, \mathbf{w} \in \mathcal{W})\, \psi(\mathbf{w}) = B(\mathbf{v}, \mathbf{w})$;
(ii) $(\forall\, \varphi \in \mathcal{V}')(\exists!\, \mathbf{w} \in \mathcal{W})(\forall\, \mathbf{v} \in \mathcal{V})\, \varphi(\mathbf{v}) = B(\mathbf{v}, \mathbf{w})$.

Proof.

(i) The map $\Phi_B : \mathcal{V} \to \mathcal{W}'$ is an isomorphism by Definition 4.4.4(iv), and hence a bijection by Proposition 1.6.7.
Thus $(\forall\, \psi \in \mathcal{W}')(\exists!\, \mathbf{v} \in \mathcal{V})\, \psi = \Phi_B\mathbf{v}$. For this $\mathbf{v}$, $(\forall\, \mathbf{w} \in \mathcal{W})\, \psi(\mathbf{w}) = B(\mathbf{v}, \mathbf{w})$ by Definition 4.4.1(iii).
(ii) The map $\Psi_B : \mathcal{W} \to \mathcal{V}'$ is an isomorphism by Definition 4.4.4(iv), and hence a bijection by Proposition 1.6.7.
Thus $(\forall\, \varphi \in \mathcal{V}')(\exists!\, \mathbf{w} \in \mathcal{W})\, \varphi = \Psi_B\mathbf{w}$. For this $\mathbf{w}$, $(\forall\, \mathbf{v} \in \mathcal{V})\, \varphi(\mathbf{v}) = B(\mathbf{v}, \mathbf{w})$ by Definition 4.4.1(iii).

Structural Commentary: Bijectivity of the two induced maps supplies the two unique representatives.
Key Insight: Perfect pairings turn functionals into uniquely paired vectors. □

Definition 4.4.8. *Matrix Congruence*
For $n \geq 1$, matrices $M, N \in \text{Mat}(n, n, \mathbb{F})$ are *congruent* if $(\exists\, P \in \text{Mat}(n, n, \mathbb{F}))[P \text{ is invertible} \wedge N = P^t M P]$.

Proposition 4.4.9. *Two-Sided Basis Change for Pairings*
Let $\dim(\mathcal{U}) = p \geq 1$ *and* $\dim(\mathcal{W}) = q \geq 1$, *let $B : \mathcal{U} \times \mathcal{W} \to \mathbb{F}$ be bilinear, let $\alpha, \widetilde{\alpha}$ be ordered bases of $\mathcal{U}$, let $\beta, \widetilde{\beta}$ be ordered bases of $\mathcal{W}$.*
Set $M := [B]_{\alpha,\beta}$, $\widetilde{M} := [B]_{\widetilde{\alpha},\widetilde{\beta}}$, $P := C_{\alpha\leftarrow\widetilde{\alpha}}$, and $Q := C_{\beta\leftarrow\widetilde{\beta}}$. Then:

(i) $\widetilde{M} = P^t M Q$;
(ii) if $\mathcal{U} = \mathcal{W}$, $\alpha = \beta$, and $\widetilde{\alpha} = \widetilde{\beta}$, then $\widetilde{M}$ is congruent to M.

Proof.

(i) For $\mathbf{u} \in \mathcal{U}$ and $\mathbf{w} \in \mathcal{W}$, set $\mathbf{x} := [\mathbf{u}]_{\widetilde{\alpha}}$ and $\mathbf{y} := [\mathbf{w}]_{\widetilde{\beta}}$. Then $[\mathbf{u}]_\alpha = P\mathbf{x}$ and $[\mathbf{w}]_\beta = Q\mathbf{y}$ by Definition 3.5.1.
By Proposition 4.4.2 and Proposition 3.1.16, $\mathbf{x}^t \widetilde{M} \mathbf{y} = B(\mathbf{u}, \mathbf{w}) = (P\mathbf{x})^t M (Q\mathbf{y}) = \mathbf{x}^t P^t M Q \mathbf{y}$.
The coordinate maps are surjective by Proposition 3.2.2(iii), so $(\forall\, \mathbf{x} \in \mathbb{F}^p)(\forall\, \mathbf{y} \in \mathbb{F}^q)\, \mathbf{x}^t \widetilde{M} \mathbf{y} = \mathbf{x}^t P^t M Q \mathbf{y}$.
The relation $(\forall\, i \in \{1, \ldots, p\})(\forall\, j \in \{1, \ldots, q\})\, \widetilde{M}_{i,j} = (P^t M Q)_{i,j}$ holds by substituting the standard coordinate columns.
Hence $\widetilde{M} = P^t M Q$ by Definition 3.1.1(i).

(ii) Under the stated equalities of spaces and bases, $P = Q$ and P is invertible by Theorem 3.5.2(i).
Thus $\widetilde{M} = P^t M P$ by (i), so $\widetilde{M}$ is congruent to M by Definition 4.4.8.

Structural Commentary: Coordinate evaluation transforms each slot; entry comparison proves the two-sided formula.
Key Insight: Each input slot contributes its own basis-change factor. □

Proposition 4.4.10. *Basis Change for a Square Bilinear Form*
Let $\dim(\mathcal{V}) = n \geq 1$, *let* $B : \mathcal{V} \times \mathcal{V} \to \mathbb{F}$ *be bilinear, and let* β, γ *be ordered bases of* $\mathcal{V}$.
Set $M_\beta := [B]_{\beta,\beta}$, $M_\gamma := [B]_{\gamma,\gamma}$, *and* $C := C_{\beta \leftarrow \gamma}$. *Then:*

(i) $M_\gamma = C^t M_\beta C$;
(ii) M_β *and* M_γ *are congruent.*

Proof.

(i) With $\mathcal{U} = \mathcal{W} = \mathcal{V}$, old basis β in both slots, and new basis γ in both slots, $M_\gamma = C^t M_\beta C$ by Proposition 4.4.9(i).

(ii) The matrix C is invertible by Theorem 3.5.2(i), and $M_\gamma = C^t M_\beta C$ by (i). Hence M_β and M_γ are congruent by Definition 4.4.8.

Structural Commentary: The square case specializes both slot changes to one invertible matrix.
Key Insight: Reusing one basis change produces congruence. □

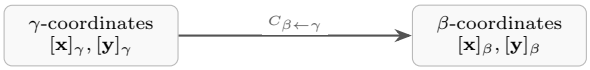

Figure 15: The same coordinate transition acts in both slots, producing $M_\gamma = C_{\beta \leftarrow \gamma}^t M_\beta C_{\beta \leftarrow \gamma}$.

Figure 15 depicts $C_{\beta \leftarrow \gamma}$ acting in both input slots; the formula belongs to Proposition 4.4.10, not to the illustration. The induced maps Φ_B and Ψ_B encode bilinear pairings in dual spaces. Part 4 develops real bilinear metric forms and complex sesquilinear inner products, while Part 8 constructs tensor products; neither later theory is used here.

Part III
Linear Maps and Matrix Representations

1 Linear Maps and Operations

1.1 Further Linear Map Operations and Examples

Operator polynomials encode powers and polynomial equations satisfied by a linear operator.

Definition 1.1.1. *Operator Powers*
Let $T \in \mathcal{L}(\mathcal{V})$. The *powers* of T are $T^m := \underbrace{T \cdots T}_{m \text{ times}}$ for $m \in \mathbb{N}$, with $T^0 := I_{\mathcal{V}}$. If T is invertible, set $T^{-m} := (T^{-1})^m$.

Definition 1.1.2. *Polynomial Applied to an Operator*
Let $T \in \mathcal{L}(\mathcal{V})$. For $p(z) = \sum_{j=0}^{m} a_j z^j \in \mathbb{F}[z]$, the *polynomial p applied to T* is $p(T) := \sum_{j=0}^{m} a_j T^j$.

Definition 1.1.3. *Annihilating Polynomial*
Let $T \in \mathcal{L}(\mathcal{V})$. A polynomial $p \in \mathbb{F}[z]$ is an *annihilating polynomial* for T if $p(T) = 0_{\mathcal{L}(\mathcal{V})}$; equivalently, p *annihilates* T.

Definition 1.1.4. *Product of Polynomials*
If $p, q \in \mathbb{F}[z]$, their product $pq \in \mathbb{F}[z]$ is defined by $(pq)(z) = p(z)q(z)$ for $z \in \mathbb{F}$.

Definition 1.1.5. *Monic Polynomial*
A nonzero polynomial is *monic* if its highest-degree coefficient is 1.

Proposition 1.1.6. *Multiplicative Properties of Operator Polynomials*
Let $p, q \in \mathbb{F}[z]$ and $T \in \mathcal{L}(\mathcal{V})$. Then
(i) $(pq)(T) = p(T)q(T)$;
(ii) $p(T)q(T) = q(T)p(T)$.

Proof.
(i) Write $p(z) = \sum_{j=0}^{m} a_j z^j$ and $q(z) = \sum_{k=0}^{n} b_k z^k$. Then $(pq)(z) = \sum_{j=0}^{m} \sum_{k=0}^{n} a_j b_k z^{j+k}$.
Substituting T gives $(pq)(T) = \sum_{j=0}^{m} \sum_{k=0}^{n} a_j b_k T^{j+k} = \left(\sum_{j=0}^{m} a_j T^j \right) \left(\sum_{k=0}^{n} b_k T^k \right) = p(T)q(T)$.
(ii) Since polynomial multiplication is commutative, $pq = qp$. By part (i), $p(T)q(T) = (pq)(T) = (qp)(T) = q(T)p(T)$.
Structural Commentary: Polynomial evaluation preserves products.
Key Insight: Expanding a polynomial product works the same with T as with z. □

Proposition 1.1.7. *Existence of Annihilating Polynomials*
Let $\mathcal{V}$ be finite-dimensional with $n = \dim(\mathcal{V}) > 0$, and let $T \in \mathcal{L}(\mathcal{V})$.
Then T has a nonconstant annihilating polynomial of degree at most n^2.

Proof. By Theorem 3.4.5, the vector space $\mathcal{L}(\mathcal{V})$ has dimension n^2, so the $n^2 + 1$ operators $I_{\mathcal{V}}, T, T^2, \ldots, T^{n^2}$ are linearly dependent.
Hence there are scalars $a_0, \ldots, a_{n^2}$, not all zero, such that $\sum_{j=0}^{n^2} a_j T^j = 0$.
If $a_1 = \cdots = a_{n^2} = 0$, then $a_0 I_{\mathcal{V}} = 0$, forcing $a_0 = 0$ because $\mathcal{V} \neq \{\mathbf{0}\}$, a contradiction.
Thus $p(z) = \sum_{j=0}^{n^2} a_j z^j$ is a nonconstant annihilating polynomial.
Structural Commentary: Finite-dimensionality makes the powers of one operator linearly dependent inside $\mathcal{L}(\mathcal{V})$.
Key Insight: A dependence among $I_{\mathcal{V}}, T, \ldots, T^{n^2}$ is exactly a polynomial equation satisfied by T. □

Proposition 1.1.8. *Polynomial Evaluation on Eigenvectors*
Let $T \in \mathcal{L}(\mathcal{V})$, let $p \in \mathbb{F}[z]$, and suppose $T\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$. Then $p(T)\mathbf{v} = p(\lambda)\mathbf{v}$.

Proof. Induct on j to get $T^j\mathbf{v} = \lambda^j\mathbf{v}$ $\forall j \geq 0$. If $p(z) = \sum_{j=0}^{m} a_j z^j$, then $p(T)\mathbf{v} = \sum_{j=0}^{m} a_j T^j\mathbf{v} = \sum_{j=0}^{m} a_j \lambda^j \mathbf{v} = p(\lambda)\mathbf{v}$.
Structural Commentary: On a one-dimensional eigenspace, T acts like the scalar λ.
Key Insight: Polynomial expressions in T reduce to the same polynomial evaluated at λ. □

Theorem 1.1.9. *Annihilating Polynomials Control the Spectrum*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional, let $T \in \mathcal{L}(\mathcal{V})$, and let p be a nonconstant annihilating polynomial for T.
(i) Every eigenvalue of T is a root of p.
(ii) If $\mathbb{F} = \mathbb{C}$, then at least one root of p is an eigenvalue of T.

Proof.
(i) If $T\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then Proposition 1.1.8 gives $0 = p(T)\mathbf{v} = p(\lambda)\mathbf{v}$. Since $\mathbf{v} \neq \mathbf{0}$, $p(\lambda) = 0$.
(ii) Factor $p(z) = c(z - \lambda_1) \cdots (z - \lambda_m)$ over $\mathbb{C}$, with $c \neq 0$. Then $0 = p(T) = c(T - \lambda_1 I_{\mathcal{V}}) \cdots (T - \lambda_m I_{\mathcal{V}})$. At least one factor $T - \lambda_j I_{\mathcal{V}}$ is not injective; otherwise product would be injective. Hence λ_j is an eigenvalue.
Structural Commentary: Annihilating polynomial restricts spectrum to its roots; over $\mathbb{C}$, one root must appear.
Key Insight: Eigenvectors turn $p(T)$ into $p(\lambda)$. □

2 Kernels, Images, Rank, and Nullity

2.1 Shift Operators and Kernel-Range Examples

Fix a field $\mathbb{F}$, let $\mathcal{E} := \mathbb{F}^{(\mathbb{N})}$ be its finitely supported sequence space, and set $\mathbf{e}_1 := (1, 0, 0, \ldots)$ and $\mathcal{E}_0 := \{\mathbf{x} \in \mathcal{E} : x_1 = 0\}$.

Proposition 2.1.1. *Shift Operators on Finitely Supported Sequences*
Define $R, S : \mathcal{E} \to \mathcal{E}$ by $R(x_1, x_2, \ldots) := (0, x_1, x_2, \ldots)$ and $S(x_1, x_2, \ldots) := (x_2, x_3, \ldots)$. Then:

(i) $R, S \in \mathcal{L}(\mathcal{E})$.
(ii) $\ker(R) = \{\mathbf{0}_\mathcal{E}\}$.
(iii) $\text{range}(R) = \mathcal{E}_0$.
(iv) $\ker(S) = \text{span}(\mathbf{e}_1)$.
(v) $\text{range}(S) = \mathcal{E}$.
(vi) *R is injective but not surjective, whereas S is surjective but not injective.*
(vii) *$\mathcal{E}$ is infinite-dimensional.*

Proof.

(i) For $\mathbf{x} \in \mathcal{E}$, $|\text{supp}(R\mathbf{x})| = |\text{supp}(\mathbf{x})| < \infty$ and $|\text{supp}(S\mathbf{x})| \leq |\text{supp}(\mathbf{x})|$, so R and S are well-defined.
Coordinatewise operations establish $(\forall T \in \{R, S\})(\forall a, b \in \mathbb{F})(\forall \mathbf{x}, \mathbf{y} \in \mathcal{E})\, T(a\mathbf{x} + b\mathbf{y}) = aT\mathbf{x} + bT\mathbf{y}$; hence $R, S \in \mathcal{L}(\mathcal{E})$.
(ii) For $\mathbf{x} = (x_1, x_2, \ldots) \in \mathcal{E}$, $R\mathbf{x} = \mathbf{0}_\mathcal{E} \iff (\forall j \in \mathbb{N})\, x_j = 0 \iff \mathbf{x} = \mathbf{0}_\mathcal{E}$. Thus $\ker(R) = \{\mathbf{0}_\mathcal{E}\}$.
(iii) By definition, $\text{range}(R) \subseteq \mathcal{E}_0$. Conversely, $\mathbf{y} = (0, y_2, y_3, \ldots) \in \mathcal{E}_0$ has $\mathbf{x} := (y_2, y_3, \ldots) \in \mathcal{E}$ with $R\mathbf{x} = \mathbf{y}$; hence $\text{range}(R) = \mathcal{E}_0$.
(iv) For $\mathbf{x} = (x_1, x_2, \ldots) \in \mathcal{E}$, $S\mathbf{x} = \mathbf{0}_\mathcal{E} \iff (\forall j \in \mathbb{N} \setminus \{1\})\, x_j = 0 \iff \mathbf{x} = x_1\mathbf{e}_1$. Thus $\ker(S) = \text{span}(\mathbf{e}_1)$.
(v) The identity $(\forall \mathbf{y} \in \mathcal{E})\, S(R\mathbf{y}) = \mathbf{y}$ holds by the definitions, with $R\mathbf{y} \in \mathcal{E}$ by (i); hence $\text{range}(S) = \mathcal{E}$.
(vi) The map R is injective by Proposition 1.6.2 with (ii), and R is not surjective by (iii), since $\mathbf{e}_1 \notin \mathcal{E}_0$.
The map S is surjective by (v) and not injective by Proposition 1.6.2 with (iv), since $\mathbf{e}_1 \neq \mathbf{0}_\mathcal{E}$.
(vii) The assumption $\dim(\mathcal{E}) < \infty$ would make R surjective by Theorem 1.7.7 with (i) and injectivity from (vi), contradicting (vi).

Structural Commentary: Matched claim items verify linearity, fibers, images, map properties, and the dimension obstruction.
Key Insight: The shifts exchange a missing coordinate with a nontrivial kernel. □

Example 2.1.2. *Shift Operators Show Noncommutativity*
For the shifts above, $SR, RS \in \mathcal{L}(\mathcal{E})$ by Proposition 1.5.7(i). For $\mathbf{x} = (x_1, x_2, \ldots) \in \mathcal{E}$, $SR\mathbf{x} = \mathbf{x}$ and $RS\mathbf{x} = (0, x_2, x_3, \ldots)$.
Hence $SR = I_\mathcal{E}$ by Assumption 3.1.2. Since $RS\mathbf{e}_1 = \mathbf{0}_\mathcal{E} \neq \mathbf{e}_1 = SR\mathbf{e}_1$, $RS \neq SR$ and $\mathcal{L}(\mathcal{E})$ is noncommutative.

4 Row Reduction and Elementary Matrices

4.1 Row Reduction and Elementary Matrices

Definition 4.1.1. *Elementary Row Operations and Elementary Matrices*
Let $m \geq 1$. For $i, j \in \{1, \ldots, m\}$, the *elementary row operations* are:

(i) *Row scaling*: $R_i \leftarrow cR_i$, where $c \in \mathbb{F}^\times$;
(ii) *Row swap*: $R_i \leftrightarrow R_j$, where $i \neq j$;
(iii) *Row replacement*: $R_i \leftarrow R_i + cR_j$, where $i \neq j$ and $c \in \mathbb{F}$.

For an elementary row operation ϵ on m rows, its *elementary matrix* is $E_\epsilon := \epsilon(I_m)$.

Proposition 4.1.2. *Elementary Matrices Perform Row Operations*
Let $A \in \text{Mat}(m, n, \mathbb{F})$, let ϵ be an elementary operation on m rows, and set $E_\epsilon := \epsilon(I_m)$. Then:

(i) $E_\epsilon A = \epsilon(A)$.
(ii) $E_\epsilon^{-1} = E_{\epsilon^{-1}}$; *in particular, every elementary matrix has an elementary inverse.*
(iii) *If η is an elementary operation on n rows and $F_\eta := \eta(I_n)^t$, then $AF_\eta = (\eta(A^t))^t$.*
Thus right multiplication by F_η performs the corresponding column operation.

Proof.

(i) The rows of E_ϵ identify the rows of $E_\epsilon A$ by matrix multiplication:
  (a) For scaling, $(E_\epsilon)_{i,\cdot} = c\mathbf{e}_i^t$, while every other row is standard; hence $(E_\epsilon A)_{i,\cdot} = cA_{i,\cdot}$ and the other rows are unchanged.
  (b) For a swap, $(E_\epsilon)_{i,\cdot} = \mathbf{e}_j^t$ and $(E_\epsilon)_{j,\cdot} = \mathbf{e}_i^t$; hence $E_\epsilon A$ exchanges rows i and j, with every other row fixed.
  (c) For replacement, $(E_\epsilon)_{i,\cdot} = \mathbf{e}_i^t + c\mathbf{e}_j^t$, so $(E_\epsilon A)_{i,\cdot} = A_{i,\cdot} + cA_{j,\cdot}$; the other coordinate rows preserve their rows.
(ii) The inverse of a scaling by c is scaling by c^{-1}, a swap is self-inverse, and the inverse of replacement by c is replacement by $-c$.
Therefore $E_{\epsilon^{-1}} E_\epsilon = \epsilon^{-1}(\epsilon(I_m)) = I_m$ and $E_\epsilon E_{\epsilon^{-1}} = \epsilon(\epsilon^{-1}(I_m)) = I_m$ by part (i).
(iii) $(AF_\eta)^t = F_\eta^t A^t = \eta(I_n)A^t = \eta(A^t)$ by Proposition 3.1.16, Proposition 3.1.14(i), and part (i).
After transposition, $(AF_\eta)^{tt} = AF_\eta$, so $AF_\eta = (\eta(A^t))^t$.

Structural Commentary: The proof translates row operations, their inverses, and transposition into multiplication identities.
Key Insight: Elementary matrices store row operations as left factors. □

Definition 4.1.3. *Row Equivalence and Reduced Row Echelon Form*
For $A, B \in \mathrm{Mat}(m,n,\mathbb{F})$, $k=0$ interpreted as I_m; $A \sim_{\mathrm{row}} B \iff B = E_k \cdots E_1 A$ for $k \in \mathbb{N}_0$, elementary $E_1, \dots, E_k \in \mathrm{Mat}(m,m,\mathbb{F})$.
A matrix $R = [r_{i,j}] \in \mathrm{Mat}(m,n,\mathbb{F})$ is in *reduced row echelon form* if $(\exists s \in \{0,\dots,m\})(\exists p_1,\dots,p_s \in \{1,\dots,n\})$ such that:
(i) $(\forall i \in \{1,\dots,s\})\, R_{i,\cdot} \neq \mathbf{0}^t$ and $(\forall i \in \{s+1,\dots,m\})\, R_{i,\cdot} = \mathbf{0}^t$;
(ii) $(\forall i \in \{1,\dots,s\})\, [r_{i,p_i} = 1 \wedge (\forall j \in \{1,\dots,p_i-1\})\, r_{i,j} = 0]$;
(iii) $p_1 < \cdots < p_s$;
(iv) $(\forall i \in \{1,\dots,s\})(\forall \ell \in \{1,\dots,m\} \setminus \{i\})\, r_{\ell,p_i} = 0$.
The indices $p_1,\dots,p_s$ are the *pivot columns* of R.

Theorem 4.1.4. *Reduced Row Echelon Form*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$. Then $(\exists!\, R \in \mathrm{Mat}(m,n,\mathbb{F}))\, [R$ is in RREF $\wedge\, A \sim_{\mathrm{row}} R]$. Write $\mathrm{rref}(A) := R$.

Proof.
(i) *Construction*: Set $i=1$ and $p_0 = 0$. Suppose rows $1,\dots,i-1$ have pivot columns $p_1 < \cdots < p_{i-1}$, these pivot columns are coordinate columns, and the remaining rows vanish in columns $1,\dots,p_{i-1}$.
If the remaining rows are zero, stop. Otherwise let p_i be the least column containing a nonzero entry in rows $i,\dots,m$.
Swap such an entry into row i, scale it to 1, and clear column p_i by row replacement.
The new pivot row vanishes before p_i, so these operations preserve the preceding pivot columns and extend the stated invariant.
(ii) *Verification*: Each stage increases both the pivot-row index and the pivot-column index, so the construction stops after at most $\min(m,n)$ stages. At termination, the invariant is exactly the four RREF conditions.
Each step is elementary, and hence the resulting matrix R satisfies $R = E_k \cdots E_1 A$ by Proposition 4.1.2. Thus $A \sim_{\mathrm{row}} R$.
(iii) *Leading Indices*: Let R and S be RREF matrices row-equivalent to A. Every elementary row operation replaces rows by linear combinations of rows, and its elementary inverse reverses the inclusion by Proposition 4.1.2(i)–(ii).
Hence $\mathrm{row}(R) = \mathrm{row}(A) = \mathrm{row}(S) := \mathcal{W}$. If $\mathcal{W} = \{\mathbf{0}\}$, then $R = S = 0$; assume $\mathcal{W} \neq \{\mathbf{0}\}$.
For $\mathbf{v} \in \mathcal{W} \setminus \{\mathbf{0}\}$, set $\ell(\mathbf{v}) := \min\{j : v_j \neq 0\}$. Let $X \in \{R, S\}$ have nonzero rows $X_{1,\cdot}, \dots, X_{h,\cdot}$ and pivot columns $q_1 < \cdots < q_h$.
$\mathbf{v} = \sum_{i=1}^{h} c_i X_{i,\cdot}^t$, set $a := \min\{i : c_i \neq 0\}$. The RREF conditions imply $(\forall j \in \{1,\dots,q_a-1\})\, v_j = 0$ and $v_{q_a} = c_a \neq 0$, so $\ell(\mathbf{v}) = q_a$.
Conversely, $\ell(X_{i,\cdot}^t) = q_i$. Therefore $\{\ell(\mathbf{v}) : \mathbf{v} \in \mathcal{W} \setminus \{\mathbf{0}\}\}$ is the pivot set of both R and S.
(iv) *Uniqueness*: Let $p_1 < \cdots < p_s$ be the common pivot columns.
For $i \in \{1,\dots,s\}$, the vector $\mathbf{d}_i := R_{i,\cdot}^t - S_{i,\cdot}^t$ belongs to $\mathcal{W}$ and $(\forall j \in \{1,\dots,s\})\, (\mathbf{d}_i)_{p_j} = 0$.
If $\mathbf{d}_i \neq \mathbf{0}$, then its leading index is a pivot column by part (iii), contradicting these zero pivot coordinates.
Thus $R_{i,\cdot} = S_{i,\cdot}$ for $i \leq s$, while every row with index greater than s is zero. Hence $R = S$.

Structural Commentary: Elimination constructs a representative; leading-index invariance proves uniqueness in the common row space.
Key Insight: A reduced row space determines every pivot row. □

Lemma 4.1.5. *Invertible Matrices Row-Reduce to the Identity*
Let $P \in \mathrm{Mat}(m,m,\mathbb{F})$ be invertible. Then:
(i) $\mathrm{rref}(P) = I_m$.
(ii) $I_m = E_k \cdots E_1 P$ *for a* $k \in \mathbb{N}_0$ *and elementary* $E_1,\dots,E_k \in \mathrm{Mat}(m,m,\mathbb{F})$.

Proof.
(i) Set $R = [r_{i,j}] := \mathrm{rref}(P)$. Then $R = E_k \cdots E_1 P$ by Theorem 4.1.4 and the definition of row equivalence.
Each E_i is invertible by Proposition 4.1.2(ii), so R is invertible by repeated use of Corollary 3.1.17(i). Consequently, $\ker(R) = \{\mathbf{0}\}$.
Let $p_1 < \cdots < p_s$ be the pivot columns of R. If $s < m$, choose $j \in \{1,\dots,m\} \setminus \{p_1,\dots,p_s\}$ and define $\mathbf{x} \in \mathbb{F}^m$ by $x_j = 1$, $(\forall i \in \{1,\dots,s\})\, x_{p_i} = -r_{i,j}$, and $(\forall \ell \in \{1,\dots,m\} \setminus \{j, p_1,\dots,p_s\})\, x_\ell = 0$.
Then $(\forall i \in \{1,\dots,s\})\, (R\mathbf{x})_i = x_{p_i} + r_{i,j} x_j = 0$ and $(\forall i \in \{s+1,\dots,m\})\, (R\mathbf{x})_i = 0$. This contradicts $\ker(R) = \{\mathbf{0}\}$, so $s = m$.
The strictly increasing pivot indices $p_1,\dots,p_m \in \{1,\dots,m\}$ satisfy $p_i = i$.
Every pivot column is therefore the corresponding coordinate column, so $R = I_m$.
(ii) By part (i), $P \sim_{\mathrm{row}} \mathrm{rref}(P) = I_m$. Thus $I_m = E_k \cdots E_1 P$ by the definition of row equivalence.

Structural Commentary: Kernel triviality excludes free columns; the square pivot set then forces the identity.
Key Insight: An invertible reduced matrix has no free variable. □

Corollary 4.1.6. *Row Equivalence Characterization*
For $A, B \in \mathrm{Mat}(m,n,\mathbb{F})$, the following are equivalent:
(i) $A \sim_{\mathrm{row}} B$.
(ii) $\mathrm{rref}(A) = \mathrm{rref}(B)$.
(iii) $(\exists\, P \in \mathrm{Mat}(m,m,\mathbb{F})^{\times})\, B = PA$.

Proof.
(i) $\Rightarrow$ *(ii)* Write $B = G_q \cdots G_1 A$ and set $G := G_q \cdots G_1$.
The matrix G is invertible, $G^{-1} = G_1^{-1} \cdots G_q^{-1}$, and each G_j^{-1} is elementary by Proposition 4.1.2(ii) and Corollary 3.1.17(i).
For $R := \mathrm{rref}(A)$, write $R = E_k \cdots E_1 A$. Then $R = E_k \cdots E_1 G^{-1} B$, so $B \sim_{\mathrm{row}} R$ and $R = \mathrm{rref}(B)$ by Theorem 4.1.4.
(ii) $\Rightarrow$ *(iii)* Let $R := \mathrm{rref}(A) = \mathrm{rref}(B)$ and write $R = E_k \cdots E_1 A = F_\ell \cdots F_1 B$. For $E := E_k \cdots E_1$ and $F := F_\ell \cdots F_1$, the matrix $P := F^{-1}E$ is invertible by Proposition 4.1.2(ii) and Corollary 3.1.17(i), and $B = PA$.
(iii) $\Rightarrow$ *(i)* Let $B = PA$ with P invertible. Choose elementary matrices satisfying $E_k \cdots E_1 P = I_m$ by Lemma 4.1.5(ii).
Then $P = E_1^{-1} \cdots E_k^{-1}$, and each E_i^{-1} is elementary by Proposition 4.1.2(ii). Hence $A \sim_{\mathrm{row}} B$.

Structural Commentary: The implication cycle passes among canonical representatives, elementary products, and invertible left factors.
Key Insight: Row equivalence is exactly invertible left multiplication. □

Computation Method 4.1.7. *Inverse Computation by Gauss–Jordan Reduction*
For $A \in \mathrm{Mat}(n,n,\mathbb{F})$, this procedure returns A^{-1} or certifies that A is not invertible.

(i) Form $[\,A \mid I_n\,]$ and perform each Gauss–Jordan row operation on the entire augmented matrix until the left block is $\mathrm{rref}(A)$.
(ii) If the result is $[\,I_n \mid B\,]$, choose $P \in \mathrm{Mat}(n,n,\mathbb{F})^\times$ such that $[\,I_n \mid B\,] = P[\,A \mid I_n\,] = [\,PA \mid P\,]$ by Corollary 4.1.6. Then $P = B$, $BA = I_n$, and $AB = I_n$ by Theorem 3.4.2; return $B = A^{-1}$.
(iii) If $\mathrm{rref}(A) \neq I_n$, then A is not invertible by Lemma 4.1.5(i).

5 Change of Basis

5.1 Further Change of Basis and Coordinate Transformations

Theorem 5.1.1. *Change of Basis Formula*
Let $n \geq 1$, let $\dim(\mathcal{V}) = n$, let $T \in \mathcal{L}(\mathcal{V})$, and fix a basis β of $\mathcal{V}$. Set $A := [T]_{\beta \leftarrow \beta}$.

(i) If γ is a basis of $\mathcal{V}$ and $S = C_{\gamma \leftarrow \beta}$, then $[T]_{\gamma \leftarrow \gamma} = SAS^{-1}$.
(ii) If $S \in \mathrm{Mat}(n,n,\mathbb{F})^\times$, then some basis γ of $\mathcal{V}$ satisfies $[T]_{\gamma \leftarrow \gamma} = SAS^{-1}$.

Proof.

(i) Suppose γ is a basis and $S = C_{\gamma \leftarrow \beta}$. Then $S^{-1} = C_{\beta \leftarrow \gamma}$ by Theorem 3.5.2(i). Hence $[T]_{\gamma \leftarrow \gamma} = C_{\gamma \leftarrow \beta} A C_{\beta \leftarrow \gamma} = SAS^{-1}$ by Theorem 3.5.3, with β as both original bases and γ as both new bases.
(ii) Let $S \in \mathrm{Mat}(n,n,\mathbb{F})^\times$. Choose a basis γ satisfying $S = C_{\gamma \leftarrow \beta}$ by Theorem 3.5.2(ii). Then $[T]_{\gamma \leftarrow \gamma} = SAS^{-1}$ by part (i).

Structural Commentary: The proof specializes two-sided transport, then realizes an arbitrary invertible coordinate map.
Key Insight: Conjugation records one operator after a simultaneous coordinate change. □

6 Matrix Equivalence and Similarity

6.1 Matrix Equivalence and Rank Normal Forms

Throughout this subsection, $m, n \geq 1$, and all vector spaces and matrices are over the same fixed field $\mathbb{F}$.

Definition 6.1.1. *Matrix Equivalence*
For $A, B \in \mathrm{Mat}(m,n,\mathbb{F})$, write $A \sim_{\mathrm{eq}} B$ iff $(\exists\, P \in \mathrm{Mat}(m,m,\mathbb{F})^\times)(\exists\, Q \in \mathrm{Mat}(n,n,\mathbb{F})^\times)\; B = PAQ$.

Proposition 6.1.2. *Matrix Equivalence and Elementary Operations*
Let $A, B \in \mathrm{Mat}(m,n,\mathbb{F})$. Then:

(i) The relation $\sim_{\mathrm{eq}}$ is an equivalence relation on $\mathrm{Mat}(m,n,\mathbb{F})$.
(ii) $A \sim_{\mathrm{eq}} B$ iff B can be obtained from A by finitely many elementary row and column operations.

Proof.

(i) The relation is reflexive by Definition 6.1.1, with $A = I_m A I_n$.
If $B = PAQ$ with P, Q invertible, then $A = P^{-1}BQ^{-1}$, so symmetry holds by Definition 6.1.1.
If $B = P_1 A Q_1$ and $C = P_2 B Q_2$, then $C = (P_2 P_1) A (Q_1 Q_2)$, and both products are invertible by Corollary 3.1.17(i).
Hence transitivity holds by Definition 6.1.1.
(ii) ($\Rightarrow$) Suppose $A \sim_{\mathrm{eq}} B$. Choose $P \in \mathrm{Mat}(m,m,\mathbb{F})^\times$ and $Q \in \mathrm{Mat}(n,n,\mathbb{F})^\times$ satisfying $B = PAQ$ by Definition 6.1.1.
The matrix Q^t is invertible by Corollary 3.1.17(ii). The matrices P and Q^t are products of elementary matrices by Lemma 4.1.5(ii) and Proposition 4.1.2(ii). Hence left multiplication by the factors of P performs elementary row operations, while right multiplication by the transposes of the factors of Q^t performs elementary column operations by Proposition 4.1.2(i),(iii).
Thus these operations transform A into $PAQ = B$.
(ii) ($\Leftarrow$) Suppose B is obtained from A by finitely many elementary row and column operations.
Each elementary row operation is left multiplication by an invertible elementary matrix by Proposition 4.1.2(i),(ii).
Each elementary column operation is right multiplication by the transpose of an invertible elementary matrix by Proposition 4.1.2(ii),(iii) and Corollary 3.1.17(ii). Associativity collects the left factors into P and the right factors into Q, so the operation sequence has the form $B = PAQ$ with P, Q invertible by Corollary 3.1.17(i). Hence $A \sim_{\mathrm{eq}} B$ by Definition 6.1.1.

Structural Commentary: Part (i) uses invertible-factor algebra; part (ii) translates elementary operations into factors.
Key Insight: Two-sided factors are exactly row and column operations. □

Theorem 6.1.3. *Equivalent Matrices Represent the Same Linear Map*
Let $\dim \mathcal{V} = n$, $\dim \mathcal{W} = m$, and $A, B \in \mathrm{Mat}(m,n,\mathbb{F})$.
Then $A \sim_{\mathrm{eq}} B$ iff some $T \in \mathcal{L}(\mathcal{V},\mathcal{W})$ and bases β, β' of $\mathcal{V}$ and γ, γ' of $\mathcal{W}$ satisfy $A = [T]_{\gamma \leftarrow \beta}$ and $B = [T]_{\gamma' \leftarrow \beta'}$.

Proof.

($\Rightarrow$) Suppose $A \sim_{\mathrm{eq}} B$. Choose $P \in \mathrm{Mat}(m,m,\mathbb{F})^\times$ and $Q \in \mathrm{Mat}(n,n,\mathbb{F})^\times$ satisfying $B = PAQ$ by Definition 6.1.1.
Choose bases β, γ by Corollary 1.3.14, and choose $T \in \mathcal{L}(\mathcal{V},\mathcal{W})$ satisfying $[T]_{\gamma \leftarrow \beta} = A$ by Theorem 3.4.5(i).
Choose bases γ' and β' satisfying $P = C_{\gamma' \leftarrow \gamma}$ and $Q^{-1} = C_{\beta' \leftarrow \beta}$ by Theorem 3.5.2(ii).
Then $Q = C_{\beta \leftarrow \beta'}$ by Theorem 3.5.2(i), and $[T]_{\gamma' \leftarrow \beta'} = PAQ = B$ by Theorem 3.5.3.
($\Leftarrow$) Choose $T \in \mathcal{L}(\mathcal{V},\mathcal{W})$ and bases β, β' of $\mathcal{V}$ and γ, γ' of $\mathcal{W}$ satisfying $A = [T]_{\gamma \leftarrow \beta}$ and $B = [T]_{\gamma' \leftarrow \beta'}$ by the hypothesis.
Then $B = C_{\gamma' \leftarrow \gamma} A C_{\beta \leftarrow \beta'}$ by Theorem 3.5.3, so $A \sim_{\mathrm{eq}} B$ by Definition 6.1.1.

Structural Commentary: One direction realizes invertible factors as basis changes; the converse reads coordinate transport.
Key Insight: Domain and codomain coordinates account for both factors. □

Definition 6.1.4. *Matrix Rank Normal Form*
For $0 \leq r \leq \min(m,n)$, define $J_r^{m,n} \in \mathrm{Mat}(m,n,\mathbb{F})$ as follows:

(i) $J_0^{m,n} := 0$.
(ii) If $r \geq 1$, then $J_r^{m,n} := \begin{pmatrix} I_r & 0_{r \times (n-r)} \\ 0_{(m-r) \times r} & 0_{(m-r) \times (n-r)} \end{pmatrix}$.

Theorem 6.1.5. *Rank Classifies Matrix Equivalence*
For $A, B \in \mathrm{Mat}(m,n,\mathbb{F})$:
(i) $A \sim_{\mathrm{eq}} J^{m,n}_{\mathrm{rank}(A)}$.
(ii) $A \sim_{\mathrm{eq}} B$ *iff* $\mathrm{rank}(A) = \mathrm{rank}(B)$.

Proof.
(*i*) Set $r := \mathrm{rank}(A)$ and $T_A(\mathbf{x}) := A\mathbf{x}$ for $\mathbf{x} \in \mathbb{F}^n$. Then $T_A \in \mathcal{L}(\mathbb{F}^n, \mathbb{F}^m)$ by Proposition 3.1.8.
Choose $\mathcal{M}_A \leq \mathbb{F}^n$ satisfying $\mathbb{F}^n = \ker(T_A) \oplus \mathcal{M}_A$ by Proposition 2.3.6.
The restriction $T_A|_{\mathcal{M}_A} : \mathcal{M}_A \to \mathrm{range}(T_A)$ is an isomorphism by Proposition 2.3.8(i). The equality $\mathrm{range}(T_A) = \mathrm{col}(A)$ holds by Proposition 3.1.9 and Definition 3.1.12; hence $\dim(\mathcal{M}_A) = r$ by Theorem 1.7.9 and Definition 3.1.12.
Choose a basis $\mathbf{u} := (\mathbf{u}_1, \ldots, \mathbf{u}_r)$ of $\mathcal{M}_A$ and a basis κ of $\ker(T_A)$ by Corollary 1.3.14, where $\mathbf{u}$ is empty if $r = 0$.
The list $(T_A\mathbf{u}_1, \ldots, T_A\mathbf{u}_r)$ is a basis of $\mathrm{range}(T_A)$ by Proposition 1.7.8; extend it to a basis γ_A of $\mathbb{F}^m$ by Theorem 1.3.13.
Equality $\mathbb{F}^n = \mathcal{M}_A \oplus \ker(T_A)$ holds by Proposition 2.1.8. Hence concatenation $\beta_A := (\mathbf{u}, \kappa)$ is basis of $\mathbb{F}^n$ by Theorem 2.3.4(ii).
The first r basis vectors map to the first r vectors of γ_A, while the remaining basis vectors lie in $\ker(T_A)$.
Thus $[T_A]_{\gamma_A \leftarrow \beta_A} = J^{m,n}_r$ by Definition 3.2.3 and Definition 6.1.4.
The standard-basis matrix of T_A is A by Definition 3.1.7 and Definition 3.2.3. Therefore $A \sim_{\mathrm{eq}} J^{m,n}_r$ by Theorem 6.1.3.
(*ii*) ($\Rightarrow$) If $A \sim_{\mathrm{eq}} B$, then $B = PAQ$ for invertible P, Q by Definition 6.1.1, and $\mathrm{rank}(B) = \mathrm{rank}(A)$ by Theorem 3.6.6(ii).
(*ii*) ($\Leftarrow$) If $\mathrm{rank}(A) = \mathrm{rank}(B) = r$, then $A \sim_{\mathrm{eq}} J^{m,n}_r \sim_{\mathrm{eq}} B$ and $A \sim_{\mathrm{eq}} B$ by part (i) and Proposition 6.1.2(i).
Structural Commentary: Complement bases construct the normal form; rank preservation proves classification.
Key Insight: Kernel and range dimensions determine the two-sided orbit. □

Corollary 6.1.6. *Rank Normal Form for Linear Maps*
Let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, $\dim \mathcal{V} = n$, $\dim \mathcal{W} = m$, and $\mathrm{rank}(T) = r$. Then some bases β of $\mathcal{V}$ and γ of $\mathcal{W}$ satisfy $[T]_{\gamma \leftarrow \beta} = J^{m,n}_r$.

Proof. Choose initial bases β_0, γ_0 by Corollary 1.3.14, and set $A := [T]_{\gamma_0 \leftarrow \beta_0}$.
Then $\{[\mathbf{y}]_{\gamma_0} : \mathbf{y} \in \mathrm{range}(T)\} = \{A\mathbf{x} : \mathbf{x} \in \mathbb{F}^n\} = \mathrm{col}(A)$ by Proposition 3.2.5, 3.2.2(iii), 3.1.9, and Definition 3.1.12.
The coordinate map is linear and injective by Proposition 3.2.2(i),(ii), so its restriction is an isomorphism from $\mathrm{range}(T)$ onto $\mathrm{col}(A)$.
Hence $\mathrm{rank}(A) = \mathrm{rank}(T) = r$ by Theorem 1.7.9 and the definitions of matrix and operator rank.
Thus $A \sim_{\mathrm{eq}} J^{m,n}_r$ by Theorem 6.1.5(i); choose invertible P, Q satisfying $J^{m,n}_r = PAQ$ by Definition 6.1.1.
Choose bases γ, β satisfying $P = C_{\gamma \leftarrow \gamma_0}$ and $Q^{-1} = C_{\beta \leftarrow \beta_0}$ by Theorem 3.5.2(ii).
Then $Q = C_{\beta_0 \leftarrow \beta}$ by Theorem 3.5.2(i), and $[T]_{\gamma \leftarrow \beta} = J^{m,n}_r$ by Theorem 3.5.3.
Structural Commentary: Matrix normal form supplies factors that are realized as coordinate changes.
Key Insight: Rank fixes the canonical coordinate matrix. □

Corollary 6.1.7. *Linear Maps Classified by Rank*
Let $\dim \mathcal{V} = n$, $\dim \mathcal{W} = m$. For $S, T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, $S \sim_{\mathrm{bc}} T$ iff some bases β_S, β_T of $\mathcal{V}$ and γ_S, γ_T of $\mathcal{W}$ satisfy $[S]_{\gamma_S \leftarrow \beta_S} = [T]_{\gamma_T \leftarrow \beta_T}$. Then $S \sim_{\mathrm{bc}} T$ iff $\mathrm{rank}(S) = \mathrm{rank}(T)$.

Proof.
($\Rightarrow$) Suppose $S \sim_{\mathrm{bc}} T$. Choose bases β_S, β_T of $\mathcal{V}$ and γ_S, γ_T of $\mathcal{W}$ satisfying $[S]_{\gamma_S \leftarrow \beta_S} = [T]_{\gamma_T \leftarrow \beta_T}$ by the definition of $\sim_{\mathrm{bc}}$, and set $A := [S]_{\gamma_S \leftarrow \beta_S}$. For $R \in \{S, T\}$, interpret β_R and γ_R accordingly.
Then $\{[\mathbf{y}]_{\gamma_R} : \mathbf{y} \in \mathrm{range}(R)\} = \{A\mathbf{x} : \mathbf{x} \in \mathbb{F}^n\} = \mathrm{col}(A)$ by Proposition 3.2.5, 3.2.2(iii), 3.1.9, and Definition 3.1.12.
The restricted coordinate map is an isomorphism by Proposition 3.2.2(i),(ii).
Thus $(\forall R \in \{S, T\})\ \mathrm{rank}(R) = \dim(\mathrm{col}(A))$ by Theorem 1.7.9 and Definition 1.7.2, so $\mathrm{rank}(S) = \mathrm{rank}(T)$.
($\Leftarrow$) If $\mathrm{rank}(S) = \mathrm{rank}(T) = r$, choose bases satisfying $[S]_{\gamma_S \leftarrow \beta_S} = J^{m,n}_r = [T]_{\gamma_T \leftarrow \beta_T}$ by Corollary 6.1.6.
Structural Commentary: Both directions compare operator ranks with the shared rank normal form.
Key Insight: Equal ranks select the same canonical matrix. □

6.2 Similarity and Operator Coordinates

Throughout this subsection, $m, n \geq 1$, and all vector spaces and matrices are over the same fixed field $\mathbb{F}$.

Definition 6.2.1. *Similarity*
Matrices $A, B \in \mathrm{Mat}(n,n,\mathbb{F})$ are similar iff $(\exists\, P \in \mathrm{Mat}(n,n,\mathbb{F})^{\times})\ B = PAP^{-1}$.

Proposition 6.2.2. *Similarity Is an Equivalence Relation*
Similarity is an equivalence relation on $\mathrm{Mat}(n,n,\mathbb{F})$.

Proof. Let $A, B, C \in \mathrm{Mat}(n,n,\mathbb{F})$. Similarity is reflexive by Definition 6.2.1, with $P = I_n$.
If $B = PAP^{-1}$ for invertible P, then $A = P^{-1}BP$, so symmetry holds by Definition 6.2.1. If $B = PAP^{-1}$ and $C = QBQ^{-1}$ for invertible P, Q, then $C = (QP)A(QP)^{-1}$ and QP is invertible by Corollary 3.1.17(i), so transitivity holds by Definition 6.2.1.
Structural Commentary: Identity, inverse, and product witnesses verify reflexivity, symmetry, and transitivity.
Key Insight: Conjugation is an orbit relation under invertible matrices. □

Remark 6.2.3. *Similarity Convention*
The forms PAP^{-1} and $M^{-1}AM$ are the same convention with $P = M^{-1}$. In Theorem 5.1.1, this means choosing opposite coordinate-change directions.

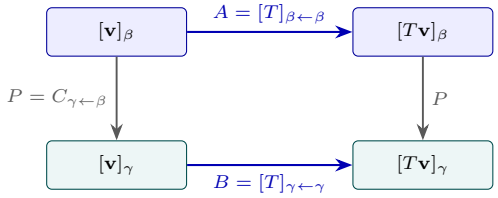

Figure 16: One operator in two bases: $PA = BP$, so $B = PAP^{-1}$.

In Figure 16, $A = [T]_{\beta\leftarrow\beta}$, $B = [T]_{\gamma\leftarrow\gamma}$, and $P = C_{\gamma\leftarrow\beta}$, so the coordinate square commutes as $PA = BP$. Theorem 5.1.1 owns the exact conjugation identity.

Corollary 6.2.4. *Similarity as One Operator in Two Bases*
For $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$, the following are equivalent:

(i) A and B are similar.
(ii) Some n-dimensional vector space $\mathcal{V}$, bases β, γ of $\mathcal{V}$, and $T \in \mathcal{L}(\mathcal{V})$ satisfy $A = [T]_{\beta\leftarrow\beta}$ and $B = [T]_{\gamma\leftarrow\gamma}$.

Proof.

(*i*) $\Rightarrow$ (*ii*) Suppose A and B are similar. Choose $P \in \mathrm{Mat}(n, n, \mathbb{F})^\times$ satisfying $B = PAP^{-1}$ by Definition 6.2.1.
Let $\mathcal{V} := \mathbb{F}^n$, let β be its standard basis, and set $T_A(\mathbf{x}) := A\mathbf{x}$, which is linear by Proposition 3.1.8.
Then $[T_A]_{\beta\leftarrow\beta} = A$ by Definition 3.1.7 and Definition 3.2.3. Choose a basis γ satisfying $P = C_{\gamma\leftarrow\beta}$ by Theorem 3.5.2(ii).
Hence $[T_A]_{\gamma\leftarrow\gamma} = PAP^{-1} = B$ by Theorem 5.1.1(i).

(*ii*) $\Rightarrow$ (*i*) Suppose $A = [T]_{\beta\leftarrow\beta}$ and $B = [T]_{\gamma\leftarrow\gamma}$. Set $P := C_{\gamma\leftarrow\beta}$. Then P is invertible with $P^{-1} = C_{\beta\leftarrow\gamma}$ by Theorem 3.5.2(i), and $B = PAP^{-1}$ by Theorem 5.1.1(i). Thus A and B are similar by Definition 6.2.1.

Structural Commentary: One direction realizes conjugation as basis change; the converse reads the transport formula.
Key Insight: Similarity is one operator in two coordinate systems. □

Perspective 6.2.5. *Similarity as Same Operator, New Coordinates*
For matrices, similarity means that they represent the same operator in two bases, not merely that their entries are related.
This is the structural content behind change of basis.

Definition 6.2.6. *Similarity of Operators*
For $T \in \mathcal{L}(\mathcal{V})$ and $S \in \mathcal{L}(\mathcal{W})$, $T \sim S$ iff $(\exists\, \Phi : \mathcal{V} \xrightarrow{\sim} \mathcal{W})\, S = \Phi T \Phi^{-1}$.
When $\mathcal{V} = \mathcal{W}$, the witnesses lie in $\mathrm{Aut}(\mathcal{V})$, so similarity is conjugacy in $\mathcal{L}(\mathcal{V})$.

Proposition 6.2.7. *Operator Similarity and Common Matrix Representatives*
Let $\dim \mathcal{V} = \dim \mathcal{W} = n$, $T \in \mathcal{L}(\mathcal{V})$, and $S \in \mathcal{L}(\mathcal{W})$.
Then $T \sim S$ iff some bases β of $\mathcal{V}$ and γ of $\mathcal{W}$ satisfy $[T]_{\beta\leftarrow\beta} = [S]_{\gamma\leftarrow\gamma}$.

Proof.

($\Rightarrow$) Suppose $T \sim S$. Choose an isomorphism $\Phi : \mathcal{V} \to \mathcal{W}$ satisfying $S = \Phi T \Phi^{-1}$ by Definition 6.2.6.
Choose a basis $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ of $\mathcal{V}$ by Corollary 1.3.14. Set $\gamma := (\Phi\mathbf{v}_1, \ldots, \Phi\mathbf{v}_n)$, which is a basis of $\mathcal{W}$ by Proposition 1.7.8.
The identities $(\forall\, \mathbf{v} \in \mathcal{V})\, [\Phi\mathbf{v}]_\gamma = [\mathbf{v}]_\beta$ and $S\Phi = \Phi T$ hold by Definition 3.2.1 and Proposition 1.5.7(ii),(iii), respectively.
Consequently, each $j \in \{1, \ldots, n\}$ satisfies $[S(\Phi\mathbf{v}_j)]_\gamma = [T\mathbf{v}_j]_\beta$. These are the respective jth columns of $[S]_{\gamma\leftarrow\gamma}$ and $[T]_{\beta\leftarrow\beta}$ by Definition 3.2.3; hence the matrices are equal by Definition 3.1.1(i).

($\Leftarrow$) Suppose bases $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ and $\gamma = (\mathbf{w}_1, \ldots, \mathbf{w}_n)$ satisfy $[T]_{\beta\leftarrow\beta} = [S]_{\gamma\leftarrow\gamma}$.
Choose $\Phi \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ satisfying $(\forall\, j \in \{1, \ldots, n\})\, \Phi\mathbf{v}_j = \mathbf{w}_j$ by Proposition 1.5.8. Its range is $\mathrm{span}(\gamma) = \mathcal{W}$ by Theorem 1.7.1(i), so Φ is surjective and hence injective by Corollary 1.7.6(ii). Therefore Φ is an isomorphism by Proposition 1.6.7.
The identity $(\forall\, \mathbf{v} \in \mathcal{V})\, [\Phi\mathbf{v}]_\gamma = [\mathbf{v}]_\beta$ holds by Definition 3.2.1.
Thus $(\forall\, j \in \{1, \ldots, n\})\, [\Phi T\mathbf{v}_j]_\gamma = [S\Phi\mathbf{v}_j]_\gamma$ by Definition 3.2.3, and $(\forall\, j \in \{1, \ldots, n\})\, \Phi T\mathbf{v}_j = S\Phi\mathbf{v}_j$ by Proposition 3.2.2(ii).
The compositions are linear by Proposition 1.5.7(i), so $\Phi T = S\Phi$ by Proposition 1.5.8.
Thus $S = \Phi T \Phi^{-1}$ by Proposition 1.5.7(ii),(iii), so $T \sim S$ by Definition 6.2.6.

Structural Commentary: A conjugating isomorphism transports a basis; a shared matrix reconstructs the isomorphism.
Key Insight: Matching basis actions force operator conjugacy. □

Theorem 6.2.8. *Similarity and Scalar Shifts*
Let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) If A and B are similar, then $(\forall\, \lambda \in \mathbb{F})\, [A - \lambda I_n$ is similar to $B - \lambda I_n]$.
(ii) If $(\exists\, \lambda \in \mathbb{F})\, [A - \lambda I_n$ is similar to $B - \lambda I_n]$, then A and B are similar.

Proof.

(i) Choose $P \in \mathrm{Mat}(n, n, \mathbb{F})^\times$ satisfying $B = PAP^{-1}$ by the hypothesis and Definition 6.2.1.
For $\lambda \in \mathbb{F}$, $B - \lambda I_n = PAP^{-1} - \lambda PP^{-1} = P(A - \lambda I_n)P^{-1}$, so the shifted matrices are similar by Definition 6.2.1.

(ii) Choose $\lambda \in \mathbb{F}$ and $P \in \mathrm{Mat}(n, n, \mathbb{F})^\times$ satisfying $B - \lambda I_n = P(A - \lambda I_n)P^{-1}$ by the hypothesis and Definition 6.2.1.
After adding $\lambda I_n = \lambda PP^{-1}$, the equality becomes $B = PAP^{-1}$, so A and B are similar by Definition 6.2.1.

Structural Commentary: Both directions add or remove the central term λI_n inside a conjugation.
Key Insight: Scalar identity shifts commute with every basis change. □

Proposition 6.2.9. *Upper Block-Triangular Similarity Shift*
Let $B \in \mathrm{Mat}(m, m, \mathbb{F})$, $D \in \mathrm{Mat}(n, n, \mathbb{F})$, $C, X \in \mathrm{Mat}(m, n, \mathbb{F})$. Set $M := \left(\begin{smallmatrix} B & C \\ 0 & D \end{smallmatrix}\right)$, $N := \left(\begin{smallmatrix} B & C+XD-BX \\ 0 & D \end{smallmatrix}\right)$. Then M and N are similar.

Proof. Set $U := \left(\begin{smallmatrix} I_m & X \\ 0 & I_n \end{smallmatrix}\right)$. By block multiplication, $U^{-1} = \left(\begin{smallmatrix} I_m & -X \\ 0 & I_n \end{smallmatrix}\right)$ and $UMU^{-1} = \left(\begin{smallmatrix} B & -BX+C+XD \\ 0 & D \end{smallmatrix}\right) = N$.
Thus M and N are similar by Definition 6.2.1.
Structural Commentary: Block multiplication verifies the inverse and computes the conjugated coupling block.
Key Insight: Unit upper conjugation preserves diagonal blocks and shears the coupling. □

Part IV
Geometric and Spectral Linear Algebra

1 Inner Product Geometry

1.1 Inner Products and Norms

Throughout, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$. This subsection develops the norm and metric geometry determined by an inner product.

Definition 1.1.1. *Preliminary Terminology*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$.

(i) For $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$, the *dot product* is $\mathbf{x} \cdot \mathbf{y} := x_1 y_1 + \cdots + x_n y_n$.
(ii) For $z = a + bi \in \mathbb{C}$ with $a, b \in \mathbb{R}$, its *complex conjugate* and *modulus* are $\overline{z} := a - bi$ and $|z| := \sqrt{a^2 + b^2}$.
(iii) A map $f : \mathcal{V} \to \mathbb{F}$ is *conjugate linear* if $(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})(\forall\, \lambda \in \mathbb{F})\ \big(f(\mathbf{u} + \mathbf{v}) = f(\mathbf{u}) + f(\mathbf{v}) \wedge f(\lambda \mathbf{v}) = \overline{\lambda} f(\mathbf{v})\big)$.
(iv) A map $B : \mathcal{V} \times \mathcal{V} \to \mathbb{F}$ is *sesquilinear* if it is linear in its first slot and conjugate linear in its second slot.

Motivation 1.1.2. *From Dot Products to Inner Products*
For $\mathbf{x} \in \mathbb{R}^n$, Euclidean squared length is $\mathbf{x} \cdot \mathbf{x} = \sum_{j=1}^{n} x_j^2$.

For $z \in \mathbb{C}$, the scalar z^2 need not be real, whereas $z\overline{z} = |z|^2 \geq 0$.
Conjugating one factor therefore preserves nonnegative squared length and motivates the following axioms.

Definition 1.1.3. *Inner Product*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$. An *inner product* on $\mathcal{V}$ is a map $\langle \cdot, \cdot \rangle : \mathcal{V} \times \mathcal{V} \to \mathbb{F}$ satisfying, for $(\mathbf{u}, \mathbf{v}, \mathbf{w}, \lambda) \in \mathcal{V}^3 \times \mathbb{F}$:

(i) *positivity*: $\langle \mathbf{v}, \mathbf{v} \rangle \in [0, \infty)$;
(ii) *definiteness*: $\langle \mathbf{v}, \mathbf{v} \rangle = 0 \iff \mathbf{v} = \mathbf{0}$;
(iii) *additivity in the first slot*: $\langle \mathbf{u} + \mathbf{v}, \mathbf{w} \rangle = \langle \mathbf{u}, \mathbf{w} \rangle + \langle \mathbf{v}, \mathbf{w} \rangle$;
(iv) *homogeneity in the first slot*: $\langle \lambda \mathbf{u}, \mathbf{v} \rangle = \lambda \langle \mathbf{u}, \mathbf{v} \rangle$;
(v) *conjugate symmetry*: $\langle \mathbf{u}, \mathbf{v} \rangle = \overline{\langle \mathbf{v}, \mathbf{u} \rangle}$.

Definition 1.1.4. *Inner-Product Space*
An *inner-product space* is a vector space $\mathcal{V}$ together with an inner product on $\mathcal{V}$.

Henceforth, unless stated otherwise, $\mathcal{V}$ denotes an inner-product space over $\mathbb{F}$.

Definition 1.1.5. *Norm Induced by an Inner Product*
For $\mathbf{v} \in \mathcal{V}$, the *norm* of $\mathbf{v}$ is $\|\mathbf{v}\| := \sqrt{\langle \mathbf{v}, \mathbf{v} \rangle}$.

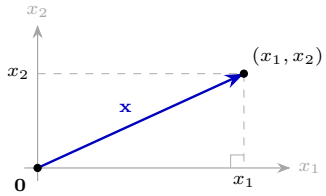

Figure 17: The norm is vector length, with $\|\mathbf{x}\|^2 = \langle \mathbf{x}, \mathbf{x} \rangle$.

Figure 17 draws $\mathbf{x} \in \mathbb{R}^2$ with coordinate legs x_1, x_2, so its length realizes $\|\mathbf{x}\|^2 = x_1^2 + x_2^2$.

Example 1.1.6. *Standard Inner Product on $\mathbb{F}^n$*
For $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$, set $\langle \mathbf{x}, \mathbf{y} \rangle := \sum_{j=1}^{n} x_j \overline{y_j}$. Sesquilinearity and conjugate symmetry hold componentwise, while $\langle \mathbf{x}, \mathbf{x} \rangle = \sum_{j=1}^{n} |x_j|^2$ verifies positivity and definiteness. For $\mathbb{F} = \mathbb{R}$, this is the dot product.

Example 1.1.7. *Function and Matrix Inner Products*

(i) If $a < b$, then $\langle f, g \rangle := \int_a^b f(t)\overline{g(t)}\, dt$ is an inner product on $C_{\mathbb{F}}[a, b]$.
Positivity and definiteness follow from $\langle f, f \rangle = \int_a^b |f(t)|^2\, dt \geq 0$, with equality only for $f = 0$ by continuity.

(ii) On $\mathrm{Mat}(m, n, \mathbb{F})$, the *Frobenius inner product* is $\langle A, B \rangle_F := \sum_{i=1}^{m} \sum_{j=1}^{n} a_{ij} \overline{b_{ij}}$.
Sesquilinearity holds entrywise, and $\langle A, A \rangle_F = \sum_{i=1}^{m} \sum_{j=1}^{n} |a_{ij}|^2$ is nonnegative and vanishes exactly when $A = 0$.

Example 1.1.8. *Square-Summable Sequences*
Set $\ell^2(\mathbb{F}) := \left\{ (x_j)_{j \geq 1} : \sum_{j=1}^{\infty} |x_j|^2 < \infty \right\}$ and $\langle \mathbf{x}, \mathbf{y} \rangle := \sum_{j=1}^{\infty} x_j \overline{y_j}$. The bound $|x_j \overline{y_j}| \leq \frac{1}{2}(|x_j|^2 + |y_j|^2)$ ensures absolute convergence.
Termwise algebra verifies sesquilinearity and conjugate symmetry, while $\langle \mathbf{x}, \mathbf{x} \rangle = \sum_{j=1}^{\infty} |x_j|^2$ verifies positivity and definiteness.
Thus $\ell^2(\mathbb{F})$ is an inner-product space containing $\mathbb{F}^{(\mathbb{N})}$.

Proposition 1.1.9. *Basic Inner-Product Identities*
For $(\mathbf{u}, \mathbf{v}, \mathbf{w}, \lambda) \in \mathcal{V}^3 \times \mathbb{F}$:

(i) for fixed $\mathbf{u}$, the map $\mathbf{v} \mapsto \langle \mathbf{v}, \mathbf{u} \rangle$ is linear;
(ii) $\langle \mathbf{0}, \mathbf{u} \rangle = 0$ and $\langle \mathbf{u}, \mathbf{0} \rangle = 0$;

(iii) $\langle \mathbf{u}, \mathbf{v}+\mathbf{w}\rangle = \langle \mathbf{u}, \mathbf{v}\rangle + \langle \mathbf{u}, \mathbf{w}\rangle$;
(iv) $\langle \mathbf{u}, \lambda\mathbf{v}\rangle = \overline{\lambda}\,\langle \mathbf{u}, \mathbf{v}\rangle$.

Proof.

(i) The map $\mathbf{v} \mapsto \langle \mathbf{v}, \mathbf{u}\rangle$ is linear by first-slot additivity and homogeneity.
(ii) $\langle \mathbf{0}, \mathbf{u}\rangle = 0$ by (i), and $\langle \mathbf{u}, \mathbf{0}\rangle = \overline{\langle \mathbf{0}, \mathbf{u}\rangle} = 0$ by conjugate symmetry.
(iii) $\langle \mathbf{u}, \mathbf{v}+\mathbf{w}\rangle = \overline{\langle \mathbf{v}+\mathbf{w}, \mathbf{u}\rangle} = \overline{\langle \mathbf{v}, \mathbf{u}\rangle} + \overline{\langle \mathbf{w}, \mathbf{u}\rangle} = \langle \mathbf{u}, \mathbf{v}\rangle + \langle \mathbf{u}, \mathbf{w}\rangle$ by conjugate symmetry and additivity.
(iv) $\langle \mathbf{u}, \lambda\mathbf{v}\rangle = \overline{\langle \lambda\mathbf{v}, \mathbf{u}\rangle} = \overline{\lambda}\,\overline{\langle \mathbf{v}, \mathbf{u}\rangle} = \overline{\lambda}\,\langle \mathbf{u}, \mathbf{v}\rangle$ by conjugate symmetry and homogeneity.

Structural Commentary: Conjugate symmetry transfers the first-slot axioms to the second slot.
Key Insight: One linear slot determines conjugate linearity in the other. □

Lemma 1.1.10. *Inner Products Separate Vectors*
For $\mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathcal{V}$:
(i) $\big((\forall\, \mathbf{x} \in \mathcal{V})\ \langle \mathbf{x}, \mathbf{u}\rangle = \langle \mathbf{x}, \mathbf{v}\rangle\big) \Longrightarrow \mathbf{u} = \mathbf{v}$;
(ii) $\big((\forall\, \mathbf{x} \in \mathcal{V})\ \langle \mathbf{x}, \mathbf{w}\rangle = 0\big) \Longleftrightarrow \mathbf{w} = \mathbf{0}$.

Proof.

(i) With $\mathbf{x} = \mathbf{u} - \mathbf{v}$, $\|\mathbf{u}-\mathbf{v}\|^2 = \langle \mathbf{u}-\mathbf{v}, \mathbf{u}\rangle - \langle \mathbf{u}-\mathbf{v}, \mathbf{v}\rangle = 0$ by Proposition 1.1.9. The equality $\mathbf{u} = \mathbf{v}$ holds by definiteness.
(ii) $(\Rightarrow)$ $\|\mathbf{w}\|^2 = \langle \mathbf{w}, \mathbf{w}\rangle = 0$ by the hypothesis with $\mathbf{x} = \mathbf{w}$, and $\mathbf{w} = \mathbf{0}$ by definiteness.
(ii) $(\Leftarrow)$ If $\mathbf{w} = \mathbf{0}$, then $(\forall\, \mathbf{x} \in \mathcal{V})\ \langle \mathbf{x}, \mathbf{w}\rangle = 0$ by Proposition 1.1.9(ii).

Structural Commentary: Each claim tests a difference vector against a strategically chosen argument.
Key Insight: Testing a vector against itself detects whether it vanishes. □

Example 1.1.11. *Norms from Standard Inner Products*

(i) On $\mathbb{F}^n$, the standard inner product induces the *Euclidean norm* $\|(x_1, \ldots, x_n)\|_2 = \sqrt{\sum_{j=1}^{n} |x_j|^2}$.

(ii) On $C_{\mathbb{F}}[a,b]$ with $a < b$, the integral inner product induces the *L^2 norm* $\|f\|_2 = \sqrt{\int_a^b |f(t)|^2\, dt}$.

(iii) On $\mathrm{Mat}(m,n,\mathbb{F})$, the Frobenius inner product induces $\|A\|_F = \sqrt{\langle A, A\rangle_F} = \sqrt{\sum_{i=1}^{m}\sum_{j=1}^{n} |a_{ij}|^2}$ for $A = [a_{ij}]$.

This is the *Frobenius*, *Schur*, or *Hilbert–Schmidt norm*.

Proposition 1.1.12. *Basic Properties of the Derived Norm*
For $(\mathbf{v}, \lambda) \in \mathcal{V} \times \mathbb{F}$:
(i) $\|\mathbf{v}\|$ *is real and nonnegative;*
(ii) $\|\mathbf{v}\| = 0 \Longleftrightarrow \mathbf{v} = \mathbf{0}$;
(iii) $\|\lambda\mathbf{v}\| = |\lambda|\,\|\mathbf{v}\|$.

Proof.

(i) The scalar $\|\mathbf{v}\| = \sqrt{\langle \mathbf{v}, \mathbf{v}\rangle}$ is real and nonnegative by positivity.
(ii) $(\Rightarrow)$ If $\|\mathbf{v}\| = 0$, then $\langle \mathbf{v}, \mathbf{v}\rangle = 0$, and $\mathbf{v} = \mathbf{0}$ by definiteness.
(ii) $(\Leftarrow)$ If $\mathbf{v} = \mathbf{0}$, then $\langle \mathbf{v}, \mathbf{v}\rangle = 0$ by definiteness and $\|\mathbf{v}\| = 0$ by the norm definition.
(iii) $\|\lambda\mathbf{v}\|^2 = \langle \lambda\mathbf{v}, \lambda\mathbf{v}\rangle = \lambda\overline{\lambda}\,\langle \mathbf{v}, \mathbf{v}\rangle = |\lambda|^2\,\|\mathbf{v}\|^2$ by sesquilinearity. The equality $\|\lambda\mathbf{v}\| = |\lambda|\,\|\mathbf{v}\|$ holds by nonnegative square roots.

Structural Commentary: Positivity controls the square root, while sesquilinearity controls scalar rescaling.
Key Insight: Squared length is easier to manipulate than length itself. □

Theorem 1.1.13. *Cauchy–Schwarz Inequality*
For $\mathbf{u}, \mathbf{v} \in \mathcal{V}$:
(i) $\big|\langle \mathbf{u}, \mathbf{v}\rangle\big| \le \|\mathbf{u}\|\,\|\mathbf{v}\|$;
(ii) equality in (i) holds if and only if $\mathbf{u}, \mathbf{v}$ *are linearly dependent.*

Proof.

(i) If $\mathbf{v} = \mathbf{0}$, the inequality is an equality. Suppose $\mathbf{v} \neq \mathbf{0}$ and set $\lambda := \frac{\langle \mathbf{u}, \mathbf{v}\rangle}{\|\mathbf{v}\|^2}$.

Then $0 \le \|\mathbf{u} - \lambda\mathbf{v}\|^2 = \|\mathbf{u}\|^2 - \frac{|\langle \mathbf{u}, \mathbf{v}\rangle|^2}{\|\mathbf{v}\|^2}$ by positivity, sesquilinearity, and conjugate symmetry.

The inequality $\big|\langle \mathbf{u}, \mathbf{v}\rangle\big| \le \|\mathbf{u}\|\,\|\mathbf{v}\|$ follows by multiplication by $\|\mathbf{v}\|^2$ and nonnegative square roots.
(ii) $(\Rightarrow)$ If equality holds and $\mathbf{v} = \mathbf{0}$, then $\mathbf{u}, \mathbf{v}$ are linearly dependent.
If $\mathbf{v} \neq \mathbf{0}$, then $\|\mathbf{u} - \lambda\mathbf{v}\| = 0$ by equality in (i) and the preceding identity, and $\mathbf{u} = \lambda\mathbf{v}$ by Proposition 1.1.12(ii).
(ii) $(\Leftarrow)$ If $\mathbf{v} = \mathbf{0}$, equality holds. Else linear dependence has form $\mathbf{u} = \lambda\mathbf{v}$; $\big|\langle \mathbf{u}, \mathbf{v}\rangle\big| = |\lambda|\,\|\mathbf{v}\|^2 = \|\mathbf{u}\|\,\|\mathbf{v}\|$ by Proposition 1.1.12(iii).

Structural Commentary: A least-residual scalar supplies the bound and characterizes equality.
Key Insight: Positivity controls the mixed term through optimal scalar comparison. □

Theorem 1.1.14. *Triangle Inequality*
For $\mathbf{u}, \mathbf{v} \in \mathcal{V}$:
(i) $\|\mathbf{u}+\mathbf{v}\| \le \|\mathbf{u}\| + \|\mathbf{v}\|$;
(ii) equality in (i) holds if and only if one of $\mathbf{u}, \mathbf{v}$ *is a nonnegative real multiple of the other.*

Proof.

(i) $\|\mathbf{u}+\mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2 + 2\,\mathrm{Re}\,\langle \mathbf{u}, \mathbf{v}\rangle$ by sesquilinearity and conjugate symmetry.
By Theorem 1.1.13(i), this is at most $\big(\|\mathbf{u}\| + \|\mathbf{v}\|\big)^2$. The inequality $\|\mathbf{u}+\mathbf{v}\| \le \|\mathbf{u}\| + \|\mathbf{v}\|$ follows by nonnegative square roots.

(*ii*) (⇒) If either vector is $\mathbf{0}$, it is a nonnegative multiple of the other.
Otherwise equality requires $\operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle = |\langle \mathbf{u}, \mathbf{v}\rangle|$ and equality in Cauchy–Schwarz.
Choose $a \in \mathbb{F}$ with $\mathbf{u} = a\mathbf{v}$ by Theorem 1.1.13(ii). Then $a \in [0, \infty)$ by $a\|\mathbf{v}\|^2 = \langle \mathbf{u}, \mathbf{v}\rangle \in [0, \infty)$.
(*ii*) (⇐) If $\mathbf{u} = a\mathbf{v}$ for $a \in [0, \infty)$, then $\|\mathbf{u} + \mathbf{v}\| = (a + 1)\|\mathbf{v}\| = \|\mathbf{u}\| + \|\mathbf{v}\|$. Interchanging $\mathbf{u}, \mathbf{v}$ in this calculation covers $\mathbf{v} = a\mathbf{u}$.

Structural Commentary: Cauchy–Schwarz bounds the cross term, and its equality case fixes the direction.
Key Insight: Equality requires aligned vectors with nonnegative relative scale. □

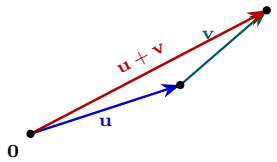

Figure 18: The direct displacement $\mathbf{u} + \mathbf{v}$ is no longer than the two-step path with legs $\mathbf{u}$ and $\mathbf{v}$.

Figure 18 identifies the three vectors compared by the triangle inequality; it does not supply the proof.

Proposition 1.1.15. *Reverse Triangle Inequality*
$(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})\ |\|\mathbf{u}\| - \|\mathbf{v}\|| \le \|\mathbf{u} - \mathbf{v}\|$.

Proof. $\|\mathbf{u}\| - \|\mathbf{v}\| \le \|\mathbf{u} - \mathbf{v}\|$ by Theorem 1.1.14(i) applied to $\mathbf{u} = (\mathbf{u} - \mathbf{v}) + \mathbf{v}$.
Likewise, $\|\mathbf{v}\| - \|\mathbf{u}\| \le \|\mathbf{u} - \mathbf{v}\|$ by the same result with $\mathbf{u}, \mathbf{v}$ interchanged.
The two bounds are equivalent to the asserted absolute-value inequality.
Structural Commentary: Two triangle-inequality bounds control both possible signs of the norm difference.
Key Insight: Distance bounds the change in length in either direction. □

Definition 1.1.16. *Norm and Normed Vector Space*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$. A *norm* on $\mathcal{V}$ is a map $\|\cdot\| : \mathcal{V} \to [0, \infty)$ satisfying, for $(\mathbf{u}, \mathbf{v}, \lambda) \in \mathcal{V}^2 \times \mathbb{F}$:

(i) $\|\mathbf{u}\| \ge 0$;
(ii) $\|\mathbf{u}\| = 0 \iff \mathbf{u} = \mathbf{0}$;
(iii) $\|\lambda\mathbf{u}\| = |\lambda|\,\|\mathbf{u}\|$;
(iv) $\|\mathbf{u} + \mathbf{v}\| \le \|\mathbf{u}\| + \|\mathbf{v}\|$.

A *normed vector space* is a vector space equipped with a norm. Its *unit ball* is $\{\mathbf{v} \in \mathcal{V} : \|\mathbf{v}\| \le 1\}$.

Definition 1.1.17. *Distance Induced by an Inner Product*
The *distance induced by the inner product* is $d : \mathcal{V} \times \mathcal{V} \to [0, \infty)$ defined by $d(\mathbf{u}, \mathbf{v}) := \|\mathbf{u} - \mathbf{v}\|$.

Proposition 1.1.18. *Inner-Product Distance Is a Metric*
For $d(\mathbf{u}, \mathbf{v}) := \|\mathbf{u} - \mathbf{v}\|$ and $\mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathcal{V}$:

(i) $d(\mathbf{u}, \mathbf{v}) \ge 0$;
(ii) $d(\mathbf{u}, \mathbf{v}) = 0 \iff \mathbf{u} = \mathbf{v}$;
(iii) $d(\mathbf{u}, \mathbf{v}) = d(\mathbf{v}, \mathbf{u})$;
(iv) $d(\mathbf{u}, \mathbf{v}) \le d(\mathbf{u}, \mathbf{w}) + d(\mathbf{w}, \mathbf{v})$.

Proof.

(*i*) $d(\mathbf{u}, \mathbf{v}) = \|\mathbf{u} - \mathbf{v}\| \ge 0$ by Proposition 1.1.12(i).
(*ii*) (⇒) If $d(\mathbf{u}, \mathbf{v}) = 0$, then $\mathbf{u} - \mathbf{v} = \mathbf{0}$ by Proposition 1.1.12(ii); equivalently, $\mathbf{u} = \mathbf{v}$.
(*ii*) (⇐) If $\mathbf{u} = \mathbf{v}$, then $d(\mathbf{u}, \mathbf{v}) = \|\mathbf{0}\| = 0$ by Proposition 1.1.12(ii).
(*iii*) $d(\mathbf{u}, \mathbf{v}) = \|-(\mathbf{v} - \mathbf{u})\| = \|\mathbf{v} - \mathbf{u}\| = d(\mathbf{v}, \mathbf{u})$ by Proposition 1.1.12(iii) with $\lambda = -1$.
(*iv*) Since $\mathbf{u} - \mathbf{v} = (\mathbf{u} - \mathbf{w}) + (\mathbf{w} - \mathbf{v})$, $d(\mathbf{u}, \mathbf{v}) \le d(\mathbf{u}, \mathbf{w}) + d(\mathbf{w}, \mathbf{v})$ by Theorem 1.1.14(i).

Structural Commentary: Each metric axiom reduces to the corresponding norm property on a difference vector.
Key Insight: Distances are norms of displacements. □

Perspective 1.1.19. *Metric Viewpoint*
Because $d(\mathbf{v}_n, \mathbf{v}) = \|\mathbf{v}_n - \mathbf{v}\|$, metric convergence is exactly norm convergence.
Closedness, continuity, and completeness require topological results developed later; no such conclusion is used as authority here.

Theorem 1.1.20. *Parallelogram Identity*
$(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})\ \|\mathbf{u} + \mathbf{v}\|^2 + \|\mathbf{u} - \mathbf{v}\|^2 = 2\big(\|\mathbf{u}\|^2 + \|\mathbf{v}\|^2\big)$.

Proof. For $\varepsilon \in \{1, -1\}$, $\|\mathbf{u} + \varepsilon\mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2 + 2\varepsilon \operatorname{Re}\langle \mathbf{u}, \mathbf{v}\rangle$ by sesquilinearity and conjugate symmetry.
The asserted identity is the sum of the cases $\varepsilon = 1, -1$.
Structural Commentary: Paired expansions cancel the cross terms while preserving both squared norms.
Key Insight: Opposite diagonals erase the mixed inner-product contribution. □

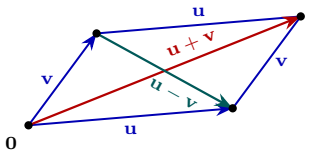

Figure 19: A parallelogram with side vectors $\mathbf{u}, \mathbf{v}$ and diagonal vectors $\mathbf{u} + \mathbf{v}, \mathbf{u} - \mathbf{v}$.

Figure 19 identifies the sides and diagonals whose squared lengths occur in the parallelogram identity.

Proposition 1.1.21. *Coordinate Norms on $\mathbb{F}^n$*
For $\mathbf{x} = (x_1, \dots, x_n) \in \mathbb{F}^n$, each of the following defines a norm on $\mathbb{F}^n$:

(i) $\|\mathbf{x}\|_1 := \sum_{j=1}^{n} |x_j|$;

(ii) $\|\mathbf{x}\|_2 := \left(\sum_{j=1}^{n} |x_j|^2 \right)^{1/2}$;

(iii) $\|\mathbf{x}\|_\infty := \max_{1 \le j \le n} |x_j|$.

Proof.

(i) Nonnegativity, definiteness, and absolute homogeneity of $\|\cdot\|_1$ hold by the corresponding scalar properties.
Its triangle inequality is $\|\mathbf{x}+\mathbf{y}\|_1 = \sum_{j=1}^{n} |x_j + y_j| \le \sum_{j=1}^{n} (|x_j| + |y_j|) = \|\mathbf{x}\|_1 + \|\mathbf{y}\|_1$ by the scalar triangle inequality.

(ii) Standard inner product induces $\|\cdot\|_2$, first 3 norm axioms hold (Proposition 1.1.12), triangle inequality hold (Theorem 1.1.14(i)).

(iii) Nonnegativity and absolute homogeneity of $\|\cdot\|_\infty$ hold by modulus, and $\|\mathbf{x}\|_\infty = 0 \iff (\forall\, j \in \{1, \dots, n\})\, x_j = 0 \iff \mathbf{x} = \mathbf{0}$.
Choose $k \in \{1, \dots, n\}$ with $\|\mathbf{x}+\mathbf{y}\|_\infty = |x_k + y_k|$.
Then $\|\mathbf{x}+\mathbf{y}\|_\infty \le |x_k| + |y_k| \le \|\mathbf{x}\|_\infty + \|\mathbf{y}\|_\infty$ by the scalar triangle inequality and the definition of the maximum.

Structural Commentary: Scalar modulus handles the ℓ_1 and ℓ_∞ cases; inner-product geometry handles the ℓ_2 case.
Key Insight: Distinct coordinate aggregations satisfy the same norm axioms. □

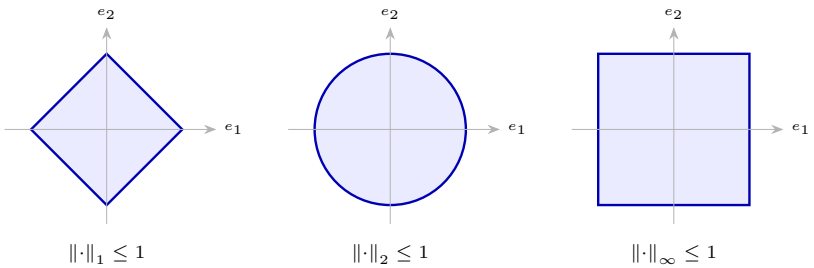

Figure 20: The ℓ_1, ℓ_2, and ℓ_∞ unit balls in $\mathbb{R}^2$ are respectively a diamond, a disk, and a square.

Figure 20 contrasts the three unit-ball shapes without serving as proof of the norm axioms.

Corollary 1.1.22. *ℓ_1 and ℓ_∞ Are Not Inner-Product Norms*
If $n \ge 2$, then the norms $\|\cdot\|_1$ and $\|\cdot\|_\infty$ on $\mathbb{F}^n$ are not induced by any inner product.

Proof. For the first two coordinate vectors $\mathbf{e}_1, \mathbf{e}_2$, direct evaluation makes the two sides of the parallelogram identity 8 and 4 under $\|\cdot\|_1$, and 2 and 4 under $\|\cdot\|_\infty$. Neither norm is induced by an inner product by Theorem 1.1.20.
Structural Commentary: Two coordinate tests contradict the necessary parallelogram identity.
Key Insight: A failed parallelogram identity excludes every inducing inner product. □

Theorem 1.1.23. *Polarization Identities*
For $\mathbf{u}, \mathbf{v} \in \mathcal{V}$:

(i) If $\mathbb{F} = \mathbb{R}$, then $\langle \mathbf{u}, \mathbf{v} \rangle = \frac{1}{4}\left(\|\mathbf{u}+\mathbf{v}\|^2 - \|\mathbf{u}-\mathbf{v}\|^2 \right)$.

(ii) If $\mathbb{F} = \mathbb{C}$, then $\langle \mathbf{u}, \mathbf{v} \rangle = \frac{1}{4}\left(\|\mathbf{u}+\mathbf{v}\|^2 - \|\mathbf{u}-\mathbf{v}\|^2 + i\,\|\mathbf{u}+i\mathbf{v}\|^2 - i\,\|\mathbf{u}-i\mathbf{v}\|^2 \right)$.

Proof. Let $z := \langle \mathbf{u}, \mathbf{v} \rangle$.

(i) If $\mathbb{F} = \mathbb{R}$, then $\|\mathbf{u}+\mathbf{v}\|^2 - \|\mathbf{u}-\mathbf{v}\|^2 = 4 \operatorname{Re} z = 4z$ by sesquilinearity, which is equivalent to (i).

(ii) If $\mathbb{F} = \mathbb{C}$, then $\|\mathbf{u}+\mathbf{v}\|^2 - \|\mathbf{u}-\mathbf{v}\|^2 = 4 \operatorname{Re} z$ and $\|\mathbf{u}+i\mathbf{v}\|^2 - \|\mathbf{u}-i\mathbf{v}\|^2 = 4 \operatorname{Im} z$ by sesquilinearity.
Substitution into $z = \operatorname{Re} z + i \operatorname{Im} z$ is exactly (ii).

Structural Commentary: Norm differences recover the real part directly and the imaginary part after rotation.
Key Insight: The norm determines both components of every complex inner product. □

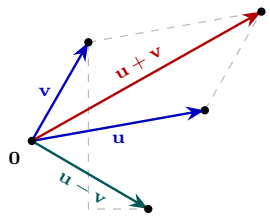

Figure 21: The sum and difference vectors isolate $4 \operatorname{Re} \langle \mathbf{u}, \mathbf{v} \rangle$ through their squared-length difference.

Figure 21 illustrates the real-part identity; the complex identity also compares $\mathbf{u} \pm i\mathbf{v}$.

Proposition 1.1.24. *Operator Zero Tests from Inner Products*
Let $T \in \mathcal{L}(\mathcal{V})$.

(i) $\big((\forall\, \mathbf{v}, \mathbf{w} \in \mathcal{V})\ \langle T\mathbf{v}, \mathbf{w} \rangle = 0 \big) \Longrightarrow T = 0$.

(ii) *If* $\mathbb{F} = \mathbb{C}$, *then* $\big((\forall\, \mathbf{v} \in \mathcal{V})\ \langle T\mathbf{v}, \mathbf{v}\rangle = 0\big) \Longrightarrow T = 0$.
(iii) *If* $\mathbb{F} = \mathbb{R}$, *the implication in (ii) can fail.*

Proof.

(i) $(\forall\, \mathbf{v} \in \mathcal{V})\ \|T\mathbf{v}\|^2 = \langle T\mathbf{v}, T\mathbf{v}\rangle = 0$ by the hypothesis with $\mathbf{w} = T\mathbf{v}$; $T = 0$ by definiteness.
(ii) Set $Q(\mathbf{x}) := \langle T\mathbf{x}, \mathbf{x}\rangle$. For fixed $\mathbf{x}, \mathbf{y} \in \mathcal{V}$, set $a := \langle T\mathbf{x}, \mathbf{y}\rangle$ and $b := \langle T\mathbf{y}, \mathbf{x}\rangle$.
For $r \in \mathbb{C}$, $0 = Q(r\mathbf{x} + \mathbf{y}) = ra + \overline{r}b$ by the hypothesis and sesquilinearity.
The choices $r = 1, i$ establish $a + b = a - b = 0$, and $a = b = 0$ by these equations.
The identity $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\ \langle T\mathbf{x}, \mathbf{y}\rangle = 0$ holds by the arbitrary choice of $\mathbf{x}, \mathbf{y}$, and $T = 0$ by (i).
(iii) On standard $\mathbb{R}^2$, define $T(x_1, x_2) := (-x_2, x_1)$. Then $(\forall\, \mathbf{v} \in \mathbb{R}^2)\ \langle T\mathbf{v}, \mathbf{v}\rangle = -v_2v_1 + v_1v_2 = 0$, while $T(1, 0) = (0, 1) \neq \mathbf{0}$.

Structural Commentary: Self-testing handles (i), complex scalar probes handle (ii), and rotation refutes the real analogue.
Key Insight: Complex phases recover mixed terms that real diagonal tests miss. □

Principle 1.1.25. *Geometry from Algebra*
For inner-product norms, expanding $\|\mathbf{u} \pm \mathbf{v}\|^2$ exposes the cross terms that control angles, inequalities, and polarization.
This heuristic does not apply to arbitrary norms, as the ℓ_1 and ℓ_∞ countertests demonstrate.

1.2 Unit Vectors and Orthogonality

Throughout this subsection, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ and $\mathcal{V}$ is an inner-product space over $\mathbb{F}$.

Definition 1.2.1. *Unit Vector and Normalization*
A vector $\mathbf{u} \in \mathcal{V}$ is a *unit vector* if $\|\mathbf{u}\| = 1$. If $\mathbf{v} \neq \mathbf{0}$, then $\frac{\mathbf{v}}{\|\mathbf{v}\|}$ is called the *normalization* of $\mathbf{v}$.

Proposition 1.2.2. *Properties of Normalization*
For $\mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\}$:
(i) $\frac{\mathbf{v}}{\|\mathbf{v}\|}$ *is a unit vector;*
(ii) $\frac{\mathbf{v}}{\|\mathbf{v}\|}$ *is a positive real scalar multiple of* $\mathbf{v}$.

Proof.

(i) Since $\mathbf{v} \neq \mathbf{0}$, $\|\mathbf{v}\| > 0$ by Proposition 1.1.12(i)–(ii). The identity $\left\|\frac{\mathbf{v}}{\|\mathbf{v}\|}\right\| = \frac{1}{\|\mathbf{v}\|}\|\mathbf{v}\| = 1$ holds by Proposition 1.1.12(iii).
(ii) $\frac{\mathbf{v}}{\|\mathbf{v}\|} = \lambda\mathbf{v}$ for $\lambda := \frac{1}{\|\mathbf{v}\|} \in \mathbb{R}_{>0}$ by Proposition 1.1.12(i)–(ii).

Structural Commentary: Normalization changes scale but preserves the generated one-dimensional subspace.
Key Insight: Divide by the length to make the length equal to one. □

Definition 1.2.3. *Orthogonal Vectors and Finite Lists*
Vectors $\mathbf{u}, \mathbf{v} \in \mathcal{V}$ are *orthogonal*, written $\mathbf{u} \perp \mathbf{v}$, if $\langle \mathbf{u}, \mathbf{v}\rangle = 0$.
A finite list $(\mathbf{v}_1, \ldots, \mathbf{v}_m)$ in $\mathcal{V}$ is *mutually orthogonal* if $(\forall\, j, k \in \{1, \ldots, m\})[j \neq k \Longrightarrow \langle \mathbf{v}_j, \mathbf{v}_k\rangle = 0]$.

Proposition 1.2.4. *Orthogonality and the Zero Vector*
For $\mathbf{u}, \mathbf{v} \in \mathcal{V}$:
(i) $\mathbf{u} \perp \mathbf{v} \Longleftrightarrow \mathbf{v} \perp \mathbf{u}$.
(ii) $(\forall\, \mathbf{x} \in \mathcal{V})\,(\mathbf{0} \perp \mathbf{x} \wedge \mathbf{x} \perp \mathbf{0})$.
(iii) $\mathbf{v} \perp \mathbf{v} \Longrightarrow \mathbf{v} = \mathbf{0}$.

Proof.

(i) $(\Rightarrow)$ If $\mathbf{u} \perp \mathbf{v}$, then $\langle \mathbf{u}, \mathbf{v}\rangle = 0$ by Definition 1.2.3. Conjugate symmetry implies $\langle \mathbf{v}, \mathbf{u}\rangle = \overline{\langle \mathbf{u}, \mathbf{v}\rangle} = 0$, so $\mathbf{v} \perp \mathbf{u}$.
(i) $(\Leftarrow)$ If $\mathbf{v} \perp \mathbf{u}$, then $\langle \mathbf{v}, \mathbf{u}\rangle = 0$ by Definition 1.2.3. Conjugate symmetry implies $\langle \mathbf{u}, \mathbf{v}\rangle = \overline{\langle \mathbf{v}, \mathbf{u}\rangle} = 0$, so $\mathbf{u} \perp \mathbf{v}$.
(ii) $(\forall\, \mathbf{x} \in \mathcal{V})\ \big(\langle \mathbf{0}, \mathbf{x}\rangle = 0 \wedge \langle \mathbf{x}, \mathbf{0}\rangle = 0\big)$ by Proposition 1.1.9(ii).
(iii) If $\mathbf{v} \perp \mathbf{v}$, then $\langle \mathbf{v}, \mathbf{v}\rangle = 0$ by Definition 1.2.3, and $\mathbf{v} = \mathbf{0}$ by definiteness.

Structural Commentary: Conjugate symmetry makes orthogonality symmetric, and definiteness isolates $\mathbf{0}$.
Key Insight: Conjugate symmetry preserves the equation "equals zero." □

Proposition 1.2.5. *Mutually Orthogonal Nonzero Vectors Are Independent*
Mutually orthogonal nonzero vectors $\mathbf{v}_1, \ldots, \mathbf{v}_m \in \mathcal{V}$ *are linearly independent.*

Proof. Suppose $\sum_{j=1}^{m} c_j\mathbf{v}_j = \mathbf{0}$ for $c_1, \ldots, c_m \in \mathbb{F}$, and fix $k \in \{1, \ldots, m\}$.

By Proposition 1.1.9(i)–(ii) and mutual orthogonality, $0 = \langle \mathbf{0}, \mathbf{v}_k\rangle = \left\langle \sum_{j=1}^{m} c_j\mathbf{v}_j, \mathbf{v}_k \right\rangle = c_k \langle \mathbf{v}_k, \mathbf{v}_k\rangle = c_k \|\mathbf{v}_k\|^2$.

Since $\mathbf{v}_k \neq \mathbf{0}$, $\|\mathbf{v}_k\| > 0$ by Proposition 1.1.12(i)–(ii), so $c_k = 0$. The index k was arbitrary, hence every coefficient vanishes.
Structural Commentary: Orthogonality isolates one coefficient at a time.
Key Insight: Pair a dependence relation with one vector from the list; every cross term disappears. □

1.3 Orthonormal Bases and Gram–Schmidt

Throughout this subsection, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ and $\mathcal{V}$ is an inner-product space over $\mathbb{F}$.

Definition 1.3.1. *Orthogonal and Orthonormal Families*
For an index set I, a family $(\mathbf{u}_i)_{i\in I}$ in $\mathcal{V}$ is *orthogonal* if $(\forall\, i,j\in I)[i\neq j \Longrightarrow \langle \mathbf{u}_i,\mathbf{u}_j\rangle = 0]$. It is *orthonormal* if $(\forall\, i,j\in I)\ \langle \mathbf{u}_i,\mathbf{u}_j\rangle = \delta_{ij}$.
Thus a finite list $(\mathbf{e}_1,\dots,\mathbf{e}_m)$ is orthonormal exactly when $(\forall\, j,k\in\{1,\dots,m\})\ \langle \mathbf{e}_j,\mathbf{e}_k\rangle = \delta_{jk}$.
Equivalently, the vectors in the list are unit and mutually orthogonal.
If $(\mathbf{u}_i)_{i\in I}$ is orthogonal and $(\forall\, i\in I)\,\mathbf{u}_i\neq\mathbf{0}$, then $\left(\frac{\mathbf{u}_i}{\|\mathbf{u}_i\|}\right)_{i\in I}$ is orthonormal.

Proposition 1.3.2. *Norm of an Orthonormal Linear Combination*
If $(\mathbf{e}_1,\dots,\mathbf{e}_m)$ is orthonormal, then $(\forall\,(a_1,\dots,a_m)\in\mathbb{F}^m)\left[\left\|\sum_{j=1}^m a_j\mathbf{e}_j\right\|^2 = \sum_{j=1}^m |a_j|^2\right]$.

Proof. $\left\|\sum_{j=1}^m a_j\mathbf{e}_j\right\|^2 = \left\langle \sum_{j=1}^m a_j\mathbf{e}_j, \sum_{k=1}^m a_k\mathbf{e}_k\right\rangle = \sum_{j=1}^m\sum_{k=1}^m a_j\overline{a_k}\,\langle \mathbf{e}_j,\mathbf{e}_k\rangle = \sum_{j=1}^m |a_j|^2$ by sesquilinearity and orthonormality.
Structural Commentary: Orthonormality deletes every cross term in the squared-norm expansion.
Key Insight: In orthonormal coordinates, length is computed coefficient-by-coefficient. □

Corollary 1.3.3. *Orthonormal Lists Are Linearly Independent*
If $(\mathbf{e}_1,\dots,\mathbf{e}_m)$ is orthonormal in $\mathcal{V}$, then it is linearly independent.

Proof. Suppose $\sum_{j=1}^m a_j\mathbf{e}_j = \mathbf{0}$ for $(a_1,\dots,a_m)\in\mathbb{F}^m$. Then $0 = \|\mathbf{0}\|^2 = \sum_{j=1}^m |a_j|^2$ by Proposition 1.3.2.
Each $a_j = 0$ by nonnegativity of the summands, so the list is linearly independent.
Structural Commentary: The norm identity converts a linear relation into a sum of nonnegative scalars.
Key Insight: A zero orthonormal linear combination can only have zero coefficients. □

Definition 1.3.4. *Orthonormal Basis*
An *orthonormal basis* of $\mathcal{V}$ is a basis of $\mathcal{V}$ that is an orthonormal list.

Proposition 1.3.5. *Right-Length Orthonormal Lists Are Bases*
If $\dim(\mathcal{V}) = n < \infty$ and $(\mathbf{e}_1,\dots,\mathbf{e}_n)$ is orthonormal, then it is an orthonormal basis of $\mathcal{V}$.

Proof. The list is linearly independent by Corollary 1.3.3. It is a basis by Proposition 1.4.4 because its length is $\dim(\mathcal{V})$.
Structural Commentary: Orthonormality supplies independence; the dimension criterion supplies spanning.
Key Insight: In finite dimensions, n independent vectors in an n-dimensional space already form a basis. □

Theorem 1.3.6. *Gram–Schmidt Process*
Let $m\geq 1$ and let $(\mathbf{v}_1,\dots,\mathbf{v}_m)$ be linearly independent in $\mathcal{V}$. Define $\mathbf{u}_1 := \mathbf{v}_1$ and $\mathbf{e}_1 := \frac{\mathbf{u}_1}{\|\mathbf{u}_1\|}$.
For $2\leq j\leq m$, define $\mathbf{u}_j := \mathbf{v}_j - \sum_{k=1}^{j-1}\langle \mathbf{v}_j,\mathbf{e}_k\rangle\,\mathbf{e}_k$.
For $2\leq j\leq m$, set $\mathbf{e}_j := \frac{\mathbf{u}_j}{\|\mathbf{u}_j\|}$. Then:
(i) $(\forall\, j\in\{1,\dots,m\})[\operatorname{span}(\mathbf{v}_1,\dots,\mathbf{v}_j) = \operatorname{span}(\mathbf{e}_1,\dots,\mathbf{e}_j)]$;
(ii) $(\mathbf{e}_1,\dots,\mathbf{e}_m)$ *is orthonormal.*

Proof.
(*i*) Put $V_j := \operatorname{span}(\mathbf{v}_1,\dots,\mathbf{v}_j)$ and $E_j := \operatorname{span}(\mathbf{e}_1,\dots,\mathbf{e}_j)$. Induct on j.
Since $\mathbf{v}_1\neq\mathbf{0}$, $\mathbf{e}_1$ is a nonzero scalar multiple of $\mathbf{v}_1$, so $V_1 = E_1$. Suppose $V_{j-1} = E_{j-1}$.
The correction term in $\mathbf{u}_j$ lies in $E_{j-1} = V_{j-1}$, so $\mathbf{u}_j\in V_j$.
If $\mathbf{u}_j = \mathbf{0}$, then $\mathbf{v}_j\in V_{j-1}$, contrary to linear independence; hence $\mathbf{u}_j\neq\mathbf{0}$ and $\mathbf{e}_j\in V_j$, so $E_j\subseteq V_j$.
Conversely, $\mathbf{v}_j = \|\mathbf{u}_j\|\,\mathbf{e}_j + \sum_{k=1}^{j-1}\langle \mathbf{v}_j,\mathbf{e}_k\rangle\,\mathbf{e}_k\in E_j$, so $V_j\subseteq E_j$.
(*ii*) $(\forall\, j\in\{1,\dots,m\})\left[\|\mathbf{e}_j\| = \left\|\frac{1}{\|\mathbf{u}_j\|}\mathbf{u}_j\right\| = 1\right]$ by Proposition 1.1.12(iii) and nonvanishing established in (i). Induct on j to verify mutual orthogonality. If $(\mathbf{e}_1,\dots,\mathbf{e}_{j-1})$ is orthonormal and $k<j$, then $\langle \mathbf{u}_j,\mathbf{e}_k\rangle = \langle \mathbf{v}_j,\mathbf{e}_k\rangle - \sum_{i=1}^{j-1}\langle \mathbf{v}_j,\mathbf{e}_i\rangle\,\langle \mathbf{e}_i,\mathbf{e}_k\rangle = 0$.
Hence $\mathbf{e}_j\perp\mathbf{e}_k$ by first-slot homogeneity, and the reverse relation holds by Proposition 1.2.4(i). Thus the full list is orthonormal.
Structural Commentary: Prefix-span induction establishes well-definedness before orthogonality is verified.
Key Insight: Each remainder removes precisely the earlier orthonormal components. □

Theorem 1.3.7. *Gram–Schmidt for Arbitrary Finite Lists*
Let $m\geq 1$ and let $(\mathbf{v}_1,\dots,\mathbf{v}_m)$ be a finite list in $\mathcal{V}$. Set $\mathbf{u}_1 := \mathbf{v}_1$. For $2\leq k\leq m$, define $\mathcal{J}_{k-1} := \{j\in\{1,\dots,k-1\} : \mathbf{u}_j\neq\mathbf{0}\}$.
For $2\leq k\leq m$, set $\mathbf{u}_k := \mathbf{v}_k - \sum_{j\in\mathcal{J}_{k-1}}\frac{\langle \mathbf{v}_k,\mathbf{u}_j\rangle}{\langle \mathbf{u}_j,\mathbf{u}_j\rangle}\mathbf{u}_j$. Set $U_k := \operatorname{span}(\mathbf{u}_1,\dots,\mathbf{u}_k)$, $V_k := \operatorname{span}(\mathbf{v}_1,\dots,\mathbf{v}_k)$, with $U_0 = V_0 := \{\mathbf{0}\}$. Then:
(i) $(\mathbf{u}_1,\dots,\mathbf{u}_m)$ *is orthogonal;*
(ii) $(\forall\, k\in\{1,\dots,m\})[U_k = V_k]$.

Proof.
(*i*) Induct on k. A one-vector list is orthogonal. Suppose $(\mathbf{u}_1,\dots,\mathbf{u}_{k-1})$ is orthogonal and fix $i<k$.
If $\mathbf{u}_i = \mathbf{0}$, then $\mathbf{u}_k\perp\mathbf{u}_i$ by Proposition 1.2.4(ii). If $\mathbf{u}_i\neq\mathbf{0}$, then $i\in\mathcal{J}_{k-1}$ and $\langle \mathbf{u}_k,\mathbf{u}_i\rangle = \langle \mathbf{v}_k,\mathbf{u}_i\rangle - \sum_{j\in\mathcal{J}_{k-1}}\frac{\langle \mathbf{v}_k,\mathbf{u}_j\rangle}{\langle \mathbf{u}_j,\mathbf{u}_j\rangle}\langle \mathbf{u}_j,\mathbf{u}_i\rangle = 0$
by the induction hypothesis: all terms with $j\neq i$ vanish, and the $j=i$ term cancels the first term.
The reverse orthogonality relation holds by Proposition 1.2.4(i), so the full list is orthogonal.

(*ii*) Induct on k, starting from $U_0 = V_0$. Suppose $U_{k-1} = V_{k-1}$.
The correction term in $\mathbf{u}_k$ lies in $U_{k-1} = V_{k-1}$, so $\mathbf{u}_k \in V_k$ and $U_k \subseteq V_k$.
The recursion also expresses $\mathbf{v}_k$ as $\mathbf{u}_k$ plus a vector in U_{k-1}, so $\mathbf{v}_k \in U_k$ and $V_k \subseteq U_k$. Therefore $U_k = V_k$.

Structural Commentary: Orthogonality and prefix-span preservation follow by separate inductions.
Key Insight: Subtracting all nonzero earlier directions preserves the generated span. □

Corollary 1.3.8. *Zero Remainders Detect Dependence*
For the construction in Theorem 1.3.7, $(\forall\, k \in \{1, \dots, m\})[\mathbf{u}_k = \mathbf{0} \iff \mathbf{v}_k \in V_{k-1}]$.

Proof. Fix $k \in \{1, \dots, m\}$.
(⇒) Suppose $\mathbf{u}_k = \mathbf{0}$. If $k = 1$, then $\mathbf{v}_1 = \mathbf{0} \in V_0$. If $k \geq 2$, the recursion places $\mathbf{v}_k$ in $U_{k-1} = V_{k-1}$ by Theorem 1.3.7(ii).
(⇐) Suppose $\mathbf{v}_k \in V_{k-1}$. If $k = 1$, then $\mathbf{v}_1 = \mathbf{0} = \mathbf{u}_1$.
If $k \geq 2$, then $V_{k-1} = U_{k-1}$ by Theorem 1.3.7(ii), so write $\mathbf{v}_k = \sum_{j \in \mathcal{J}_{k-1}} a_j \mathbf{u}_j$ for a coefficient family $(a_j)_{j \in \mathcal{J}_{k-1}}$.
The nonzero vectors in this sum are orthogonal by Theorem 1.3.7(i), and $(\forall\, i \in \mathcal{J}_{k-1})\ \langle \mathbf{v}_k, \mathbf{u}_i \rangle = a_i \langle \mathbf{u}_i, \mathbf{u}_i \rangle$ by orthogonality.
Thus $(\forall\, i \in \mathcal{J}_{k-1})\, a_i = \frac{\langle \mathbf{v}_k, \mathbf{u}_i \rangle}{\langle \mathbf{u}_i, \mathbf{u}_i \rangle}$, so the correction term equals $\mathbf{v}_k$ and $\mathbf{u}_k = \mathbf{0}$ by the recursion.

Structural Commentary: Each direction compares the recursion with the preserved prefix span.
Key Insight: A zero remainder means the new vector adds no direction. □

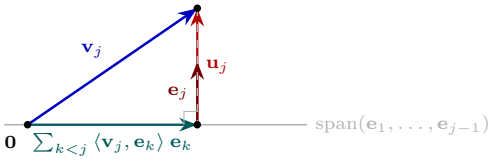

Figure 22: One Gram–Schmidt step: subtract the previous-span component, then normalize.

Figure 22 depicts the residual after removal of the previous-span component; normalization changes its length while preserving its generated one-dimensional subspace.

Example 1.3.9. *Legendre Polynomials from Gram–Schmidt*
Equip $\mathbb{R}[x]$ with $\langle p, q \rangle := \int_{-1}^{1} p(x) q(x)\, dx$ and perform Gram–Schmidt on $(1, x, x^2, x^3, \dots)$.
Parity annihilates mixed even–odd inner products. Since $\langle 1, 1 \rangle = 2$, $\langle x^2, 1 \rangle = \frac{2}{3}$, $\langle x, x \rangle = \frac{2}{3}$, and $\langle x^3, x \rangle = \frac{2}{5}$, the first remainders are $u_1(x) = 1$, $u_2(x) = x$, $u_3(x) = x^2 - \frac{1}{3}$, and $u_4(x) = x^3 - \frac{3}{5}x$.
These are nonzero scalar multiples of the first four Legendre polynomials.
Structural Commentary: Orthogonal polynomials are orthogonalized monomials.
Key Insight: Changing the inner product changes the polynomial family produced by Gram–Schmidt.

Lemma 1.3.10. *Gram–Schmidt on Orthogonal Lists*
Let $m \geq 1$ and let $(\mathbf{v}_1, \dots, \mathbf{v}_m)$ be a mutually orthogonal list of nonzero vectors. Then:
(i) $(\forall\, j \in \{1, \dots, m\})\, \mathbf{e}_j = \frac{\mathbf{v}_j}{\|\mathbf{v}_j\|}$;
(ii) if the original list is orthonormal, then $(\forall\, j \in \{1, \dots, m\})\, \mathbf{e}_j = \mathbf{v}_j$.

Proof.
(*i*) The list is linearly independent by Proposition 1.2.5, so the construction is defined by Theorem 1.3.6. Induct on j.
The claim holds for $j = 1$. Suppose $(\forall\, i < j)\, \mathbf{e}_i = \frac{\mathbf{v}_i}{\|\mathbf{v}_i\|}$. Then $(\forall\, i < j)\ \langle \mathbf{v}_j, \mathbf{e}_i \rangle = \frac{1}{\|\mathbf{v}_i\|} \langle \mathbf{v}_j, \mathbf{v}_i \rangle = 0$ by mutual orthogonality.
Thus $\mathbf{u}_j = \mathbf{v}_j$ in the recursion and $\mathbf{e}_j = \frac{\mathbf{v}_j}{\|\mathbf{v}_j\|}$.
(*ii*) If the input is orthonormal, then $(\forall\, j \in \{1, \dots, m\})\ \|\mathbf{v}_j\| = 1$ by orthonormality, so $\mathbf{e}_j = \mathbf{v}_j$ by (i).

Structural Commentary: Induction verifies that every orthogonal correction term vanishes.
Key Insight: Orthogonal input already has no earlier-direction component. □

Corollary 1.3.11. *Existence of Orthonormal Bases*
If $\dim(\mathcal{V}) < \infty$, then $\mathcal{V}$ has an orthonormal basis.

Proof. If $\mathcal{V} = \{\mathbf{0}\}$, the empty list is an orthonormal basis. Suppose $\dim(\mathcal{V}) = n \geq 1$ and choose a basis $(\mathbf{v}_1, \dots, \mathbf{v}_n)$.
By Theorem 1.3.6(i)–(ii), its Gram–Schmidt output is orthonormal and has span $\mathcal{V}$, so it is an orthonormal basis.
Structural Commentary: Gram–Schmidt orthonormalizes a basis without changing its span.
Key Insight: Finite-dimensional inner-product spaces always admit geometry-friendly coordinates. □

Corollary 1.3.12. *Extending an Orthonormal List*
If $\dim(\mathcal{V}) < \infty$ and $(\mathbf{e}_1, \dots, \mathbf{e}_m)$ is orthonormal, then it extends to an orthonormal basis of $\mathcal{V}$.

Proof. If $m = 0$, an orthonormal basis exists by Corollary 1.3.11 and extends the empty list.
Suppose $m \geq 1$. The list is linearly independent by Corollary 1.3.3. $\exists\, \mathbf{v}_{m+1}, \dots, \mathbf{v}_n$ such that $(\mathbf{e}_1, \dots, \mathbf{e}_m, \mathbf{v}_{m+1}, \dots, \mathbf{v}_n)$ is a basis by Theorem 1.3.13. Let $(\mathbf{f}_1, \dots, \mathbf{f}_n)$ be its Gram–Schmidt output.
The first m steps depend only on the orthonormal prefix, so $(\forall\, j \in \{1, \dots, m\})\, \mathbf{f}_j = \mathbf{e}_j$ by Lemma 1.3.10(ii). The output is orthonormal by Theorem 1.3.6(ii), and it spans $\mathcal{V}$ by Theorem 1.3.6(i) with $j = n$. Thus $(\mathbf{f}_1, \dots, \mathbf{f}_n)$ is the required extension.
Structural Commentary: Extend linearly first, then orthonormalize while preserving the original prefix.
Key Insight: Gram–Schmidt leaves an orthonormal prefix fixed. □

1.4 Orthonormal Coordinates and Inner-Product Identities

Throughout this subsection, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ and $\mathcal{V}$ is an inner-product space over $\mathbb{F}$.

Theorem 1.4.1. *Coordinates in an Orthonormal Basis*
Let $\dim(\mathcal{V}) = n \geq 1$ *and let* $\beta = (\mathbf{e}_1, \ldots, \mathbf{e}_n)$ *be an orthonormal basis. For* $\mathbf{v} \in \mathcal{V}$*:*

(i) $\mathbf{v} = \sum_{j=1}^{n} \langle \mathbf{v}, \mathbf{e}_j \rangle \, \mathbf{e}_j$*;*

(ii) $\|\mathbf{v}\|^2 = \sum_{j=1}^{n} \left| \langle \mathbf{v}, \mathbf{e}_j \rangle \right|^2$*;*

(iii) $[\mathbf{v}]_\beta = \big(\langle \mathbf{v}, \mathbf{e}_1 \rangle, \ldots, \langle \mathbf{v}, \mathbf{e}_n \rangle \big)^t$.

Proof.

(i) Write $\mathbf{v} = \sum_{j=1}^{n} a_j \mathbf{e}_j$. For $k \in \{1, \ldots, n\}$, $\langle \mathbf{v}, \mathbf{e}_k \rangle = \sum_{j=1}^{n} a_j \langle \mathbf{e}_j, \mathbf{e}_k \rangle = a_k$ by orthonormality, which proves the expansion.

(ii) By (i) and Proposition 1.3.2, $\|\mathbf{v}\|^2 = \sum_{j=1}^{n} \left| \langle \mathbf{v}, \mathbf{e}_j \rangle \right|^2$.

(iii) The coefficient computation in (i) means $[\mathbf{v}]_\beta = \big(\langle \mathbf{v}, \mathbf{e}_1 \rangle, \ldots, \langle \mathbf{v}, \mathbf{e}_n \rangle \big)^t$ by the coordinate-vector definition.

Structural Commentary: Pairing with each basis vector extracts the coefficients before the norm and coordinate formulas follow.
Key Insight: Orthonormality turns coefficient extraction into an inner-product calculation. □

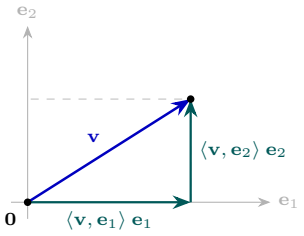

Figure 23: An orthonormal basis resolves a vector into perpendicular coordinate components.

Figure 23 illustrates Theorem 1.4.1(i) for $n = 2$: the two perpendicular coordinate components sum to $\mathbf{v}$.

Remark 1.4.2. *Cross Terms*
The mixed terms $\langle \mathbf{u}, \mathbf{v} \rangle$ and $\langle \mathbf{v}, \mathbf{u} \rangle$ in $\|\mathbf{u} + \mathbf{v}\|^2$ are called *cross terms*; $\|\mathbf{u}\|^2$ and $\|\mathbf{v}\|^2$ are the pure squared-length terms.

Theorem 1.4.3. *Pythagorean Theorem*
$(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V}) \big[\mathbf{u} \perp \mathbf{v} \implies \|\mathbf{u} + \mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2 \big]$.

Proof. Fix $\mathbf{u}, \mathbf{v} \in \mathcal{V}$ with $\mathbf{u} \perp \mathbf{v}$. Then $\langle \mathbf{u}, \mathbf{v} \rangle = 0$ by orthogonality and $\langle \mathbf{v}, \mathbf{u} \rangle = 0$ by Proposition 1.2.4(i).
Hence $\|\mathbf{u} + \mathbf{v}\|^2 = \langle \mathbf{u} + \mathbf{v}, \mathbf{u} + \mathbf{v} \rangle = \|\mathbf{u}\|^2 + \langle \mathbf{u}, \mathbf{v} \rangle + \langle \mathbf{v}, \mathbf{u} \rangle + \|\mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2$.
Structural Commentary: Orthogonality cancels the cross terms in the squared-norm expansion.
Key Insight: Perpendicular components add in squared length, not in length. □

Proposition 1.4.4. *Pythagorean Converse over* $\mathbb{R}$
If $\mathbb{F} = \mathbb{R}$*, then* $(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V}) \big[\mathbf{u} \perp \mathbf{v} \iff \|\mathbf{u} + \mathbf{v}\|^2 = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2 \big]$.

Proof. Fix $\mathbf{u}, \mathbf{v} \in \mathcal{V}$. Conjugate symmetry over $\mathbb{R}$ implies $\langle \mathbf{v}, \mathbf{u} \rangle = \langle \mathbf{u}, \mathbf{v} \rangle$, so $\|\mathbf{u} + \mathbf{v}\|^2 = \|\mathbf{u}\|^2 + 2 \langle \mathbf{u}, \mathbf{v} \rangle + \|\mathbf{v}\|^2$.
($\Rightarrow$) If $\mathbf{u} \perp \mathbf{v}$, then $\langle \mathbf{u}, \mathbf{v} \rangle = 0$ by orthogonality, so the identity follows from the expansion.
($\Leftarrow$) If the identity holds, then $2 \langle \mathbf{u}, \mathbf{v} \rangle = 0$ by the expansion, so $\mathbf{u} \perp \mathbf{v}$ by orthogonality.
Structural Commentary: The two directions compare the norm identity with its single real cross term.
Key Insight: Over $\mathbb{R}$, vanishing length excess is equivalent to orthogonality. □

Theorem 1.4.5. *Bessel's Inequality*
Let $m \geq 1$ *and let* $(\mathbf{e}_1, \ldots, \mathbf{e}_m)$ *be orthonormal in* $\mathcal{V}$*. Then* $(\forall\, \mathbf{v} \in \mathcal{V}) \sum_{j=1}^{m} \left| \langle \mathbf{v}, \mathbf{e}_j \rangle \right|^2 \leq \|\mathbf{v}\|^2$.

Proof. Fix $\mathbf{v} \in \mathcal{V}$ and set $\mathbf{p} := \sum_{j=1}^{m} \langle \mathbf{v}, \mathbf{e}_j \rangle \, \mathbf{e}_j$. For $k \in \{1, \ldots, m\}$, $\langle \mathbf{v} - \mathbf{p}, \mathbf{e}_k \rangle = \langle \mathbf{v}, \mathbf{e}_k \rangle - \sum_{j=1}^{m} \langle \mathbf{v}, \mathbf{e}_j \rangle \langle \mathbf{e}_j, \mathbf{e}_k \rangle = 0$ by orthonormality.
Hence $\langle \mathbf{v} - \mathbf{p}, \mathbf{p} \rangle = \sum_{j=1}^{m} \overline{\langle \mathbf{v}, \mathbf{e}_j \rangle} \langle \mathbf{v} - \mathbf{p}, \mathbf{e}_j \rangle = 0$, so $\mathbf{p} \perp (\mathbf{v} - \mathbf{p})$ by Proposition 1.2.4(i).
By Theorem 1.4.3 and Proposition 1.3.2, respectively, $\|\mathbf{v}\|^2 = \|\mathbf{p}\|^2 + \|\mathbf{v} - \mathbf{p}\|^2$ and $\|\mathbf{p}\|^2 = \sum_{j=1}^{m} \left| \langle \mathbf{v}, \mathbf{e}_j \rangle \right|^2$. Thus $\sum_{j=1}^{m} \left| \langle \mathbf{v}, \mathbf{e}_j \rangle \right|^2 \leq \|\mathbf{v}\|^2$.
Structural Commentary: The coordinate sum and its perpendicular residual split the squared norm by Pythagoras.
Key Insight: The residual norm is the nonnegative energy missing from selected coordinates. □

Corollary 1.4.6. *Coefficients Against an Orthonormal Sequence Vanish*
If $(\mathbf{e}_n)_{n \geq 1}$ *is orthonormal in* $\mathcal{V}$*, then* $(\forall\, \mathbf{v} \in \mathcal{V}) \lim_{n \to \infty} \langle \mathbf{v}, \mathbf{e}_n \rangle = 0$.

Proof. Fix $\mathbf{v} \in \mathcal{V}$ and $\epsilon > 0$, and set $S_\epsilon := \{j \in \mathbb{N}_{\geq 1} : |\langle \mathbf{v}, \mathbf{e}_j \rangle| \geq \epsilon\}$.
If S_ϵ were infinite, choose $N \in \mathbb{N}_{\geq 1}$ with $N\epsilon^2 > \|\mathbf{v}\|^2$ and distinct $j_1, \ldots, j_N \in S_\epsilon$.
For this orthonormal sublist, $N\epsilon^2 \leq \sum_{k=1}^{N} |\langle \mathbf{v}, \mathbf{e}_{j_k} \rangle|^2 \leq \|\mathbf{v}\|^2$ by Theorem 1.4.5, contradicting $N\epsilon^2 > \|\mathbf{v}\|^2$. Thus S_ϵ is finite.
Choose $N_0 \in \mathbb{N}_{\geq 1}$ greater than every member of S_ϵ, with $N_0 = 1$ when $S_\epsilon = \varnothing$. Then $(\forall\, n \geq N_0)\ |\langle \mathbf{v}, \mathbf{e}_n \rangle| < \epsilon$, so $\langle \mathbf{v}, \mathbf{e}_n \rangle \to 0$.
Structural Commentary: A contradiction argument applies Bessel to arbitrarily many allegedly large coefficients.
Key Insight: Finite total energy permits only finitely many coefficients above each threshold. □

Theorem 1.4.7. *Parseval's Identity*
Let $\dim(\mathcal{V}) = n \geq 1$ *and let* $\beta = (\mathbf{e}_1, \ldots, \mathbf{e}_n)$ *be an orthonormal basis. For* $\mathbf{v}, \mathbf{w} \in \mathcal{V}$*:*

(i) $\langle \mathbf{v}, \mathbf{w} \rangle = \sum_{j=1}^{n} \langle \mathbf{v}, \mathbf{e}_j \rangle \overline{\langle \mathbf{w}, \mathbf{e}_j \rangle}$*;*

(ii) $\langle \mathbf{v}, \mathbf{w} \rangle = \big\langle [\mathbf{v}]_\beta, [\mathbf{w}]_\beta \big\rangle_{\mathbb{F}^n}$*.*

Proof.

(i) Set $c_j := \langle \mathbf{v}, \mathbf{e}_j \rangle$ and $d_j := \langle \mathbf{w}, \mathbf{e}_j \rangle$ $(j \in \{1, \ldots, n\})$. Then $\mathbf{v} = \sum_{j=1}^{n} c_j \mathbf{e}_j$ and $\mathbf{w} = \sum_{k=1}^{n} d_k \mathbf{e}_k$ by Theorem 1.4.1(i).
Hence $\langle \mathbf{v}, \mathbf{w} \rangle = \sum_{j=1}^{n} \sum_{k=1}^{n} c_j \overline{d_k} \langle \mathbf{e}_j, \mathbf{e}_k \rangle = \sum_{j=1}^{n} c_j \overline{d_j}$ by sesquilinearity and orthonormality.

(ii) By Theorem 1.4.1(iii), $[\mathbf{v}]_\beta = (c_1, \ldots, c_n)^t$ and $[\mathbf{w}]_\beta = (d_1, \ldots, d_n)^t$. Therefore $\big\langle [\mathbf{v}]_\beta, [\mathbf{w}]_\beta \big\rangle_{\mathbb{F}^n} = \sum_{j=1}^{n} c_j \overline{d_j} = \langle \mathbf{v}, \mathbf{w} \rangle$ by (i).

Structural Commentary: Basis expansions remove cross terms before the coordinate formula identifies the remaining sum.
Key Insight: Orthonormal coordinates preserve the inner product itself. □

Theorem 1.4.8. *Matrix Entries from an Orthonormal Codomain Basis*
Let $\dim(\mathcal{V}) = n \geq 1$ *and* $\dim(\mathcal{W}) = m \geq 1$*, with* $\mathcal{W}$ *an inner-product space.*
Fix a basis $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ *of* $\mathcal{V}$ *and an orthonormal basis* $\gamma = (\mathbf{w}_1, \ldots, \mathbf{w}_m)$ *of* $\mathcal{W}$*. Then:*

(i) $(\forall\, T \in \mathcal{L}(\mathcal{V}, \mathcal{W}),\ i \in \{1, \ldots, m\},\ j \in \{1, \ldots, n\})\ \big([T]_{\gamma \leftarrow \beta}\big)_{i,j} = \langle T\mathbf{v}_j, \mathbf{w}_i \rangle$*;*

(ii) $(\forall\, A \in \mathrm{Mat}(m, n, \mathbb{F}))(\exists!\, T \in \mathcal{L}(\mathcal{V}, \mathcal{W}))\ [T]_{\gamma \leftarrow \beta} = A$*.*

Proof.

(i) Fix $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$, $i \in \{1, \ldots, m\}$, and $j \in \{1, \ldots, n\}$. The jth column of $[T]_{\gamma \leftarrow \beta}$ is $[T\mathbf{v}_j]_\gamma = \big(\langle T\mathbf{v}_j, \mathbf{w}_1 \rangle, \ldots, \langle T\mathbf{v}_j, \mathbf{w}_m \rangle\big)^t$ by Theorem 1.4.1(iii). Therefore its ith entry is $\langle T\mathbf{v}_j, \mathbf{w}_i \rangle$.

(ii) The map $\Phi : \mathcal{L}(\mathcal{V}, \mathcal{W}) \to \mathrm{Mat}(m, n, \mathbb{F})$ defined by $\Phi(T) := [T]_{\gamma \leftarrow \beta}$ is an isomorphism by Theorem 3.4.5(i).
Hence every $A \in \mathrm{Mat}(m, n, \mathbb{F})$ has a unique preimage T under Φ.

Structural Commentary: Coordinate extraction identifies entries; the earlier encoding isomorphism supplies existence and uniqueness.
Key Insight: Entry (i, j) measures the jth basis image along output direction i. □

Figure 24 visualizes Theorem 1.4.8(i): applying T to $\mathbf{v}_j$ forms column j, and pairing with $\mathbf{w}_i$ reads entry (i, j).

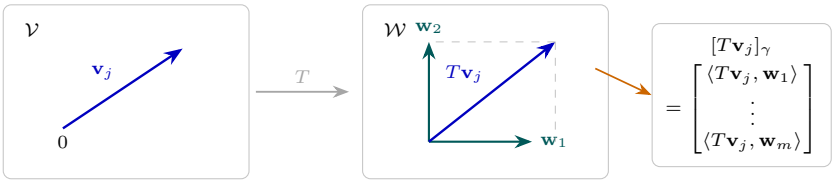

Figure 24: The jth column of $[T]_{\gamma \leftarrow \beta}$ is obtained by resolving $T\mathbf{v}_j$ against the orthonormal basis of $\mathcal{W}$.

Corollary 1.4.9. *Inner Products Through an Operator Matrix*
Let $\dim(\mathcal{V}) = n \geq 1$ *and let* $\beta = (\mathbf{e}_1, \ldots, \mathbf{e}_n)$ *be an orthonormal basis.*
For $T \in \mathcal{L}(\mathcal{V})$*, set* $A := [T]_{\beta \leftarrow \beta}$*. Then* $(\forall\, \mathbf{v}, \mathbf{w} \in \mathcal{V})\ \langle T\mathbf{v}, \mathbf{w} \rangle = \big\langle A[\mathbf{v}]_\beta, [\mathbf{w}]_\beta \big\rangle_{\mathbb{F}^n}$*.*

Proof. Fix $\mathbf{v}, \mathbf{w} \in \mathcal{V}$. The identity $[T\mathbf{v}]_\beta = A[\mathbf{v}]_\beta$ holds by Proposition 3.2.5. Hence $\langle T\mathbf{v}, \mathbf{w} \rangle = \big\langle A[\mathbf{v}]_\beta, [\mathbf{w}]_\beta \big\rangle_{\mathbb{F}^n}$ by Theorem 1.4.7(ii).
Structural Commentary: Matrix action computes the first coordinate vector before Parseval transfers the inner product.
Key Insight: Orthonormal coordinates convert operator geometry into matrix algebra. □

1.5 Gram Matrices

Throughout this subsection, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ and $\mathcal{V}$ is an inner-product space over $\mathbb{F}$.

Definition 1.5.1. *Gram Matrix*
For $n \geq 1$ and $\mathbf{u}_1, \ldots, \mathbf{u}_n \in \mathcal{V}$, the *Gram matrix* is $\mathrm{Gram}(\mathbf{u}_1, \ldots, \mathbf{u}_n) := [\langle \mathbf{u}_j, \mathbf{u}_i \rangle]_{i,j=1}^{n} \in \mathrm{Mat}(n, n, \mathbb{F})$.

Definition 1.5.2. *Gram Determinant*
Let $n \in \mathbb{Z}_{>0}$, let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and let $\mathbf{u}_1, \ldots, \mathbf{u}_n$ belong to an inner-product space $\mathcal{V}$ over $\mathbb{F}$.
Their *Gram determinant* is $\mathrm{GramDet}(\mathbf{u}_1, \ldots, \mathbf{u}_n) := \det \mathrm{Gram}(\mathbf{u}_1, \ldots, \mathbf{u}_n)$.

Proposition 1.5.3. *Gram Matrix Quadratic Form*
Let $n \geq 1$*, let* $\mathbf{u}_1, \ldots, \mathbf{u}_n \in \mathcal{V}$*, and set* $G = [g_{ij}] := \mathrm{Gram}(\mathbf{u}_1, \ldots, \mathbf{u}_n)$*. Then:*

(i) $(\forall\, i, j \in \{1, \ldots, n\})\ g_{ij} = \overline{g_{ji}}$*, so* G *is Hermitian;*

(ii) $(\forall\, \mathbf{c} = (c_1, \ldots, c_n)^t \in \mathbb{F}^n)\ \mathbf{c}^* G \mathbf{c} = \left\| \sum_{j=1}^{n} c_j \mathbf{u}_j \right\|^2 \geq 0$*;*

(iii) if $\mathbf{u}_1, \dots, \mathbf{u}_n$ are linearly independent, then $(\forall\, \mathbf{c} \in \mathbb{F}^n \setminus \{\mathbf{0}\})\, \mathbf{c}^* G \mathbf{c} > 0$.

Proof.

(i) For $i, j \in \{1, \dots, n\}$, $g_{ij} = \langle \mathbf{u}_j, \mathbf{u}_i \rangle = \overline{\langle \mathbf{u}_i, \mathbf{u}_j \rangle} = \overline{g_{ji}}$ by conjugate symmetry.

(ii) Fix $\mathbf{c} = (c_1, \dots, c_n)^t \in \mathbb{F}^n$ and set $\mathbf{x} := \sum_{j=1}^{n} c_j \mathbf{u}_j$.

By sesquilinearity and definiteness, $\mathbf{c}^* G \mathbf{c} = \sum_{i=1}^{n} \sum_{j=1}^{n} \overline{c_i}\, \langle \mathbf{u}_j, \mathbf{u}_i \rangle\, c_j = \langle \mathbf{x}, \mathbf{x} \rangle = \|\mathbf{x}\|^2 \geq 0$.

(iii) Suppose $\mathbf{u}_1, \dots, \mathbf{u}_n$ are linearly independent and fix $\mathbf{c} = (c_1, \dots, c_n)^t \neq \mathbf{0}$.

Then $\sum_{j=1}^{n} c_j \mathbf{u}_j \neq \mathbf{0}$ by linear independence, so $\mathbf{c}^* G \mathbf{c} > 0$ by (ii) and definiteness.

Structural Commentary: Entry symmetry and a norm-square expansion establish Hermitian positivity; independence makes it strict.
Key Insight: Gram quadratic forms measure norms of coefficient-weighted vector sums. □

1.6 Finite-Dimensional Riesz Representation

Throughout this subsection, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ and $\mathcal{V}$ is an inner-product space over $\mathbb{F}$.

Theorem 1.6.1. *Riesz Representation Theorem*
Suppose $\dim(\mathcal{V}) < \infty$ and let $\varphi \in \mathcal{V}'$. Then:
(i) $(\exists\, \mathbf{u} \in \mathcal{V})(\forall\, \mathbf{v} \in \mathcal{V})\, \varphi(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u} \rangle$;
(ii) $(\forall\, \mathbf{u}_1, \mathbf{u}_2 \in \mathcal{V})\big[(\forall\, \mathbf{v} \in \mathcal{V})\, \varphi(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u}_1 \rangle = \langle \mathbf{v}, \mathbf{u}_2 \rangle \implies \mathbf{u}_1 = \mathbf{u}_2\big]$.

Proof.

(i) If $\mathcal{V} = \{\mathbf{0}\}$, then $\varphi(\mathbf{0}) = 0$ by linearity, so $\mathbf{u} = \mathbf{0}$ represents φ.

Suppose $\dim(\mathcal{V}) = n \geq 1$ and choose an orthonormal basis $(\mathbf{e}_1, \dots, \mathbf{e}_n)$ by Corollary 1.3.11. Set $\mathbf{u} := \sum_{j=1}^{n} \overline{\varphi(\mathbf{e}_j)} \mathbf{e}_j$.

Fix $\mathbf{v} \in \mathcal{V}$. By Theorem 1.4.1(i), linearity of φ, and Proposition 1.1.9(iii)–(iv), $\varphi(\mathbf{v}) = \sum_{j=1}^{n} \langle \mathbf{v}, \mathbf{e}_j \rangle\, \varphi(\mathbf{e}_j) = \langle \mathbf{v}, \mathbf{u} \rangle$.

(ii) Suppose $(\forall\, \mathbf{v} \in \mathcal{V})\, \varphi(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u}_1 \rangle = \langle \mathbf{v}, \mathbf{u}_2 \rangle$. Then $\mathbf{u}_1 = \mathbf{u}_2$ by Lemma 1.1.10(i).

Structural Commentary: An orthonormal expansion constructs the representative; inner-product separation proves uniqueness.
Key Insight: Functional values become conjugated coordinates of one vector. □

Definition 1.6.2. *Riesz Vector*
If $\dim(\mathcal{V}) < \infty$ and $\varphi \in \mathcal{V}'$, the unique $\mathbf{u} \in \mathcal{V}$ satisfying $(\forall\, \mathbf{v} \in \mathcal{V})\, \varphi(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u} \rangle$ is the *Riesz vector* representing φ.

Theorem 1.6.3. *Riesz Map*
Suppose $\dim(\mathcal{V}) < \infty$ and define $\tau : \mathcal{V} \to \mathcal{V}'$ by $\tau(\mathbf{u}) := \langle \cdot, \mathbf{u} \rangle$. Then:
(i) τ is conjugate linear: $(\forall\, a \in \mathbb{F})(\forall\, \mathbf{u}, \mathbf{w} \in \mathcal{V})\, \tau(a\mathbf{u} + \mathbf{w}) = \overline{a}\, \tau(\mathbf{u}) + \tau(\mathbf{w})$;
(ii) τ is bijective;
(iii) $R := \tau^{-1}$ is conjugate linear: $(\forall\, a \in \mathbb{F})(\forall\, \varphi, \psi \in \mathcal{V}')\, R(a\varphi + \psi) = \overline{a}\, R(\varphi) + R(\psi)$;
(iv) if $\mathbb{F} = \mathbb{R}$, then τ and R are linear.

Proof.

(i) $(\forall\, \mathbf{u} \in \mathcal{V})\, \tau(\mathbf{u}) \in \mathcal{V}'$ by Proposition 1.1.9(i). Fix $a \in \mathbb{F}$, $\mathbf{u}, \mathbf{w}, \mathbf{v} \in \mathcal{V}$. Then $\tau(a\mathbf{u} + \mathbf{w})(\mathbf{v}) = \overline{a}\, \tau(\mathbf{u})(\mathbf{v}) + \tau(\mathbf{w})(\mathbf{v})$ by Proposition 1.1.9(iii)–(iv), so $\tau(a\mathbf{u} + \mathbf{w}) = \overline{a}\, \tau(\mathbf{u}) + \tau(\mathbf{w})$ by equality of functions.

(ii) If $\tau(\mathbf{u}) = \tau(\mathbf{w})$, then $\|\mathbf{u} - \mathbf{w}\|^2 = \tau(\mathbf{u} - \mathbf{w})(\mathbf{u} - \mathbf{w}) = 0$ by (i), so $\mathbf{u} = \mathbf{w}$ by definiteness.
Thus τ is injective. For $\varphi \in \mathcal{V}'$, $(\exists\, \mathbf{u} \in \mathcal{V})\, \tau(\mathbf{u}) = \varphi$ by Theorem 1.6.1(i), so τ is surjective.

(iii) Fix $a \in \mathbb{F}$ and $\varphi, \psi \in \mathcal{V}'$. By (i) and the definition of R, $\tau\big(\overline{a}\, R(\varphi) + R(\psi)\big) = a\varphi + \psi = \tau\big(R(a\varphi + \psi)\big)$.
Hence $R(a\varphi + \psi) = \overline{a}\, R(\varphi) + R(\psi)$ by injectivity from (ii).

(iv) If $\mathbb{F} = \mathbb{R}$, then $\overline{a} = a$ in (i) and (iii), so both maps are linear.

Structural Commentary: Conjugate-linearity, separation, and representation establish the bijection and its inverse law.
Key Insight: Conjugating the representing slot conjugates scalar multiplication. □

Figure 25 depicts Theorem 1.6.3: the vector $\mathbf{u}$ corresponds to the functional $\mathbf{v} \mapsto \langle \mathbf{v}, \mathbf{u} \rangle$.

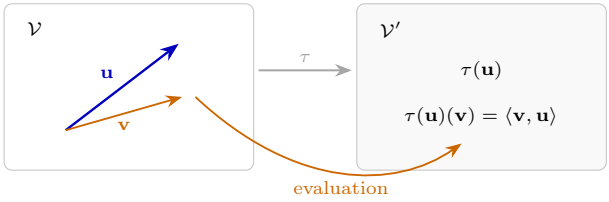

Figure 25: The map τ sends each vector to the functional it represents.

Perspective 1.6.4. *Riesz as Coordinate Duality*

For an orthonormal basis $(\mathbf{e}_1, \dots, \mathbf{e}_n)$, Theorem 1.6.1(i) constructs the Riesz vector of $\varphi \in \mathcal{V}'$ as $\sum_{j=1}^{n} \overline{\varphi(\mathbf{e}_j)} \mathbf{e}_j$.

Although this formula uses the basis, uniqueness in part (ii) makes its value basis-independent.

2 Orthogonality, Projections, and Least Squares

2.1 Orthogonal Complements

Throughout this subsection, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ and $\mathcal{V}$ is an inner-product space over $\mathbb{F}$.

Orthogonal complements turn orthogonality into a subspace operation and organize canonical direct-sum decompositions.

Definition 2.1.1. *Orthogonality and Orthogonal Direct Sums*
Let $\mathcal{X}, \mathcal{Y} \subseteq \mathcal{V}$ and let $\mathcal{S}, \mathcal{T} \leq \mathcal{V}$.

(i) $\mathcal{X}$ and $\mathcal{Y}$ are *orthogonal*, written $\mathcal{X} \perp \mathcal{Y}$, if $(\forall\, \mathbf{x} \in \mathcal{X})(\forall\, \mathbf{y} \in \mathcal{Y})\ \langle \mathbf{x}, \mathbf{y} \rangle = 0$.
(ii) $\mathcal{V}$ is the *orthogonal direct sum* of $\mathcal{S}$ and $\mathcal{T}$, written $\mathcal{V} = \mathcal{S} \odot \mathcal{T}$, if $\mathcal{V} = \mathcal{S} \oplus \mathcal{T}$ and $\mathcal{S} \perp \mathcal{T}$.

Definition 2.1.2. *Orthogonal Complement*
For $\mathcal{U} \subseteq \mathcal{V}$, its *orthogonal complement* is $\mathcal{U}^{\perp} := \{\mathbf{v} \in \mathcal{V} : (\forall\, \mathbf{u} \in \mathcal{U})\ \langle \mathbf{v}, \mathbf{u} \rangle = 0\}$.

Proposition 2.1.3. *Basic Properties of Orthogonal Complements*
For subsets $\mathcal{U}, \mathcal{W} \subseteq \mathcal{V}$,

(i) $\mathcal{U}^{\perp}$ is a subspace of $\mathcal{V}$;
(ii) $\{\mathbf{0}\}^{\perp} = \mathcal{V}$;
(iii) $\mathcal{V}^{\perp} = \{\mathbf{0}\}$;
(iv) $\mathcal{U} \cap \mathcal{U}^{\perp} \subseteq \{\mathbf{0}\}$;
(v) if $\mathcal{U} \subseteq \mathcal{W}$, then $\mathcal{W}^{\perp} \subseteq \mathcal{U}^{\perp}$.

Proof.

(i) $\mathbf{0} \in \mathcal{U}^{\perp}$ by Proposition 1.1.9(ii). Fix $\mathbf{v}, \mathbf{w} \in \mathcal{U}^{\perp}$ and $a \in \mathbb{F}$.
Then $(\forall\, \mathbf{u} \in \mathcal{U})\ \langle a\mathbf{v} + \mathbf{w}, \mathbf{u} \rangle = a\langle \mathbf{v}, \mathbf{u} \rangle + \langle \mathbf{w}, \mathbf{u} \rangle = 0$ by linearity, so $a\mathbf{v} + \mathbf{w} \in \mathcal{U}^{\perp}$. Hence $\mathcal{U}^{\perp} \leq \mathcal{V}$ by Theorem 1.2.2.
(ii) $(\forall\, \mathbf{v} \in \mathcal{V})\ \langle \mathbf{v}, \mathbf{0} \rangle = 0$ by Proposition 1.1.9(ii), so $\{\mathbf{0}\}^{\perp} = \mathcal{V}$.
(iii) $\mathbf{0} \in \mathcal{V}^{\perp}$ by (i). If $\mathbf{v} \in \mathcal{V}^{\perp}$, then $\|\mathbf{v}\|^2 = \langle \mathbf{v}, \mathbf{v} \rangle = 0$, so $\mathbf{v} = \mathbf{0}$ by definiteness.
(iv) If $\mathbf{v} \in \mathcal{U} \cap \mathcal{U}^{\perp}$, then $\|\mathbf{v}\|^2 = \langle \mathbf{v}, \mathbf{v} \rangle = 0$, so $\mathbf{v} = \mathbf{0}$ by definiteness.
(v) Suppose $\mathcal{U} \subseteq \mathcal{W}$ and fix $\mathbf{v} \in \mathcal{W}^{\perp}$. Then $(\forall\, \mathbf{u} \in \mathcal{U})\ \langle \mathbf{v}, \mathbf{u} \rangle = 0$, so $\mathbf{v} \in \mathcal{U}^{\perp}$.

Structural Commentary: Subspace closure, definiteness, and reversed constraint inclusion establish the five properties.
Key Insight: Larger tested sets impose stronger orthogonality constraints. □

Remark 2.1.4. *Definiteness Matters*
For a bilinear form $B : \mathcal{V} \times \mathcal{V} \to \mathbb{F}$ and $\mathcal{U} \subseteq \mathcal{V}$, set $\mathcal{U}^{\perp_B} := \{\mathbf{v} \in \mathcal{V} : (\forall\, \mathbf{u} \in \mathcal{U})\, B(\mathbf{v}, \mathbf{u}) = 0\}$.
Bilinearity makes $\mathcal{U}^{\perp_B}$ a subspace, but without definiteness one may have $\mathcal{V}^{\perp_B} \neq \{\mathbf{0}\}$ or $\mathcal{U} \cap \mathcal{U}^{\perp_B} \neq \{\mathbf{0}\}$.
Thus $\mathcal{V} = \mathcal{U} \oplus \mathcal{U}^{\perp_B}$ is an inner-product conclusion, not a consequence of bilinearity alone.

Theorem 2.1.5. *Direct Sum with the Orthogonal Complement*
If $\mathcal{U}$ is a finite-dimensional subspace of $\mathcal{V}$, then $\mathcal{V} = \mathcal{U} \oplus \mathcal{U}^{\perp}$.

Proof. If $\mathcal{U} = \{\mathbf{0}\}$, then $\mathcal{U}^{\perp} = \mathcal{V}$ by Proposition 2.1.3(ii), and hence $\mathcal{V} = \mathcal{U} \oplus \mathcal{U}^{\perp}$.
Suppose $\dim(\mathcal{U}) = m \geq 1$ and choose an orthonormal basis $(\mathbf{e}_1, \ldots, \mathbf{e}_m)$ by Corollary 1.3.11.
Fix $\mathbf{v} \in \mathcal{V}$ and set $\mathbf{u} := \sum_{j=1}^{m} \langle \mathbf{v}, \mathbf{e}_j \rangle\, \mathbf{e}_j \in \mathcal{U}$ and $\mathbf{w} := \mathbf{v} - \mathbf{u}$.
For $k \in \{1, \ldots, m\}$, $\langle \mathbf{w}, \mathbf{e}_k \rangle = \langle \mathbf{v}, \mathbf{e}_k \rangle - \sum_{j=1}^{m} \langle \mathbf{v}, \mathbf{e}_j \rangle \langle \mathbf{e}_j, \mathbf{e}_k \rangle = 0$ by orthonormality.
Fix $\mathbf{x} \in \mathcal{U}$ and write $\mathbf{x} = \sum_{k=1}^{m} a_k \mathbf{e}_k$. Then $\langle \mathbf{w}, \mathbf{x} \rangle = \sum_{k=1}^{m} \overline{a_k} \langle \mathbf{w}, \mathbf{e}_k \rangle = 0$ by Proposition 1.1.9(iii)–(iv), so $\mathbf{w} \in \mathcal{U}^{\perp}$ and $\mathbf{v} = \mathbf{u} + \mathbf{w}$.
Hence $\mathcal{V} = \mathcal{U} + \mathcal{U}^{\perp}$. The identity $\mathcal{U} \cap \mathcal{U}^{\perp} = \{\mathbf{0}\}$ holds by Proposition 2.1.3(i),(iv), so the sum is direct.
Structural Commentary: An orthonormal expansion constructs the component; definiteness makes the decomposition direct.
Key Insight: Every vector splits into a subspace component and orthogonal residual. □

Proposition 2.1.6. *Orthogonal Direct Sum Characterization*
For $\mathcal{S}, \mathcal{T} \leq \mathcal{V}$, the following are equivalent:

(i) $\mathcal{V} = \mathcal{S} \odot \mathcal{T}$.
(ii) $\mathcal{V} = \mathcal{S} \oplus \mathcal{T}$ and $\mathcal{T} = \mathcal{S}^{\perp}$.

Proof.

(i) $\Rightarrow$ (ii) Suppose $\mathcal{V} = \mathcal{S} \odot \mathcal{T}$. Then $\mathcal{V} = \mathcal{S} \oplus \mathcal{T}$ by orthogonal-direct-sum definition, and $\mathcal{T} \subseteq \mathcal{S}^{\perp}$ by Proposition 1.2.4(i).
Fix $\mathbf{v} \in \mathcal{S}^{\perp}$ and write $\mathbf{v} = \mathbf{s} + \mathbf{t}$ with $\mathbf{s} \in \mathcal{S}$ and $\mathbf{t} \in \mathcal{T}$.
Then $\mathbf{s} = \mathbf{v} - \mathbf{t} \in \mathcal{S}^{\perp}$, so $\mathbf{s} = \mathbf{0}$ by Proposition 2.1.3(iv). Hence $\mathbf{v} = \mathbf{t} \in \mathcal{T}$ and $\mathcal{T} = \mathcal{S}^{\perp}$.
(ii) $\Rightarrow$ (i) Suppose $\mathcal{V} = \mathcal{S} \oplus \mathcal{T}$ and $\mathcal{T} = \mathcal{S}^{\perp}$. Then $\mathcal{S} \perp \mathcal{T}$ by Proposition 1.2.4(i), so $\mathcal{V} = \mathcal{S} \odot \mathcal{T}$ by orthogonal-direct-sum definition.

Structural Commentary: Direct-sum uniqueness forces an orthogonal partner to be maximal.
Key Insight: A full orthogonal summand is exactly the complement. □

Corollary 2.1.7. *Dimension of the Orthogonal Complement*
If $\mathcal{V}$ is finite-dimensional and $\mathcal{U}$ is a subspace of $\mathcal{V}$, then $\dim(\mathcal{U}^{\perp}) = \dim(\mathcal{V}) - \dim(\mathcal{U})$.

Proof. The subspace $\mathcal{U}$ is finite-dimensional by Corollary 1.3.14.
By Theorem 2.1.5, $\mathcal{V} = \mathcal{U} \oplus \mathcal{U}^{\perp}$, so $\dim(\mathcal{V}) = \dim(\mathcal{U}) + \dim(\mathcal{U}^{\perp})$ by Corollary 2.3.2. Rearranging proves the formula.
Structural Commentary: The direct-sum dimension formula converts decomposition into subtraction.
Key Insight: The complement contains precisely the unused dimensions. □

Corollary 2.1.8. *Double Orthogonal Complement*
If $\mathcal{U}$ is a finite-dimensional subspace of $\mathcal{V}$, then $\mathcal{U} = (\mathcal{U}^{\perp})^{\perp}$.

Proof. Fix $\mathbf{u} \in \mathcal{U}$. For $\mathbf{w} \in \mathcal{U}^\perp$, $\langle \mathbf{w}, \mathbf{u} \rangle = 0$ by membership, so $\langle \mathbf{u}, \mathbf{w} \rangle = 0$ by Proposition 1.2.4(i). Hence $\mathcal{U} \subseteq (\mathcal{U}^\perp)^\perp$.
Conversely, fix $\mathbf{v} \in (\mathcal{U}^\perp)^\perp$. By Theorem 2.1.5, write $\mathbf{v} = \mathbf{u}_0 + \mathbf{w}$ with $\mathbf{u}_0 \in \mathcal{U}$ and $\mathbf{w} \in \mathcal{U}^\perp$.
Since $(\mathcal{U}^\perp)^\perp$ is a subspace by Proposition 2.1.3(i), the established inclusion implies $\mathbf{w} = \mathbf{v} - \mathbf{u}_0 \in (\mathcal{U}^\perp)^\perp$.
Thus $\mathbf{w} \in \mathcal{U}^\perp \cap (\mathcal{U}^\perp)^\perp$, so $\mathbf{w} = \mathbf{0}$ by Proposition 2.1.3(iv), and $\mathbf{v} = \mathbf{u}_0 \in \mathcal{U}$.
Structural Commentary: Symmetry establishes one inclusion; the orthogonal decomposition eliminates every excess vector.
Key Insight: Double orthogonality adds no new finite-dimensional direction. □

Corollary 2.1.9. *Double Complement of a Finite Span*
If $\mathcal{X} \subseteq \mathcal{V}$ and $\operatorname{span}(\mathcal{X})$ is finite-dimensional, then $(\mathcal{X}^\perp)^\perp = \operatorname{span}(\mathcal{X})$.

Proof. Let $\mathcal{W} = \operatorname{span}(\mathcal{X})$. Since $\mathcal{X} \subseteq \mathcal{W}$, $\mathcal{W}^\perp \subseteq \mathcal{X}^\perp$ by Proposition 2.1.3(v).
Conversely, fix $\mathbf{v} \in \mathcal{X}^\perp$ and $\mathbf{w} \in \mathcal{W}$. Write $\mathbf{w} = \sum_{j=1}^{r} a_j \mathbf{x}_j$ with $\mathbf{x}_j \in \mathcal{X}$.
Then $\langle \mathbf{v}, \mathbf{w} \rangle = \sum_{j=1}^{r} \overline{a_j} \langle \mathbf{v}, \mathbf{x}_j \rangle = 0$ by Proposition 1.1.9(iii)–(iv), so $\mathbf{v} \in \mathcal{W}^\perp$.
Therefore $\mathcal{X}^\perp = \mathcal{W}^\perp$, and $(\mathcal{X}^\perp)^\perp = (\mathcal{W}^\perp)^\perp = \mathcal{W}$ by Corollary 2.1.8.
Structural Commentary: Span invariance reduces the double complement to the preceding corollary.
Key Insight: Orthogonality depends on the span of the tested set. □

Perspective 2.1.10. *Orthogonal Versus Complementary*
Let $\mathcal{U}, \mathcal{W} \leq \mathcal{V}$ with $\mathcal{U} \perp \mathcal{W}$. By Definitions 2.1.1 and 2.1.2, $\mathcal{W} \subseteq \mathcal{U}^\perp$ and $\mathcal{U} \subseteq \mathcal{W}^\perp$, not necessarily equality.
If $\mathcal{V}$ is finite-dimensional and $\dim(\mathcal{U}) + \dim(\mathcal{W}) = \dim(\mathcal{V})$, then $\dim(\mathcal{U}^\perp) = \dim(\mathcal{W})$ and $\dim(\mathcal{W}^\perp) = \dim(\mathcal{U})$ by Corollary 2.1.7.
The two inclusions are therefore equalities by Proposition 1.4.3(ii).

Figure 26 contrasts a proper inclusion $\mathcal{W} \subsetneq \mathcal{U}^\perp$ with the saturated decomposition $\mathcal{V} = \mathcal{U} \oplus \mathcal{U}^\perp$.

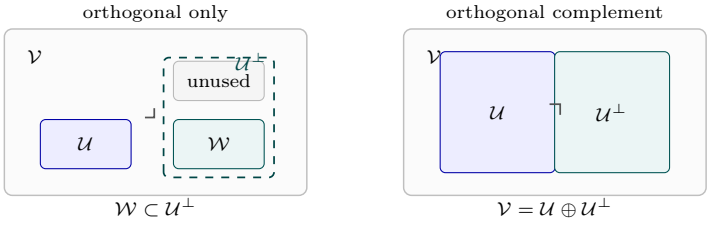

Figure 26: Orthogonal subspaces are complements only when their sum fills $\mathcal{V}$.

2.2 Orthogonal Projections

Throughout this subsection, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ and $\mathcal{V}$ is an inner-product space over $\mathbb{F}$.

Proposition 2.2.1. *Orthogonal Projection onto a Line*
Let $\mathbf{u}, \mathbf{v} \in \mathcal{V}$ with $\mathbf{v} \neq \mathbf{0}$, and set $c := \frac{\langle \mathbf{u}, \mathbf{v} \rangle}{\|\mathbf{v}\|^2}$ and $\mathbf{w} := \mathbf{u} - c\mathbf{v}$. Then $\mathbf{u} = c\mathbf{v} + \mathbf{w}$ and $\mathbf{w} \perp \mathbf{v}$.
The vector $\operatorname{proj}_{\mathbf{v}}(\mathbf{u}) := c\mathbf{v} = \left\langle \mathbf{u}, \frac{\mathbf{v}}{\|\mathbf{v}\|} \right\rangle \frac{\mathbf{v}}{\|\mathbf{v}\|}$ is the orthogonal projection of $\mathbf{u}$ onto $\operatorname{span}(\mathbf{v})$.

Proof. Since $\mathbf{v} \neq \mathbf{0}$, $\|\mathbf{v}\|^2 > 0$ by definiteness, so c is well-defined. The identity $\mathbf{w} = \mathbf{u} - c\mathbf{v}$ implies $\mathbf{u} = c\mathbf{v} + \mathbf{w}$.
By linearity, $\langle \mathbf{w}, \mathbf{v} \rangle = \langle \mathbf{u}, \mathbf{v} \rangle - c \langle \mathbf{v}, \mathbf{v} \rangle = \langle \mathbf{u}, \mathbf{v} \rangle - \frac{\langle \mathbf{u}, \mathbf{v} \rangle}{\|\mathbf{v}\|^2} \|\mathbf{v}\|^2 = 0$, so $\mathbf{w} \perp \mathbf{v}$.
Since $\|\mathbf{v}\| \in \mathbb{R}_{>0}$, $\left\langle \mathbf{u}, \frac{\mathbf{v}}{\|\mathbf{v}\|} \right\rangle \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle \mathbf{u}, \mathbf{v} \rangle}{\|\mathbf{v}\|^2} \mathbf{v} = c\mathbf{v}$ by Proposition 1.1.9(iv).
Structural Commentary: The chosen coefficient makes the residual orthogonal.
Key Insight: Projection isolates the parallel component and leaves an orthogonal residual. □

Figure 27 depicts the decomposition $\mathbf{u} = c\mathbf{v} + \mathbf{w}$ with $c\mathbf{v} \in \operatorname{span}(\mathbf{v})$ and $\mathbf{w} \perp \mathbf{v}$.

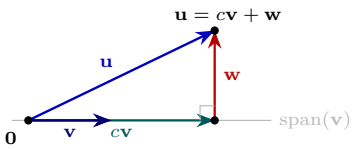

Figure 27: Writing $\mathbf{u}$ as a component parallel to $\mathbf{v}$ plus a component orthogonal to $\mathbf{v}$.

Definition 2.2.2. *Orthogonal Projection onto a Subspace*
Let $\mathcal{U}$ be finite-dimensional subspace of $\mathcal{V}$. By Theorem 2.1.5, every $\mathbf{v} \in \mathcal{V}$ has unique decomposition $\mathbf{v} = \mathbf{u} + \mathbf{w}$ with $\mathbf{u} \in \mathcal{U}$, $\mathbf{w} \in \mathcal{U}^\perp$.
The *orthogonal projection* of $\mathcal{V}$ onto $\mathcal{U}$ is the map $P_{\mathcal{U}} : \mathcal{V} \to \mathcal{V}$ defined by $P_{\mathcal{U}}\mathbf{v} := \mathbf{u}$.

Figure 28 illustrates the $\mathcal{U}$-component $P_{\mathcal{U}}\mathbf{v}$ and the residual $\mathbf{v} - P_{\mathcal{U}}\mathbf{v} \in \mathcal{U}^\perp$.

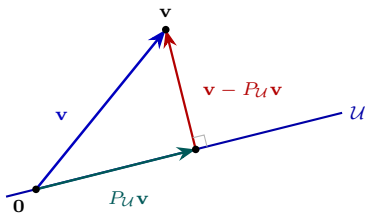

Figure 28: Orthogonal projection decomposes $\mathbf{v}$ into $P_{\mathcal{U}}\mathbf{v}$ plus an orthogonal residual.

Proposition 2.2.3. *Properties of Orthogonal Projection*
Let $\mathcal{U}$ be a finite-dimensional subspace of $\mathcal{V}$. Then:

(i) $P_{\mathcal{U}} \in \mathcal{L}(\mathcal{V})$;
(ii) $(\forall\, \mathbf{u} \in \mathcal{U})\, P_{\mathcal{U}}\mathbf{u} = \mathbf{u}$;
(iii) $(\forall\, \mathbf{w} \in \mathcal{U}^{\perp})\, P_{\mathcal{U}}\mathbf{w} = \mathbf{0}$;
(iv) $\operatorname{range}(P_{\mathcal{U}}) = \mathcal{U}$;
(v) $(\forall\, \mathbf{v} \in \mathcal{V})\, \mathbf{v} - P_{\mathcal{U}}\mathbf{v} \in \mathcal{U}^{\perp}$;
(vi) $\ker(P_{\mathcal{U}}) = \mathcal{U}^{\perp}$;
(vii) $P_{\mathcal{U}}^2 = P_{\mathcal{U}}$;
(viii) $(\forall\, \mathbf{v} \in \mathcal{V})\, \|P_{\mathcal{U}}\mathbf{v}\| \le \|\mathbf{v}\|$;
(ix) if $(\mathbf{e}_1, \dots, \mathbf{e}_m)$ is an orthonormal basis of $\mathcal{U}$, then $(\forall\, \mathbf{v} \in \mathcal{V})\, P_{\mathcal{U}}\mathbf{v} = \sum_{j=1}^{m} \langle \mathbf{v}, \mathbf{e}_j \rangle\, \mathbf{e}_j$.

Proof.

(i) Fix $a \in \mathbb{F}$ and $\mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}$. By Theorem 2.1.5, write $\mathbf{v}_r = \mathbf{u}_r + \mathbf{w}_r$ with $\mathbf{u}_r \in \mathcal{U}$ and $\mathbf{w}_r \in \mathcal{U}^{\perp}$ for $r \in \{1, 2\}$.
Since $\mathcal{U}$ and $\mathcal{U}^{\perp}$ are subspaces, $a\mathbf{v}_1 + \mathbf{v}_2 = (a\mathbf{u}_1 + \mathbf{u}_2) + (a\mathbf{w}_1 + \mathbf{w}_2)$ is its orthogonal decomposition.
Uniqueness therefore implies $P_{\mathcal{U}}(a\mathbf{v}_1 + \mathbf{v}_2) = aP_{\mathcal{U}}\mathbf{v}_1 + P_{\mathcal{U}}\mathbf{v}_2$, so $P_{\mathcal{U}} \in \mathcal{L}(\mathcal{V})$.
(ii) Fix $\mathbf{u} \in \mathcal{U}$. The decomposition $\mathbf{u} = \mathbf{u} + \mathbf{0}$ has $\mathbf{0} \in \mathcal{U}^{\perp}$ by Proposition 2.1.3(i), so $P_{\mathcal{U}}\mathbf{u} = \mathbf{u}$.
(iii) Fix $\mathbf{w} \in \mathcal{U}^{\perp}$. The decomposition $\mathbf{w} = \mathbf{0} + \mathbf{w}$ has $\mathbf{0} \in \mathcal{U}$, so $P_{\mathcal{U}}\mathbf{w} = \mathbf{0}$.
(iv) The defining decomposition places every value of $P_{\mathcal{U}}$ in $\mathcal{U}$, so $\operatorname{range}(P_{\mathcal{U}}) \subseteq \mathcal{U}$. The reverse inclusion holds by (ii).
(v) Fix $\mathbf{v} \in \mathcal{V}$. The defining decomposition is $\mathbf{v} = P_{\mathcal{U}}\mathbf{v} + (\mathbf{v} - P_{\mathcal{U}}\mathbf{v})$ with $\mathbf{v} - P_{\mathcal{U}}\mathbf{v} \in \mathcal{U}^{\perp}$.
(vi) The inclusion $\mathcal{U}^{\perp} \subseteq \ker(P_{\mathcal{U}})$ holds by (iii). Conversely, if $P_{\mathcal{U}}\mathbf{v} = \mathbf{0}$, then $\mathbf{v} = \mathbf{v} - P_{\mathcal{U}}\mathbf{v} \in \mathcal{U}^{\perp}$ by (v).
(vii) Fix $\mathbf{v} \in \mathcal{V}$. By (iv), $P_{\mathcal{U}}\mathbf{v} \in \mathcal{U}$, so $P_{\mathcal{U}}(P_{\mathcal{U}}\mathbf{v}) = P_{\mathcal{U}}\mathbf{v}$ by (ii). Hence $P_{\mathcal{U}}^2 = P_{\mathcal{U}}$.
(viii) Fix $\mathbf{v} \in \mathcal{V}$ and set $\mathbf{p} := P_{\mathcal{U}}\mathbf{v}$ and $\mathbf{r} := \mathbf{v} - \mathbf{p}$. Then $\mathbf{p} \in \mathcal{U}$ by (iv) and $\mathbf{r} \in \mathcal{U}^{\perp}$ by (v).
Hence $\|\mathbf{v}\|^2 = \|\mathbf{p}\|^2 + \|\mathbf{r}\|^2 \ge \|\mathbf{p}\|^2$ by Theorem 1.4.3. Nonnegativity of norms implies $\|P_{\mathcal{U}}\mathbf{v}\| \le \|\mathbf{v}\|$.
(ix) Fix $\mathbf{v} \in \mathcal{V}$ and set $\mathbf{p} := \sum_{j=1}^{m} \langle \mathbf{v}, \mathbf{e}_j \rangle\, \mathbf{e}_j \in \mathcal{U}$. For $k \in \{1, \dots, m\}$, $\langle \mathbf{v} - \mathbf{p}, \mathbf{e}_k \rangle = \langle \mathbf{v}, \mathbf{e}_k \rangle - \sum_{j=1}^{m} \langle \mathbf{v}, \mathbf{e}_j \rangle \langle \mathbf{e}_j, \mathbf{e}_k \rangle = 0$ by orthonormality.
If $\mathbf{x} \in \mathcal{U}$, write $\mathbf{x} = \sum_{k=1}^{m} a_k \mathbf{e}_k$; then $\langle \mathbf{v} - \mathbf{p}, \mathbf{x} \rangle = \sum_{k=1}^{m} \overline{a_k}\, \langle \mathbf{v} - \mathbf{p}, \mathbf{e}_k \rangle = 0$ by Proposition 1.1.9(iii)–(iv).
Thus $\mathbf{v} - \mathbf{p} \in \mathcal{U}^{\perp}$, and $P_{\mathcal{U}}\mathbf{v} = \mathbf{p}$ by uniqueness in Theorem 2.1.5.

Structural Commentary: The orthogonal decomposition organizes all nine arguments.
Key Insight: Projection preserves the $\mathcal{U}$-component and annihilates the $\mathcal{U}^{\perp}$-component. □

Definition 2.2.4. *Rank-One Projection Matrix*
Let $\mathbf{u} = (u_1, \dots, u_n)^t \in \mathbb{F}^n$ be a unit vector. The *rank-one projection matrix* onto $\operatorname{span}(\mathbf{u})$ is $P_{\mathbf{u}} := [u_i \overline{u_j}]_{i,j=1}^{n} \in \operatorname{Mat}(n, n, \mathbb{F})$.
It satisfies $(\forall\, \mathbf{x} \in \mathbb{F}^n)\, P_{\mathbf{u}}\mathbf{x} = \langle \mathbf{x}, \mathbf{u} \rangle_{\mathbb{F}^n}\, \mathbf{u}$.

Proposition 2.2.5. *Properties of Rank-One Projection Matrices*
Let $\mathbf{u} \in \mathbb{F}^n$ be a unit vector. Then:

(i) $\operatorname{range}(P_{\mathbf{u}}) = \operatorname{span}(\mathbf{u})$;
(ii) $\ker(P_{\mathbf{u}}) = \operatorname{span}(\mathbf{u})^{\perp}$;
(iii) $(\forall, i, j \in \{1, \dots, n\})\, (P_{\mathbf{u}})_{ij} = \overline{(P_{\mathbf{u}})_{ji}}$;
(iv) $P_{\mathbf{u}}^2 = P_{\mathbf{u}}$.

Proof.

(i) For $\mathbf{x} \in \mathbb{F}^n$, $P_{\mathbf{u}}\mathbf{x} = \langle \mathbf{x}, \mathbf{u} \rangle_{\mathbb{F}^n}\, \mathbf{u} \in \operatorname{span}(\mathbf{u})$, so $\operatorname{range}(P_{\mathbf{u}}) \subseteq \operatorname{span}(\mathbf{u})$. Since $P_{\mathbf{u}}\mathbf{u} = \langle \mathbf{u}, \mathbf{u} \rangle_{\mathbb{F}^n}\, \mathbf{u} = \mathbf{u}$, the reverse inclusion also holds.
(ii) Fix $\mathbf{x} \in \mathbb{F}^n$. Since $\mathbf{u} \neq \mathbf{0}$, $P_{\mathbf{u}}\mathbf{x} = \langle \mathbf{x}, \mathbf{u} \rangle_{\mathbb{F}^n}\, \mathbf{u} = \mathbf{0}$ if and only if $\langle \mathbf{x}, \mathbf{u} \rangle_{\mathbb{F}^n} = 0$, which is equivalent to $\mathbf{x} \in \operatorname{span}(\mathbf{u})^{\perp}$.
(iii) For $i, j \in \{1, \dots, n\}$, $(P_{\mathbf{u}})_{ij} = u_i \overline{u_j} = \overline{u_j \overline{u_i}} = \overline{(P_{\mathbf{u}})_{ji}}$.
(iv) For $i, k \in \{1, \dots, n\}$, $(P_{\mathbf{u}}^2)_{ik} = \sum_{j=1}^{n} u_i \overline{u_j} u_j \overline{u_k} = u_i \overline{u_k} \sum_{j=1}^{n} |u_j|^2 = u_i \overline{u_k} = (P_{\mathbf{u}})_{ik}$ because $\mathbf{u}$ is a unit vector.

Structural Commentary: The projection formula proves all four matrix identities.
Key Insight: The matrix preserves the $\mathbf{u}$ direction and annihilates its orthogonal complement. □

Theorem 2.2.6. *Orthogonal Projection Minimizes Distance*
Let $\mathcal{U}$ be a finite-dimensional subspace of $\mathcal{V}$. If $\mathbf{v} \in \mathcal{V}$ and $\mathbf{u} \in \mathcal{U}$, then $\|\mathbf{v} - P_{\mathcal{U}}\mathbf{v}\| \le \|\mathbf{v} - \mathbf{u}\|$, with equality if and only if $\mathbf{u} = P_{\mathcal{U}}\mathbf{v}$.

Proof. Set $\mathbf{p} := P_{\mathcal{U}}\mathbf{v}$, $\mathbf{r} := \mathbf{v} - \mathbf{p}$, and $\mathbf{h} := \mathbf{p} - \mathbf{u}$. By Proposition 2.2.3(iv)–(v), $\mathbf{p}, \mathbf{h} \in \mathcal{U}$ and $\mathbf{r} \in \mathcal{U}^{\perp}$, so $\mathbf{r} \perp \mathbf{h}$.
Since $\mathbf{v} - \mathbf{u} = \mathbf{r} + \mathbf{h}$, $\|\mathbf{v} - \mathbf{u}\|^2 = \|\mathbf{r}\|^2 + \|\mathbf{h}\|^2 \ge \|\mathbf{r}\|^2 = \|\mathbf{v} - P_{\mathcal{U}}\mathbf{v}\|^2$ by Theorem 1.4.3. Nonnegativity of norms proves the inequality.
($\Rightarrow$) If equality holds, then the preceding identity forces $\|\mathbf{h}\| = 0$, so $\mathbf{h} = \mathbf{0}$ by definiteness and $\mathbf{u} = \mathbf{p} = P_{\mathcal{U}}\mathbf{v}$.
($\Leftarrow$) If $\mathbf{u} = P_{\mathcal{U}}\mathbf{v}$, then $\mathbf{h} = \mathbf{0}$ and equality holds in the same identity.

Structural Commentary: Pythagoras isolates the nonnegative correction term.
Key Insight: The orthogonal projection is the unique nearest point in the subspace. □

Definition 2.2.7. *Distance to a Subspace*
Let $\mathcal{U}$ be a nonempty subset of $\mathcal{V}$. The *distance* from $\mathbf{v} \in \mathcal{V}$ to $\mathcal{U}$ is $d(\mathbf{v},\mathcal{U}) := \inf_{\mathbf{u}\in\mathcal{U}} \|\mathbf{v}-\mathbf{u}\|$.
If $\mathcal{U}$ is a finite-dimensional subspace, then $d(\mathbf{v},\mathcal{U}) = \|\mathbf{v} - P_{\mathcal{U}}\mathbf{v}\|$ by Theorem 2.2.6.

Definition 2.2.8. *Fourier Coefficients and Expansion*
Let $\mathcal{O} = (\mathbf{e}_1,\dots,\mathbf{e}_m)$ be orthonormal list, $\mathbf{v} \in \mathcal{V}$. The *Fourier coefficients* of $\mathbf{v}$ relative to $\mathcal{O}$ are $c_j(\mathbf{v}) := \langle \mathbf{v}, \mathbf{e}_j\rangle$ for $j \in \{1,\dots,m\}$.
The *Fourier expansion* of $\mathbf{v}$ onto $\mathcal{O}$ is $\widehat{\mathbf{v}}_{\mathcal{O}} := \sum_{j=1}^{m} c_j(\mathbf{v})\mathbf{e}_j$.

Theorem 2.2.9. *Fourier Expansion onto a Finite Orthonormal Set*
Let $\mathcal{O} = (\mathbf{e}_1,\dots,\mathbf{e}_m)$ be orthonormal, let $\mathcal{S} = \operatorname{span}(\mathcal{O})$, and let $\mathbf{v} \in \mathcal{V}$. Then:
(i) $\widehat{\mathbf{v}}_{\mathcal{O}}$ is the unique $\mathbf{s} \in \mathcal{S}$ with $\mathbf{v} - \mathbf{s} \in \mathcal{S}^{\perp}$;
(ii) $(\forall\, \mathbf{s} \in \mathcal{S})\ \|\mathbf{v} - \widehat{\mathbf{v}}_{\mathcal{O}}\| \le \|\mathbf{v} - \mathbf{s}\|$, and $\widehat{\mathbf{v}}_{\mathcal{O}}$ is the only $\mathbf{s} \in \mathcal{S}$ for which equality holds;
(iii) $\|\widehat{\mathbf{v}}_{\mathcal{O}}\| \le \|\mathbf{v}\|$.

Proof.
(i) By construction, $\widehat{\mathbf{v}}_{\mathcal{O}} \in \mathcal{S}$. For $k \in \{1,\dots,m\}$, $\langle \mathbf{v} - \widehat{\mathbf{v}}_{\mathcal{O}}, \mathbf{e}_k\rangle = c_k(\mathbf{v}) - \sum_{j=1}^{m} c_j(\mathbf{v})\delta_{jk} = 0$.
If $\mathbf{x} \in \mathcal{S}$, write $\mathbf{x} = \sum_{k=1}^{m} a_k\mathbf{e}_k$; then $\langle \mathbf{v} - \widehat{\mathbf{v}}_{\mathcal{O}}, \mathbf{x}\rangle = \sum_{k=1}^{m} \overline{a_k}\langle \mathbf{v} - \widehat{\mathbf{v}}_{\mathcal{O}}, \mathbf{e}_k\rangle = 0$ by Proposition 1.1.9(iii)–(iv). Hence $\mathbf{v} - \widehat{\mathbf{v}}_{\mathcal{O}} \in \mathcal{S}^{\perp}$.
If $\mathbf{s} \in \mathcal{S}$ also satisfies $\mathbf{v} - \mathbf{s} \in \mathcal{S}^{\perp}$, then $\mathbf{s} - \widehat{\mathbf{v}}_{\mathcal{O}} = (\mathbf{v} - \widehat{\mathbf{v}}_{\mathcal{O}}) - (\mathbf{v} - \mathbf{s}) \in \mathcal{S} \cap \mathcal{S}^{\perp}$, so $\mathbf{s} = \widehat{\mathbf{v}}_{\mathcal{O}}$ by Proposition 2.1.3(iv).
(ii) By (i), $\widehat{\mathbf{v}}_{\mathcal{O}} = P_{\mathcal{S}}\mathbf{v}$. The inequality and equality condition hold by Theorem 2.2.6.
(iii) If $m = 0$, then $\widehat{\mathbf{v}}_{\mathcal{O}} = \mathbf{0}$ and the claim is immediate. Suppose $m \ge 1$.
By Proposition 1.3.2 and Theorem 1.4.5, $\|\widehat{\mathbf{v}}_{\mathcal{O}}\|^2 = \sum_{j=1}^{m} |c_j(\mathbf{v})|^2 \le \|\mathbf{v}\|^2$, so $\|\widehat{\mathbf{v}}_{\mathcal{O}}\| \le \|\mathbf{v}\|$ by nonnegativity of norms.

Structural Commentary: Coordinate construction and nearest-point optimality prove all three claims.
Key Insight: Fourier expansion is orthogonal projection expressed in orthonormal coordinates. □

Theorem 2.2.10. *Characterizing Finite Orthonormal Bases*
Let $\mathcal{O} = (\mathbf{e}_1,\dots,\mathbf{e}_m)$ be orthonormal, $\mathcal{S} = \operatorname{span}(\mathcal{O})$. Write $c_j(\mathbf{v})$, $\widehat{\mathbf{v}} := \widehat{\mathbf{v}}_{\mathcal{O}}$ as in Definition 2.2.8. The following are equivalent:
(i) $\mathcal{S} = \mathcal{V}$.
(ii) $\mathcal{S}^{\perp} = \{\mathbf{0}\}$.
(iii) $(\forall\, \mathbf{v} \in \mathcal{V})\ \widehat{\mathbf{v}} = \mathbf{v}$.
(iv) $(\forall\, \mathbf{v},\mathbf{w} \in \mathcal{V})\ \langle \mathbf{v},\mathbf{w}\rangle = \sum_{j=1}^{m} c_j(\mathbf{v})\overline{c_j(\mathbf{w})}$.
(v) $(\forall\, \mathbf{v} \in \mathcal{V})\ \|\widehat{\mathbf{v}}\| = \|\mathbf{v}\|$.

Proof.
(i) ⇒ *(ii)* If $\mathcal{S} = \mathcal{V}$, then $\mathcal{S}^{\perp} = \mathcal{V}^{\perp} = \{\mathbf{0}\}$ by Proposition 2.1.3(iii).
(ii) ⇒ *(iii)* Fix $\mathbf{v} \in \mathcal{V}$. By Theorem 2.2.9(i), $\mathbf{v} - \widehat{\mathbf{v}} \in \mathcal{S}^{\perp} = \{\mathbf{0}\}$, so $\widehat{\mathbf{v}} = \mathbf{v}$.
(iii) ⇒ *(iv)* Fix $\mathbf{v},\mathbf{w} \in \mathcal{V}$. By (iii), $\mathbf{v} = \sum_{j=1}^{m} c_j(\mathbf{v})\mathbf{e}_j$ and $\mathbf{w} = \sum_{k=1}^{m} c_k(\mathbf{w})\mathbf{e}_k$.
Then $\langle \mathbf{v},\mathbf{w}\rangle = \sum_{j=1}^{m} c_j(\mathbf{v})\overline{c_j(\mathbf{w})}$ by Proposition 1.1.9(iii)–(iv) and orthonormality.
(iv) ⇒ *(v)* Fix $\mathbf{v} \in \mathcal{V}$ and set $\mathbf{w} = \mathbf{v}$ in (iv). Then $\|\mathbf{v}\|^2 = \sum_{j=1}^{m} |c_j(\mathbf{v})|^2 = \|\widehat{\mathbf{v}}\|^2$ by Proposition 1.3.2, so $\|\widehat{\mathbf{v}}\| = \|\mathbf{v}\|$.
(v) ⇒ *(i)* Fix $\mathbf{v} \in \mathcal{V}$. By Theorem 2.2.9(i), $\widehat{\mathbf{v}} \in \mathcal{S}$ and $\mathbf{v} - \widehat{\mathbf{v}} \in \mathcal{S}^{\perp}$. Hence $\|\mathbf{v}\|^2 = \|\widehat{\mathbf{v}}\|^2 + \|\mathbf{v} - \widehat{\mathbf{v}}\|^2$ by Theorem 1.4.3.
Condition (v) implies $\|\mathbf{v} - \widehat{\mathbf{v}}\| = 0$, so $\mathbf{v} = \widehat{\mathbf{v}} \in \mathcal{S}$ by definiteness. Thus $\mathcal{V} \subseteq \mathcal{S}$, while $\mathcal{S} \subseteq \mathcal{V}$ by construction, therefore $\mathcal{S} = \mathcal{V}$.

Structural Commentary: A five-step implication cycle proves equivalence.
Key Insight: An orthonormal list is a basis exactly when its projection loses no component. □

Perspective 2.2.11. *Why the Finite-Dimensional Hypothesis Matters*
In $\ell^2(\mathbb{F})$, let $\mathcal{S} = \mathbb{F}^{(\mathbb{N})} = \operatorname{span}\{\mathbf{e}_j : j \ge 1\}$. If $\mathbf{x} \in \mathcal{S}^{\perp}$, then $(\forall\, j \in \mathbb{N})\ x_j = \langle \mathbf{x}, \mathbf{e}_j\rangle = 0$, so $\mathcal{S}^{\perp} = \{\mathbf{0}\}$.
The vector $(2^{-j})_{j\ge1}$ belongs to $\ell^2(\mathbb{F})$ but not to $\mathcal{S}$, hence $\mathcal{S} \subsetneq \ell^2(\mathbb{F})$ and $\mathcal{S} \oplus \mathcal{S}^{\perp} \neq \ell^2(\mathbb{F})$.

2.3 Adjoints and Fundamental Subspaces

Adjoints express dual action in inner-product language. They become conjugate transposes in orthonormal coordinates and exchange kernels, ranges, and orthogonal complements.

Throughout this subsection, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$.

Definition 2.3.1. *Adjoint of a Linear Map*
Let $\mathcal{V}$ and $\mathcal{W}$ be inner-product spaces and let $T \in \mathcal{L}(\mathcal{V},\mathcal{W})$.
A map $S : \mathcal{W} \to \mathcal{V}$ is an *adjoint* of T if $(\forall\, \mathbf{v} \in \mathcal{V})(\forall\, \mathbf{w} \in \mathcal{W})\ \langle T\mathbf{v},\mathbf{w}\rangle_{\mathcal{W}} = \langle \mathbf{v}, S\mathbf{w}\rangle_{\mathcal{V}}$.

Perspective 2.3.2. *Dual Map and Inner-Product Adjoint*
By Definition 4.2.4, the *dual map* of $T \in \mathcal{L}(\mathcal{V},\mathcal{W})$ is the pullback $T' : \mathcal{W}' \to \mathcal{V}'$, $T'\varphi = \varphi \circ T$.
This algebraic adjoint, sometimes written $T^{\times}$, is distinct from the inner-product adjoint T^*, whose construction requires inner products.

Lemma 2.3.3. *Uniqueness of Adjoints*
Let $\mathcal{V}$ and $\mathcal{W}$ be inner-product spaces and let $T \in \mathcal{L}(\mathcal{V},\mathcal{W})$. Then T has at most one adjoint.

Proof. Suppose $S_1, S_2 : \mathcal{W} \to \mathcal{V}$ are adjoints of T and fix $\mathbf{w} \in \mathcal{W}$.
Then $(\forall\, \mathbf{v} \in \mathcal{V})\ \langle \mathbf{v}, S_1\mathbf{w}\rangle_{\mathcal{V}} = \langle \mathbf{v}, S_2\mathbf{w}\rangle_{\mathcal{V}}$ by the two adjoint identities.
Thus $S_1\mathbf{w} = S_2\mathbf{w}$ by Lemma 1.1.10(i), and $S_1 = S_2$ by pointwise equality.
Structural Commentary: Pointwise comparison reduces uniqueness to separation by inner products.
Key Insight: Distinct vectors cannot agree against every inner-product test. □

Theorem 2.3.4. *Existence of the Adjoint*
Let $\mathcal{V}$ be a finite-dimensional inner-product space, let $\mathcal{W}$ be an inner-product space, and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Then:
(i) T has an adjoint $T^* : \mathcal{W} \to \mathcal{V}$;
(ii) the adjoint T^* is unique;
(iii) $T^* \in \mathcal{L}(\mathcal{W}, \mathcal{V})$.

Proof.
(i) Fix $\mathbf{w} \in \mathcal{W}$. The map $\varphi_{\mathbf{w}} := \langle T(\cdot), \mathbf{w} \rangle_{\mathcal{W}}$ belongs to $\mathcal{V}'$ by linearity of T and the first inner-product slot.
By Theorem 1.6.1, $(\exists!\, \mathbf{u}_{\mathbf{w}} \in \mathcal{V})(\forall\, \mathbf{v} \in \mathcal{V})\, \varphi_{\mathbf{w}}(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u}_{\mathbf{w}} \rangle_{\mathcal{V}}$.
Define $T^*\mathbf{w} := \mathbf{u}_{\mathbf{w}}$. Since $\mathbf{w}$ was arbitrary, $T^* : \mathcal{W} \to \mathcal{V}$ is an adjoint of T.
(ii) The adjoint T^* is unique by Lemma 2.3.3.
(iii) Fix $a \in \mathbb{F}$ and $\mathbf{w}_1, \mathbf{w}_2 \in \mathcal{W}$, and set $\mathbf{x} := aT^*\mathbf{w}_1 + T^*\mathbf{w}_2$.
For $\mathbf{v} \in \mathcal{V}$, $\langle \mathbf{v}, T^*(a\mathbf{w}_1 + \mathbf{w}_2) - \mathbf{x} \rangle_{\mathcal{V}} = 0$ by the adjoint identity and conjugate linearity in the second slot.
Thus $T^*(a\mathbf{w}_1 + \mathbf{w}_2) = \mathbf{x}$ by Lemma 1.1.10(ii), so $T^* \in \mathcal{L}(\mathcal{W}, \mathcal{V})$.
Structural Commentary: Riesz representation constructs codomain-indexed vectors; separation verifies that their assignment is linear.
Key Insight: Riesz vectors assemble pointwise into the adjoint. □

Figure 29 records the inner-product identity that transfers T from the first slot to T^* in the second slot.

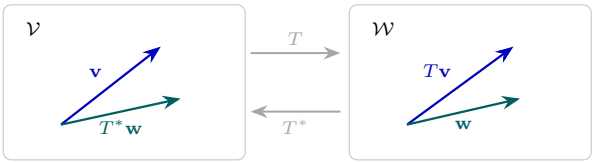

Figure 29: Adjoint relation: $\langle T\mathbf{v}, \mathbf{w} \rangle_{\mathcal{W}} = \langle \mathbf{v}, T^*\mathbf{w} \rangle_{\mathcal{V}}$.

Proposition 2.3.5. *Riesz Transport of the Dual Map*
Let $\mathcal{V}$ and $\mathcal{W}$ be finite-dimensional inner-product spaces.
For $\mathcal{X} \in \{\mathcal{V}, \mathcal{W}\}$, let $R_{\mathcal{X}} : \mathcal{X}' \to \mathcal{X}$ be the Riesz map characterized by $(\forall\, \varphi \in \mathcal{X}')(\forall\, \mathbf{x} \in \mathcal{X})\, \varphi(\mathbf{x}) = \langle \mathbf{x}, R_{\mathcal{X}}\varphi \rangle_{\mathcal{X}}$.
Then $(\forall\, T \in \mathcal{L}(\mathcal{V}, \mathcal{W}))\, T' = (R_{\mathcal{V}})^{-1} \circ T^* \circ R_{\mathcal{W}}$, equivalently $R_{\mathcal{V}} T' = T^* R_{\mathcal{W}}$.

Proof. Fix $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ and $\varphi \in \mathcal{W}'$, and set $\mathbf{u} := T^* R_{\mathcal{W}} \varphi$ and $\psi := (R_{\mathcal{V}})^{-1}\mathbf{u}$.
For $\mathbf{v} \in \mathcal{V}$, $\psi(\mathbf{v}) = \langle \mathbf{v}, \mathbf{u} \rangle_{\mathcal{V}} = \langle T\mathbf{v}, R_{\mathcal{W}}\varphi \rangle_{\mathcal{W}} = \varphi(T\mathbf{v}) = (T'\varphi)(\mathbf{v})$ by the Riesz-map, adjoint, and dual-map identities.
Thus $T' = (R_{\mathcal{V}})^{-1} T^* R_{\mathcal{W}}$ by pointwise equality, and composition with $R_{\mathcal{V}}$ proves the equivalent identity.
Structural Commentary: Pointwise evaluation identifies Riesz transport with the dual-map pullback.
Key Insight: Two conjugate-linear Riesz maps recover the linear dual map. □

Figure 30 displays the commuting square expressed by $R_{\mathcal{V}} T' = T^* R_{\mathcal{W}}$.

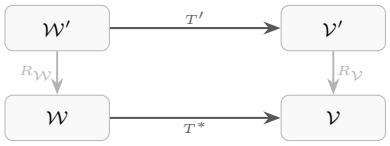

Figure 30: Riesz transports the dual map to the adjoint: $R_{\mathcal{V}} T' = T^* R_{\mathcal{W}}$.

Definition 2.3.6. *Conjugate Transpose*
For $A = [a_{ij}] \in \mathrm{Mat}(m, n, \mathbb{F})$, the *conjugate transpose* of A is $A^* = [\overline{a_{ji}}] \in \mathrm{Mat}(n, m, \mathbb{F})$.
Over $\mathbb{R}$, the conjugate transpose is the ordinary transpose.

Theorem 2.3.7. *Matrix of the Adjoint*
Let $\beta = (\mathbf{e}_1, \ldots, \mathbf{e}_n)$ and $\gamma = (\mathbf{f}_1, \ldots, \mathbf{f}_m)$ be orthonormal bases of the finite-dimensional inner-product spaces $\mathcal{V}$ and $\mathcal{W}$, respectively.
Then $(\forall\, T \in \mathcal{L}(\mathcal{V}, \mathcal{W}))\, [T^*]_{\beta \leftarrow \gamma} = ([T]_{\gamma \leftarrow \beta})^*$.

Proof. Set $A := [T]_{\gamma \leftarrow \beta}$ and $B := [T^*]_{\beta \leftarrow \gamma}$.
If $n = 0$ or $m = 0$, then B and A^* are the unique $n \times m$ matrix, so $B = A^*$. Suppose $n, m \geq 1$.
For $i \in \{1, \ldots, n\}$ and $j \in \{1, \ldots, m\}$, $A_{j,i} = \langle T\mathbf{e}_i, \mathbf{f}_j \rangle_{\mathcal{W}}$ by Theorem 1.4.8(i).
By the same theorem for T^*, $B_{i,j} = \langle T^*\mathbf{f}_j, \mathbf{e}_i \rangle_{\mathcal{V}}$.
The identity $B_{i,j} = \overline{\langle \mathbf{e}_i, T^*\mathbf{f}_j \rangle_{\mathcal{V}}} = \overline{A_{j,i}}$ holds by conjugate symmetry and the adjoint identity. Since i, j were arbitrary, $B = A^*$.
Structural Commentary: Empty dimensions are immediate; orthonormal coordinates match each remaining entry after conjugation.
Key Insight: Moving an operator across an inner product becomes conjugate transposition in orthonormal bases. □

Proposition 2.3.8. *Basic Adjoint Identities*
Let $\mathcal{U}$, $\mathcal{V}$, and $\mathcal{W}$ be finite-dimensional inner-product spaces. Then:
(i) $(aS + T)^* = \overline{a}S^* + T^*$ for $S, T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ and $a \in \mathbb{F}$;
(ii) $(SR)^* = R^*S^*$ for $R \in \mathcal{L}(\mathcal{U}, \mathcal{V})$ and $S \in \mathcal{L}(\mathcal{V}, \mathcal{W})$;
(iii) $(T^*)^* = T$ for $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$;
(iv) $I_{\mathcal{V}}^* = I_{\mathcal{V}}$.

Proof. Each claim follows by Lemma 2.3.3 once the asserted adjoint verifies its defining identity.
(i) For $\mathbf{v} \in \mathcal{V}$ and $\mathbf{w} \in \mathcal{W}$, $\langle (aS + T)\mathbf{v}, \mathbf{w} \rangle_{\mathcal{W}} = \langle \mathbf{v}, (\overline{a}S^* + T^*)\mathbf{w} \rangle_{\mathcal{V}}$ by linearity and the adjoint identities.

(ii) For $\mathbf{u} \in \mathcal{U}$ and $\mathbf{w} \in \mathcal{W}$, $\langle SR\mathbf{u}, \mathbf{w}\rangle_{\mathcal{W}} = \langle \mathbf{u}, R^*S^*\mathbf{w}\rangle_{\mathcal{U}}$ by the two adjoint identities.
(iii) The identity $(\forall\, \mathbf{w} \in \mathcal{W})(\forall\, \mathbf{v} \in \mathcal{V})\ \langle T^*\mathbf{w}, \mathbf{v}\rangle_{\mathcal{V}} = \langle \mathbf{w}, T\mathbf{v}\rangle_{\mathcal{W}}$ holds by conjugate symmetry and the adjoint identity.
Thus T is the adjoint of T^*, so $(T^*)^* = T$.
(iv) For $\mathbf{v}, \mathbf{w} \in \mathcal{V}$, $\langle I_{\mathcal{V}}\mathbf{v}, \mathbf{w}\rangle = \langle \mathbf{v}, I_{\mathcal{V}}\mathbf{w}\rangle$. Thus $I_{\mathcal{V}}^* = I_{\mathcal{V}}$.

Structural Commentary: Each algebraic operation is transported through the two inner-product slots and then settled by uniqueness.
Key Insight: Adjoint formation conjugates scalars, reverses products, and is involutive. □

Proposition 2.3.9. *Adjoints of Inverses and Polynomials*
Let $T \in \mathcal{L}(\mathcal{V})$ on a finite-dimensional inner-product space. For $p(z) = \sum_{j=0}^{m} a_j z^j \in \mathbb{F}[z]$, set $p^{\#}(z) := \sum_{j=0}^{m} \overline{a_j} z^j$.

(i) If T is invertible, then $(T^*)^{-1} = (T^{-1})^*$.
(ii) $p(T)^* = p^{\#}(T^*)$.
(iii) $p \in \mathbb{R}[z] \Longrightarrow p(T)^* = p(T^*)$.

Proof.

(i) The identities $(T^{-1})^*T^* = (TT^{-1})^* = I_{\mathcal{V}}$ and $T^*(T^{-1})^* = (T^{-1}T)^* = I_{\mathcal{V}}$ hold by Proposition 2.3.8(ii),(iv).
Thus $(T^*)^{-1} = (T^{-1})^*$ by uniqueness of two-sided inverses.
(ii) The base identity $(T^0)^* = I_{\mathcal{V}} = (T^*)^0$ holds by Proposition 2.3.8(iv).
If $(T^j)^* = (T^*)^j$, then $(T^{j+1})^* = (T^jT)^* = T^*(T^j)^* = (T^*)^{j+1}$ by Proposition 2.3.8(ii).
Thus $(\forall\, j \in \{0, \dots, m\})\ (T^j)^* = (T^*)^j$ by induction.
The identity $p(T)^* = \sum_{j=0}^{m} \overline{a_j}(T^j)^* = \sum_{j=0}^{m} \overline{a_j}(T^*)^j = p^{\#}(T^*)$ holds by Proposition 2.3.8(i) and the power identity.
(iii) If $p \in \mathbb{R}[z]$, then $p^{\#} = p$, so $p(T)^* = p(T^*)$ by (ii).

Structural Commentary: The product law controls inverses and powers, while conjugate additivity controls polynomial coefficients.
Key Insight: Adjoint formation applies coefficientwise conjugation to polynomial expressions in an operator. □

Proposition 2.3.10. *Adjoint Kernel-Range Orthogonality*
Let $\mathcal{V}$ and $\mathcal{W}$ be finite-dimensional inner-product spaces and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Then:

(i) $\ker(T^*) = (\mathrm{range}(T))^{\perp}$;
(ii) $\ker(T) = (\mathrm{range}(T^*))^{\perp}$;
(iii) $\mathrm{range}(T^*) = (\ker(T))^{\perp}$;
(iv) $\mathrm{range}(T) = (\ker(T^*))^{\perp}$.

Equivalently, an adjoint annihilates exactly the vectors orthogonal to the range of the original map.

Proof.

(i) For $\mathbf{w} \in \mathcal{W}$, $\mathbf{w} \in \ker(T^*) \iff (\forall\, \mathbf{v} \in \mathcal{V})\ \langle \mathbf{v}, T^*\mathbf{w}\rangle_{\mathcal{V}} = 0$ by Lemma 1.1.10(ii).
The latter condition is equivalent to $(\forall\, \mathbf{v} \in \mathcal{V})\ \langle \mathbf{w}, T\mathbf{v}\rangle_{\mathcal{W}} = 0$ by the adjoint identity and conjugate symmetry.
Hence $\mathbf{w} \in \ker(T^*) \iff \mathbf{w} \in (\mathrm{range}(T))^{\perp}$ by the orthogonal-complement definition.
(ii) The identity $\ker(T) = \ker((T^*)^*) = (\mathrm{range}(T^*))^{\perp}$ holds by (i) for T^* and Proposition 2.3.8(iii).
(iii) Taking orthogonal complements in (ii), $(\ker(T))^{\perp} = ((\mathrm{range}(T^*))^{\perp})^{\perp} = \mathrm{range}(T^*)$ by Corollary 2.1.8.
(iv) Taking orthogonal complements in (i), $(\ker(T^*))^{\perp} = ((\mathrm{range}(T))^{\perp})^{\perp} = \mathrm{range}(T)$ by Corollary 2.1.8.

Structural Commentary: The kernel formula, involution, and double complementation establish all four identities.
Key Insight: Kernels and ranges are exchanged by taking an adjoint and an orthogonal complement. □

Proposition 2.3.11. *Adjoint Products and Algebraic Projections*
Let $\mathcal{V}$ and $\mathcal{W}$ be finite-dimensional inner-product spaces and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$.

(i) $(\ker(T^*T), \ker(TT^*)) = (\ker(T), \ker(T^*))$.
(ii) $(\mathrm{range}(T^*T), \mathrm{range}(TT^*)) = (\mathrm{range}(T^*), \mathrm{range}(T))$.
(iii) If $\mathcal{V} = \mathcal{U} \oplus \mathcal{Z}$, then $\mathcal{V} = \mathcal{Z}^{\perp} \oplus \mathcal{U}^{\perp}$.
In this decomposition, $(\rho_{\mathcal{U},\mathcal{Z}})^* = \rho_{\mathcal{Z}^{\perp},\mathcal{U}^{\perp}}$.

Proof.

(i) For $\mathbf{v} \in \mathcal{V}$, $\langle \mathbf{v}, T^*T\mathbf{v}\rangle_{\mathcal{V}} = \|T\mathbf{v}\|^2$ by the adjoint identity.
Thus $\mathbf{v} \in \ker(T^*T) \iff T\mathbf{v} = \mathbf{0} \iff \mathbf{v} \in \ker(T)$ by this identity and definiteness.
The equality $\ker(TT^*) = \ker(T^*)$ follows by this result for T^* and Proposition 2.3.8(iii).
(ii) The identities $(T^*T)^* = T^*T$ and $(TT^*)^* = TT^*$ hold by Proposition 2.3.8(ii),(iii).
The identity $\mathrm{range}(T^*T) = (\ker(T^*T))^{\perp} = (\ker(T))^{\perp} = \mathrm{range}(T^*)$ holds by (i) and Proposition 2.3.10(iii).
The identity $\mathrm{range}(TT^*) = (\ker(TT^*))^{\perp} = (\ker(T^*))^{\perp} = \mathrm{range}(T)$ holds by (i) and Proposition 2.3.10(iv).
(iii) Suppose $\mathcal{V} = \mathcal{U} \oplus \mathcal{Z}$ and set $P := \rho_{\mathcal{U},\mathcal{Z}}$.
Fix $\mathbf{c} \in \mathcal{Z}^{\perp} \cap \mathcal{U}^{\perp}$. For $\mathbf{x} \in \mathcal{V}$, write $\mathbf{x} = \mathbf{u} + \mathbf{z}$ with $(\mathbf{u}, \mathbf{z}) \in \mathcal{U} \times \mathcal{Z}$.
Then $\langle \mathbf{c}, \mathbf{x}\rangle = \langle \mathbf{c}, \mathbf{u}\rangle + \langle \mathbf{c}, \mathbf{z}\rangle = 0$, so $\mathbf{c} \in \mathcal{V}^{\perp} = \{\mathbf{0}\}$ by Proposition 2.1.3(iii).
Hence $\mathcal{Z}^{\perp} \cap \mathcal{U}^{\perp} = \{\mathbf{0}\}$.
By Corollaries 2.1.7 and 2.3.2, $\dim(\mathcal{Z}^{\perp} \oplus \mathcal{U}^{\perp}) = 2\dim(\mathcal{V}) - \dim(\mathcal{Z}) - \dim(\mathcal{U}) = \dim(\mathcal{V})$.
Thus $\mathcal{V} = \mathcal{Z}^{\perp} \oplus \mathcal{U}^{\perp}$ by Proposition 1.4.3(ii).
Set $Q := \rho_{\mathcal{Z}^{\perp},\mathcal{U}^{\perp}}$.
For $\mathbf{x}, \mathbf{y} \in \mathcal{V}$, write $(\mathbf{x}, \mathbf{y}) = (\mathbf{u} + \mathbf{z}, \mathbf{a} + \mathbf{b})$ with $(\mathbf{u}, \mathbf{z}, \mathbf{a}, \mathbf{b}) \in \mathcal{U} \times \mathcal{Z} \times \mathcal{Z}^{\perp} \times \mathcal{U}^{\perp}$.
Then $P\mathbf{x} = \mathbf{u}$, $Q\mathbf{y} = \mathbf{a}$, and $\langle \mathbf{u}, \mathbf{b}\rangle = \langle \mathbf{z}, \mathbf{a}\rangle = 0$ by the projection formulas and conjugate symmetry.
Consequently, $\langle P\mathbf{x}, \mathbf{y}\rangle = \langle \mathbf{u}, \mathbf{a}\rangle = \langle \mathbf{x}, Q\mathbf{y}\rangle$.
Thus $P^* = Q$ by Lemma 2.3.3.

Structural Commentary: Positivity fixes kernels, complementation fixes ranges, and decomposition fixes projection adjoints.
Key Insight: Adjoints preserve effective directions and orthogonally exchange projection complements. □

Corollary 2.3.12. *Matrix Fundamental Subspaces as Orthogonal Complements*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ act as $A : \mathbb{F}^n \to \mathbb{F}^m$ with the standard inner products. Then:

(i) $\ker(A) = \mathrm{col}(A^*)^\perp$;
(ii) $\mathrm{col}(A^*) = \ker(A)^\perp$;
(iii) $\ker(A^*) = \mathrm{col}(A)^\perp$;
(iv) $\mathrm{col}(A) = \ker(A^*)^\perp$.
(v) $\mathbb{F} = \mathbb{R} \Longrightarrow \mathbb{R}^n = \ker(A) \odot \mathrm{row}(A)$.
(vi) $\mathbb{F} = \mathbb{R} \Longrightarrow \mathbb{R}^m = \ker(A^t) \odot \mathrm{col}(A)$.

Proof. The induced map and its adjoint have ranges $\mathrm{col}(A)$ and $\mathrm{col}(A^*)$, respectively, by Theorem 2.3.7.

(i) The identity $\ker(A) = \mathrm{col}(A^*)^\perp$ holds by Proposition 2.3.10(ii).
(ii) The identity $\mathrm{col}(A^*) = \ker(A)^\perp$ holds by Proposition 2.3.10(iii).
(iii) The identity $\ker(A^*) = \mathrm{col}(A)^\perp$ holds by Proposition 2.3.10(i).
(iv) The identity $\mathrm{col}(A) = \ker(A^*)^\perp$ holds by Proposition 2.3.10(iv).
(v) If $\mathbb{F} = \mathbb{R}$, then $A^* = A^t$ and $\mathrm{col}(A^t) = \mathrm{row}(A)$.
Hence $\mathbb{R}^n = \ker(A) \odot \mathrm{row}(A)$ by (ii) and Theorem 2.1.5.
(vi) If $\mathbb{F} = \mathbb{R}$, then $A^* = A^t$.
Hence $\mathbb{R}^m = \ker(A^t) \odot \mathrm{col}(A)$ by (iv) and Theorem 2.1.5.

Structural Commentary: Standard coordinates convert operator formulas into matrix fundamental-subspace identities.
Key Insight: The row space complements $\ker(A)$, while the column space complements $\ker(A^*)$. □

2.4 Least Squares and Metric Optimization

Least squares is projection theory as optimization: normal equations, full-rank formulas, and minimum-norm solutions.

Throughout this subsection, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$.

Principle 2.4.1. *Least Squares as Orthogonal Projection*
Let $\mathcal{U}$ be a finite-dimensional subspace of an inner-product space $\mathcal{V}$, and let $\mathbf{v} \in \mathcal{V}$.
The identity $\arg\min_{\mathbf{u}\in\mathcal{U}} \|\mathbf{v}-\mathbf{u}\| = \{P_{\mathcal{U}}\mathbf{v}\}$ holds by Theorem 2.2.6. The residual $\mathbf{v} - P_{\mathcal{U}}\mathbf{v}$ belongs to $\mathcal{U}^\perp$ by Proposition 2.2.3(v).

Definition 2.4.2. *Matrix Least-Squares Solution*
For $A \in \mathrm{Mat}(m,n,\mathbb{F})$ and $\mathbf{y} \in \mathbb{F}^m$, define $\mathrm{LS}(A,\mathbf{y}) := \arg\min_{\mathbf{x}\in\mathbb{F}^n} \|A\mathbf{x}-\mathbf{y}\|_2$.

An element $\mathbf{x}_0 \in \mathrm{LS}(A,\mathbf{y})$ is a *least-squares solution* of $A\mathbf{x} = \mathbf{y}$. Its *fitted vector* is $A\mathbf{x}_0$, and its *residual* is $\mathbf{y} - A\mathbf{x}_0$.

Theorem 2.4.3. *Normal Equations for Projection*
Let $\mathcal{U} = \mathrm{span}(\mathbf{u}_1,\dots,\mathbf{u}_n)$ be a finite-dimensional subspace of an inner-product space $\mathcal{V}$, and fix $\mathbf{v} \in \mathcal{V}$.
For $\mathbf{c} = (c_1,\dots,c_n) \in \mathbb{F}^n$, set $\mathsf{N}(\mathbf{c}) := (\forall\, i \in \{1,\dots,n\}) \sum_{j=1}^{n} c_j \langle \mathbf{u}_j, \mathbf{u}_i\rangle = \langle \mathbf{v}, \mathbf{u}_i\rangle$. Then:

(i) $(\forall\, \mathbf{c} \in \mathbb{F}^n)\,[P_{\mathcal{U}}\mathbf{v} = \sum_{j=1}^{n} c_j\mathbf{u}_j \iff \mathsf{N}(\mathbf{c})]$;
(ii) $(\exists\, \mathbf{c} \in \mathbb{F}^n)\,\mathsf{N}(\mathbf{c})$;
(iii) if $(\mathbf{u}_1,\dots,\mathbf{u}_n)$ is linearly independent, then $(\exists!\, \mathbf{c} \in \mathbb{F}^n)\,\mathsf{N}(\mathbf{c})$.

Proof.

(i) ($\Rightarrow$) Fix $\mathbf{c} = (c_1,\dots,c_n) \in \mathbb{F}^n$ with $P_{\mathcal{U}}\mathbf{v} = \sum_{j=1}^{n} c_j\mathbf{u}_j$. The residual belongs to $\mathcal{U}^\perp$ by Proposition 2.2.3(v).

Thus $(\forall\, i \in \{1,\dots,n\})\, 0 = \langle \mathbf{v} - P_{\mathcal{U}}\mathbf{v}, \mathbf{u}_i\rangle = \langle \mathbf{v}, \mathbf{u}_i\rangle - \sum_{j=1}^{n} c_j \langle \mathbf{u}_j, \mathbf{u}_i\rangle$, so $\mathsf{N}(\mathbf{c})$ holds.

(i) ($\Leftarrow$) Fix $\mathbf{c} = (c_1,\dots,c_n) \in \mathbb{F}^n$ with $\mathsf{N}(\mathbf{c})$, and set $\mathbf{q} := \sum_{j=1}^{n} c_j\mathbf{u}_j \in \mathcal{U}$.

For $\mathbf{u} = \sum_{i=1}^{n} a_i\mathbf{u}_i \in \mathcal{U}$, $\langle \mathbf{v}-\mathbf{q}, \mathbf{u}\rangle = \sum_{i=1}^{n} \overline{a_i}\,\langle \mathbf{v}-\mathbf{q}, \mathbf{u}_i\rangle = 0$ by $\mathsf{N}(\mathbf{c})$ and Proposition 1.1.9(iii)–(iv).
Hence $\mathbf{v}-\mathbf{q} \in \mathcal{U}^\perp$, and $\mathbf{q} = P_{\mathcal{U}}\mathbf{v}$ by uniqueness in Theorem 2.1.5.

(ii) Relation $P_{\mathcal{U}}\mathbf{v} \in \mathrm{span}(\mathbf{u}_1,\dots,\mathbf{u}_n)$ holds by Proposition 2.2.3(iv). Choose $\mathbf{c} \in \mathbb{F}^n$ with $P_{\mathcal{U}}\mathbf{v} = \sum_{j=1}^{n} c_j\mathbf{u}_j$; then $\mathsf{N}(\mathbf{c})$ holds by (i).

(iii) Suppose $(\mathbf{u}_1,\dots,\mathbf{u}_n)$ is linearly independent. Existence holds by (ii).
If $\mathsf{N}(\mathbf{c})$ and $\mathsf{N}(\mathbf{d})$, then $\sum_{j=1}^{n} c_j\mathbf{u}_j = P_{\mathcal{U}}\mathbf{v} = \sum_{j=1}^{n} d_j\mathbf{u}_j$ by (i), and hence $\mathbf{c} = \mathbf{d}$ by linear independence.

Structural Commentary: Projection coordinates construct solutions; residual orthogonality characterizes every coefficient vector.
Key Insight: Normal equations are the spanning-vector tests for an orthogonal residual. □

Figure 31 depicts the residual orthogonality tested against two spanning vectors.

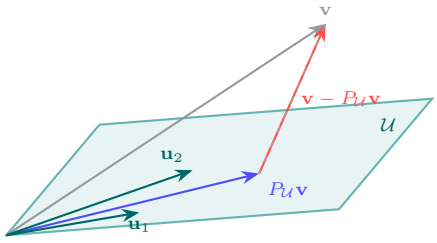

Figure 31: Normal equations impose $(\forall\, i \in \{1,\dots,n\})\ \langle \mathbf{v} - P_{\mathcal{U}}\mathbf{v}, \mathbf{u}_i\rangle = 0$.

Theorem 2.4.4. *Matrix Least Squares and Normal Equations*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ *and* $\mathbf{y} \in \mathbb{F}^m$. *Then:*

(i) $(\forall\, \mathbf{x}_0 \in \mathbb{F}^n)\,[\mathbf{x}_0 \in \mathrm{LS}(A,\mathbf{y}) \iff A^*A\mathbf{x}_0 = A^*\mathbf{y}]$;
(ii) $(\exists\, \mathbf{x}_0 \in \mathbb{F}^n)\, A^*A\mathbf{x}_0 = A^*\mathbf{y}$;
(iii) $[(\exists!\, \mathbf{x}_0 \in \mathbb{F}^n)\, A^*A\mathbf{x}_0 = A^*\mathbf{y}] \iff \mathrm{rank}(A) = n$.

Proof. Set $\mathcal{U} := \mathrm{col}(A)$.

(i) ($\Rightarrow$) Fix $\mathbf{x}_0 \in \mathrm{LS}(A,\mathbf{y})$. Then $A\mathbf{x}_0 = P_{\mathcal{U}}\mathbf{y}$ by Theorem 2.2.6.
The relation $\mathbf{y} - A\mathbf{x}_0 \in \mathcal{U}^\perp = \ker(A^*)$ holds by Proposition 2.2.3(v) and Corollary 2.3.12(iii). Hence $A^*A\mathbf{x}_0 = A^*\mathbf{y}$.
(i) ($\Leftarrow$) Suppose $A^*A\mathbf{x}_0 = A^*\mathbf{y}$. Then $\mathbf{y} - A\mathbf{x}_0 \in \ker(A^*) = \mathcal{U}^\perp$ by Corollary 2.3.12(iii).
Since $A\mathbf{x}_0 \in \mathcal{U}$, the identity $A\mathbf{x}_0 = P_{\mathcal{U}}\mathbf{y}$ holds by uniqueness in Theorem 2.1.5. Thus $\mathbf{x}_0 \in \mathrm{LS}(A,\mathbf{y})$ by Theorem 2.2.6.
(ii) The relation $P_{\mathcal{U}}\mathbf{y} \in \mathcal{U} = \mathrm{col}(A)$ holds by Proposition 2.2.3(iv). Choose $\mathbf{x}_0 \in \mathbb{F}^n$ with $A\mathbf{x}_0 = P_{\mathcal{U}}\mathbf{y}$; then $A^*A\mathbf{x}_0 = A^*\mathbf{y}$ by (i).
(iii) ($\Rightarrow$) Suppose the normal equations have the unique solution $\mathbf{x}_0$.
For $\mathbf{z} \in \ker(A)$, $A^*A(\mathbf{x}_0 + \mathbf{z}) = A^*A\mathbf{x}_0 = A^*\mathbf{y}$, so $\mathbf{z} = \mathbf{0}$ by uniqueness. Thus $\dim(\ker(A)) = 0$ and $\mathrm{rank}(A) = n$ by Corollary 3.3.1(i).
(iii) ($\Leftarrow$) Suppose $\mathrm{rank}(A) = n$. Existence holds by (ii), and $\ker(A) = \{\mathbf{0}\}$ by Corollary 3.3.1(i).
If $\mathbf{x}_0$ and $\mathbf{x}_1$ solve the normal equations, then $\mathbf{x}_0 - \mathbf{x}_1 \in \ker(A^*A) = \ker(A) = \{\mathbf{0}\}$ by Proposition 2.3.11(i).
Thus $\mathbf{x}_0 = \mathbf{x}_1$.

Structural Commentary: Projection converts optimality to residual orthogonality; kernel identities control existence and uniqueness.
Key Insight: The normal equations place the residual in $\ker(A^*) = \mathrm{col}(A)^\perp$. □

Figure 32 shows the fitted vector and its orthogonal residual in the codomain.

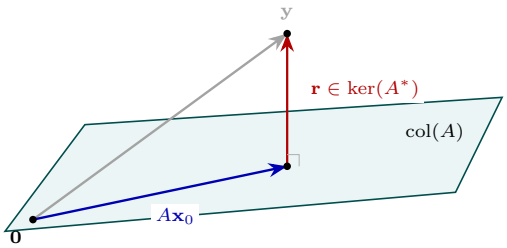

Figure 32: Fitted vector and residual: $A\mathbf{x}_0 = P_{\mathrm{col}(A)}\mathbf{y}$ and $\mathbf{y} - A\mathbf{x}_0 \in \mathrm{col}(A)^\perp = \ker(A^*)$.

Proposition 2.4.5. *Least-Squares Solution Set and Minimum Norm*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ *and* $\mathbf{y} \in \mathbb{F}^m$. *Fix* $\mathbf{x}_0 \in \mathrm{LS}(A,\mathbf{y})$ *and set* $\mathbf{s} := P_{(\ker(A))^\perp}\mathbf{x}_0$. *Then:*

(i) $\mathrm{LS}(A,\mathbf{y}) = \mathbf{x}_0 + \ker(A)$;
(ii) $\mathrm{LS}(A,\mathbf{y}) \cap (\ker(A))^\perp = \{\mathbf{s}\}$;
(iii) $\underset{\mathbf{x}\in\mathrm{LS}(A,\mathbf{y})}{\arg\min}\ \|\mathbf{x}\|_2 = \{\mathbf{s}\}$.

Proof.

(i) For $\mathbf{x} \in \mathbb{F}^n$, $\mathbf{x} \in \mathrm{LS}(A,\mathbf{y}) \iff A\mathbf{x} = P_{\mathrm{col}(A)}\mathbf{y}$ by Theorem 2.2.6.
The equality $A\mathbf{x}_0 = P_{\mathrm{col}(A)}\mathbf{y}$ holds by $\mathbf{x}_0 \in \mathrm{LS}(A,\mathbf{y})$ and Theorem 2.2.6.
Thus $\mathbf{x} \in \mathrm{LS}(A,\mathbf{y}) \iff A\mathbf{x} = A\mathbf{x}_0 \iff \mathbf{x} - \mathbf{x}_0 \in \ker(A)$, and hence $\mathrm{LS}(A,\mathbf{y}) = \mathbf{x}_0 + \ker(A)$.
(ii) The relation $\mathbf{s} \in (\ker(A))^\perp$ holds by Proposition 2.2.3(iv).
The identity $\mathbf{x}_0 - \mathbf{s} \in ((\ker(A))^\perp)^\perp = \ker(A)$ holds by Proposition 2.2.3(v) and Corollary 2.1.8. Hence $\mathbf{s} \in \mathrm{LS}(A,\mathbf{y})$ by (i).
If $\mathbf{u} \in \mathrm{LS}(A,\mathbf{y}) \cap (\ker(A))^\perp$, then $\mathbf{u} - \mathbf{s} \in \ker(A) \cap (\ker(A))^\perp = \{\mathbf{0}\}$ by (i) and Proposition 2.1.3(iv), so $\mathbf{u} = \mathbf{s}$.
(iii) Fix $\mathbf{x} \in \mathrm{LS}(A,\mathbf{y})$ and set $\mathbf{z} := \mathbf{x} - \mathbf{s} \in \ker(A)$ by (i)–(ii).
Then $\mathbf{s} \perp \mathbf{z}$, and $\|\mathbf{x}\|_2^2 = \|\mathbf{s}\|_2^2 + \|\mathbf{z}\|_2^2 \geq \|\mathbf{s}\|_2^2$ by Theorem 1.4.3, with equality iff $\mathbf{z} = \mathbf{0}$, equivalently $\mathbf{x} = \mathbf{s}$.

Structural Commentary: Kernel translation describes every minimizer; orthogonal decomposition isolates the shortest representative.
Key Insight: Norm excess is exactly the squared kernel-component norm. □

Corollary 2.4.6. *Projection Formula for Full Column Rank*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ *satisfy* $\mathrm{rank}(A) = n$. *Then:*

(i) A^*A *is invertible;*
(ii) $P_{\mathrm{col}(A)} = A(A^*A)^{-1}A^*$.

Proof.

(i) The identities $\ker(A^*A) = \ker(A) = \{\mathbf{0}\}$ hold by Proposition 2.3.11(i) and Corollary 3.3.1(i).
Hence A^*A is injective and therefore invertible by Theorem 1.7.7.
(ii) Fix $\mathbf{y} \in \mathbb{F}^m$ and set $\mathbf{x}_0 := (A^*A)^{-1}A^*\mathbf{y}$. Then $A^*A\mathbf{x}_0 = A^*\mathbf{y}$.
The relation $\mathbf{x}_0 \in \mathrm{LS}(A,\mathbf{y})$ holds by Theorem 2.4.4(i). Thus $P_{\mathrm{col}(A)}\mathbf{y} = A\mathbf{x}_0 = A(A^*A)^{-1}A^*\mathbf{y}$ by Theorem 2.2.6.
The operator identity follows by arbitrariness of $\mathbf{y}$.

Structural Commentary: Kernel equality makes A^*A invertible; normal-equation coordinates identify the projection operator.
Key Insight: Full column rank turns the normal equations into an explicit projector. □

Definition 2.4.7. *Minimum-Norm Solution*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ and $\mathbf{y} \in \mathrm{col}(A)$. A vector $\mathbf{s} \in \mathbb{F}^n$ is a *minimum-norm solution* of $A\mathbf{x} = \mathbf{y}$ if:

(i) $A\mathbf{s} = \mathbf{y}$;
(ii) $(\forall\, \mathbf{x} \in \mathbb{F}^n)\,[A\mathbf{x} = \mathbf{y} \implies \|\mathbf{s}\|_2 \leq \|\mathbf{x}\|_2]$.

Theorem 2.4.8. *Minimum-Norm Solution of a Consistent Linear System*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$, let $\mathbf{y} \in \mathbb{F}^m$, and suppose $A\mathbf{x} = \mathbf{y}$ is consistent. Then:

(i) $(\exists!\, \mathbf{s} \in \mathbb{F}^n)\,[A\mathbf{s} = \mathbf{y} \wedge (\forall\, \mathbf{x} \in \mathbb{F}^n)\,(A\mathbf{x} = \mathbf{y} \Longrightarrow \|\mathbf{s}\|_2 \leq \|\mathbf{x}\|_2)]$;
(ii) for the vector $\mathbf{s}$ *in (i),* $\{\mathbf{x} \in \mathrm{col}(A^*) : A\mathbf{x} = \mathbf{y}\} = \{\mathbf{s}\}$;
(iii) $(\exists\, \mathbf{u} \in \mathbb{F}^m)\, AA^*\mathbf{u} = \mathbf{y}$;
(iv) for the vector $\mathbf{s}$ *in (i),* $(\forall\, \mathbf{u}_0 \in \mathbb{F}^m)\,[AA^*\mathbf{u}_0 = \mathbf{y} \Longrightarrow \mathbf{s} = A^*\mathbf{u}_0]$.

Proof. The identity $(\mathrm{col}(A^*), \ker(A)) = ((\ker(A))^\perp, (\mathrm{col}(A^*))^\perp)$ holds by Corollary 2.3.12(ii),(i).
Hence $\mathbb{F}^n = \mathrm{col}(A^*) \odot \ker(A)$ by Theorem 2.1.5.

(i) Choose $\mathbf{x}_0 \in \mathbb{F}^n$ with $A\mathbf{x}_0 = \mathbf{y}$ by consistency.
Write $\mathbf{x}_0 = \mathbf{s} + \mathbf{v}$ with $\mathbf{s} \in \mathrm{col}(A^*)$ and $\mathbf{v} \in \ker(A)$ by the established orthogonal direct sum. Then $A\mathbf{s} = \mathbf{y}$.
For $\mathbf{x} \in \mathbb{F}^n$ with $A\mathbf{x} = \mathbf{y}$, set $\mathbf{w} := \mathbf{x} - \mathbf{s}$. Then $A\mathbf{w} = A\mathbf{x} - A\mathbf{s} = \mathbf{0}$, so $\mathbf{w} \in \ker(A)$.
Since $\mathbf{s} \perp \mathbf{w}$, $\|\mathbf{x}\|_2^2 = \|\mathbf{s}\|_2^2 + \|\mathbf{w}\|_2^2 \geq \|\mathbf{s}\|_2^2$ by Theorem 1.4.3.
Equality holds iff $\mathbf{w} = \mathbf{0}$, equivalently $\mathbf{x} = \mathbf{s}$; hence $\mathbf{s}$ is the unique minimum-norm solution.
(ii) The vector $\mathbf{s}$ from (i) is a solution in $\mathrm{col}(A^*)$.
For any solution $\mathbf{s}' \in \mathrm{col}(A^*)$, $\mathbf{s}' - \mathbf{s} \in \ker(A) \cap \mathrm{col}(A^*) = \{\mathbf{0}\}$ by the established direct sum, so $\mathbf{s}' = \mathbf{s}$.
(iii) Choose $\mathbf{u} \in \mathbb{F}^m$ with $\mathbf{s} = A^*\mathbf{u}$ by $\mathbf{s} \in \mathrm{col}(A^*)$. Then $AA^*\mathbf{u} = A\mathbf{s} = \mathbf{y}$.
(iv) If $AA^*\mathbf{u}_0 = \mathbf{y}$, then $A^*\mathbf{u}_0$ is a solution in $\mathrm{col}(A^*)$, so $A^*\mathbf{u}_0 = \mathbf{s}$ by (ii).

Structural Commentary: Orthogonal splitting removes the kernel component; the adjoint range supplies the AA^* representation.
Key Insight: $\mathrm{col}(A^*) = (\ker(A))^\perp$ contains the unique shortest feasible vector. □

Figure 33 depicts the orthogonal intersection of the solution set with $\mathrm{col}(A^*)$.

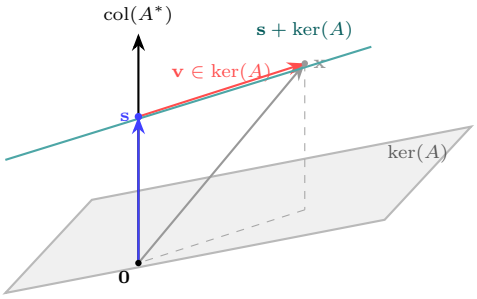

Figure 33: The solution set $\mathbf{s} + \ker(A)$ meets $\mathrm{col}(A^*) = (\ker(A))^\perp$ at its unique minimum-norm point $\mathbf{s}$.

Perspective 2.4.9. *Roadmap to the Pseudoinverse*
Theorem 2.4.4 identifies the fitted vector with the projection of $\mathbf{y}$ onto $\mathrm{col}(A)$.
Proposition 2.4.5 selects its minimum-norm preimage in $(\ker(A))^\perp = \mathrm{col}(A^*)$ by Theorem 2.4.8.
Later, Definition 5.2.4 and Theorem 5.2.9 package both choices as $A^\dagger\mathbf{y}$.

2.5 Self-Adjoint Operators and Orthogonal Projections

Throughout this subsection, $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$.

Definition 2.5.1. *Self-Adjoint and Hermitian*

(i) Let $\mathcal{V}$ be a finite-dimensional inner-product space over $\mathbb{F}$. An operator $T \in \mathcal{L}(\mathcal{V})$ is *self-adjoint* if $T^* = T$.
(ii) For $n \geq 1$, a matrix $A \in \mathrm{Mat}(n,n,\mathbb{F})$ is *Hermitian* if $A^* = A$.

These conditions agree in orthonormal coordinates by Theorem 2.3.7.

Lemma 2.5.2. *Vanishing Complex Diagonal Values*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space and let $T \in \mathcal{L}(\mathcal{V})$. If $(\forall\, \mathbf{v} \in \mathcal{V})\ \langle T\mathbf{v}, \mathbf{v}\rangle = 0$, then $T = 0$.

Proof. Define $Q : \mathcal{V} \to \mathbb{C}$ by $Q(\mathbf{x}) := \langle T\mathbf{x}, \mathbf{x}\rangle$.
For $(\mathbf{u}, \mathbf{w}) \in \mathcal{V} \times \mathcal{V}$, $4\langle T\mathbf{u}, \mathbf{w}\rangle = Q(\mathbf{u}+\mathbf{w}) - Q(\mathbf{u}-\mathbf{w}) + iQ(\mathbf{u}+i\mathbf{w}) - iQ(\mathbf{u}-i\mathbf{w})$ by direct expansion.
Thus $(\forall (\mathbf{u}, \mathbf{w}) \in \mathcal{V} \times \mathcal{V})\ \langle T\mathbf{u}, \mathbf{w}\rangle = 0$ by the hypothesis. Taking $\mathbf{w} = T\mathbf{u}$, $(\forall\, \mathbf{u} \in \mathcal{V})\ \|T\mathbf{u}\|^2 = 0$; hence $T = 0$ by positive definiteness.
Structural Commentary: Complex polarization recovers every mixed value from the vanishing diagonal map Q.
Key Insight: Diagonal vanishing forces the entire sesquilinear form to vanish. □

Proposition 2.5.3. *Self-Adjointness from Real Diagonal Values*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space and let $T \in \mathcal{L}(\mathcal{V})$. Then $T = T^* \iff (\forall\, \mathbf{v} \in \mathcal{V})\ \langle T\mathbf{v}, \mathbf{v}\rangle \in \mathbb{R}$.

Proof.
($\Rightarrow$) Suppose $T = T^*$ and fix $\mathbf{v} \in \mathcal{V}$.
Then $\langle T\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \overline{\langle T\mathbf{v}, \mathbf{v}\rangle}$ by the adjoint identity and conjugate symmetry; hence $\langle T\mathbf{v}, \mathbf{v}\rangle \in \mathbb{R}$.
($\Leftarrow$) Suppose $(\forall\, \mathbf{v} \in \mathcal{V})\ \langle T\mathbf{v}, \mathbf{v}\rangle \in \mathbb{R}$ and set $S := T - T^*$. Then $(\forall\, \mathbf{v} \in \mathcal{V})\ \langle S\mathbf{v}, \mathbf{v}\rangle = \langle T\mathbf{v}, \mathbf{v}\rangle - \overline{\langle T\mathbf{v}, \mathbf{v}\rangle} = 0$.
Thus $S = 0$ by Lemma 2.5.2, and $T = T^*$ by the definition of S.
Structural Commentary: Adjoint symmetry proves reality; complex polarization annihilates the skew-adjoint part $T - T^*$.
Key Insight: Real diagonal values force the skew-adjoint part to vanish. □

Proposition 2.5.4. *Vanishing Diagonal Values for Self-Adjoint Operators*
Let $\mathcal{V}$ be a finite-dimensional inner-product space over $\mathbb{F}$ and let $T \in \mathcal{L}(\mathcal{V})$ satisfy $T^* = T$. If $(\forall\, \mathbf{v} \in \mathcal{V})\ \langle T\mathbf{v}, \mathbf{v}\rangle = 0$, then $T = 0$.

Proof. If $\mathbb{F} = \mathbb{C}$, then $T = 0$ by Lemma 2.5.2. Suppose $\mathbb{F} = \mathbb{R}$.
For $(\mathbf{u}, \mathbf{w}) \in \mathcal{V} \times \mathcal{V}$, $\langle T\mathbf{w}, \mathbf{u}\rangle = \langle \mathbf{w}, T\mathbf{u}\rangle = \langle T\mathbf{u}, \mathbf{w}\rangle$ by self-adjointness and symmetry.
Hence $4\langle T\mathbf{u}, \mathbf{w}\rangle = \langle T(\mathbf{u}+\mathbf{w}), \mathbf{u}+\mathbf{w}\rangle - \langle T(\mathbf{u}-\mathbf{w}), \mathbf{u}-\mathbf{w}\rangle = 0$ by direct expansion and the hypothesis.
Taking $\mathbf{w} = T\mathbf{u}$, $(\forall\, \mathbf{u} \in \mathcal{V})\ \|T\mathbf{u}\|^2 = 0$; hence $T = 0$ by positive definiteness.
Structural Commentary: Complex polarization handles $\mathbb{C}$; self-adjoint symmetry enables the real polarization identity.
Key Insight: Self-adjoint symmetry makes diagonal values determine every mixed value. □

Definition 2.5.5. *Orthogonal Projection Matrix*
For $n \geq 1$, a matrix $P \in \mathrm{Mat}(n, n, \mathbb{F})$ is an *orthogonal projection matrix* if $P^2 = P$ and $P^* = P$.

Theorem 2.5.6. *Orthogonal Projections as Self-Adjoint Idempotents*
Let $\mathcal{V}$ be a finite-dimensional inner-product space and let $P \in \mathcal{L}(\mathcal{V})$. Then $P = P_{\mathrm{range}(P)} \iff [P^2 = P \wedge P^* = P]$.

Proof.
($\Rightarrow$) Set $\mathcal{U} := \mathrm{range}(P)$ and suppose $P = P_{\mathcal{U}}$. Then $P^2 = P$ by Proposition 2.2.3(vii).
The identity $P = \rho_{\mathcal{U},\mathcal{U}^\perp}$ holds by the definitions of orthogonal and algebraic projection.
The identity $P^* = \rho_{(\mathcal{U}^\perp)^\perp,\mathcal{U}^\perp}$ holds by Proposition 2.3.11(iii). Thus $P^* = \rho_{\mathcal{U},\mathcal{U}^\perp} = P$ by Corollary 2.1.8 and the preceding identity.
($\Leftarrow$) Set $\mathcal{U} := \mathrm{range}(P)$ and suppose $P^2 = P$ and $P^* = P$. Then $\mathcal{V} = \mathcal{U} \oplus \ker(P)$ and $P = \rho_{\mathcal{U},\ker(P)}$ by Proposition 2.4.2(i).
The identity $\ker(P) = \ker(P^*) = \mathcal{U}^\perp$ holds by $P^* = P$ and Proposition 2.3.10(i).
Therefore $P = \rho_{\mathcal{U},\mathcal{U}^\perp} = P_{\mathcal{U}}$ by the definitions of algebraic and orthogonal projection.

Structural Commentary: Idempotence supplies the range–kernel split; self-adjointness identifies $\ker(P)$ with $\mathcal{U}^\perp$.
Key Insight: For idempotent P, orthogonality is exactly $\ker(P) = (\mathrm{range}(P))^\perp$. □

2.6 Isometries and Unitary Matrices

Throughout this subsection, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.

Definition 2.6.1. *Isometry and Isometric Isomorphism*
Let $\mathcal{V}$ and $\mathcal{W}$ be inner-product spaces and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$.
(i) T is an *isometry* if $(\forall\, \mathbf{v} \in \mathcal{V})\ \|T\mathbf{v}\| = \|\mathbf{v}\|$.
(ii) T is an *isometric isomorphism* if it is a bijective isometry. Spaces $\mathcal{V}$ and $\mathcal{W}$ are *isometrically isomorphic* if such a map T exists.

Proposition 2.6.2. *Basic Properties of Isometries*
Let $\mathcal{V}$ be an inner-product space and let $S, T \in \mathcal{L}(\mathcal{V})$ be isometries.
(i) ST is an isometry;
(ii) T is injective;
(iii) if $\mathcal{V}$ is finite-dimensional, then T is invertible;
(iv) if $\mathcal{V}$ is finite-dimensional, then T^{-1} is an isometry.

Proof.
(i) $(\forall\, \mathbf{v} \in \mathcal{V})\ \|ST\mathbf{v}\| = \|T\mathbf{v}\| = \|\mathbf{v}\|$.
(ii) If $\mathbf{v} \in \ker(T)$, then $\|\mathbf{v}\| = \|T\mathbf{v}\| = 0$, so $\mathbf{v} = \mathbf{0}$ by positive definiteness. Hence $\ker(T) = \{\mathbf{0}\}$, and T is injective.
(iii) T is invertible by (ii) and Theorem 1.7.7.
(iv) Suppose $\dim(\mathcal{V}) < \infty$. Then T^{-1} exists by (iii). $(\forall\, \mathbf{u} \in \mathcal{V})\ \left\|T^{-1}\mathbf{u}\right\| = \left\|TT^{-1}\mathbf{u}\right\| = \|\mathbf{u}\|$.
Structural Commentary: Norm identities establish closure and injectivity before finite-dimensional invertibility controls the inverse.
Key Insight: Length preservation forces the kernel to vanish. □

Counterexample 2.6.3. *An Isometry Need Not Be Onto*
Define $T : \ell^2(\mathbb{F}) \to \ell^2(\mathbb{F})$ by $T(x_1, x_2, \ldots) = (0, x_1, x_2, \ldots)$. The map T is linear by coordinatewise operations.
For $\mathbf{x} = (x_j)_{j\geq 1}$, $\|T\mathbf{x}\|_2^2 = \sum_{j=1}^{\infty} |x_j|^2 = \|\mathbf{x}\|_2^2$, so T is an isometry.
Every vector in $\mathrm{range}(T)$ has first coordinate 0, whereas $(1, 0, 0, \ldots) \notin \mathrm{range}(T)$.
Thus T is not surjective, so an infinite-dimensional isometry need not be an isomorphism.

Theorem 2.6.4. *Isometries Preserve Inner Products*
Let $\mathcal{V}$ and $\mathcal{W}$ be inner-product spaces and let $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$. Then $(\forall\, \mathbf{x} \in \mathcal{V})\ \|T\mathbf{x}\| = \|\mathbf{x}\| \iff (\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})\ \langle T\mathbf{u}, T\mathbf{v}\rangle_{\mathcal{W}} = \langle \mathbf{u}, \mathbf{v}\rangle_{\mathcal{V}}$.

Proof.
($\Rightarrow$) Suppose T preserves norms and fix $\mathbf{u}, \mathbf{v} \in \mathcal{V}$.
By linearity and norm preservation, the polarization formulas for $(T\mathbf{u}, T\mathbf{v})$ and $(\mathbf{u}, \mathbf{v})$ have equal norm terms.
Thus $\langle T\mathbf{u}, T\mathbf{v}\rangle_{\mathcal{W}} = \langle \mathbf{u}, \mathbf{v}\rangle_{\mathcal{V}}$ by Theorem 1.1.23.
($\Leftarrow$) If T preserves inner products, then $(\forall\, \mathbf{u} \in \mathcal{V})\ \|T\mathbf{u}\|^2 = \langle T\mathbf{u}, T\mathbf{u}\rangle_{\mathcal{W}} = \langle \mathbf{u}, \mathbf{u}\rangle_{\mathcal{V}} = \|\mathbf{u}\|^2$.
Thus T preserves norms by nonnegativity.
Structural Commentary: Polarization transfers the norm identity to mixed inner products; diagonal evaluation reverses the transfer.
Key Insight: A norm determines its inducing inner product. □

Remark 2.6.5. *Isometry Conventions*
For linear maps, norm and inner-product preservation are equivalent by Theorem 2.6.4.
Thus either convention defines the same isometries.
For possibly degenerate bilinear forms, form preservation need not imply injectivity.
An isometry is therefore often required to be bijective and form-preserving.

Theorem 2.6.6. *Isometries and the Adjoint Product*
Let $\mathcal{V}$ be a finite-dimensional inner-product space and let $T \in \mathcal{L}(\mathcal{V})$. Then $(\forall\, \mathbf{v} \in \mathcal{V})\ \|T\mathbf{v}\| = \|\mathbf{v}\| \iff T^*T = I_{\mathcal{V}}$.

Proof.

($\Rightarrow$) Suppose T preserves norms and set $A := T^*T - I_{\mathcal{V}}$. Then $(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})\ \langle \mathbf{u}, A\mathbf{v}\rangle = 0$ by adjointness and Theorem 2.6.4.
Taking $\mathbf{u} = A\mathbf{v}$, $(\forall\, \mathbf{v} \in \mathcal{V})\ \|A\mathbf{v}\|^2 = 0$. Hence $A = 0$ by positive definiteness, so $T^*T = I_{\mathcal{V}}$.
($\Leftarrow$) If $T^*T = I_{\mathcal{V}}$, then $(\forall\, \mathbf{u} \in \mathcal{V})\ \|T\mathbf{u}\|^2 = \langle T\mathbf{u}, T\mathbf{u}\rangle = \langle \mathbf{u}, T^*T\mathbf{u}\rangle = \|\mathbf{u}\|^2$ by the adjoint relation.
Thus T preserves norms by nonnegativity.

Structural Commentary: Adjointness converts preserved inner products into the vanishing of $T^*T - I_{\mathcal{V}}$.
Key Insight: The Gram operator of an isometry is the identity. □

Definition 2.6.7. *Unitary and Orthogonal*

(i) Let $\mathcal{V}$ be a finite-dimensional inner-product space. An operator $U \in \mathcal{L}(\mathcal{V})$ is *unitary* if $U^*U = UU^* = I_{\mathcal{V}}$.
(ii) Let $n \geq 1$. A matrix $U \in \mathrm{Mat}(n, n, \mathbb{F})$ is *unitary* if $U^*U = I_n$. If $\mathbb{F} = \mathbb{R}$, a unitary matrix is *orthogonal*.

Theorem 2.6.8. *Equivalent Conditions for a Unitary Matrix*
Let $n \geq 1$ and let $U = [\mathbf{u}_1\ \cdots\ \mathbf{u}_n] \in \mathrm{Mat}(n, n, \mathbb{F})$. The following conditions are equivalent:

(i) $U^*U = I_n$;
(ii) *the columns* $\mathbf{u}_1, \ldots, \mathbf{u}_n$ *are orthonormal in* $\mathbb{F}^n$;
(iii) $UU^* = I_n$;
(iv) U^* *is unitary;*
(v) *the rows of* U *are orthonormal;*
(vi) U *is invertible and* $U^{-1} = U^*$;
(vii) $(\forall\, \mathbf{x} \in \mathbb{F}^n)\ \|U\mathbf{x}\|_2 = \|\mathbf{x}\|_2$;
(viii) $(\forall\, \mathbf{x}, \mathbf{y} \in \mathbb{F}^n)\ \langle U\mathbf{x}, U\mathbf{y}\rangle_{\mathbb{F}^n} = \langle \mathbf{x}, \mathbf{y}\rangle_{\mathbb{F}^n}$.

Proof.

(i) $\Rightarrow$ *(ii)* For $i, j \in J_n$, $(U^*U)_{ij} = \mathbf{u}_i^*\mathbf{u}_j = \langle \mathbf{u}_j, \mathbf{u}_i\rangle_{\mathbb{F}^n}$. Hence $U^*U = I_n$ if and only if the columns are orthonormal.
(ii) $\Rightarrow$ *(iii)* Column orthonormality implies $U^*U = I_n$, so $UU^* = I_n$ by Theorem 3.4.2.
(iii) $\Rightarrow$ *(iv)* The identity $(U^*)^*U^* = UU^* = I_n$ holds by conjugate-transpose involution, so U^* is unitary.
(iv) $\Rightarrow$ *(v)* Unitarity of U^* implies $UU^* = I_n$.
Let $\mathbf{r}_i$ denote row i of U. Then $(\forall\, i, j \in J_n)\ (UU^*)_{ij} = \langle \mathbf{r}_i, \mathbf{r}_j\rangle_{\mathbb{F}^n}$, so the rows are orthonormal.
(v) $\Rightarrow$ *(vi)* Row orthonormality implies $UU^* = I_n$. Thus U is invertible and $U^{-1} = U^*$ by Theorem 3.4.2.
(vi) $\Rightarrow$ *(vii)* The identity $U^*U = I_n$ holds by $U^{-1} = U^*$.
Hence $(\forall\, \mathbf{x} \in \mathbb{F}^n)\ \|U\mathbf{x}\|_2^2 = \langle \mathbf{x}, U^*U\mathbf{x}\rangle_{\mathbb{F}^n} = \|\mathbf{x}\|_2^2$ by the conjugate-transpose adjoint relation.
Thus U preserves norms by nonnegativity.
(vii) $\Rightarrow$ *(viii)* The map $\mathbf{x} \mapsto U\mathbf{x}$ preserves inner products by Theorem 2.6.4.
(viii) $\Rightarrow$ *(i)* Set $A := U^*U - I_n$. Then $(\forall\, \mathbf{x}, \mathbf{y} \in \mathbb{F}^n)\ \langle \mathbf{x}, A\mathbf{y}\rangle_{\mathbb{F}^n} = 0$ by the conjugate-transpose adjoint relation and (viii).
Taking $\mathbf{x} = A\mathbf{y}$, $(\forall\, \mathbf{y} \in \mathbb{F}^n)\ \|A\mathbf{y}\|_2^2 = 0$. Hence $A = 0$ by positive definiteness, so $U^*U = I_n$.

Structural Commentary: The implication cycle connects column and row Gram identities through inverse and invariance relations.
Key Insight: Both Gram products encode orthonormal coordinate frames. □

Figure 34 depicts the geometric invariance in Theorem 2.6.8.

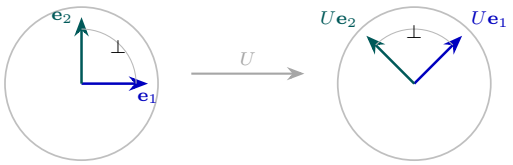

Figure 34: A unitary map preserves the lengths and right angle of an orthonormal pair.

Definition 2.6.9. *Unitary and Permutation Similarity*
Let $n \geq 1$ and let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) The matrices A and B are *unitarily similar* if $A = UBU^*$ for a unitary $U \in \mathrm{Mat}(n, n, \mathbb{F})$.
(ii) They are *orthogonally similar* if $\mathbb{F} = \mathbb{R}$ and $A = UBU^*$ for an orthogonal $U \in \mathrm{Mat}(n, n, \mathbb{R})$.
(iii) A matrix $P = [p_{ij}] \in \mathrm{Mat}(n, n, \mathbb{R})$ is a *permutation matrix* if $(\forall\, i, j \in J_n)\ p_{ij} \in \{0, 1\}$ and $(\forall\, i \in J_n)\ \sum_{j=1}^{n} p_{ij} = \sum_{j=1}^{n} p_{ji} = 1$.
(iv) The matrices A and B are *permutation similar* if $A = PBP^*$ for a permutation matrix P.

Proposition 2.6.10. *Permutation Matrices Are Orthogonal*
Let $n \geq 1$, let $\sigma \in \mathfrak{S}_n$, and set $P := [\mathbf{e}_{\sigma(1)}\ \cdots\ \mathbf{e}_{\sigma(n)}] \in \mathrm{Mat}(n, n, \mathbb{R})$. Then $P^*P = PP^* = I_n$, so P is orthogonal.

Proof. The columns of P are a permutation of the standard orthonormal basis of $\mathbb{R}^n$.
Hence $P^*P = PP^* = I_n$ by Theorem 2.6.8(ii)–(iii). Therefore P is orthogonal by the real-field definition.
Structural Commentary: Standard-basis permutation converts column orthonormality directly into both Gram identities.
Key Insight: Reordering an orthonormal basis preserves its Gram matrix. □

Theorem 2.6.11. *Unitary Coordinate Form of an Orthogonal Projection*
Let $n \geq 1$, let $P \in \mathrm{Mat}(n, n, \mathbb{F})$ be an orthogonal projection matrix, and set $r := \mathrm{rank}(P)$.
Then $(\exists\, U \in \mathrm{Mat}(n, n, \mathbb{F}))\ [U^*U = I_n \wedge U^*PU = I_r \oplus 0_{n-r}]$. Equivalently, P is unitarily similar to $I_r \oplus 0_{n-r}$.

Proof.

(i) *Projection Operator*: Define $T_P : \mathbb{F}^n \to \mathbb{F}^n$ $T_P\mathbf{x} := P\mathbf{x}$.
Set $\mathcal{U} := \mathrm{range}(T_P) = \mathrm{col}(P)$. Then $T_P^2 = T_P = T_P^*$ by $P^2 = P = P^*$ and Theorem 2.3.7.
Hence $T_P = P_{\mathcal{U}}$ by Theorem 2.5.6. Therefore $(T_P|_{\mathcal{U}}, T_P|_{\mathcal{U}^\perp}) = (I_{\mathcal{U}}, 0)$ by Proposition 2.2.3(ii)–(iii).

(ii) *Adapted Basis*: Choose an orthonormal basis $(\mathbf{u}_1, \dots, \mathbf{u}_r)$ of $\mathcal{U}$ by Corollary 1.3.11.
Extend it to an orthonormal basis $(\mathbf{u}_1, \dots, \mathbf{u}_n)$ of $\mathbb{F}^n$ by Corollary 1.3.12.
Set $U := [\mathbf{u}_1 \ \cdots \ \mathbf{u}_n]$. Then $U^*U = I_n$ by Theorem 2.6.8(i)–(ii).
(iii) *Block Form*: If $j \in J_r$, then $U^*PU\mathbf{e}_j = U^*P\mathbf{u}_j = U^*\mathbf{u}_j = \mathbf{e}_j$. If $j \in J_n \setminus J_r$, then $U^*PU\mathbf{e}_j = \mathbf{0}$.
Thus $U^*PU = I_r \oplus 0_{n-r}$ by equality on the standard basis.
(iv) *Similarity*: The identity $UU^* = I_n$ holds by Theorem 2.6.8(i),(iii).
Multiplication by U on the left and U^* on the right establishes $P = U(I_r \oplus 0_{n-r})U^*$.

Structural Commentary: The induced projection supplies an adapted orthonormal basis whose matrix action is block diagonal.
Key Insight: Projection is coordinate truncation in range–kernel coordinates. □

Figure 35 depicts the range–kernel coordinates in Theorem 2.6.11.

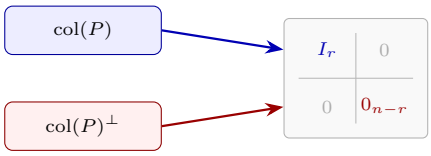

Figure 35: Unitary coordinates make an orthogonal projection the identity on $\mathrm{col}(P)$ and zero on $\mathrm{col}(P)^\perp$.

Proposition 2.6.12. *Algebra of Unitary Matrices*
Let $m, n \geq 1$, let $U, V \in \mathrm{Mat}(n, n, \mathbb{F})$, and let $W \in \mathrm{Mat}(m, m, \mathbb{F})$. Let $V \oplus W$ denote the block diagonal matrix with blocks V and W.
(i) $[U^*U = I_n \wedge V^*V = I_n] \implies (UV)^*(UV) = I_n$;
(ii) $[(V \oplus W)^*(V \oplus W) = I_{n+m}] \iff [V^*V = I_n \wedge W^*W = I_m]$.

Proof.
(i) The identity $(UV)^*(UV) = V^*U^*UV = V^*V = I_n$ holds by the hypotheses.
(ii) ($\Rightarrow$) If $(V \oplus W)^*(V \oplus W) = I_{n+m}$, then $V^*V \oplus W^*W = I_n \oplus I_m$.
Hence $V^*V = I_n$ and $W^*W = I_m$ by equality of the diagonal blocks.
(ii) ($\Leftarrow$) If $V^*V = I_n$ and $W^*W = I_m$, then $(V \oplus W)^*(V \oplus W) = I_n \oplus I_m = I_{n+m}$.

Structural Commentary: Product reversal proves closure under multiplication; blockwise adjoints reduce direct sums componentwise.
Key Insight: Unitary identities multiply and split blockwise. □

Theorem 2.6.13. *Extending Isometric Columns to a Unitary Matrix*
Let $m, n \geq 1$ and let $X \in \mathrm{Mat}(m, n, \mathbb{F})$ satisfy $X^*X = I_n$. Then:
(i) $n \leq m$;
(ii) $(\exists\, X' \in \mathrm{Mat}(m, m-n, \mathbb{F}))\, [X \ X']^*[X \ X'] = I_m$.

Proof. Write $X = [\mathbf{x}_1 \ \cdots \ \mathbf{x}_n]$. For $i, j \in J_n$, $(X^*X)_{ij} = \langle \mathbf{x}_j, \mathbf{x}_i \rangle_{\mathbb{F}^m} = \delta_{ij}$ by hypothesis. Hence $(\mathbf{x}_1, \dots, \mathbf{x}_n)$ is orthonormal in $\mathbb{F}^m$.
(i) The list is linearly independent by Corollary 1.3.3, so $n \leq m$ by Theorem 1.3.11.
(ii) Extend the list to an orthonormal basis $(\mathbf{x}_1, \dots, \mathbf{x}_m)$ of $\mathbb{F}^m$ by Corollary 1.3.12.
Set $X' := [\mathbf{x}_{n+1} \ \cdots \ \mathbf{x}_m]$. Then $[X \ X']^*[X \ X'] = I_m$ by Theorem 2.6.8(i)–(ii).

Structural Commentary: The Gram identity turns the columns into an orthonormal list, then basis extension completes it.
Key Insight: A partial orthonormal frame extends to a unitary frame. □

2.7 Householder Reflections

Throughout this subsection, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.

Definition 2.7.1. *Householder Matrix*
Let $n \geq 1$ and $\mathbf{w} \in \mathbb{F}^n \setminus \{\mathbf{0}\}$, and set $\mathbf{u} := \frac{\mathbf{w}}{\|\mathbf{w}\|_2}$. The *Householder matrix* associated with $\mathbf{w}$ is $U_{\mathbf{w}} := I_n - 2P_{\mathbf{u}} = I_n - 2\frac{\mathbf{w}\mathbf{w}^*}{\|\mathbf{w}\|_2^2}$.
Equivalently, $(\forall\, \mathbf{x} \in \mathbb{F}^n)\, U_{\mathbf{w}}\mathbf{x} = \mathbf{x} - 2\langle \mathbf{x}, \mathbf{u} \rangle_{\mathbb{F}^n} \mathbf{u}$.

Theorem 2.7.2. *Householder Matrices Are Unitary Reflections*
Let $n \geq 1$ and let $\mathbf{w} \in \mathbb{F}^n \setminus \{\mathbf{0}\}$. Then:
(i) $U_{\mathbf{w}}^* = U_{\mathbf{w}}$;
(ii) $U_{\mathbf{w}}^2 = I_n$;
(iii) $U_{\mathbf{w}}^* U_{\mathbf{w}} = I_n$, *so $U_{\mathbf{w}}$ is unitary;*
(iv) $(\forall\, \mathbf{x} \in \mathbf{w}^\perp)\, U_{\mathbf{w}}\mathbf{x} = \mathbf{x}$;
(v) $(\forall\, \mathbf{x} \in \mathrm{span}(\mathbf{w}))\, U_{\mathbf{w}}\mathbf{x} = -\mathbf{x}$;
(vi) $\mathbf{w} \in \mathbb{R}^n \implies U_{\mathbf{w}}$ *is symmetric and orthogonal over $\mathbb{R}$.*

Proof. Set $\mathbf{u} := \frac{\mathbf{w}}{\|\mathbf{w}\|_2}$ and $P := P_{\mathbf{u}}$.
(i) The identity $P^* = P$ holds by Proposition 2.2.5(iii). Hence $U_{\mathbf{w}}^* = I_n - 2P = U_{\mathbf{w}}$.
(ii) The identity $P^2 = P$ holds by Proposition 2.2.5(iv). Hence $U_{\mathbf{w}}^2 = (I_n - 2P)^2 = I_n - 4P + 4P^2 = I_n$.
(iii) The identity $U_{\mathbf{w}}^* U_{\mathbf{w}} = U_{\mathbf{w}}^2 = I_n$ holds by (i)–(ii), so $U_{\mathbf{w}}$ is unitary.
(iv) Fix $\mathbf{x} \in \mathbf{w}^\perp = \mathrm{span}(\mathbf{u})^\perp$. Then $P\mathbf{x} = \mathbf{0}$ by Proposition 2.2.5(ii), so $U_{\mathbf{w}}\mathbf{x} = \mathbf{x}$.
(v) Fix $\mathbf{x} \in \mathrm{span}(\mathbf{w}) = \mathrm{span}(\mathbf{u})$, and choose $a \in \mathbb{F}$ with $\mathbf{x} = a\mathbf{u}$. Then $P\mathbf{x} = \langle a\mathbf{u}, \mathbf{u} \rangle\, \mathbf{u} = a\mathbf{u} = \mathbf{x}$ by $\|\mathbf{u}\|_2 = 1$, so $U_{\mathbf{w}}\mathbf{x} = -\mathbf{x}$.
(vi) Suppose $\mathbf{w} \in \mathbb{R}^n$. Then $\mathbf{u}$, P, and $U_{\mathbf{w}}$ have real entries.
The identities $U_{\mathbf{w}}^t = U_{\mathbf{w}}$ and $U_{\mathbf{w}}^t U_{\mathbf{w}} = I_n$ hold by (i) and (iii), respectively.

Structural Commentary: Self-adjoint idempotence proves unitarity; the range–kernel split identifies the two eigenspaces.
Key Insight: $I_n - 2P_{\mathbf{u}}$ fixes $\ker(P_{\mathbf{u}})$ and negates $\mathrm{range}(P_{\mathbf{u}})$. □

Figure 36 illustrates the two eigenspace actions in Theorem 2.7.2(iv)–(v).

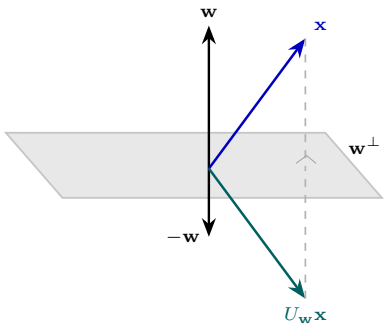

Figure 36: Householder reflection: $U_{\mathbf{w}}$ preserves the $\mathbf{w}^{\perp}$ component of $\mathbf{x}$ and negates its span($\mathbf{w}$) component.

Theorem 2.7.3. *Householder Map Between Equal-Norm Vectors*
Let $n \geq 1$ and let $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$ satisfy $\|\mathbf{x}\|_2 = \|\mathbf{y}\|_2 \neq 0$. Set $z := \langle \mathbf{x}, \mathbf{y} \rangle_{\mathbb{F}^n}$.
Choose $\sigma \in \mathbb{F}$ with $\sigma = 1$ for $z = 0$ and $\sigma = -\frac{\overline{z}}{|z|}$ for $z \neq 0$. Set $\mathbf{w} := \mathbf{y} - \sigma\mathbf{x}$. Then:

(i) $|\sigma| = 1$;
(ii) $\mathbf{w} \neq \mathbf{0}$;
(iii) $\sigma U_{\mathbf{w}} \mathbf{x} = \mathbf{y}$.

Proof. Set $r := \|\mathbf{x}\|_2 = \|\mathbf{y}\|_2$.
(i) The identity $|\sigma| = 1$ holds by the two defining cases.
(ii) The identity $\sigma z = -|z|$ holds by the two defining cases.
Thus $\|\mathbf{w}\|_2^2 = 2r^2 - 2\operatorname{Re}(\sigma z) = 2(r^2 + |z|) > 0$ by (i) and conjugate symmetry. Hence $\mathbf{w} \neq \mathbf{0}$ by positive definiteness.
(iii) By $\mathbf{y} = \mathbf{w} + \sigma\mathbf{x}$ and Definition 2.7.1, $\sigma U_{\mathbf{w}} \mathbf{x} = \mathbf{y} - \mathbf{w} - 2\sigma \frac{\langle \mathbf{x}, \mathbf{w} \rangle}{\|\mathbf{w}\|_2^2} \mathbf{w}$.
The identity $2\sigma \langle \mathbf{x}, \mathbf{w} \rangle = 2\sigma z - 2r^2 = -\|\mathbf{w}\|_2^2$ holds by the definition of $\mathbf{w}$ and (i)–(ii). Therefore $\sigma U_{\mathbf{w}} \mathbf{x} = \mathbf{y}$.
Structural Commentary: The phase makes σz nonpositive real; the norm identity then cancels the reflected component.
Key Insight: $2\sigma \langle \mathbf{x}, \mathbf{w} \rangle = -\|\mathbf{w}\|_2^2$ annihilates the residual $\mathbf{w}$-coefficient. □

Corollary 2.7.4. *Householder Unitary Annihilator*
Let $n \geq 1$ and $\mathbf{x} = [x_1 \ \cdots \ x_n]^t \in \mathbb{F}^n \setminus \{\mathbf{0}\}$. Choose $\sigma \in \mathbb{F}$ with $\sigma = 1$ for $x_1 = 0$ and $\sigma = -\frac{\overline{x_1}}{|x_1|}$ for $x_1 \neq 0$.
Set $\mathbf{w} := \|\mathbf{x}\|_2 \mathbf{e}_1 - \sigma\mathbf{x}$. Then:

(i) $\mathbf{w} \neq \mathbf{0}$;
(ii) $\sigma U_{\mathbf{w}} \mathbf{x} = \|\mathbf{x}\|_2 \mathbf{e}_1$;
(iii) $\|\mathbf{x}\|_2 = 1 \Longrightarrow \overline{\sigma} U_{\mathbf{w}}$ *is unitary with* $(\overline{\sigma} U_{\mathbf{w}}) \mathbf{e}_1 = \mathbf{x}$.

Proof. Set $\mathbf{y} := \|\mathbf{x}\|_2 \mathbf{e}_1$. Then $\|\mathbf{y}\|_2 = \|\mathbf{x}\|_2$ and $\langle \mathbf{x}, \mathbf{y} \rangle = x_1 \|\mathbf{x}\|_2$.
Since $\|\mathbf{x}\|_2 > 0$, the defining cases for σ coincide with those determined by $\langle \mathbf{x}, \mathbf{y} \rangle$.
(i) The relation $\mathbf{w} \neq \mathbf{0}$ holds by Theorem 2.7.3(ii) with this $\mathbf{y}$.
(ii) The identity $\sigma U_{\mathbf{w}} \mathbf{x} = \|\mathbf{x}\|_2 \mathbf{e}_1$ holds by Theorem 2.7.3(iii) with this $\mathbf{y}$.
(iii) Suppose $\|\mathbf{x}\|_2 = 1$ and set $A := \sigma U_{\mathbf{w}}$. The identity $A^* A = |\sigma|^2 U_{\mathbf{w}}^* U_{\mathbf{w}} = I_n$ holds by Theorem 2.7.3(i) and Theorem 2.7.2(iii).
Thus A^* is unitary by Theorem 2.6.8(i),(iv) with $U = A$. By (ii), $A\mathbf{x} = \mathbf{e}_1$, so $A^* \mathbf{e}_1 = A^* A \mathbf{x} = \mathbf{x}$.
The identity $A^* = \overline{\sigma} U_{\mathbf{w}}$ holds by Theorem 2.7.2(i).
Structural Commentary: Equal-norm reflection constructs $A\mathbf{x} = \mathbf{e}_1$; unitarity transfers this identity to the first column of A^*.
Key Insight: The adjoint reverses the annihilation map and installs $\mathbf{x}$ as a column. □

3 Bilinear and Quadratic Forms

3.1 Bilinear Form Types and Congruence Invariants

Metric vector spaces retain the algebraic structure of inner-product geometry without imposing positivity.
Unless stated otherwise, $\mathbb{F}$ is an arbitrary field and every vector space is finite-dimensional.
General bilinear pairings, their radicals, their matrices, and their basis-change law were established earlier.
Here the two input spaces coincide, and a fixed bilinear form B is written $B(\mathbf{x}, \mathbf{y}) = \langle \mathbf{x}, \mathbf{y} \rangle$.

Definition 3.1.1. *Symmetric, Skew-Symmetric, and Alternating Forms*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$ and let $B : \mathcal{V} \times \mathcal{V} \to \mathbb{F}$ be bilinear.

(i) B is a *bilinear form* on $\mathcal{V}$; when fixed, write $B(\mathbf{x}, \mathbf{y}) = \langle \mathbf{x}, \mathbf{y} \rangle$.
(ii) $\operatorname{Sym}(B)$ means $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\, B(\mathbf{x}, \mathbf{y}) = B(\mathbf{y}, \mathbf{x})$; then B is *symmetric*.
(iii) $\operatorname{Skew}(B)$ means $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\, B(\mathbf{x}, \mathbf{y}) = -B(\mathbf{y}, \mathbf{x})$; then B is *skew-symmetric*.
(iv) $\operatorname{Alt}(B)$ means $(\forall\, \mathbf{x} \in \mathcal{V})\, B(\mathbf{x}, \mathbf{x}) = 0$; then B is *alternating*.
(v) A *metric vector space* is a pair $(\mathcal{V}, B)$ such that $\operatorname{Sym}(B)$, $\operatorname{Skew}(B)$, or $\operatorname{Alt}(B)$ holds.
The symmetric and alternating cases define *orthogonal geometry* and *symplectic geometry*, respectively.

Proposition 3.1.2. *Characteristic Controls the Form Types*
Let $B(\mathbf{x}, \mathbf{y}) = \langle \mathbf{x}, \mathbf{y} \rangle$ be a bilinear form on $\mathcal{V}$.

(i) $\operatorname{Alt}(B) \Rightarrow \operatorname{Skew}(B)$.
(ii) If $\operatorname{char}(\mathbb{F}) \neq 2$, *then* $\operatorname{Sym}(B) \wedge \operatorname{Alt}(B) \Rightarrow B = 0$.

(iii) *If* $\operatorname{char}(\mathbb{F}) \neq 2$, *then* $\operatorname{Alt}(B) \iff \operatorname{Skew}(B)$.
(iv) *If* $\operatorname{Sym}(B)$, $\operatorname{Skew}(B)$, *or* $\operatorname{Alt}(B)$, *then* $\operatorname{rad}_L(B) = \operatorname{rad}_R(B)$.
(v) *If* $\operatorname{char}(\mathbb{F}) = 2$, *then* $\operatorname{Sym}(B) \iff \operatorname{Skew}(B)$.
(vi) *If* $\operatorname{char}(\mathbb{F}) = 2$, *then* $\operatorname{Alt}(B) \Rightarrow \operatorname{Sym}(B)$.

Proof.

(*i*) Under $\operatorname{Alt}(B)$, $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\, 0 = B(\mathbf{x}+\mathbf{y}, \mathbf{x}+\mathbf{y}) = B(\mathbf{x}, \mathbf{y}) + B(\mathbf{y}, \mathbf{x})$ by bilinearity, so $\operatorname{Skew}(B)$.
(*ii*) Under $\operatorname{char}(\mathbb{F}) \neq 2$, $\operatorname{Sym}(B)$, and $\operatorname{Alt}(B)$, the relation $\operatorname{Skew}(B)$ holds by (i).
Thus $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\, 2B(\mathbf{x}, \mathbf{y}) = 0$, and $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\, B(\mathbf{x}, \mathbf{y}) = 0$ by $2 \neq 0$; therefore $B = 0$.
(*iii*) ($\Rightarrow$) $\operatorname{Alt}(B) \Rightarrow \operatorname{Skew}(B)$ by (i).
(*iii*) ($\Leftarrow$) If $\operatorname{char}(\mathbb{F}) \neq 2$ and $\operatorname{Skew}(B)$, then $(\forall\, \mathbf{x} \in \mathcal{V})\, 2B(\mathbf{x}, \mathbf{x}) = 0$. Thus $(\forall\, \mathbf{x} \in \mathcal{V})\, B(\mathbf{x}, \mathbf{x}) = 0$ by $2 \neq 0$, so $\operatorname{Alt}(B)$.
(*iv*) Under $\operatorname{Sym}(B) \vee \operatorname{Skew}(B)$, $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\, [B(\mathbf{x}, \mathbf{y}) = 0 \iff B(\mathbf{y}, \mathbf{x}) = 0]$.
The same equivalence holds under $\operatorname{Alt}(B)$ by (i), so $\operatorname{rad}_L(B) = \operatorname{rad}_R(B)$ by Definition 4.4.4(i).
(*v*) ($\Rightarrow$) Under $\operatorname{Sym}(B)$, $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\, B(\mathbf{x}, \mathbf{y}) = B(\mathbf{y}, \mathbf{x}) = -B(\mathbf{y}, \mathbf{x})$, so $\operatorname{Skew}(B)$.
(*v*) ($\Leftarrow$) Under $\operatorname{Skew}(B)$, $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\, B(\mathbf{x}, \mathbf{y}) = -B(\mathbf{y}, \mathbf{x}) = B(\mathbf{y}, \mathbf{x})$, so $\operatorname{Sym}(B)$.
(*vi*) If $\operatorname{char}(\mathbb{F}) = 2$ and $\operatorname{Alt}(B)$, then $\operatorname{Skew}(B)$ by (i) and $\operatorname{Sym}(B)$ by (v).

Structural Commentary: Diagonal expansion controls form types; argument reversal preserves zeros and identifies radicals.
Key Insight: The scalar 2 is invertible off characteristic 2 and vanishes in characteristic 2. □

Henceforth, $B : \mathcal{V} \times \mathcal{V} \to \mathbb{F}$ is symmetric, skew-symmetric, or alternating.
Its left and right radicals agree by Proposition 3.1.2(iv), so a single radical and a single orthogonality notation suffice.

Definition 3.1.3. *Matrix, Rank, and Discriminant of a Form*
Let $(\mathcal{V}, B)$ be a metric vector space with ordered basis $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$, where $n \geq 1$.

(i) The *matrix of the form* in β is $M_\beta := [\langle \mathbf{v}_i, \mathbf{v}_j \rangle]_{i,j}$.
(ii) The *rank* of the form is $\operatorname{rank}(M_\beta)$.
(iii) The *discriminant set* is $\Delta(\mathcal{V}) := \{r^2 \det(M_\beta) : r \in \mathbb{F}^\times\}$.
(iv) If $\det(M_\beta) \neq 0$, then $\Delta(\mathcal{V}) = \det(M_\beta)(\mathbb{F}^\times)^2$. This set represents the square class of $\det(M_\beta)$ in $\mathbb{F}^\times/(\mathbb{F}^\times)^2$.

Proposition 3.1.4. *Matrices and Invariants under Congruence*
Let $n = \dim(\mathcal{V}) \geq 1$ *and let* β, γ *be ordered bases of* $\mathcal{V}$. *Put* $C := C_{\beta \leftarrow \gamma}$.

(i) $\langle \mathbf{x}, \mathbf{y} \rangle = [\mathbf{x}]_\beta^t M_\beta [\mathbf{y}]_\beta$.
(ii) $M_\gamma = C^t M_\beta C$.
(iii) $\{M_\delta : \delta$ *is an ordered basis of* $\mathcal{V}\} = \{P^t M_\beta P : P \in \operatorname{Mat}(n, n, \mathbb{F})^\times\}$.
(iv) $\operatorname{rank}(M_\gamma) = \operatorname{rank}(M_\beta)$.
(v) $\Delta(\mathcal{V})$ *is independent of the ordered basis used in its definition.*

Proof.

(*i*) By Proposition 4.4.2, $\langle \mathbf{x}, \mathbf{y} \rangle = [\mathbf{x}]_\beta^t M_\beta [\mathbf{y}]_\beta$.
(*ii*) By Proposition 4.4.10(i), $M_\gamma = C^t M_\beta C$.
(*iii*) For $\subseteq$, let δ be an ordered basis of $\mathcal{V}$. Then $M_\delta = C_{\beta \leftarrow \delta}^t M_\beta C_{\beta \leftarrow \delta}$ by (ii), and $C_{\beta \leftarrow \delta} \in \operatorname{Mat}(n, n, \mathbb{F})^\times$ by Theorem 3.5.2(i).
For $\supseteq$, fix $P \in \operatorname{Mat}(n, n, \mathbb{F})^\times$. Choose an ordered basis δ satisfying $P^{-1} = C_{\delta \leftarrow \beta}$ by Theorem 3.5.2(ii).
Then $P = C_{\beta \leftarrow \delta}$ by Theorem 3.5.2(i), so $P^t M_\beta P = M_\delta$ by (ii).
(*iv*) The matrices C and C^t are invertible by Theorem 3.5.2(i) and Corollary 3.6.4, respectively.
Thus $\operatorname{rank}(M_\gamma) = \operatorname{rank}(M_\beta)$ by (ii) and Theorem 3.6.6(ii).
(*v*) Put $D_\eta := \{r^2 \det(M_\eta) : r \in \mathbb{F}^\times\}$ $(\eta \in \{\beta, \gamma\})$ and $c := \det(C)$. Then $c \in \mathbb{F}^\times$ by invertibility of C.
The identity $\det(M_\gamma) = \det(C^t) \det(M_\beta) \det(C) = c^2 \det(M_\beta)$ holds by (ii) and the determinant product and transpose laws.
Therefore $D_\gamma = D_\beta$ by the bijection $r \mapsto rc$ of $\mathbb{F}^\times$.

Structural Commentary: Congruence exhausts basis matrices; invertible factors preserve rank and square class.
Key Insight: Both arguments transform by the same basis-change matrix. □

3.2 Quadratic Forms and Polar Forms

Throughout this subsection, $\mathcal{V}$ is a vector space over an arbitrary field $\mathbb{F}$.

Definition 3.2.1. *Quadratic Forms and Polar Forms*
A *quadratic form* on $\mathcal{V}$ is a map $Q : \mathcal{V} \to \mathbb{F}$ satisfying:

(i) $(\forall\, a \in \mathbb{F})(\forall\, \mathbf{v} \in \mathcal{V})\, Q(a\mathbf{v}) = a^2 Q(\mathbf{v})$;
(ii) the *polar form* $B_Q : \mathcal{V} \times \mathcal{V} \to \mathbb{F}$ defined by $B_Q(\mathbf{u}, \mathbf{v}) := Q(\mathbf{u}+\mathbf{v}) - Q(\mathbf{u}) - Q(\mathbf{v})$ is bilinear.

Proposition 3.2.2. *Quadratic Forms and Symmetric Bilinear Forms*

(i) *If* $Q : \mathcal{V} \to \mathbb{F}$ *is quadratic, then* $\operatorname{Sym}(B_Q)$.
(ii) *Let* $\operatorname{char}(\mathbb{F}) \neq 2$ *and let* $B : \mathcal{V} \times \mathcal{V} \to \mathbb{F}$ *be bilinear with* $\operatorname{Sym}(B)$. *Define* $Q_B(\mathbf{x}) := \frac{1}{2} B(\mathbf{x}, \mathbf{x})$; Q_B *is quadratic and* $B_{Q_B} = B$.
(iii) *Let* $\operatorname{char}(\mathbb{F}) \neq 2$ *and let* $Q : \mathcal{V} \to \mathbb{F}$ *be quadratic. Define* $Q_{B_Q}(\mathbf{x}) := \frac{1}{2} B_Q(\mathbf{x}, \mathbf{x})$. *Then* $Q_{B_Q} = Q$.

Proof.

(*i*) $(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})\, B_Q(\mathbf{u}, \mathbf{v}) = B_Q(\mathbf{v}, \mathbf{u})$ by commutativity of vector addition. $\operatorname{Sym}(B_Q)$ by this identity.
(*ii*) $(\forall\, a \in \mathbb{F})(\forall\, \mathbf{x} \in \mathcal{V})\, Q_B(a\mathbf{x}) = a^2 Q_B(\mathbf{x})$ by bilinearity.
$(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})\, B_{Q_B}(\mathbf{u}, \mathbf{v}) = \frac{1}{2}\big(B(\mathbf{u}, \mathbf{v}) + B(\mathbf{v}, \mathbf{u})\big) = B(\mathbf{u}, \mathbf{v})$ by bilinearity and symmetry.
$B_{Q_B} = B$ by this identity, and Q_B is quadratic by the homogeneity identity and bilinearity of B_{Q_B}.
(*iii*) $(\forall\, \mathbf{x} \in \mathcal{V})\, Q_{B_Q}(\mathbf{x}) = \frac{1}{2} B_Q(\mathbf{x}, \mathbf{x}) = Q(\mathbf{x})$ by quadratic homogeneity. $Q_{B_Q} = Q$ by this pointwise identity.

Structural Commentary: Symmetry places B_Q among symmetric forms; items (ii)–(iii) establish inverse reconstruction.
Key Insight: The identity $B_Q(\mathbf{x}, \mathbf{x}) = 2Q(\mathbf{x})$ makes diagonal evaluation invert polarization. □

Proposition 3.2.3. *Polar Forms in Characteristic Two*
Let $Q : \mathcal{V} \to \mathbb{F}$ be quadratic. If $\operatorname{char}(\mathbb{F}) = 2$, then $\operatorname{Alt}(B_Q)$.

Proof. $Q(\mathbf{0}) = 0$ by quadratic homogeneity at scalar 0.
$(\forall\, \mathbf{x} \in \mathcal{V})\, B_Q(\mathbf{x}, \mathbf{x}) = Q(2\mathbf{x}) - 2Q(\mathbf{x}) = Q(\mathbf{0}) = 0$ by $\operatorname{char}(\mathbb{F}) = 2$. $\operatorname{Alt}(B_Q)$ by the preceding identity.
Structural Commentary: Homogeneity supplies $Q(\mathbf{0}) = 0$; characteristic 2 then collapses the polar diagonal.
Key Insight: The identities $2\mathbf{x} = \mathbf{0}$ and $2Q(\mathbf{x}) = 0$ force diagonal vanishing. □

Proposition 3.2.4. *Square Perturbations in Characteristic Two*
Assume $\operatorname{char}(\mathbb{F}) = 2$.

(i) Let $Q : \mathcal{V} \to \mathbb{F}$ be quadratic and $L : \mathcal{V} \to \mathbb{F}$ linear, and define $L^2(\mathbf{v}) := L(\mathbf{v})^2$. Then $Q + L^2$ is quadratic and $B_{Q+L^2} = B_Q$.
(ii) On $\mathbb{F}^2$, define $Q_0(x, y) := xy$ and $Q_1(x, y) := xy + x^2$.
Then Q_0, Q_1 are quadratic, $Q_0 \neq Q_1$, and $B_{Q_0} = B_{Q_1} = B$ for $B((x, y), (u, v)) := xv + uy$.

Proof.

(i) $(\forall\, a \in \mathbb{F})(\forall\, \mathbf{v} \in \mathcal{V})\, (Q+L^2)(a\mathbf{v}) = a^2(Q+L^2)(\mathbf{v})$ by homogeneity of Q and linearity of L. $(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})\, B_{Q+L^2}(\mathbf{u}, \mathbf{v}) - B_Q(\mathbf{u}, \mathbf{v}) = 2L(\mathbf{u})L(\mathbf{v}) = 0$ by linearity of L and characteristic 2.
$B_{Q+L^2} = B_Q$ by this identity, and $Q + L^2$ is quadratic by the homogeneity identity and bilinearity of B_Q.

(ii) Define $L : \mathbb{F}^2 \to \mathbb{F}$ by $L(x, y) := x$.
$(\forall\, a, x, y \in \mathbb{F})\, Q_0(ax, ay) = a^2 Q_0(x, y)$ and $B_{Q_0} = B$ by direct expansion.
Q_0 is quadratic by this homogeneity identity and bilinearity of B.
Q_1 is quadratic and $B_{Q_1} = B_{Q_0} = B$ by $Q_1 = Q_0 + L^2$ and (i). $Q_0 \neq Q_1$ by $Q_0(1, 0) = 0 \neq 1 = Q_1(1, 0)$.

Structural Commentary: Item (i) isolates the polarization kernel; item (ii) realizes it through the coordinate square x^2.
Key Insight: In characteristic 2, linear-functional squares are invisible to polarization. □

Example 3.2.5. *Alternating versus Nonalternating Symmetric Forms*
Assume $\operatorname{char}(\mathbb{F}) = 2$ and let $H = \left[\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right]$. The associated symmetric bilinear form on $\mathbb{F}^2$ is $B_H((x, y), (u, v)) = xv + yu$.
The form is alternating by $(\forall\, x, y \in \mathbb{F})\, B_H((x, y), (x, y)) = 2xy = 0$. The form is nonsingular by $H^2 = I_2$ and Proposition 4.4.6.
A diagonal matrix D congruent to H would represent B_H in an ordered basis by Proposition 3.1.4(iii).
Alternation would force $D = 0$. Congruence would instead force $\operatorname{rank}(D) = \operatorname{rank}(H) = 2$ by Proposition 3.1.4(iv).
H is not congruent to any diagonal matrix by this rank contradiction.
By contrast, [1] is symmetric and nonalternating because its basis vector has self-pairing 1.
Structural Commentary: The forms represented by H and [1] separate alternating from nonalternating symmetry.
Key Insight: Alternation forces a zero diagonal, but nonsingularity forbids the zero matrix.

3.3 Orthogonality, Radicals, and Nonsingular Metric Spaces

Throughout this subsection, metric vector spaces are finite-dimensional over an arbitrary field $\mathbb{F}$.

Definition 3.3.1. *Orthogonality, Isotropy, and Radical*
Let $\mathcal{V}$ be a metric vector space. Symmetric and skew-symmetric forms satisfy $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\, [\langle \mathbf{x}, \mathbf{y} \rangle = 0 \iff \langle \mathbf{y}, \mathbf{x} \rangle = 0]$.
An alternating form is skew-symmetric by Proposition 3.1.2(i); thus left and right orthogonality agree in every case.

(i) $\mathbf{x} \perp \mathbf{y} \iff \langle \mathbf{x}, \mathbf{y} \rangle = 0$; then $\mathbf{x}, \mathbf{y}$ are *orthogonal*. For $S \subseteq \mathcal{V}$, set $S^\perp := \{\mathbf{v} \in \mathcal{V} : (\forall\, \mathbf{s} \in S)\ \langle \mathbf{v}, \mathbf{s} \rangle = 0\}$.
(ii) A subspace $\mathcal{S} \leq \mathcal{V}$ is *totally isotropic* or *totally degenerate* if $\mathcal{S} \subseteq \mathcal{S}^\perp$. It is *nonsingular* if $\mathcal{S} \cap \mathcal{S}^\perp = \{\mathbf{0}\}$.
(iii) A vector $\mathbf{x} \neq \mathbf{0}$ is *isotropic* or *null* if $\langle \mathbf{x}, \mathbf{x} \rangle = 0$, and *nonisotropic* otherwise.
The space $\mathcal{V}$ is *isotropic* if $(\exists\, \mathbf{x} \in \mathcal{V} \setminus \{\mathbf{0}\})\ \langle \mathbf{x}, \mathbf{x} \rangle = 0$. It is *anisotropic* if $(\forall\, \mathbf{x} \in \mathcal{V} \setminus \{\mathbf{0}\})\ \langle \mathbf{x}, \mathbf{x} \rangle \neq 0$.
(iv) A vector $\mathbf{x}$ is *degenerate* if $(\forall\, \mathbf{v} \in \mathcal{V})\ \langle \mathbf{x}, \mathbf{v} \rangle = 0$. The *radical* is $\operatorname{rad}(\mathcal{V}) := \mathcal{V}^\perp$.
(v) The space $\mathcal{V}$ is *nonsingular* or *nondegenerate* if $\operatorname{rad}(\mathcal{V}) = \{\mathbf{0}\}$, and *singular* otherwise.
(vi) The space $\mathcal{V}$ is *totally singular* or *totally degenerate* if $\operatorname{rad}(\mathcal{V}) = \mathcal{V}$.

Proposition 3.3.2. *Metric Radical and Perfection*
Let $\mathcal{V}$ be a metric vector space with form $B(\mathbf{x}, \mathbf{y}) = \langle \mathbf{x}, \mathbf{y} \rangle$.

(i) $\operatorname{rad}_L(B) = \operatorname{rad}_R(B) = \operatorname{rad}(\mathcal{V})$.
(ii) $\mathcal{V}$ is nonsingular $\iff$ B is perfect.

Proof.

(i) The identity $\operatorname{rad}(\mathcal{V}) = \operatorname{rad}_L(B)$ holds by the definitions of $\mathcal{V}^\perp$ and the left radical.
The equality $\operatorname{rad}_L(B) = \operatorname{rad}_R(B)$ holds by Proposition 3.1.2(iv).

(ii) ($\Rightarrow$) Suppose $\mathcal{V}$ is nonsingular. Both form-induced maps are linear by Proposition 4.4.3(i).
Their kernels equal $\{\mathbf{0}\}$ by (i) and Proposition 4.4.5(i). Thus both maps are injective by Proposition 1.6.2.
Their domains and codomains have equal dimension by Theorem 4.1.4(ii).
Hence both maps are surjective by Corollary 1.7.6(ii). They are isomorphisms by Proposition 1.6.7, so B is perfect.

(ii) ($\Leftarrow$) Suppose B is perfect. Then Φ_B is an isomorphism by the definition of perfection. It is injective by Proposition 1.6.7.
Hence $\ker(\Phi_B) = \{\mathbf{0}\}$ by Proposition 1.6.2. Thus $\operatorname{rad}(\mathcal{V}) = \operatorname{rad}_L(B) = \ker(\Phi_B) = \{\mathbf{0}\}$ by (i) and Proposition 4.4.5(i).

Structural Commentary: The common radical is the kernel obstruction; equal dimensions convert injectivity into perfection.
Key Insight: A metric form is perfect exactly when its radical vanishes. □

Proposition 3.3.3. *Coordinate Criteria for Nonsingularity*
Let $\mathcal{V}$ be a metric vector space with $n := \dim(\mathcal{V}) \geq 1$. Let β be an ordered basis, and set $M := M_\beta$.

(i) $\{[\mathbf{x}]_\beta : \mathbf{x} \in \operatorname{rad}(\mathcal{V})\} = \ker(M^t)$.
(ii) $\dim \operatorname{rad}(\mathcal{V}) = n - \operatorname{rank}(M)$.
(iii) $\mathcal{V}$ is nonsingular $\iff$ M is invertible.

Proof.

(*i*) For $\mathbf{x} \in \mathcal{V}$, set $X := [\mathbf{x}]_\beta$. The relation $(\forall\, Y \in \mathbb{F}^n)(\exists\, \mathbf{y} \in \mathcal{V})\, Y = [\mathbf{y}]_\beta$ holds by Proposition 3.2.2(i).
Thus $\mathbf{x} \in \operatorname{rad}(\mathcal{V}) \iff (\forall\, Y \in \mathbb{F}^n)\, X^t M Y = 0$ by Proposition 3.1.4(i).
The equivalence $(\forall\, Y \in \mathbb{F}^n)\, X^t M Y = 0 \iff M^t X = 0$ holds by evaluation at the standard coordinate columns. QED.

(*ii*) By (i) and Proposition 3.2.2(i), $\operatorname{rad}(\mathcal{V}) \cong \ker(M^t)$. Hence their dimensions agree by Theorem 1.7.9.
Thus $\dim \operatorname{rad}(\mathcal{V}) = n - \operatorname{rank}(M^t)$ by Corollary 3.3.1(i). Finally, $\operatorname{rank}(M^t) = \operatorname{rank}(M)$ by Theorem 3.3.2.

(*iii*) ($\Rightarrow$) Suppose $\mathcal{V}$ is nonsingular. Then $\operatorname{rank}(M) = n$ by (ii). Hence M is invertible by Corollary 3.6.2.

(*iii*) ($\Leftarrow$) Suppose M is invertible. Then $\operatorname{rank}(M) = n$ by Corollary 3.6.2.
Hence $\dim \operatorname{rad}(\mathcal{V}) = 0$ by (ii). Hence $\operatorname{rad}(\mathcal{V}) = \{\mathbf{0}\}$ by Proposition 1.4.3(ii).

Structural Commentary: Coordinate evaluation identifies the radical kernel; rank-nullity and full rank test nonsingularity.
Key Insight: The form is nonsingular exactly when its matrix has full rank. □

Remark 3.3.4. *Subspace Radicals*
For $\mathcal{S} \leq \mathcal{V}$, the restricted form has radical $\operatorname{rad}(\mathcal{S}) = \mathcal{S} \cap \mathcal{S}^\perp$. In general, $\operatorname{rad}(\mathcal{S}) \neq \mathcal{S}^\perp$ because $\mathcal{S}^\perp$ is computed in $\mathcal{V}$.

Proposition 3.3.5. *Riesz Map Isomorphism Criterion*
Let $\mathcal{V}$ be a metric vector space and define $\tau : \mathcal{V} \to \mathcal{V}'$ by $\tau(\mathbf{x})(\mathbf{v}) = \langle \mathbf{v}, \mathbf{x} \rangle$.

(*i*) $\tau \in \mathcal{L}(\mathcal{V}, \mathcal{V}')$.
(*ii*) $\ker(\tau) = \operatorname{rad}(\mathcal{V})$.
(*iii*) *τ is an isomorphism* $\iff \operatorname{rad}(\mathcal{V}) = \{\mathbf{0}\}$.

Proof. Set $B(\mathbf{x}, \mathbf{y}) := \langle \mathbf{x}, \mathbf{y} \rangle$.

(*i*) The identity $\tau = \Psi_B \in \mathcal{L}(\mathcal{V}, \mathcal{V}')$ holds by Proposition 4.4.3(i).

(*ii*) The identity $\ker(\tau) = \operatorname{rad}_R(B)$ holds by Proposition 4.4.5(i). Hence $\ker(\tau) = \operatorname{rad}(\mathcal{V})$ by Proposition 3.3.2(i).

(*iii*) ($\Rightarrow$) If τ is an isomorphism, then it is injective by Proposition 1.6.7.
Thus $\ker(\tau) = \{\mathbf{0}\}$ by Proposition 1.6.2. Hence $\operatorname{rad}(\mathcal{V}) = \{\mathbf{0}\}$ by (ii).

(*iii*) ($\Leftarrow$) If $\operatorname{rad}(\mathcal{V}) = \{\mathbf{0}\}$, then $\ker(\tau) = \{\mathbf{0}\}$ by (ii). Thus τ is injective by Proposition 1.6.2.
The equality $\dim(\mathcal{V}) = \dim(\mathcal{V}')$ holds by Theorem 4.1.4(ii).
Thus τ is surjective by Corollary 1.7.6(ii) and is an isomorphism by Proposition 1.6.7.

Structural Commentary: The radical is the Riesz-map kernel; equal dimensions convert injectivity into invertibility.
Key Insight: The radical is precisely the kernel of the Riesz map. □

Theorem 3.3.6. *Riesz Map for Nonsingular Metric Spaces*
Let $\mathcal{V}$ be a nonsingular metric vector space. Then $(\forall\, f \in \mathcal{V}')(\exists!\, \mathbf{x} \in \mathcal{V})(\forall\, \mathbf{v} \in \mathcal{V})\, f(\mathbf{v}) = \langle \mathbf{v}, \mathbf{x} \rangle$.

Proof. Define $\tau : \mathcal{V} \to \mathcal{V}'$ by $\tau(\mathbf{x})(\mathbf{v}) = \langle \mathbf{v}, \mathbf{x} \rangle$. The map τ is an isomorphism by Proposition 3.3.5(iii). Fix $f \in \mathcal{V}'$ and set $\mathbf{x} := \tau^{-1}(f)$. Then $(\forall\, \mathbf{v} \in \mathcal{V})\, f(\mathbf{v}) = \tau(\mathbf{x})(\mathbf{v}) = \langle \mathbf{v}, \mathbf{x} \rangle$. If $\mathbf{y} \in \mathcal{V}$ satisfies $(\forall\, \mathbf{v} \in \mathcal{V})\, f(\mathbf{v}) = \langle \mathbf{v}, \mathbf{y} \rangle$, then $\tau(\mathbf{y}) = f = \tau(\mathbf{x})$; $\mathbf{y} = \mathbf{x}$ by injectivity of τ.
Structural Commentary: Riesz inversion constructs each representative; injectivity proves its uniqueness.
Key Insight: The radical is the sole obstruction to representing every functional. □

Definition 3.3.7. *Isometries and Classical Groups*
Let $\mathcal{V}, \mathcal{W}$ be metric vector spaces.

(i) An *isometry* $\sigma : \mathcal{V} \to \mathcal{W}$ is a bijective linear map satisfying $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\ \langle \sigma\mathbf{x}, \sigma\mathbf{y} \rangle = \langle \mathbf{x}, \mathbf{y} \rangle$. Write $\mathcal{V} \cong \mathcal{W}$ if one exists.

(ii) The group of isometries $\mathcal{V} \to \mathcal{V}$ is $\operatorname{Iso}(\mathcal{V})$.
For nonsingular orthogonal $\mathcal{V}$, this is the *orthogonal group* $\mathcal{O}(\mathcal{V})$. For nonsingular symplectic $\mathcal{V}$, it is the *symplectic group* $\operatorname{Sp}(\mathcal{V})$.

Proposition 3.3.8. *Matrix Criterion for Isometries*
Let $\mathcal{V}$ be a metric vector space with $n := \dim(\mathcal{V}) \geq 1$, and let β be an ordered basis. Let $\sigma \in \mathcal{L}(\mathcal{V})$, and set $M := M_\beta$ and $A := [\sigma]_{\beta \leftarrow \beta}$.

(*i*) *$\sigma \in \operatorname{Iso}(\mathcal{V}) \iff \sigma$ is bijective and $A^t M A = M$.*
(*ii*) *If $\sigma \in \operatorname{Iso}(\mathcal{V})$ and M is invertible, then $\det A = \pm 1$.*

Proof.

(*i*) ($\Rightarrow$) Suppose $\sigma \in \operatorname{Iso}(\mathcal{V})$. Then σ is bijective by definition.
The identity $(\forall\, X, Y \in \mathbb{F}^n)\, X^t A^t M A Y = X^t M Y$ holds by metric preservation and Proposition 3.1.4(i). Hence $A^t M A = M$ by evaluation at pairs of standard coordinate columns.

(*i*) ($\Leftarrow$) Suppose σ is bijective and $A^t M A = M$.
Then $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\ \langle \sigma\mathbf{x}, \sigma\mathbf{y} \rangle = \langle \mathbf{x}, \mathbf{y} \rangle$ by Proposition 3.1.4(i).
Hence $\sigma \in \operatorname{Iso}(\mathcal{V})$ by definition.

(*ii*) Suppose $\sigma \in \operatorname{Iso}(\mathcal{V})$ and M is invertible. Then $A^t M A = M$ by (i).
Thus $\det(M) = \det(A^t M A) = (\det A)^2 \det(M)$ by determinant multiplicativity and transpose invariance.
Thus $(\det A)^2 = 1$ by cancellation of $\det(M) \neq 0$.
Hence $(\det A - 1)(\det A + 1) = 0$, so $\det A \in \{1, -1\}$ by the no-zero-divisor property of $\mathbb{F}$.

Structural Commentary: Coordinate evaluation identifies metric preservation with congruence; determinants constrain its stabilizer.
Key Insight: Isometries are exactly the invertible solutions of $A^t M A = M$. □

Definition 3.3.9. *Adjoint for a Nonsingular Bilinear Form*
Let $\mathcal{V}$ be nonsingular and $T \in \mathcal{L}(\mathcal{V})$. An operator $S \in \mathcal{L}(\mathcal{V})$ is a *metric adjoint* of $T \iff (\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\ \langle T\mathbf{x}, \mathbf{y} \rangle = \langle \mathbf{x}, S\mathbf{y} \rangle$.
If this operator is unique, denote it by T^*.

Proposition 3.3.10. *Metric Adjoints and Isometries*
Let $\mathcal{V}$ be nonsingular with form $B(\mathbf{x}, \mathbf{y}) = \langle \mathbf{x}, \mathbf{y} \rangle$. Let $T \in \mathcal{L}(\mathcal{V})$, and set $n := \dim(\mathcal{V})$.

(*i*) *$(\exists!\, T^* \in \mathcal{L}(\mathcal{V}))(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\ \langle T\mathbf{x}, \mathbf{y} \rangle = \langle \mathbf{x}, T^*\mathbf{y} \rangle$.*
(*ii*) *If $n \geq 1$ and β is an ordered basis, set $M := M_\beta$ and $A := [T]_\beta$; then $[T^*]_\beta = M^{-1} A^t M$.*
(*iii*) *T is an isometry $\iff T$ is bijective and $T^* T = I$.*
(*iv*) *If T is bijective, then $T^* T = I \iff T^* = T^{-1}$.*

Proof.

(*i*) Define $\tau : \mathcal{V} \to \mathcal{V}'$ by $\tau(\mathbf{y})(\mathbf{x}) = \langle \mathbf{x}, \mathbf{y} \rangle$. Define $F : \mathcal{V} \to \mathcal{V}'$ by $F(\mathbf{y})(\mathbf{x}) = \langle T\mathbf{x}, \mathbf{y} \rangle$.
Then τ is an isomorphism by Proposition 3.3.5(iii). The relation $F \in \mathcal{L}(\mathcal{V}, \mathcal{V}')$ holds by bilinearity.
Set $T^* := \tau^{-1} \circ F \in \mathcal{L}(\mathcal{V})$. Then $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\ \langle T\mathbf{x}, \mathbf{y} \rangle = \langle \mathbf{x}, T^*\mathbf{y} \rangle$ by the definitions of τ and F.
If $S \in \mathcal{L}(\mathcal{V})$ satisfies this identity, then $\tau \circ S = F = \tau \circ T^*$. Hence $S = T^*$ by injectivity of τ.

(*ii*) Assume $n \geq 1$. The matrix M is invertible by Proposition 3.3.3(iii).
Set $D := [T^*]_\beta$. Then $(\forall\, X, Y \in \mathbb{F}^n)\ X^t A^t M Y = X^t M D Y$ by the adjoint identity and Proposition 3.1.4(i).
Hence $A^t M = MD$ by evaluation at pairs of standard coordinate columns, and therefore $D = M^{-1} A^t M$.

(*iii*) ($\Rightarrow$) Suppose T is an isometry. Then T is bijective by definition.
For $\mathbf{x}, \mathbf{y} \in \mathcal{V}$, $\langle \mathbf{x}, (T^*T - I)\mathbf{y} \rangle = \langle T\mathbf{x}, T\mathbf{y} \rangle - \langle \mathbf{x}, \mathbf{y} \rangle$ by the adjoint identity.
This difference is 0 by metric preservation, so $(T^*T - I)\mathbf{y} \in \operatorname{rad}_R(B) = \{\mathbf{0}\}$ by Proposition 3.3.2(i); hence $T^*T = I$.

(*iii*) ($\Leftarrow$) Suppose T is bijective and $T^*T = I$.
Then $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\ \langle T\mathbf{x}, T\mathbf{y} \rangle = \langle \mathbf{x}, T^*T\mathbf{y} \rangle = \langle \mathbf{x}, \mathbf{y} \rangle$ by the adjoint identity. Hence T is an isometry by definition.

(*iv*) ($\Rightarrow$) If $T^*T = I$, then $T^* = T^{-1}$ by right-composition with T^{-1}.

(*iv*) ($\Leftarrow$) If $T^* = T^{-1}$, then $T^*T = T^{-1}T = I$.

Structural Commentary: Riesz inversion constructs the adjoint; the radical test converts metric preservation into $T^*T = I$.
Key Insight: Nonsingularity turns the adjoint relation into a unique operator identity. □

Proposition 3.3.11. *Isometry Is Matrix Congruence*
Let $(\mathcal{V}, B_\mathcal{V})$ and $(\mathcal{W}, B_\mathcal{W})$ be metric vector spaces with $\dim(\mathcal{V}) = \dim(\mathcal{W}) = n \geq 1$.
Let β, γ be ordered bases with respective form matrices M_β, N_γ. Then $\mathcal{V} \cong \mathcal{W} \iff M_\beta$ and N_γ are congruent.

Proof.

($\Rightarrow$) Let $\sigma : \mathcal{V} \to \mathcal{W}$ be an isometry and set $A := [\sigma]_{\gamma \leftarrow \beta}$. The map σ is invertible by Proposition 1.6.7.
By Proposition 3.4.4, $[\sigma^{-1}]_{\beta \leftarrow \gamma} A = I_n = A[\sigma^{-1}]_{\beta \leftarrow \gamma}$, so A is invertible.
The identity $(\forall\, X, Y \in \mathbb{F}^n)\ X^t M_\beta Y = X^t A^t N_\gamma A Y$ holds by metric preservation and Proposition 3.1.4(i).
Hence $M_\beta = A^t N_\gamma A$ by evaluation at pairs of standard coordinate columns, so the matrices are congruent.

($\Leftarrow$) Suppose M_β and N_γ are congruent. Fix an invertible $P \in \operatorname{Mat}(n, n, \mathbb{F})$ such that $N_\gamma = P^t M_\beta P$, and set $A := P^{-1}$.
Then $M_\beta = A^t N_\gamma A$. Define $\sigma : \mathcal{V} \to \mathcal{W}$ by $[\sigma\mathbf{x}]_\gamma = A[\mathbf{x}]_\beta$. The map σ is linear by Proposition 3.2.2(i) and Proposition 3.1.8.
The coordinate rule with A^{-1} defines its inverse, so σ is bijective.
For $\mathbf{x}, \mathbf{y} \in \mathcal{V}$ with coordinate columns X, Y, $B_\mathcal{W}(\sigma\mathbf{x}, \sigma\mathbf{y}) = X^t A^t N_\gamma A Y$ by Proposition 3.1.4(i).
The identity $B_\mathcal{V}(\mathbf{x}, \mathbf{y}) = X^t M_\beta Y = X^t A^t N_\gamma A Y$ holds by Proposition 3.1.4(i) and the congruence identity; σ is an isometry.

Structural Commentary: Coordinate matrices translate metric preservation into congruence and reconstruct the isometry.
Key Insight: Isometry classes are exactly congruence classes of form matrices. □

Perspective 3.3.12. *Congruence versus Similarity*
Similarity $N = P^{-1}MP$ governs operator matrices. Congruence $N = P^tMP$ governs bilinear-form matrices because the same basis change acts in both slots. Over $\mathbb{R}$, transpose equals conjugate transpose, so real form classification uses congruence.

3.4 Radicals, Hyperbolic Spaces, and Witt Theory

Throughout this subsection, metric vector spaces are finite-dimensional over a fixed field $\mathbb{F}$.

Definition 3.4.1. *Orthogonal Direct Sum*
For $\mathcal{S}, \mathcal{T} \leq \mathcal{V}$, write $\mathcal{V} = \mathcal{S} \odot \mathcal{T}$ when $\mathcal{V} = \mathcal{S} \oplus \mathcal{T}$ and $\mathcal{S} \perp \mathcal{T}$; this is the *orthogonal direct sum* of $\mathcal{S}$ and $\mathcal{T}$.

Theorem 3.4.2. *Dimensions of Orthogonal Complements*
Let $\mathcal{S} \leq \mathcal{V}$.

(i) If $\mathcal{V}$ or $\mathcal{S}$ is nonsingular, then $\dim(\mathcal{S}) + \dim(\mathcal{S}^\perp) = \dim(\mathcal{V})$.
(ii) If $\mathcal{S}$ is nonsingular, then $\mathcal{V} = \mathcal{S} \odot \mathcal{S}^\perp$.
(iii) If $\mathcal{V}$ is nonsingular, then $\mathcal{S}^{\perp\perp} = \mathcal{S}$.
(iv) If $\mathcal{V}$ is nonsingular, then $\mathcal{S}$ is nonsingular $\iff \mathcal{S}^\perp$ is nonsingular.

Proof.

(*i*) Define $\rho : \mathcal{V} \to \mathcal{S}'$ by $\rho(\mathbf{x})(\mathbf{s}) = \langle \mathbf{s}, \mathbf{x} \rangle$. Then $\rho \in \mathcal{L}(\mathcal{V}, \mathcal{S}')$ and $\ker(\rho) = \mathcal{S}^\perp$ by bilinearity and the definition of $\mathcal{S}^\perp$.
Fix $f \in \mathcal{S}'$. If $\mathcal{V}$ is nonsingular, choose $\mathcal{V} = \mathcal{S} \oplus \mathcal{C}$ by Proposition 2.3.6 and define $\widetilde{f}(\mathbf{s} + \mathbf{c}) = f(\mathbf{s})$.
Then $\widetilde{f} \in \mathcal{V}'$ by the direct-sum decomposition. Fix $\mathbf{x} \in \mathcal{V}$ with $(\forall\, \mathbf{s} \in \mathcal{S})\ f(\mathbf{s}) = \widetilde{f}(\mathbf{s}) = \langle \mathbf{s}, \mathbf{x} \rangle$ by Theorem 3.3.6.
If $\mathcal{S}$ is nonsingular, fix $\mathbf{x} \in \mathcal{S}$ with $(\forall\, \mathbf{s} \in \mathcal{S})\ f(\mathbf{s}) = \langle \mathbf{s}, \mathbf{x} \rangle$ by Theorem 3.3.6 for $\mathcal{S}$. Thus ρ is surjective in either case.
The identity $\dim(\mathcal{V}) = \dim(\ker \rho) + \dim(\mathcal{S}') = \dim(\mathcal{S}^\perp) + \dim(\mathcal{S})$ holds by Theorem 1.7.3 and Theorem 4.1.4(ii).

(*ii*) If $\mathcal{S}$ is nonsingular, then $\mathcal{S} \cap \mathcal{S}^\perp = \operatorname{rad}(\mathcal{S}) = \{\mathbf{0}\}$. Thus $\mathcal{V} = \mathcal{S} \oplus \mathcal{S}^\perp$ by (i), and $\mathcal{V} = \mathcal{S} \odot \mathcal{S}^\perp$ by $\mathcal{S} \perp \mathcal{S}^\perp$.

(*iii*) Suppose that $\mathcal{V}$ is nonsingular. Then $\mathcal{S} \subseteq \mathcal{S}^{\perp\perp}$ by orthogonality.
The equality $\dim(\mathcal{S}^{\perp\perp}) = \dim(\mathcal{V}) - \dim(\mathcal{S}^\perp) = \dim(\mathcal{S})$ holds by (i). Hence $\mathcal{S}^{\perp\perp} = \mathcal{S}$ by Proposition 1.4.3(ii).

(*iv*) ($\Rightarrow$) If $\mathcal{S}$ is nonsingular, then $\operatorname{rad}(\mathcal{S}^\perp) = \mathcal{S}^\perp \cap \mathcal{S}^{\perp\perp} = \mathcal{S}^\perp \cap \mathcal{S} = \{\mathbf{0}\}$ by (iii).

(*iv*) ($\Leftarrow$) If $\mathcal{S}^\perp$ is nonsingular, then $\operatorname{rad}(\mathcal{S}) = \mathcal{S} \cap \mathcal{S}^\perp = \mathcal{S}^{\perp\perp} \cap \mathcal{S}^\perp = \{\mathbf{0}\}$ by (iii).

Structural Commentary: The restriction map has kernel $\mathcal{S}^\perp$; rank–nullity and double complementation settle (i)–(iv).
Key Insight: Nonsingularity makes orthogonal complementation dimension-reversing and involutive. □

Theorem 3.4.3. *Splitting off the Radical*
Let $R = \operatorname{rad}(\mathcal{V})$. Then $\exists\, \mathcal{S} \leq \mathcal{V}$ such that $\mathcal{V} = R \odot \mathcal{S}$, $\operatorname{rad}(\mathcal{S}) = \{\mathbf{0}\}$, and R is totally singular.

Proof. Choose $\mathcal{S} \leq \mathcal{V}$ with $\mathcal{V} = R \oplus \mathcal{S}$ by Proposition 2.3.6. Since $R \perp \mathcal{V}$, $\mathcal{V} = R \odot \mathcal{S}$ and the form on R vanishes, so $\operatorname{rad}(R) = R$.
If $\mathbf{s} \in \operatorname{rad}(\mathcal{S})$, then $\mathbf{s} \perp \mathcal{S}$ and $\mathbf{s} \perp R$, whence $\mathbf{s} \in \operatorname{rad}(\mathcal{V}) \cap \mathcal{S} = R \cap \mathcal{S} = \{\mathbf{0}\}$. Thus $\mathcal{S}$ is nonsingular.
Structural Commentary: A linear complement is automatically orthogonal to the radical and has zero restricted radical.
Key Insight: All degeneracy lies in a zero-form orthogonal summand. □

Proposition 3.4.4. *Metric Quotients*
Let $\mathcal{U} \leq \mathcal{V}$ and consider $\langle \mathbf{x}+\mathcal{U}, \mathbf{y}+\mathcal{U}\rangle_{\mathcal{V}/\mathcal{U}} := \langle \mathbf{x}, \mathbf{y}\rangle$.

(i) The rule defines a metric form on $\mathcal{V}/\mathcal{U} \iff \mathcal{U} \leq \operatorname{rad}(\mathcal{V})$.
(ii) If $\mathcal{U} \leq \operatorname{rad}(\mathcal{V})$, then $\operatorname{rad}(\mathcal{V}/\mathcal{U}) = \operatorname{rad}(\mathcal{V})/\mathcal{U}$.
(iii) The metric space $\mathcal{V}/\operatorname{rad}(\mathcal{V})$ is nonsingular.

Proof.

(i) ($\Rightarrow$) If the rule defines a metric form, then $(\forall\, \mathbf{u} \in \mathcal{U})(\forall\, \mathbf{y} \in \mathcal{V})\, 0 = \langle \mathbf{u}+\mathcal{U}, \mathbf{y}+\mathcal{U}\rangle_{\mathcal{V}/\mathcal{U}} = \langle \mathbf{u}, \mathbf{y}\rangle$, so $\mathcal{U} \leq \operatorname{rad}(\mathcal{V})$.
(i) ($\Leftarrow$) Suppose that $\mathcal{U} \leq \operatorname{rad}(\mathcal{V})$. For $\mathbf{u}, \mathbf{v} \in \mathcal{U}$ and $\mathbf{x}, \mathbf{y} \in \mathcal{V}$, $\langle \mathbf{x}+\mathbf{u}, \mathbf{y}+\mathbf{v}\rangle = \langle \mathbf{x}, \mathbf{y}\rangle$ by Proposition 3.3.2(i) and bilinearity. Thus the rule is representative-independent; bilinearity and the form type descend from $\mathcal{V}$.
(ii) Suppose that $\mathcal{U} \leq \operatorname{rad}(\mathcal{V})$. Fix $\mathbf{x} \in \mathcal{V}$. $\mathbf{x}+\mathcal{U} \in \operatorname{rad}(\mathcal{V}/\mathcal{U}) \iff (\forall\, \mathbf{y} \in \mathcal{V})\ \langle \mathbf{x}, \mathbf{y}\rangle = 0 \iff \mathbf{x} \in \operatorname{rad}(\mathcal{V})$. Hence $\operatorname{rad}(\mathcal{V}/\mathcal{U}) = \operatorname{rad}(\mathcal{V})/\mathcal{U}$.
(iii) With $\mathcal{U} = \operatorname{rad}(\mathcal{V})$, item (ii) becomes $\operatorname{rad}(\mathcal{V}/\mathcal{U}) = \operatorname{rad}(\mathcal{V})/\operatorname{rad}(\mathcal{V}) = \{\mathbf{0}\}$.

Structural Commentary: Item (i) tests representatives; item (ii) identifies the quotient radical; item (iii) removes it.
Key Insight: Precisely radical directions may be collapsed without changing pairings. □

Proposition 3.4.5. *Radicals and Orthogonal Direct Sums*
Suppose that $\mathcal{V} = \mathcal{S} \odot \mathcal{T}$, and put $R_{\mathcal{X}} := \operatorname{rad}(\mathcal{X})$ for $\mathcal{X} \in \{\mathcal{V}, \mathcal{S}, \mathcal{T}\}$.

(i) $R_{\mathcal{V}} = R_{\mathcal{S}} \odot R_{\mathcal{T}}$.
(ii) $\mathcal{V}/R_{\mathcal{V}} \cong (\mathcal{S}/R_{\mathcal{S}}) \odot (\mathcal{T}/R_{\mathcal{T}})$.
(iii) $\mathcal{V}$ is nonsingular $\iff$ $\mathcal{S}$ and $\mathcal{T}$ are nonsingular.

Proof.

(i) For $\mathbf{s} \in \mathcal{S}$ and $\mathbf{t} \in \mathcal{T}$, $\mathbf{s}+\mathbf{t} \in R_{\mathcal{V}} \iff \mathbf{s} \in R_{\mathcal{S}} \wedge \mathbf{t} \in R_{\mathcal{T}}$ by $\mathcal{S} \perp \mathcal{T}$.
Uniqueness and orthogonality of the decomposition establish $R_{\mathcal{V}} = R_{\mathcal{S}} \odot R_{\mathcal{T}}$.
(ii) Define $\Phi((\mathbf{s}+\mathbf{t}) + R_{\mathcal{V}}) = (\mathbf{s}+R_{\mathcal{S}}, \mathbf{t}+R_{\mathcal{T}})$.
The map is well-defined by (i), with inverse $\Psi(\mathbf{s}+R_{\mathcal{S}}, \mathbf{t}+R_{\mathcal{T}}) = (\mathbf{s}+\mathbf{t}) + R_{\mathcal{V}}$, and hence is a linear bijection.
For $\mathbf{s}_1, \mathbf{s}_2 \in \mathcal{S}$ and $\mathbf{t}_1, \mathbf{t}_2 \in \mathcal{T}$, $\langle \mathbf{s}_1+\mathbf{t}_1, \mathbf{s}_2+\mathbf{t}_2\rangle = \langle \mathbf{s}_1, \mathbf{s}_2\rangle + \langle \mathbf{t}_1, \mathbf{t}_2\rangle$ by orthogonality. Thus Φ is an isometry.
(iii) ($\Rightarrow$) If $\mathcal{V}$ is nonsingular, then $R_{\mathcal{S}} \odot R_{\mathcal{T}} = \{\mathbf{0}\}$ by (i), so $\mathcal{S}$ and $\mathcal{T}$ are nonsingular.
(iii) ($\Leftarrow$) If $\mathcal{S}$ and $\mathcal{T}$ are nonsingular, then $R_{\mathcal{V}} = R_{\mathcal{S}} \odot R_{\mathcal{T}} = \{\mathbf{0}\}$ by (i).

Structural Commentary: Item (i) splits the radical; item (ii) descends the splitting; item (iii) tests nonsingularity.
Key Insight: Orthogonality separates both pairings and radical directions. □

Corollary 3.4.6. *Recovering a Singular Space from Its Regular Quotient*
If $\dim(\mathcal{V}) = \dim(\mathcal{W})$ and $\mathcal{V}/\operatorname{rad}(\mathcal{V}) \cong \mathcal{W}/\operatorname{rad}(\mathcal{W})$, then $\mathcal{V} \cong \mathcal{W}$.

Proof.

(i) *Splitting*: Choose $\mathcal{V} = \operatorname{rad}(\mathcal{V}) \odot \mathcal{S}$ and $\mathcal{W} = \operatorname{rad}(\mathcal{W}) \odot \mathcal{T}$ with $\mathcal{S}, \mathcal{T}$ nonsingular by Theorem 3.4.3.
(ii) *Regular Parts*: The isometries $\mathcal{V}/\operatorname{rad}(\mathcal{V}) \cong \mathcal{S}$ and $\mathcal{W}/\operatorname{rad}(\mathcal{W}) \cong \mathcal{T}$ hold by Proposition 3.4.5(ii).
Hence $\mathcal{S} \cong \mathcal{T}$ by the assumed quotient isometry.
(iii) *Radicals*: The ambient and regular-part dimension equalities imply $\dim \operatorname{rad}(\mathcal{V}) = \dim \operatorname{rad}(\mathcal{W})$.
Fix a vector-space isomorphism between the radicals by Theorem 1.7.9; it is an isometry because both restricted forms vanish.
(iv) *Assembly*: The orthogonal direct sum of the radical isometry and an isometry $\mathcal{S} \to \mathcal{T}$ is an isometry $\mathcal{V} \to \mathcal{W}$.

Structural Commentary: Radical splittings reduce the classification to regular-part isometry and radical dimension.
Key Insight: A zero-form radical is classified solely by dimension. □

Definition 3.4.7. *Hyperbolic Pairs and Hyperbolic Spaces*

(i) A *hyperbolic pair* is $(\mathbf{u}, \mathbf{v})$ with $\langle \mathbf{u}, \mathbf{u}\rangle = \langle \mathbf{v}, \mathbf{v}\rangle = 0$ and $\langle \mathbf{u}, \mathbf{v}\rangle = 1$.
(ii) The plane $\operatorname{span}(\mathbf{u}, \mathbf{v})$ of a hyperbolic pair is a *hyperbolic plane*.
(iii) A *hyperbolic space* is an orthogonal direct sum of hyperbolic planes.
(iv) A basis $(\mathbf{u}_1, \mathbf{v}_1, \ldots, \mathbf{u}_k, \mathbf{v}_k)$ is a *hyperbolic basis* if each $(\mathbf{u}_i, \mathbf{v}_i)$ is hyperbolic and the planes $\operatorname{span}(\mathbf{u}_i, \mathbf{v}_i)$ are mutually orthogonal. In the symplectic case it is a *symplectic basis*.

Theorem 3.4.8. *Capturing Isotropic Vectors*
Let $\mathcal{V}$ be nonsingular and either symplectic, or orthogonal with $\operatorname{char}(\mathbb{F}) \neq 2$.
Then $(\forall\, \mathbf{u} \in \mathcal{V} \setminus \{\mathbf{0}\})(\langle \mathbf{u}, \mathbf{u}\rangle = 0 \Longrightarrow (\exists\, \mathbf{v} \in \mathcal{V})\ \langle \mathbf{u}, \mathbf{v}\rangle = 1 \wedge \langle \mathbf{v}, \mathbf{v}\rangle = 0)$.

Proof. Fix $\mathbf{u} \neq \mathbf{0}$ with $\langle \mathbf{u}, \mathbf{u}\rangle = 0$. Since $\mathbf{u} \notin \operatorname{rad}(\mathcal{V})$, fix $\mathbf{x} \in \mathcal{V}$ with $c := \langle \mathbf{u}, \mathbf{x}\rangle \neq 0$.
If $\mathcal{V}$ is symplectic, set $\mathbf{v} = c^{-1}\mathbf{x}$; then $\langle \mathbf{u}, \mathbf{v}\rangle = 1$ and $\langle \mathbf{v}, \mathbf{v}\rangle = 0$ by alternation. If $\mathcal{V}$ is orthogonal, set $\mathbf{v} = c^{-1}\mathbf{x} - \frac{\langle \mathbf{x}, \mathbf{x}\rangle}{2c^2}\mathbf{u}$.
Then $\langle \mathbf{u}, \mathbf{v}\rangle = 1$ and $\langle \mathbf{v}, \mathbf{v}\rangle = c^{-2}\langle \mathbf{x}, \mathbf{x}\rangle - c^{-2}\langle \mathbf{x}, \mathbf{x}\rangle = 0$ by symmetry and $\langle \mathbf{u}, \mathbf{u}\rangle = 0$. Thus $(\mathbf{u}, \mathbf{v})$ is hyperbolic.
Structural Commentary: A nonorthogonal partner is rescaled, then corrected by $\mathbf{u}$ only in the orthogonal case.
Key Insight: The correction cancels self-pairing without changing the cross-pairing. □

Theorem 3.4.9. *Nonsingular Completions*
Let $\mathcal{U} \leq \mathcal{V}$, where $\mathcal{V}$ is nonsingular and either symplectic, or orthogonal with $\operatorname{char}(\mathbb{F}) \neq 2$.
Write $\mathcal{U} = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_r) \odot \mathcal{W}$, where $(\mathbf{u}_1, \ldots, \mathbf{u}_r)$ is a basis of $\operatorname{rad}(\mathcal{U})$ and $\mathcal{W}$ is nonsingular.

(i) $(\exists\, \mathbf{v}_1, \ldots, \mathbf{v}_r \in \mathcal{V})$ such that $\mathcal{H}_r = \operatorname{span}(\mathbf{u}_1, \mathbf{v}_1, \ldots, \mathbf{u}_r, \mathbf{v}_r)$ is hyperbolic and $\widehat{\mathcal{U}} = \mathcal{H}_r \odot \mathcal{W}$ contains $\mathcal{U}$ with $\dim(\widehat{\mathcal{U}}) = \dim(\mathcal{U}) + r$.
(ii) If $\mathcal{U} \leq \mathcal{X} \leq \mathcal{V}$ and $\mathcal{X}$ is nonsingular, then $\dim(\mathcal{X}) \geq \dim(\mathcal{U}) + r$; equality is attained, and all equality cases are isometric.
(iii) Let $\widetilde{\mathcal{V}}$ be nonsingular of same kind, $\mathcal{T} \leq \widetilde{\mathcal{V}}$, and $\sigma : \mathcal{U} \xrightarrow{\sim} \mathcal{T}$. Compatible equality-case extensions admit an isometry extending σ.

Proof.

(*i*) The decomposition $\mathcal{V} = \mathcal{W} \odot \mathcal{W}^\perp$ holds by Theorem 3.4.2(ii), and $(\forall\, i \in \{1,\dots,r\})\, \mathbf{u}_i \in \mathcal{W}^\perp$.
Set $\mathcal{H}_0 = \{\mathbf{0}\}$ and proceed by induction on $j \in \{1,\dots,r\}$. Given $\mathcal{H}_{j-1}$, set $\mathcal{S}_j = \operatorname{span}(\mathbf{u}_{j+1},\dots,\mathbf{u}_r) \odot \mathcal{W} \odot \mathcal{H}_{j-1}$.
In a relation $\mathbf{u}_j \in \mathcal{S}_j$, pairing with $\mathbf{u}_1,\dots,\mathbf{u}_{j-1}$ forces all $\mathbf{v}_i$-coefficients to vanish.
Independence of $\mathbf{u}_1,\dots,\mathbf{u}_r$ modulo $\mathcal{W}$ then contradicts the relation.
Hence $\mathbf{u}_j \notin \mathcal{S}_j$. The equality $\mathcal{S}_j^{\perp\perp} = \mathcal{S}_j$ holds by Theorem 3.4.2(iii). Since $\mathbf{u}_j \notin \mathcal{S}_j^{\perp\perp}$, fix $\mathbf{x} \in \mathcal{S}_j^\perp$ with $c := \langle \mathbf{u}_j, \mathbf{x}\rangle \neq 0$.
The inclusion $\mathbf{u}_j \in \mathcal{S}_j^\perp$ holds by the radical property and the preceding stages.
Set $\mathbf{v}_j = c^{-1}\mathbf{x}$ in the symplectic case and $\mathbf{v}_j = c^{-1}\mathbf{x} - \frac{\langle \mathbf{x},\mathbf{x}\rangle}{2c^2}\mathbf{u}_j$ in the orthogonal case.
Then $\mathbf{v}_j \in \mathcal{S}_j^\perp$, $\langle \mathbf{u}_j, \mathbf{v}_j\rangle = 1$, and $\langle \mathbf{v}_j, \mathbf{v}_j\rangle = 0$ by alternation or the correction calculation. Put $\mathcal{H}_j = \mathcal{H}_{j-1} \odot \operatorname{span}(\mathbf{u}_j, \mathbf{v}_j)$.
After r stages, $\mathcal{H}_r$ is hyperbolic, $\mathcal{U} \leq \widehat{\mathcal{U}} := \mathcal{H}_r \odot \mathcal{W}$, and $\dim(\widehat{\mathcal{U}}) = 2r + \dim(\mathcal{W}) = \dim(\mathcal{U}) + r$.

(*ii*) Choose $\mathcal{X} = \mathcal{U} \oplus \mathcal{Y}$ by Proposition 2.3.6.
The pairing $\operatorname{rad}(\mathcal{U}) \times \mathcal{Y} \to \mathbb{F}$ has zero left radical: any vector in it pairs trivially with $\mathcal{U} \oplus \mathcal{Y} = \mathcal{X}$ and therefore lies in $\operatorname{rad}(\mathcal{X}) = \{\mathbf{0}\}$.
Its matrix has rank r by Proposition 4.4.5(iii), so $\dim(\mathcal{Y}) \geq r$ and $\dim(\mathcal{X}) = \dim(\mathcal{U}) + \dim(\mathcal{Y}) \geq \dim(\mathcal{U}) + r$.
Equality is attained by (i). If equality holds, the construction in (i), performed inside $\mathcal{X}$, produces $\widehat{\mathcal{U}} \leq \mathcal{X}$ with $\dim(\widehat{\mathcal{U}}) = \dim(\mathcal{X})$.
Hence $\widehat{\mathcal{U}} = \mathcal{X}$ by Proposition 1.4.3(ii). Every equality-case extension is therefore isometric to $\mathcal{W} \odot \mathcal{H}_r$.

(*iii*) Choose source partners $\mathbf{v}_1,\dots,\mathbf{v}_r$ by (i). Put $\mathbf{u}_i' = \sigma\mathbf{u}_i$ and $\mathcal{W}' = \sigma\mathcal{W}$, so $\mathcal{T} = \operatorname{span}(\mathbf{u}_1',\dots,\mathbf{u}_r') \odot \mathcal{W}'$.
Choose target partners $\mathbf{v}_1',\dots,\mathbf{v}_r'$ by (i) in $\widetilde{\mathcal{V}}$, and extend σ by $(\forall\, i \in \{1,\dots,r\})\, \mathbf{v}_i \mapsto \mathbf{v}_i'$.
This basis-to-basis map preserves the form on the hyperbolic summands, on $\mathcal{W} \to \mathcal{W}'$, and across the orthogonal summands.
It is the required isometry between equality-case extensions.

Structural Commentary: Item (i) pairs radical directions inductively; item (ii) proves minimality; item (iii) transports partners.
Key Insight: Each radical basis vector requires exactly one hyperbolic partner. □

Definition 3.4.10. *Witt Extension and Cancellation Properties*
Let $\mathcal{V} \cong \mathcal{W}$ be nonsingular metric vector spaces of the same kind, either symplectic or orthogonal with $\operatorname{char}(\mathbb{F}) \neq 2$.
Write $\tau : \mathcal{A} \xrightarrow{\sim} \mathcal{B}$ when τ is an isometry. The pair $(\mathcal{V}, \mathcal{W})$ has:

(i) the *Witt extension property* if $(\forall\, \mathcal{S} \leq \mathcal{V})(\forall\, \mathcal{T} \leq \mathcal{W})(\forall\, \tau : \mathcal{S} \xrightarrow{\sim} \mathcal{T})(\exists\, \overline{\tau} : \mathcal{V} \xrightarrow{\sim} \mathcal{W})\, \overline{\tau}|_{\mathcal{S}} = \tau$;
(ii) the *Witt cancellation property* if $(\forall\, \mathcal{S} \leq \mathcal{V})(\forall\, \mathcal{T} \leq \mathcal{W})\, [\operatorname{rad}(\mathcal{S}) = \operatorname{rad}(\mathcal{T}) = \{\mathbf{0}\} \wedge \mathcal{S} \cong \mathcal{T} \Longrightarrow \mathcal{S}^\perp \cong \mathcal{T}^\perp]$.

Proposition 3.4.11. *Witt Extension–Cancellation Bridge*
Let $\mathcal{V} \cong \mathcal{W}$ be nonsingular metric vector spaces of the same kind, either symplectic or orthogonal with $\operatorname{char}(\mathbb{F}) \neq 2$.
Then $(\mathcal{V}, \mathcal{W})$ has the Witt extension property $\Longleftrightarrow$ it has the Witt cancellation property.

Proof.

($\Rightarrow$) Let $\mathcal{S} \leq \mathcal{V}$ and $\mathcal{T} \leq \mathcal{W}$ be nonsingular, fix $\sigma : \mathcal{S} \xrightarrow{\sim} \mathcal{T}$. Decompositions $\mathcal{V} = \mathcal{S} \odot \mathcal{S}^\perp$ and $\mathcal{W} = \mathcal{T} \odot \mathcal{T}^\perp$ hold by Theorem 3.4.2(ii).
Fix an extension $\widehat{\sigma} : \mathcal{V} \xrightarrow{\sim} \mathcal{W}$ by Witt extension property. Then $\widehat{\sigma}(\mathcal{S}^\perp) = \mathcal{T}^\perp$ by form preservation and bijectivity, so $\mathcal{S}^\perp \cong \mathcal{T}^\perp$.

($\Leftarrow$) Fix $\sigma : \mathcal{S} \xrightarrow{\sim} \mathcal{T}$ for arbitrary $\mathcal{S} \leq \mathcal{V}$ and $\mathcal{T} \leq \mathcal{W}$.
Choose equality-case nonsingular extensions $\widehat{\mathcal{S}} \supseteq \mathcal{S}$ and $\widehat{\mathcal{T}} \supseteq \mathcal{T}$ and an extension $\widehat{\sigma} : \widehat{\mathcal{S}} \xrightarrow{\sim} \widehat{\mathcal{T}}$ by Theorem 3.4.9(iii).
The decompositions $\mathcal{V} = \widehat{\mathcal{S}} \odot \widehat{\mathcal{S}}^\perp$ and $\mathcal{W} = \widehat{\mathcal{T}} \odot \widehat{\mathcal{T}}^\perp$ hold by Theorem 3.4.2(ii).
Fix $\eta : \widehat{\mathcal{S}}^\perp \xrightarrow{\sim} \widehat{\mathcal{T}}^\perp$ by the Witt cancellation property. Then $\widehat{\sigma} \odot \eta : \mathcal{V} \xrightarrow{\sim} \mathcal{W}$ extends σ.

Structural Commentary: Extension identifies complements; cancellation pairs the complements of compatible completions.
Key Insight: Nonsingular completion converts arbitrary extension into orthogonal cancellation. □

Theorem 3.4.12. *Witt Extension Theorem*
Let $\mathcal{V} \cong \mathcal{W}$ be nonsingular metric vector spaces of the same kind, either symplectic or orthogonal with $\operatorname{char}(\mathbb{F}) \neq 2$.
If $\mathcal{S} \leq \mathcal{V}$, $\mathcal{T} \leq \mathcal{W}$, and $\sigma : \mathcal{S} \xrightarrow{\sim} \mathcal{T}$, then $(\exists\, \widehat{\sigma} : \mathcal{V} \xrightarrow{\sim} \mathcal{W})\, \widehat{\sigma}|_{\mathcal{S}} = \sigma$.

Proof.

(i) *Symplectic Preparation*: Any two nonsingular symplectic spaces of equal dimension are isometric.
In dimension zero, the unique linear map is an isometry.
At positive dimension, a nonzero vector belongs to a hyperbolic plane by Theorem 3.4.8. The plane splits off by Theorem 3.4.2(ii).
Its orthogonal complement is nonsingular by Theorem 3.4.2(iv).
Induction constructs a hyperbolic basis, and matching hyperbolic bases defines the required isometry.

(ii) *Orthogonal Line Extension*: Let $\mathcal{V}, \mathcal{W}$ be orthogonal, fix $\theta : \mathcal{V} \xrightarrow{\sim} \mathcal{W}$, and suppose $\langle \mathbf{s}, \mathbf{s}\rangle = \langle \mathbf{t}, \mathbf{t}\rangle \neq 0$.
Put $\mathbf{x} = \theta\mathbf{s}$, $\mathbf{y} = \mathbf{t}$, and $q(\mathbf{z}) = \langle \mathbf{z}, \mathbf{z}\rangle$. For $q(\mathbf{a}) \neq 0$, define $r_{\mathbf{a}}(\mathbf{z}) = \mathbf{z} - \frac{2\langle \mathbf{z},\mathbf{a}\rangle}{q(\mathbf{a})}\mathbf{a}$.
Direct expansion establishes $\langle r_{\mathbf{a}}\mathbf{z}, r_{\mathbf{a}}\mathbf{w}\rangle = \langle \mathbf{z}, \mathbf{w}\rangle$, $r_{\mathbf{a}}^2 = I_{\mathcal{W}}$, and $r_{\mathbf{a}}\mathbf{a} = -\mathbf{a}$. Thus $r_{\mathbf{a}}$ is isometry. If $q(\mathbf{x}-\mathbf{y}) \neq 0$, then $r_{\mathbf{x}-\mathbf{y}}\mathbf{x} = \mathbf{y}$.
If $q(\mathbf{x}-\mathbf{y}) = 0$, then $q(\mathbf{x}+\mathbf{y}) = 4q(\mathbf{y}) \neq 0$ and $r_{\mathbf{y}} r_{\mathbf{x}+\mathbf{y}}\mathbf{x} = \mathbf{y}$. Thus $r_{\mathbf{x}-\mathbf{y}}\theta$ or $r_{\mathbf{y}} r_{\mathbf{x}+\mathbf{y}}\theta$ extends $\mathbf{s} \mapsto \mathbf{t}$.

(iii) *Nonsingular Subspaces*: Suppose that $\mathcal{S}, \mathcal{T}$ are nonsingular, and induct on $\dim(\mathcal{S})$.
The zero-dimensional case is the assumed isometry $\mathcal{V} \cong \mathcal{W}$.
At positive dimension, choose a hyperbolic plane $\mathcal{A} \leq \mathcal{S}$ in the symplectic case by Theorem 3.4.8.
In the orthogonal case, fix $\mathbf{s} \in \mathcal{S}$ with $\langle \mathbf{s}, \mathbf{s}\rangle \neq 0$ by Proposition 3.1.2(ii) and nonsingularity, and set $\mathcal{A} = \operatorname{span}(\mathbf{s})$.
In either case, put $\mathcal{B} = \sigma\mathcal{A}$. In the symplectic case, $\mathcal{A}^\perp$ and $\mathcal{B}^\perp$ are nonsingular and equal-dimensional by Theorem 3.4.2(i),(iv).
In that case, fix $\beta : \mathcal{A}^\perp \xrightarrow{\sim} \mathcal{B}^\perp$ by (i), and set $\alpha = (\sigma|_{\mathcal{A}}) \odot \beta$. In orthogonal case, fix ambient isometry α extending $\sigma|_{\mathcal{A}}$ by (ii).
Set $\mathcal{S}_0 = \mathcal{S} \cap \mathcal{A}^\perp$ and $\mathcal{T}_0 = \mathcal{T} \cap \mathcal{B}^\perp$; then $\sigma(\mathcal{S}_0) = \mathcal{T}_0$. Decompositions $\mathcal{S} = \mathcal{A} \odot \mathcal{S}_0$ and $\mathcal{T} = \mathcal{B} \odot \mathcal{T}_0$ hold by Theorem 3.4.2(ii).
Spaces $\mathcal{S}_0, \mathcal{T}_0$ are nonsingular by Theorem 3.4.2(iv). Decompositions $\mathcal{V} = \mathcal{A} \odot \mathcal{A}^\perp$ and $\mathcal{W} = \mathcal{B} \odot \mathcal{B}^\perp$ hold by Theorem 3.4.2(ii).
The restriction $\alpha|_{\mathcal{A}^\perp}$ identifies the ambient complements, and $\dim(\mathcal{S}_0) < \dim(\mathcal{S})$.
Fix $\eta : \mathcal{A}^\perp \xrightarrow{\sim} \mathcal{B}^\perp$ with $\eta|_{\mathcal{S}_0} = \sigma|_{\mathcal{S}_0}$ by induction. Then $(\sigma|_{\mathcal{A}}) \odot \eta : \mathcal{V} \xrightarrow{\sim} \mathcal{W}$ extends σ.

(iv) *General Subspaces*: Choose compatible nonsingular extensions $\widehat{\mathcal{S}}, \widehat{\mathcal{T}}$ and $\widehat{\sigma} : \widehat{\mathcal{S}} \xrightarrow{\sim} \widehat{\mathcal{T}}$ extending σ by Theorem 3.4.9(iii).
An ambient isometry extending $\widehat{\sigma}$ exists by (iii), and it also extends σ.

Structural Commentary: Reflections or hyperbolic planes drive induction on nonsingular completions of arbitrary subspaces.
Key Insight: Compatible completion reduces extension to nonsingular summand induction. □

Corollary 3.4.13. *Witt Cancellation*
Let $\mathcal{V} = \mathcal{S} \odot \mathcal{A}$, $\mathcal{W} = \mathcal{T} \odot \mathcal{B}$ be nonsingular metric vector spaces of the same kind, either symplectic or orthogonal with $\operatorname{char}(\mathbb{F}) \neq 2$.
If $\mathcal{V} \cong \mathcal{W}$ and $\mathcal{S} \cong \mathcal{T}$, then $\mathcal{A} \cong \mathcal{B}$.

Proof. Fix $\sigma : \mathcal{S} \xrightarrow{\sim} \mathcal{T}$, and fix $\widehat{\sigma} : \mathcal{V} \xrightarrow{\sim} \mathcal{W}$ with $\widehat{\sigma}|_{\mathcal{S}} = \sigma$ by Theorem 3.4.12.
Identities $\mathcal{A} = \mathcal{S}^{\perp}$ and $\mathcal{B} = \mathcal{T}^{\perp}$ follow from orthogonal decompositions. Hence $\widehat{\sigma}(\mathcal{A}) = \widehat{\sigma}(\mathcal{S}^{\perp}) = (\widehat{\sigma}\mathcal{S})^{\perp} = \mathcal{T}^{\perp} = \mathcal{B}$, so $\widehat{\sigma}|_{\mathcal{A}} : \mathcal{A} \xrightarrow{\sim} \mathcal{B}$.
Structural Commentary: Witt extension sends the first summand to its mate and therefore identifies their complements.
Key Insight: An ambient isometry preserves orthogonal complements. □

Definition 3.4.14. *Witt Index*
Let $\mathcal{V}$ be nonsingular orthogonal with $\operatorname{char}(\mathbb{F}) \neq 2$. Its *Witt index* is $w(\mathcal{V}) := \max\{\dim(\mathcal{L}) : \mathcal{L} \leq \mathcal{V},\ \mathcal{L} \subseteq \mathcal{L}^{\perp}\}$.

Theorem 3.4.15. *Witt Index and Anisotropic Decomposition*
Let $\mathcal{V}$ be orthogonal over $\mathbb{F}$ with $\operatorname{char}(\mathbb{F}) \neq 2$.

(i) If $\mathcal{V}$ is nonsingular, every maximal totally isotropic subspace has dimension $w(\mathcal{V})$.
(ii) If $\mathcal{V}$ is nonsingular, every maximal hyperbolic subspace has dimension $2w(\mathcal{V})$.
(iii) Let $R = \operatorname{rad}(\mathcal{V})$ and $\mathcal{V} = R \oplus \mathcal{U}$ with $\mathcal{U}$ nonsingular.
Then $(\exists\, \mathcal{H}, \mathcal{S} \leq \mathcal{U})\ \mathcal{H}$ is hyperbolic, $\mathcal{S}$ is anisotropic, $\mathcal{V} = \mathcal{S} \odot \mathcal{H} \odot R$, and $\dim(\mathcal{H}) = 2w(\mathcal{U})$.

Proof.

(*i*) Assume that $\mathcal{V}$ is nonsingular, and let $\mathcal{L}$ be maximal totally isotropic.
Choose a totally isotropic $\mathcal{M}$ with $\dim(\mathcal{M}) = w(\mathcal{V})$ by the definition of $w(\mathcal{V})$.
As $\dim(\mathcal{L}) \leq \dim(\mathcal{M})$, choose $\mathcal{M}_0 \leq \mathcal{M}$ with $\dim(\mathcal{M}_0) = \dim(\mathcal{L})$. Fix vector-space isomorphism $\tau : \mathcal{L} \to \mathcal{M}_0$ by Theorem 1.7.9.
It is an isometry because both restricted forms vanish. Fix $\Phi \in \mathcal{O}(\mathcal{V})$ with $\Phi|_{\mathcal{L}} = \tau$ by Theorem 3.4.12.
Then $\mathcal{L} \subseteq \Phi^{-1}\mathcal{M}$, and $\Phi^{-1}\mathcal{M}$ is totally isotropic. Hence $\mathcal{L} = \Phi^{-1}\mathcal{M}$ by maximality, so $\dim(\mathcal{L}) = w(\mathcal{V})$.

(*ii*) Assume that $\mathcal{V}$ is nonsingular. If a hyperbolic subspace has k planes, the span of one first vector from each hyperbolic pair is a k-dimensional totally isotropic subspace; hence $k \leq w(\mathcal{V})$. Choose a totally isotropic $\mathcal{M}$ of dimension $w(\mathcal{V})$.
Since $\operatorname{rad}(\mathcal{M}) = \mathcal{M}$, a hyperbolic completion $\mathcal{H}_0 \supseteq \mathcal{M}$ with $\dim(\mathcal{H}_0) = 2w(\mathcal{V})$ exists by Theorem 3.4.9(i).
Suppose that a maximal hyperbolic $\mathcal{H}$ has dimension $2k < 2w(\mathcal{V})$, and choose the span $\mathcal{H}_1 \leq \mathcal{H}_0$ of k hyperbolic pairs.
Matching hyperbolic bases defines an isometry $\mathcal{H} \to \mathcal{H}_1$. Fix an extension $\Phi \in \mathcal{O}(\mathcal{V})$ by Theorem 3.4.12.
Then $\mathcal{H} \subsetneq \Phi^{-1}\mathcal{H}_0$, contrary to maximality. Therefore $\dim(\mathcal{H}) = 2w(\mathcal{V})$.

(*iii*) Since $R \perp \mathcal{V}$, the assumed complement satisfies $\mathcal{V} = R \odot \mathcal{U}$.
Choose a maximal hyperbolic $\mathcal{H} \leq \mathcal{U}$, and put $\mathcal{S} = \mathcal{H}^{\perp} \cap \mathcal{U}$. The hyperbolic basis makes $\mathcal{H}$ nonsingular.
The identities $\dim(\mathcal{H}) = 2w(\mathcal{U})$ and $\mathcal{U} = \mathcal{H} \odot \mathcal{S}$ hold by (ii) and Theorem 3.4.2(ii). Space $\mathcal{S}$ is nonsingular by Theorem 3.4.2(iv).
If $\mathcal{S}$ contained a nonzero isotropic vector, a hyperbolic plane $\mathcal{P} \leq \mathcal{S}$ would contain it by Theorem 3.4.8.
Then $\mathcal{H} \odot \mathcal{P}$ would contradict maximality of $\mathcal{H}$. Thus $\mathcal{S}$ is anisotropic and $\mathcal{V} = \mathcal{S} \odot \mathcal{H} \odot R$.

Structural Commentary: Witt extension fixes maximal isotropic and hyperbolic dimensions; splitting isolates the anisotropic residue.
Key Insight: Each hyperbolic plane contributes one maximal isotropic dimension. □

3.5 Symplectic Classification and Transvections

Throughout this subsection, symplectic geometries are finite-dimensional over a fixed arbitrary field $\mathbb{F}$.

Theorem 3.5.1. *Classification of Symplectic Geometries*
Let $\mathcal{V}$ be a symplectic geometry, $R = \operatorname{rad}(\mathcal{V})$, $n = \dim(\mathcal{V})$, and $r = \operatorname{rank}(\mathcal{V})$.

(i) If $R = \{\mathbf{0}\}$, then $\mathcal{V}$ is hyperbolic and n is even.
(ii) $\mathcal{V} = R \odot \mathcal{H}$ for a hyperbolic subspace $\mathcal{H} \leq \mathcal{V}$, and R is totally singular.
(iii) $r \in 2\mathbb{Z}_{\geq 0}$. If $r = 2k$, then $\mathcal{V}$ has a basis β. For these choices, $M_\beta = X_{2k,n-2k} := \operatorname{diag}(J_2^{\oplus k}, 0_{n-2k})$, where $J_2 := \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$.
(iv) For symplectic geometries $\mathcal{V}, \mathcal{W}$, $\mathcal{V} \cong \mathcal{W} \iff \dim \mathcal{V} = \dim \mathcal{W}\ \wedge\ \operatorname{rank}(\mathcal{V}) = \operatorname{rank}(\mathcal{W})$.

Proof.

(*i*) The claim holds for $n = 0$. Suppose $n > 0$ and fix $\mathbf{0} \neq \mathbf{x} \in \mathcal{V}$.
The vector $\mathbf{x}$ is isotropic by alternation and lies in a hyperbolic plane $\mathcal{H}_1$ by Theorem 3.4.8.
By Theorem 3.4.2(ii),(iv), $\mathcal{V} = \mathcal{H}_1 \odot \mathcal{H}_1^{\perp}$ and $\mathcal{H}_1^{\perp}$ is nonsingular.
The complement $\mathcal{H}_1^{\perp}$ is hyperbolic by induction on n, so $\mathcal{V}$ is hyperbolic and n is even.

(*ii*) By Theorem 3.4.3, $\mathcal{V} = R \odot \mathcal{S}$ for a nonsingular $\mathcal{S}$, and R is totally singular.
The subspace $\mathcal{S}$ is hyperbolic by (i), so $\mathcal{H} := \mathcal{S}$ has the required properties.

(*iii*) By (ii), $\mathcal{V} = R \odot \mathcal{H}$ with $\mathcal{H}$ hyperbolic. Since $\dim R = n - r$, $\dim \mathcal{H} = r$.
Write $\mathcal{H}$ as an orthogonal sum of k hyperbolic planes; then $r = 2k$.
A hyperbolic basis of $\mathcal{H}$ followed by a basis of R is a basis β of $\mathcal{V}$ satisfying $M_\beta = X_{2k,n-2k}$.

(*iv*) ($\Rightarrow$) Let $\sigma : \mathcal{V} \to \mathcal{W}$ be an isometry. Then $\dim \mathcal{V} = \dim \mathcal{W}$ by bijectivity.
If β is a basis of $\mathcal{V}$, then $\sigma\beta$ is a basis of $\mathcal{W}$ and $M_{\sigma\beta} = M_\beta$ by form preservation; hence $\operatorname{rank}(\mathcal{V}) = \operatorname{rank}(\mathcal{W})$.

(*iv*) ($\Leftarrow$) Suppose $\dim \mathcal{V} = \dim \mathcal{W}$ and $\operatorname{rank}(\mathcal{V}) = \operatorname{rank}(\mathcal{W})$. By (iii), $\mathcal{V}$ and $\mathcal{W}$ have bases with the same matrix $X_{2k,n-2k}$.
The basis-to-basis isomorphism is an isometry by Proposition 3.1.4(i), so $\mathcal{V} \cong \mathcal{W}$.

Structural Commentary: Radical splitting transfers classification to hyperbolic planes, whose block matrix determines isometry.
Key Insight: Every nonsingular alternating summand is exhausted by hyperbolic planes. □

Definition 3.5.2. *Symplectic Transvection*
Let $\mathcal{V}$ be a nonsingular symplectic geometry, $\mathbf{0} \neq \mathbf{v} \in \mathcal{V}$, and $a \in \mathbb{F}$. Define $\tau_{\mathbf{v},a} : \mathcal{V} \to \mathcal{V}$ by $\tau_{\mathbf{v},a}(\mathbf{x}) = \mathbf{x} + a\,\langle \mathbf{x}, \mathbf{v} \rangle\,\mathbf{v}$.
This operator is the *symplectic transvection* with direction $\mathbf{v}$ and parameter a.

Proposition 3.5.3. *Basic Properties of Symplectic Transvections*
Let $\mathcal{V}$ be a nonsingular symplectic geometry and $\mathbf{0} \neq \mathbf{v} \in \mathcal{V}$. Fix $a, b \in \mathbb{F}$, $c \in \mathbb{F}^{\times}$, and $\sigma \in \operatorname{Sp}(\mathcal{V})$.

(i) $\tau_{\mathbf{v},a} \in \operatorname{Sp}(\mathcal{V})$;
(ii) $\tau_{\mathbf{v},a} = I_{\mathcal{V}} \iff a = 0$;
(iii) $\tau_{\mathbf{v},a}\tau_{\mathbf{v},b} = \tau_{\mathbf{v},a+b}$;

(iv) $\tau_{\mathbf{v},a}^{-1} = \tau_{\mathbf{v},-a}$;
(v) $\sigma\tau_{\mathbf{v},a}\sigma^{-1} = \tau_{\sigma\mathbf{v},a}$;
(vi) $\tau_{c\mathbf{v},a} = \tau_{\mathbf{v},ac^2}$.

Proof.
(i) Put $T := \tau_{\mathbf{v},a}$, $\lambda(\mathbf{x}) := \langle \mathbf{x}, \mathbf{v}\rangle$. Then $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})\ \langle T\mathbf{x}, T\mathbf{y}\rangle - \langle \mathbf{x}, \mathbf{y}\rangle = a\lambda(\mathbf{y})\lambda(\mathbf{x}) - a\lambda(\mathbf{x})\lambda(\mathbf{y}) = 0$ by bilinearity and alternation.
$(\forall\, \mathbf{x} \in \mathcal{V})\ \tau_{\mathbf{v},-a}T(\mathbf{x}) = \mathbf{x} = T\tau_{\mathbf{v},-a}(\mathbf{x})$ by alternation. Thus T is an invertible form-preserving linear map, so $T \in \mathrm{Sp}(\mathcal{V})$.
(ii) ($\Rightarrow$) Suppose $\tau_{\mathbf{v},a} = I_{\mathcal{V}}$. If $a \neq 0$, fix $\mathbf{x}$ satisfying $\langle \mathbf{x}, \mathbf{v}\rangle \neq 0$ by nonsingularity.
Then $\tau_{\mathbf{v},a}\mathbf{x} - \mathbf{x} = a\langle \mathbf{x}, \mathbf{v}\rangle\, \mathbf{v} \neq \mathbf{0}$, a contradiction. Hence $a = 0$.
(ii) ($\Leftarrow$) If $a = 0$, then $\tau_{\mathbf{v},a} = I_{\mathcal{V}}$ by definition.
(iii) By alternation, $(\forall\, \mathbf{x} \in \mathcal{V})\ \tau_{\mathbf{v},a}\tau_{\mathbf{v},b}(\mathbf{x}) = \mathbf{x} + (a+b)\langle \mathbf{x}, \mathbf{v}\rangle\, \mathbf{v} = \tau_{\mathbf{v},a+b}(\mathbf{x})$. Hence $\tau_{\mathbf{v},a}\tau_{\mathbf{v},b} = \tau_{\mathbf{v},a+b}$.
(iv) $\tau_{\mathbf{v},a}^{-1} = \tau_{\mathbf{v},-a}$ by (ii),(iii) with $b = -a$.
(v) Fix $\mathbf{x} \in \mathcal{V}$. Then $\langle \sigma^{-1}\mathbf{x}, \mathbf{v}\rangle = \langle \mathbf{x}, \sigma\mathbf{v}\rangle$ by form preservation. Hence $\sigma\tau_{\mathbf{v},a}\sigma^{-1}(\mathbf{x}) = \mathbf{x} + a\langle \mathbf{x}, \sigma\mathbf{v}\rangle\, \sigma\mathbf{v} = \tau_{\sigma\mathbf{v},a}(\mathbf{x})$.
(vi) $(\forall\, \mathbf{x} \in \mathcal{V})\ \tau_{c\mathbf{v},a}(\mathbf{x}) = \mathbf{x} + ac^2\langle \mathbf{x}, \mathbf{v}\rangle\, \mathbf{v} = \tau_{\mathbf{v},ac^2}(\mathbf{x})$ by bilinearity.

Structural Commentary: Alternation controls preservation and composition; nonsingularity detects the zero parameter.
Key Insight: The rank-one square vanishes, and the two mixed form terms cancel. □

Theorem 3.5.4. *Symplectic Transvections Generate*
If $\mathcal{V}$ is nonsingular symplectic, then $\mathrm{Sp}(\mathcal{V}) = \langle \tau_{\mathbf{v},a} : \mathbf{0} \neq \mathbf{v} \in \mathcal{V},\ a \in \mathbb{F}\rangle$.

Proof.
(i) *Generated Subgroup*: Put $G := \langle \tau_{\mathbf{v},a} : \mathbf{0} \neq \mathbf{v} \in \mathcal{V},\ a \in \mathbb{F}\rangle$. Then $G \leq \mathrm{Sp}(\mathcal{V})$ by Proposition 3.5.3(i).
(ii) *Vector Transitivity*: Fix $\mathbf{0} \neq \mathbf{x}, \mathbf{y} \in \mathcal{V}$. If $\langle \mathbf{x}, \mathbf{y}\rangle \neq 0$, then $\tau_{\mathbf{y}-\mathbf{x},\langle \mathbf{x},\mathbf{y}\rangle^{-1}}(\mathbf{x}) = \mathbf{y}$.
Suppose $\langle \mathbf{x}, \mathbf{y}\rangle = 0$ and $\mathbf{y} = \lambda\mathbf{x}$ for $\lambda \in \mathbb{F}^\times$. Fix $\mathbf{z}$ satisfying $\langle \mathbf{x}, \mathbf{z}\rangle \neq 0$ by nonsingularity. Then $\langle \mathbf{z}, \mathbf{y}\rangle = -\lambda\langle \mathbf{x}, \mathbf{z}\rangle \neq 0$.
If $\mathbf{x}, \mathbf{y}$ are independent, choose $\mathcal{V} = \mathrm{span}(\mathbf{x}, \mathbf{y}) \oplus \mathcal{C}$ by Proposition 2.3.6. Define $f \in \mathcal{V}'$ by $f(\alpha\mathbf{x} + \beta\mathbf{y} + \mathbf{c}) = \alpha - \beta$ for $\mathbf{c} \in \mathcal{C}$.
Fix $\mathbf{z}$ satisfying $(\forall\, \mathbf{t} \in \mathcal{V})\ f(\mathbf{t}) = \langle \mathbf{t}, \mathbf{z}\rangle$ by Theorem 3.3.6. Then $\langle \mathbf{x}, \mathbf{z}\rangle = \langle \mathbf{z}, \mathbf{y}\rangle = 1$ by the definition of f and alternation.
In either case, put $c := \langle \mathbf{x}, \mathbf{z}\rangle$ and $d := \langle \mathbf{z}, \mathbf{y}\rangle$. Thus $c, d \neq 0$, $\tau_{\mathbf{z}-\mathbf{x},c^{-1}}(\mathbf{x}) = \mathbf{z}$, and $\tau_{\mathbf{y}-\mathbf{z},d^{-1}}(\mathbf{z}) = \mathbf{y}$; G is transitive on $\mathcal{V} \setminus \{\mathbf{0}\}$.
(iii) *Hyperbolic-Pair Transitivity*: Fix hyperbolic pairs $(\mathbf{u}, \mathbf{v})$ and $(\mathbf{u}', \mathbf{v}')$.
Choose $\gamma \in G$ satisfying $\gamma\mathbf{u} = \mathbf{u}'$ by (ii), and put $\mathbf{w} := \gamma\mathbf{v}$. Then $(\mathbf{u}', \mathbf{w})$ is hyperbolic. If $\mathbf{w} = \mathbf{v}'$, put $\delta := I_{\mathcal{V}}$.
If $p := \langle \mathbf{w}, \mathbf{v}'\rangle \neq 0$, put $\delta := \tau_{\mathbf{v}'-\mathbf{w},p^{-1}}$. Then $\delta\mathbf{u}' = \mathbf{u}'$ and $\delta\mathbf{w} = \mathbf{v}'$ by direct evaluation. Suppose $\mathbf{w} \neq \mathbf{v}'$ and $\langle \mathbf{w}, \mathbf{v}'\rangle = 0$.
If $a\mathbf{u}' + b\mathbf{w} + c\mathbf{v}' = \mathbf{0}$, then $b + c = 0$ and $a = 0$ by pairing with $\mathbf{u}'$ and $\mathbf{w}$.
Hence $b(\mathbf{w} - \mathbf{v}') = \mathbf{0}$, so $a = b = c = 0$ and $\mathbf{u}', \mathbf{w}, \mathbf{v}'$ are independent. Choose $\mathcal{V} = \mathrm{span}(\mathbf{u}', \mathbf{w}, \mathbf{v}') \oplus \mathcal{C}$ by Proposition 2.3.6.
Define $f \in \mathcal{V}'$ by $f(a\mathbf{u}' + b\mathbf{w} + c\mathbf{v}' + \mathbf{d}) = a + b - c$ for $\mathbf{d} \in \mathcal{C}$. Fix $\mathbf{z}$ satisfying $(\forall\, \mathbf{t} \in \mathcal{V})\ f(\mathbf{t}) = \langle \mathbf{t}, \mathbf{z}\rangle$ by Theorem 3.3.6.
Then $\langle \mathbf{u}', \mathbf{z}\rangle = \langle \mathbf{w}, \mathbf{z}\rangle = \langle \mathbf{z}, \mathbf{v}'\rangle = 1$ by the definition of f and alternation.
The transvections $\tau_{\mathbf{z}-\mathbf{w},1}$ and $\tau_{\mathbf{v}'-\mathbf{z},1}$ fix $\mathbf{u}'$. The identities $\tau_{\mathbf{z}-\mathbf{w},1}(\mathbf{w}) = \mathbf{z}$ and $\tau_{\mathbf{v}'-\mathbf{z},1}(\mathbf{z}) = \mathbf{v}'$ hold by direct evaluation.
Thus $\delta := \tau_{\mathbf{v}'-\mathbf{z},1}\tau_{\mathbf{z}-\mathbf{w},1}$ fixes $\mathbf{u}'$ and maps $\mathbf{w}$ to $\mathbf{v}'$. In every case, $\delta\gamma \in G$ maps $(\mathbf{u}, \mathbf{v})$ to $(\mathbf{u}', \mathbf{v}')$.
(iv) *Dimension Induction*: Fix $\sigma \in \mathrm{Sp}(\mathcal{V})$ and put $n := \dim \mathcal{V}$. We induct on n. If $n = 0$, then $\sigma = I_{\mathcal{V}} \in G$. Suppose $n > 0$.
Choose a hyperbolic plane $\mathcal{H} = \mathrm{span}(\mathbf{u}, \mathbf{v})$ by Theorem 3.5.1(i). By (iii), fix $\gamma \in G$ mapping $(\sigma\mathbf{u}, \sigma\mathbf{v})$ to $(\mathbf{u}, \mathbf{v})$; hence $\gamma\sigma|_{\mathcal{H}} = I_{\mathcal{H}}$.
By Theorem 3.4.2(ii),(iv), $\mathcal{V} = \mathcal{H} \odot \mathcal{H}^\perp$ and $\mathcal{H}^\perp$ is nonsingular.
The subspace $\mathcal{H}^\perp$ is $\gamma\sigma$-invariant by form preservation and pointwise fixation of $\mathcal{H}$.
Thus $(\gamma\sigma)|_{\mathcal{H}^\perp} \in \mathrm{Sp}(\mathcal{H}^\perp)$ and is a product of transvections by induction.
Each factor $\tau_{\mathbf{x},a}$ extends to the same transvection on $\mathcal{V}$. Since $\mathbf{x} \in \mathcal{H}^\perp$, it fixes $\mathcal{H}$ pointwise.
The ambient product agrees with $\gamma\sigma$ on both orthogonal summands. Therefore $\gamma\sigma \in G$ and $\sigma = \gamma^{-1}(\gamma\sigma) \in G$.

Structural Commentary: Vector transitivity upgrades to pair transitivity; hyperbolic-plane induction then factors every isometry.
Key Insight: Pair transitivity isolates a fixed hyperbolic plane for dimension induction. □

Proposition 3.5.5. *Symplectic Transformations Have Determinant One*
If $\mathcal{V}$ is nonsingular symplectic, then $(\forall\, \sigma \in \mathrm{Sp}(\mathcal{V}))\ \det(\sigma) = 1$.

Proof. Fix $\sigma \in \mathrm{Sp}(\mathcal{V})$. It is a product of transvections by Theorem 3.5.4.
By determinant multiplicativity, it suffices to prove $\det(\tau_{\mathbf{v},a}) = 1$ for $\mathbf{0} \neq \mathbf{v} \in \mathcal{V}$ and $a \in \mathbb{F}$.
The transvection $\tau_{\mathbf{v},a}$ fixes $\mathbb{F}\mathbf{v}$ by alternation and induces $I_{\mathcal{V}/\mathbb{F}\mathbf{v}}$ by its defining formula.
Thus its matrix in a basis beginning with $\mathbf{v}$ is upper triangular with unit diagonal, so $\det(\tau_{\mathbf{v},a}) = 1$.
Structural Commentary: Transvection generation reduces the determinant to one basis-adapted rank-one map.
Key Insight: Only the leading coordinate changes, so the matrix is unit upper triangular. □

3.6 Orthogonal Classification over Common Fields

Throughout this subsection, orthogonal geometries are finite-dimensional over a field $\mathbb{F}$; additional hypotheses are stated locally.

Theorem 3.6.1. *Orthogonal Bases and Diagonal Congruence*
Let $(\mathcal{V}, B)$ be an orthogonal geometry, $q(\mathbf{x}) := B(\mathbf{x}, \mathbf{x})$, $n = \dim \mathcal{V}$, and $r = \mathrm{rank}\, B$.
(i) An orthogonal basis β with $M_\beta = \mathrm{diag}(a_1, \ldots, a_r, 0_{n-r})$ and $a_1, \ldots, a_r \in \mathbb{F}^\times$ exists $\iff$ $\mathrm{char}(\mathbb{F}) \neq 2 \ \vee\ B = 0 \ \vee\ q \not\equiv 0$.
(ii) A symmetric $A \in \mathrm{Mat}(n, n, \mathbb{F})$ is congruent to a diagonal matrix $\iff$ $\mathrm{char}(\mathbb{F}) \neq 2 \ \vee\ A = 0 \ \vee\ (\exists\, \mathbf{x} \in \mathbb{F}^n)\ \mathbf{x}^t A\mathbf{x} \neq 0$.

Proof.
(i) ($\Rightarrow$) Only $\mathrm{char}(\mathbb{F}) = 2$ and $q \equiv 0$ require proof. In this case every diagonal entry of M_β equals $q(\mathbf{v}) = 0$, so $M_\beta = 0$ and $B = 0$.
(i) ($\Leftarrow$) If $B = 0$, any basis works. Assume $B \neq 0$. Then $q \not\equiv 0$ by hypothesis if $\mathrm{char}(\mathbb{F}) = 2$, and by Proposition 3.1.2(ii) otherwise.
Splitting successive nonisotropic lines by Theorem 3.4.2(ii) produces $\mathcal{V} = \mathbb{F}\mathbf{u}_1 \odot \cdots \odot \mathbb{F}\mathbf{u}_s \odot \mathcal{W}$ with $q(\mathbf{u}_i) = a_i \in \mathbb{F}^\times$ and $q|_{\mathcal{W}} \equiv 0$.
If $\mathrm{char}(\mathbb{F}) \neq 2$, then $B|_{\mathcal{W}} = 0$ by Proposition 3.1.2(ii). Appending any basis of $\mathcal{W}$ produces a diagonal Gram matrix of rank r.
Assume $\mathrm{char}(\mathbb{F}) = 2$; then $B|_{\mathcal{W}}$ alternating. By Theorem 3.5.1(ii), $\mathcal{W} = R \odot \mathcal{H}_1 \odot \cdots \odot \mathcal{H}_t$, $B|_R = 0$, each $\mathcal{H}_j$ hyperbolic.
Fix a current $\mathbf{u}$ with $q(\mathbf{u}) = a \neq 0$. For a hyperbolic basis $(\mathbf{e}, \mathbf{f})$ of $\mathcal{H}_j$, rescale $\mathbf{f}$ so that $B(\mathbf{e}, \mathbf{f}) = a$.
The vectors $\mathbf{u} + \mathbf{e}$, $\mathbf{u} + \mathbf{f}$, and $\mathbf{u} + \mathbf{e} + \mathbf{f}$ are independent by coefficient comparison.
These vectors have norm a and mutual pairings $a + a = 0$, so they form an orthogonal basis of $\mathbb{F}\mathbf{u} \odot \mathcal{H}_j$.
Retain one new line for the next plane; after t replacements, append a basis of R.
The resulting diagonal matrix has exactly r nonzero entries by rank invariance.

(*ii*) ($\Rightarrow$) Let $D = P^tAP$ be diagonal with P invertible.
If $\mathrm{char}(\mathbb{F}) = 2$ and $(\forall\, \mathbf{x} \in \mathbb{F}^n)\, \mathbf{x}^tA\mathbf{x} = 0$, then $(\forall\, j \in \{1, \dots, n\})\, D_{jj} = (P\mathbf{e}_j)^tA(P\mathbf{e}_j) = 0$. Thus $D = 0$ and $A = 0$.
(*ii*) ($\Leftarrow$) Define $B_A(\mathbf{x}, \mathbf{y}) := \mathbf{x}^tA\mathbf{y}$ on $\mathbb{F}^n$. Its norm map is $\mathbf{x} \mapsto \mathbf{x}^tA\mathbf{x}$, so the hypothesis is exactly that of (i).
Since $A = A^t$, the form B_A is symmetric, so choose an orthogonal basis by (i).
Its change-of-basis matrix diagonalizes A by Proposition 3.1.4(ii).

Structural Commentary: Split nonisotropic lines; in characteristic 2, absorb each residual hyperbolic plane into one retained line.
Key Insight: A nonzero alternating symmetric form in characteristic 2 is the sole obstruction. □

Proposition 3.6.2. *Recognizing Orthogonal Hyperbolic Planes*
Let $\mathcal{H}$ be a 2-dimensional nonsingular orthogonal geometry with $\mathrm{char}(\mathbb{F}) \neq 2$. *The following are equivalent:*

(i) $\mathcal{H}$ is a hyperbolic plane;
(ii) $(\exists\, \mathbf{u} \in \mathcal{H} \setminus \{\mathbf{0}\})\, \langle \mathbf{u}, \mathbf{u} \rangle = 0$;
(iii) $\Delta(\mathcal{H}) = -(\mathbb{F}^\times)^2$.

Proof.

(*i*) $\Rightarrow$ (*ii*) A hyperbolic basis contains a nonzero isotropic vector by the definition of a hyperbolic pair.
(*ii*) $\Rightarrow$ (*iii*) By Theorem 3.4.8, fix $\mathbf{v}$ such that $(\mathbf{u}, \mathbf{v})$ is hyperbolic.
Since $\dim \mathcal{H} = 2$, this pair is a basis. Its Gram matrix has determinant $\det \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right) = -1$, so $\Delta(\mathcal{H}) = -(\mathbb{F}^\times)^2$.
(*iii*) $\Rightarrow$ (*i*) By Theorem 3.6.1(i), write $M = \mathrm{diag}(a, b)$ with $a, b \in \mathbb{F}^\times$. Choose $c \in \mathbb{F}^\times$ with $ab = -c^2$ by the discriminant hypothesis.
Then $a\left(\frac{c}{a}\right)^2 + b = 0$, so $\left(\frac{c}{a}, 1\right)$ is a nonzero isotropic coordinate vector.
It lies in a hyperbolic plane by Theorem 3.4.8, and that plane equals $\mathcal{H}$ by dimension.

Structural Commentary: Pass from a hyperbolic basis to determinant -1, then recover isotropy from the discriminant square class.
Key Insight: In a nonsingular orthogonal plane, representing zero is exactly hyperbolicity. □

Example 3.6.3. *Characteristic Two Orthogonal-Symplectic Plane*
Assume $\mathrm{char}(\mathbb{F}) = 2$ and let $(\mathcal{H}, B)$ have basis $(\mathbf{e}, \mathbf{f})$ with Gram matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$.
The matrix is symmetric and has determinant 1, while $(\forall\, a, b \in \mathbb{F})\, B(a\mathbf{e}+b\mathbf{f}, a\mathbf{e}+b\mathbf{f}) = 2ab = 0$; hence B is nonsingular and alternating.
For $\mathbf{0} \neq \mathbf{x} \in \mathcal{H}$, alternation implies $\mathbb{F}\mathbf{x} \leq (\mathbb{F}\mathbf{x})^\perp$, and both spaces have dimension 1 by Theorem 3.4.2(i).
Thus $(\mathbb{F}\mathbf{x})^\perp = \mathbb{F}\mathbf{x}$, so no second basis vector can be orthogonal to $\mathbf{x}$. This is precisely the obstruction in Theorem 3.6.1.

Computation Method 3.6.4. *Lagrange Orthogonalization*
Let $(\mathcal{V}, B)$ be an orthogonal geometry with $\mathrm{char}(\mathbb{F}) \neq 2$ and $q(\mathbf{x}) := B(\mathbf{x}, \mathbf{x})$.
Input: a finite spanning list L. Output: an orthogonal basis of $\mathcal{V}$.

(i) Initialize $\mathcal{W}_0 = \mathcal{V}$ and $L_0 = L$. At stage k, stop with $R = \mathcal{W}_k$ if $q|_{\mathcal{W}_k} \equiv 0$.
If $(\exists\, \mathbf{x} \in L_k)\, q(\mathbf{x}) \neq 0$, take such an $\mathbf{x}$ as $\mathbf{u}_{k+1}$. Otherwise write $L_k = (\mathbf{x}_1, \dots, \mathbf{x}_{\ell_k})$.
Then $(\exists\, i, j \in \{1, \dots, \ell_k\})\, B(\mathbf{x}_i, \mathbf{x}_j) \neq 0$, since the contrary would imply $B|_{\mathcal{W}_k} = 0$ by bilinearity and spanning.
Put $\mathbf{u}_{k+1} = \mathbf{x}_i + \mathbf{x}_j$; then $q(\mathbf{u}_{k+1}) = 2B(\mathbf{x}_i, \mathbf{x}_j) \neq 0$.
(ii) Put $\mathcal{W}_{k+1} = \mathcal{W}_k \cap (\mathbb{F}\mathbf{u}_{k+1})^\perp$. Let L_{k+1} be the nonzero vectors among $\left\{\mathbf{x} - \frac{B(\mathbf{x}, \mathbf{u}_{k+1})}{q(\mathbf{u}_{k+1})}\mathbf{u}_{k+1} : \mathbf{x} \in L_k\right\}$.
By Theorem 3.4.2(ii), $\mathcal{W}_k = \mathbb{F}\mathbf{u}_{k+1} \odot \mathcal{W}_{k+1}$. The displayed update is the projection onto $\mathcal{W}_{k+1}$, so its image L_{k+1} spans $\mathcal{W}_{k+1}$.
(iii) Since $\dim \mathcal{W}_{k+1} = \dim \mathcal{W}_k - 1$, the process stops. For any basis $(\mathbf{z}_1, \dots, \mathbf{z}_m)$ of R, output $\beta = (\mathbf{u}_1, \dots, \mathbf{u}_s, \mathbf{z}_1, \dots, \mathbf{z}_m)$.
Selected lines are mutually orthogonal and orthogonal to R. Since $q|_R \equiv 0$, $B|_R = 0$ by Proposition 3.1.2(ii); hence β is orthogonal.

Definition 3.6.5. *Universal Orthogonal Geometry*
An orthogonal geometry $\mathcal{V}$ over $\mathbb{F}$ is *universal* if its norm map $q(\mathbf{x}) := \langle \mathbf{x}, \mathbf{x} \rangle$ satisfies $q(\mathcal{V}) = \mathbb{F}$.

Proposition 3.6.6. *Finite-Field Square Classes and Universality*
Let $\mathbb{F}_q$ be a finite field and put $S = (\mathbb{F}_q^\times)^2$. For an orthogonal geometry $\mathcal{V}$, write $q_{\mathcal{V}}(\mathbf{x}) := \langle \mathbf{x}, \mathbf{x} \rangle$.

(i) If $\mathrm{char}(\mathbb{F}_q) = 2$, then $x \mapsto x^2$ is a bijection of $\mathbb{F}_q$.
(ii) If $\mathrm{char}(\mathbb{F}_q) \neq 2$, then $|S| = \frac{q-1}{2}$.
(iii) If $\mathrm{char}(\mathbb{F}_q) \neq 2$, then $(\forall\, d \in \mathbb{F}_q^\times \setminus S)\, \mathbb{F}_q^\times \setminus S = dS$.
(iv) If $\mathcal{V}$ is orthogonal over odd $\mathbb{F}_q$ and contains a nonsingular subspace of dimension at least 2, then $q_{\mathcal{V}}(\mathcal{V}) = \mathbb{F}_q$.

Proof.

(i) If $x^2 = y^2$, then $(x - y)^2 = 0$ in characteristic 2, so $x = y$. Thus $x \mapsto x^2$ is injective and hence bijective on the finite set $\mathbb{F}_q$.
(ii) For $x, y \in \mathbb{F}_q^\times$, $x^2 = y^2 \iff (x - y)(x + y) = 0 \iff x = \pm y$.
Since $x \neq -x$, the $\frac{q-1}{2}$ pairs $\{x, -x\}$ are exactly the fibers of $x \mapsto x^2$, so $|S| = \frac{q-1}{2}$.
(iii) Fix $d \in \mathbb{F}_q^\times \setminus S$. If $dS \cap S \neq \varnothing$, choose $s_1, s_2 \in S$ with $ds_1 = s_2$. Then $d = s_2 s_1^{-1} \in S$, a contradiction.
Hence $dS \cap S = \varnothing$. Since $|dS| = |S| = \frac{q-1}{2}$ by (ii), $\mathbb{F}_q^\times \setminus S = dS$.
(iv) Put $Q = q_{\mathcal{V}}$. By Theorem 3.6.1(i), the nonsingular subspace contains orthogonal $\mathbf{u}, \mathbf{v}$. Put $a := Q(\mathbf{u}) \neq 0$ and $b := Q(\mathbf{v}) \neq 0$.
Let $T := \{\alpha^2 : \alpha \in \mathbb{F}_q\}$. By (ii), $|T| = \frac{q+1}{2}$. For fixed $c \in \mathbb{F}_q$, the sets aT and $c - bT$ both have $\frac{q+1}{2}$ elements, so they intersect.
Choose $\alpha, \beta \in \mathbb{F}_q$ with $a\alpha^2 = c - b\beta^2$. Orthogonality implies $Q(\alpha\mathbf{u} + \beta\mathbf{v}) = a\alpha^2 + b\beta^2 = c$, so $Q(\mathcal{V}) = \mathbb{F}_q$.

Structural Commentary: Count square-map fibers, identify the nonsquare coset, then intersect two affine square-value sets.
Key Insight: Two subsets of $\mathbb{F}_q$ of size $\frac{q+1}{2}$ must intersect. □

Theorem 3.6.7. *Canonical Orthogonal Forms over Common Fields*
Let $M = M^t \in \mathrm{Mat}(n, n, \mathbb{F})$, let $r = \mathrm{rank}\, M$, and write $M \sim N$ for congruence. If $\mathrm{char}(\mathbb{F}) = 2$, *assume M is not nonzero alternating.*

(i) If $\mathbb{F}$ is algebraically closed, then $M \sim I_r \oplus 0_{n-r}$, and rank is a complete congruence invariant.
(ii) If $\mathbb{F} = \mathbb{R}$, then $M \sim I_p \oplus (-I_m) \oplus 0_k$ for unique $p, m, k \in \mathbb{Z}_{\geq 0}$ satisfying $p + m + k = n$.
(iii) If $\mathbb{F} = \mathbb{F}_q$ has characteristic 2, then $M \sim I_r \oplus 0_{n-r}$, and rank is a complete congruence invariant among the admitted matrices.
(iv) If $\mathbb{F} = \mathbb{F}_q$ has odd characteristic and $d \in \mathbb{F}_q^\times$ is a fixed nonsquare, then $r = 0$ implies $M \sim 0_n$.
For $r > 0$, exactly one of $M \sim I_r \oplus 0_{n-r}$ and $M \sim I_{r-1} \oplus [d] \oplus 0_{n-r}$ holds.

Proof.

(i) By Theorem 3.6.1(ii), write $M \sim \operatorname{diag}(a_1, \dots, a_r, 0_{n-r})$.
By algebraic closure, choose $(s_1, \dots, s_r) \in (\mathbb{F}^\times)^r$ satisfying $(\forall\, i \in \{1, \dots, r\})\, a_i = s_i^2$.
Congruence by $\operatorname{diag}(s_1^{-1}, \dots, s_r^{-1}, I_{n-r})$ produces $I_r \oplus 0_{n-r}$.
Rank is congruence-invariant by Proposition 3.1.4(iv), so it is complete.

(ii) By Theorem 3.6.1(ii), diagonalization and rescaling produce $D = I_p \oplus (-I_m) \oplus 0_k$.
Let $E_{\le 0}$ be the coordinate subspace on which the form is nonpositive.
Every positive-definite subspace intersects $E_{\le 0}$ trivially, so its dimension is at most $\operatorname{codim} E_{\le 0} = p$.
The positive coordinate subspace has dimension p, so the maximum is p and is congruence-invariant.
The same argument for $-D$ determines m, and then $k = n - p - m$.

(iii) By Theorem 3.6.1(ii), write $M \sim \operatorname{diag}(a_1, \dots, a_r, 0_{n-r})$.
By Proposition 3.6.6(i), choose $(s_1, \dots, s_r) \in (\mathbb{F}_q^\times)^r$ satisfying $(\forall\, i \in \{1, \dots, r\})\, a_i = s_i^2$.
Congruence by $\operatorname{diag}(s_1^{-1}, \dots, s_r^{-1}, I_{n-r})$ produces $I_r \oplus 0_{n-r}$, and congruence invariance of rank proves completeness.

(iv) If $r = 0$, then $M = 0_n$. Assume $r > 0$ and put $S = (\mathbb{F}_q^\times)^2$.
By Theorem 3.6.1(ii), diagonalize M and let $\mathcal{U}$ be the nonsingular block, with norm map Q.
While $\dim \mathcal{U} \ge 2$, choose $\mathbf{u} \in \mathcal{U}$ with $Q(\mathbf{u}) = 1$ by Proposition 3.6.6(iv).
By Theorem 3.4.2(ii),(iv), split $\mathbb{F}\mathbf{u}$ with a nonsingular complement and continue there.
The nonsingular block becomes $I_{r-1} \oplus [a]$ with $a \in \mathbb{F}_q^\times$. By Proposition 3.6.6(ii),(iii), exactly one of $a \in S$ and $a \in dS$ holds.
Rescaling the final line produces the corresponding stated form.
Any congruence maps radicals onto radicals and induces an isometry of the nonsingular quotients.
The two quotients have discriminants S and dS, which are distinct because d is nonsquare.
Discriminant is isometry-invariant by Proposition 3.1.4(v), so the normal forms are not congruent.

Structural Commentary: Diagonalize, normalize coefficients by the field, then separate residual forms by inertia or discriminant.
Key Insight: Signs over $\mathbb{R}$ and square classes over finite fields survive rescaling. □

Definition 3.6.8. *Minkowski Space*
Minkowski space $\mathbb{R}^{3,1}$ is $\mathbb{R}^4$ with standard Gram matrix $\operatorname{diag}(1, 1, 1, -1)$.

Example 3.6.9. *Null Vectors in Minkowski Space*
In $\mathbb{R}^{3,1}$, $\mathcal{N} := \{\mathbf{x} \in \mathbb{R}^4 \setminus \{\mathbf{0}\} : x_1^2 + x_2^2 + x_3^2 = x_4^2\}$ is the null cone.
The vector $\mathbf{e}_1 + \mathbf{e}_4$ lies in $\mathcal{N}$. No isometry to Euclidean $\mathbb{R}^4$ exists: its matrix A would satisfy $A^t A = \operatorname{diag}(1, 1, 1, -1)$.
Taking determinants would force $(\det A)^2 = -1$, which is impossible over $\mathbb{R}$.

Example 3.6.10. *Two Rank-Two Orthogonal Planes over $\mathbb{F}_5$*
In $\mathbb{F}_5$, $(\mathbb{F}_5^\times)^2 = \{1, 4\}$ and the nonsquare class is $\{2, 3\}$. Let $q_1(x, y) := x^2 + y^2$ and $q_2(x, y) := x^2 + 2y^2$.

(i) The form q_1 has matrix I_2 and is hyperbolic by $q_1(1, 2) = 0$ and Proposition 3.6.2.

(ii) The form q_2 is anisotropic: if $q_2(x, y) = 0$ and $y = 0$, then $x = 0$; if $y \ne 0$, then $\left(\frac{x}{y}\right)^2 = 3$, contradicting that 3 is nonsquare.

Thus the two forms realize the nonsingular rank-2 classes in Theorem 3.6.7(iv).

Lemma 3.6.11. *Odd Finite-Field Isotropy Bound*
Let $\mathcal{V}$ be nonsingular orthogonal over odd $\mathbb{F}_q$ and put $q(\mathbf{x}) := \langle \mathbf{x}, \mathbf{x} \rangle$.
Write $\mathcal{H}^{\odot s}$ for an orthogonal sum of s hyperbolic planes.

(i) If $\dim \mathcal{V} \ge 3$, then $(\exists\, \mathbf{x} \in \mathcal{V} \setminus \{\mathbf{0}\})\, q(\mathbf{x}) = 0$.
(ii) $(\exists\, s \in \mathbb{Z}_{\ge 0})(\exists\, \mathcal{R} \le \mathcal{V})\, \mathcal{V} \cong \mathcal{H}^{\odot s} \odot \mathcal{R}$, where $\mathcal{R}$ is nonsingular anisotropic and $\dim \mathcal{R} \le 2$.

Proof.

(i) By Theorem 3.6.1(i), choose orthogonal nonisotropic vectors $\mathbf{u}, \mathbf{v} \in \mathcal{V}$. Put $\mathcal{P} = \operatorname{span}(\mathbf{u}, \mathbf{v})$, which is nonsingular.
By Theorem 3.4.2(i), $\dim \mathcal{P}^\perp = \dim \mathcal{V} - 2 \ge 1$; choose $\mathbf{0} \ne \mathbf{z} \in \mathcal{P}^\perp$.
If $q(\mathbf{z}) = 0$, take $\mathbf{x} = \mathbf{z}$. Otherwise choose $\mathbf{p} \in \mathcal{P}$ with $q(\mathbf{p}) = -q(\mathbf{z})$ by Proposition 3.6.6(iv).
Since $\mathcal{P} \cap \mathcal{P}^\perp = \{\mathbf{0}\}$ and $\mathcal{P} \perp \mathcal{P}^\perp$, $\mathbf{p} + \mathbf{z} \ne \mathbf{0}$ and $q(\mathbf{p} + \mathbf{z}) = 0$.

(ii) Induct on $\dim \mathcal{V}$. If $\mathcal{V}$ is anisotropic, then $\dim \mathcal{V} \le 2$ by (i); take $s = 0$ and $\mathcal{R} = \mathcal{V}$.
Otherwise choose $\mathbf{0} \ne \mathbf{x} \in \mathcal{V}$ with $q(\mathbf{x}) = 0$. By Theorem 3.4.8, $\mathbf{x}$ lies in a hyperbolic plane $\mathcal{H}$.
By Theorem 3.4.2(ii),(iv), $\mathcal{V} = \mathcal{H} \odot \mathcal{H}^\perp$, where $\mathcal{H}^\perp$ is nonsingular and has dimension $\dim \mathcal{V} - 2$.
By the induction hypothesis, $\mathcal{H}^\perp \cong \mathcal{H}^{\odot s} \odot \mathcal{R}$ with $\mathcal{R}$ nonsingular anisotropic and $\dim \mathcal{R} \le 2$. Hence $\mathcal{V} \cong \mathcal{H}^{\odot(s+1)} \odot \mathcal{R}$.

Structural Commentary: Cancel a represented value against an orthogonal line, then split the resulting hyperbolic plane inductively.
Key Insight: A nonsingular plane represents the negative norm needed to force isotropy. □

Theorem 3.6.12. *Odd Finite-Field Orthogonal Decomposition*
Let $\mathbb{F}_q$ have odd characteristic, fix a nonsquare $d \in \mathbb{F}_q^\times$, and let $\mathcal{V} \ne \{\mathbf{0}\}$ be nonsingular orthogonal.
Put $S = (\mathbb{F}_q^\times)^2$, write $\mathcal{H}^{\odot s}$ for s hyperbolic planes, and let $\langle a \rangle$ denote a line of value a. Set $\mathcal{A}_d := \langle 1 \rangle \odot \langle -d \rangle$.

(i) If $\dim \mathcal{V} = 2m + 1$, then $(\exists\, a \in \mathbb{F}_q^\times)\, \mathcal{V} \cong \mathcal{H}^{\odot m} \odot \langle a \rangle \ \wedge\ aS = (-1)^m \Delta(\mathcal{V})$.
(ii) If $\dim \mathcal{V} = 2m$, then $m \ge 1$ and exactly one of $\mathcal{V} \cong \mathcal{H}^{\odot m}$ and $\mathcal{V} \cong \mathcal{H}^{\odot(m-1)} \odot \mathcal{A}_d$ holds.
(iii) If $\dim \mathcal{V} = 2m$, then $\mathcal{V} \cong \mathcal{H}^{\odot m} \iff \Delta(\mathcal{V}) = (-1)^m S$.
(iv) If $\dim \mathcal{V} = 2m$, then $\mathcal{V} \cong \mathcal{H}^{\odot(m-1)} \odot \mathcal{A}_d \iff \Delta(\mathcal{V}) = (-1)^m dS$.

Proof.

(i) By Lemma 3.6.11(ii), write $\mathcal{V} \cong \mathcal{H}^{\odot s} \odot \mathcal{R}$ with $\mathcal{R}$ anisotropic and $\dim \mathcal{R} \le 2$.
Since $2m + 1 = 2s + \dim \mathcal{R}$, parity implies $\dim \mathcal{R} = 1$ and $s = m$. Choose $a \in \mathbb{F}_q^\times$ with $\mathcal{R} \cong \langle a \rangle$.
Since $\Delta(\mathcal{H}) = -S$, $\Delta(\mathcal{V}) = (-1)^m aS$, and hence $aS = (-1)^m \Delta(\mathcal{V})$.

(ii) Since $\mathcal{V} \ne \{\mathbf{0}\}$, $m \ge 1$. By Lemma 3.6.11(ii), write $\mathcal{V} \cong \mathcal{H}^{\odot s} \odot \mathcal{R}$ with $\dim \mathcal{R} \le 2$.
Since $2m = 2s + \dim \mathcal{R}$, $\dim \mathcal{R} \in \{0, 2\}$. If $\dim \mathcal{R} = 0$, then $s = m$ and $\mathcal{V} \cong \mathcal{H}^{\odot m}$.
Otherwise $s = m - 1$. Both $\mathcal{R}$ and $\mathcal{A}_d$ are anisotropic planes: for $\mathcal{A}_d$, $x^2 - dy^2 = 0$ forces $x = y = 0$ because d is nonsquare.
Both occupy the unique nonhyperbolic rank-2 class by Theorem 3.6.7(iv) and Proposition 3.6.2.
Hence $\mathcal{R} \cong \mathcal{A}_d$, so at least one alternative holds. Their discriminants are $(-1)^m S$ and $(-1)^m dS$.
Since d is nonsquare, these classes are distinct, so the alternatives are mutually exclusive.

(*iii*) ($\Rightarrow$) If $\mathcal{V} \cong \mathcal{H}^{\odot m}$, then $\Delta(\mathcal{V}) = (-1)^m S$ by $\Delta(\mathcal{H}) = -S$.
(*iii*) ($\Leftarrow$) By (ii), one alternative holds. Its discriminant is $(-1)^m S$ only in the first case, so $\mathcal{V} \cong \mathcal{H}^{\odot m}$.
(*iv*) ($\Rightarrow$) If $\mathcal{V} \cong \mathcal{H}^{\odot(m-1)} \odot \mathcal{A}_d$, then $\Delta(\mathcal{V}) = (-1)^m dS$ by $\Delta(\mathcal{A}_d) = -dS$.
(*iv*) ($\Leftarrow$) By (ii), one alternative holds. Its discriminant is $(-1)^m dS$ only in the second case, so $\mathcal{V} \cong \mathcal{H}^{\odot(m-1)} \odot \mathcal{A}_d$.

Structural Commentary: Split the anisotropic residue, determine its dimension by parity, then identify its class by discriminant.
Key Insight: Dimension parity fixes residue size; discriminant fixes its square class. □

3.7 Quadratic Refinements over $\mathbb{F}_2$

Throughout this subsection, vector spaces are finite-dimensional over $\mathbb{F}_2$.

Definition 3.7.1. *Quadratic Isometries and Arf Sums over $\mathbb{F}_2$*
Let $Q : \mathcal{V} \to \mathbb{F}_2$ be quadratic with nonsingular polar form B_Q. Let $\mathscr{B}_Q$ be the set of symplectic bases of B_Q.

(i) For quadratic $Q' : \mathcal{W} \to \mathbb{F}_2$, *quadratic isometry* $Q \to Q'$ is linear isomorphism $\sigma : \mathcal{V} \to \mathcal{W}$ satisfying $Q' \circ \sigma = Q$. Write $Q \cong Q'$.

(ii) For $\beta = (\mathbf{u}_i, \mathbf{v}_i)_{i=1}^m \in \mathscr{B}_Q$, its *Arf sum* is $\operatorname{Arf}_\beta(Q) := \sum_{i=1}^m Q(\mathbf{u}_i)Q(\mathbf{v}_i) \in \mathbb{F}_2$.

Example 3.7.2. *One Polar Form with Two Refinements*
On $\mathcal{V} = \mathbb{F}_2^2$, set $H(x, y) = xy$ and $A(x, y) = x^2 + xy + y^2$. Both have polar form $B((x, y), (u, v)) = xv + yu$.
The identities $B((x, y), (0, 1)) = x$ and $B((x, y), (1, 0)) = y$ imply $\operatorname{rad}(B) = \{\mathbf{0}\}$.
Moreover, $H^{-1}(0) = \{(0, 0), (1, 0), (0, 1)\}$, whereas $A^{-1}(0) = \{(0, 0)\}$. A quadratic isometry preserves zero sets, so $H \ncong A$.

Theorem 3.7.3. *Arf Classification over $\mathbb{F}_2$*
Let $Q : \mathcal{V} \to \mathbb{F}_2$ be quadratic with nonsingular polar form B_Q.
For $m \in \mathbb{Z}_{\geq 1}$ and $a \in \mathbb{F}_2$, define $Q_a^{(m)}(x_1, y_1, \ldots, x_m, y_m) := x_1y_1 + a(x_1^2 + y_1^2) + \sum_{i=2}^m x_iy_i$. Let $Q_0^{(0)}$ be the zero form on $\{\mathbf{0}\}$.

(i) $(\exists!\, m \in \mathbb{Z}_{\geq 0})\ \dim \mathcal{V} = 2m$.
(ii) For this m, $(\forall\, \beta \in \mathscr{B}_Q)\ Q \cong Q^{(m)}_{\operatorname{Arf}_\beta(Q)}$.
(iii) If $m \geq 1$, then $(\forall\, a \in \mathbb{F}_2)\ |(Q_a^{(m)})^{-1}(0)| = 2^{2m-1} + (-1)^a 2^{m-1}$.
(iv) If $m \geq 1$, then $Q_0^{(m)} \ncong Q_1^{(m)}$.
(v) $(\forall\, \beta, \gamma \in \mathscr{B}_Q)\ \operatorname{Arf}_\beta(Q) = \operatorname{Arf}_\gamma(Q)$*; denote this common value by* $\operatorname{Arf}(Q)$.
(vi) $Q \cong Q^{(m)}_{\operatorname{Arf}(Q)}$.
(vii) If $m \geq 1$, then $(\forall\, a \in \mathbb{F}_2)\ \operatorname{Arf}(Q_a^{(m)}) = a$.

Proof.

(i) The form B_Q is alternating by Proposition 3.2.3 and nonsingular by hypothesis.
By Theorem 3.5.1(i), $(\exists\, m \in \mathbb{Z}_{\geq 0})\ \dim \mathcal{V} = 2m$. Any such $m = \frac{1}{2}\dim \mathcal{V}$ is unique.

(ii) If $m = 0$, then $Q = Q_0^{(0)}$ by $Q(\mathbf{0}) = 0$. Assume $m \geq 1$ and fix $\beta = (\mathbf{u}_i, \mathbf{v}_i)_{i=1}^m \in \mathscr{B}_Q$. Put $r_i = Q(\mathbf{u}_i)$ and $s_i = Q(\mathbf{v}_i)$.
$(\forall\, x, y \in \mathbb{F}_2)\ Q(x\mathbf{u}_i + y\mathbf{v}_i) = r_ix^2 + xy + s_iy^2$ by the polar identity and symplectic pairings.
The form Q is the orthogonal sum of these plane restrictions by the vanishing cross-pairings.
If $(r_i, s_i) = (0, 0)$, the ith summand is $H(x, y) := xy$; if $(r_i, s_i) = (1, 1)$, it is $A(x, y) := x^2 + xy + y^2$.
The forms H and A are quadratic with the standard symplectic polar form by direct calculation.
For $(r_i, s_i) = (0, 1)$, the symplectic pair $(\mathbf{u}_i, \mathbf{u}_i + \mathbf{v}_i)$ has Q-values $(0, 0)$.
For $(r_i, s_i) = (1, 0)$, the symplectic pair $(\mathbf{u}_i + \mathbf{v}_i, \mathbf{v}_i)$ has Q-values $(0, 0)$.
Every basis plane is H or A after these changes. The number of A-planes modulo 2 is $\sum_{i=1}^m r_is_i = \operatorname{Arf}_\beta(Q)$.
Fix two A-planes with symplectic bases $(\mathbf{e}_1, \mathbf{f}_1)$ and $(\mathbf{e}_2, \mathbf{f}_2)$. Set $\mathbf{p}_1 = \mathbf{e}_1 + \mathbf{e}_2$ and $\mathbf{q}_1 = \mathbf{f}_1 + \mathbf{e}_2$.
Set $\mathbf{p}_2 = \mathbf{e}_1 + \mathbf{f}_1 + \mathbf{f}_2$ and $\mathbf{q}_2 = \mathbf{e}_1 + \mathbf{f}_1 + \mathbf{e}_2 + \mathbf{f}_2$.
The identity $(Q(\mathbf{p}_1), Q(\mathbf{q}_1), Q(\mathbf{p}_2), Q(\mathbf{q}_2)) = (0, 0, 0, 0)$ holds by direct calculation.
The equalities $B_Q(\mathbf{p}_1, \mathbf{q}_1) = B_Q(\mathbf{p}_2, \mathbf{q}_2) = 1$ hold by direct calculation.
Moreover, $B_Q(\mathbf{p}_1, \mathbf{p}_2) = B_Q(\mathbf{p}_1, \mathbf{q}_2) = B_Q(\mathbf{q}_1, \mathbf{p}_2) = B_Q(\mathbf{q}_1, \mathbf{q}_2) = 0$.
The tuple $(\mathbf{p}_1, \mathbf{q}_1, \mathbf{p}_2, \mathbf{q}_2)$ is a symplectic basis with zero Q-value on each basis vector by these identities.
Two A-planes are quadratically isometric to two H-planes by this basis change.
The isometry $Q \cong Q^{(m)}_{\operatorname{Arf}_\beta(Q)}$ holds by cancelling pairs of A-planes.

(iii) For $P : \mathcal{U} \to \mathbb{F}_2$, put $D(P) := \sum_{\mathbf{x} \in \mathcal{U}} (-1)^{P(\mathbf{x})}$.
If $P' : \mathcal{U}' \to \mathbb{F}_2$ and $R(\mathbf{x}, \mathbf{y}) = P(\mathbf{x}) + P'(\mathbf{y})$, then $D(R) = D(P)D(P')$ by factoring the two finite sums.
$D(H) = 1 + 1 + 1 - 1 = 2$ and $D(A) = 1 - 1 - 1 - 1 = -2$ by direct calculation.
The form $Q_0^{(m)}$ is the orthogonal sum of m copies of H by definition.
The form $Q_1^{(m)}$ is the orthogonal sum of one A and $m - 1$ copies of H by definition.
The equality $D(Q_a^{(m)}) = (-1)^a 2^m$ holds by multiplicativity, $D(H) = 2$, and $D(A) = -2$. Put $N_a = |(Q_a^{(m)})^{-1}(0)|$.
By $D(Q_a^{(m)}) = N_a - (4^m - N_a) = 2N_a - 4^m$, $N_a = 2^{2m-1} + (-1)^a 2^{m-1}$.

(iv) A quadratic isometry preserves zero-set cardinality by bijectivity.
The nonisometry $Q_0^{(m)} \ncong Q_1^{(m)}$ holds by (iii), since the two cardinalities differ by $2^m > 0$.

(v) Fix $\beta, \gamma \in \mathscr{B}_Q$. If $m = 0$, both Arf sums are empty and equal to zero.
For $m \geq 1$, put $a = \operatorname{Arf}_\beta(Q)$ and $b = \operatorname{Arf}_\gamma(Q)$. The isometry $Q_a^{(m)} \cong Q_b^{(m)}$ holds by (ii).
The equality $a = b$ holds by (iv), because $a \neq b$ would identify this isometry with $Q_0^{(m)} \cong Q_1^{(m)}$.
The invariant $\operatorname{Arf}(Q)$ is well-defined by these two cases.

(vi) The isometry $Q \cong Q^{(m)}_{\operatorname{Arf}(Q)}$ holds by (ii) and (v).

(vii) Fix $a \in \mathbb{F}_2$. The map $Q_a^{(m)}$ is quadratic by direct calculation from its defining formula.
Its polar form has standard symplectic basis $\beta_a = (\mathbf{e}_i, \mathbf{f}_i)_{i=1}^m$ by the same calculation.

By definition, $Q_a^{(m)}(\mathbf{e}_1) = Q_a^{(m)}(\mathbf{f}_1) = a$. $(\forall\, i \in \mathbb{Z},\ 2 \le i \le m)\, Q_a^{(m)}(\mathbf{e}_i) = Q_a^{(m)}(\mathbf{f}_i) = 0$ by definition.
The equality $\mathrm{Arf}_{\beta_a}(Q_a^{(m)}) = a^2 = a$ holds by these values. By (v), $\mathrm{Arf}(Q_a^{(m)}) = a$.

Structural Commentary: Plane normalization and A-pair cancellation reduce Q; exponential sums separate the two residues.
Key Insight: The parity of anisotropic planes is the basis-independent quadratic residue. □

3.8 Orthogonal Isometries and Symmetry Groups

Throughout, all spaces are finite-dimensional over a fixed field $\mathbb{F}$; characteristic hypotheses are stated locally.

Proposition 3.8.1. *Isometries from Quadratic Values*
Let $\mathcal{V}$ be nonsingular orthogonal with $\mathrm{char}(\mathbb{F}) \neq 2$, and put $q(\mathbf{x}) := \langle \mathbf{x}, \mathbf{x} \rangle$. For $T \in \mathrm{GL}(\mathcal{V})$, $T \in \mathcal{O}(\mathcal{V}) \iff (\forall\, \mathbf{x} \in \mathcal{V})\, q(T\mathbf{x}) = q(\mathbf{x})$.

Proof.
(⇒) If $T \in \mathcal{O}(\mathcal{V})$, then $(\forall\, \mathbf{x} \in \mathcal{V})\, q(T\mathbf{x}) = \langle T\mathbf{x}, T\mathbf{x} \rangle = \langle \mathbf{x}, \mathbf{x} \rangle = q(\mathbf{x})$.
(⇐) Assume $q \circ T = q$. For $\mathbf{x}, \mathbf{y} \in \mathcal{V}$, $2\langle T\mathbf{x}, T\mathbf{y} \rangle = q(T(\mathbf{x}+\mathbf{y})) - q(T\mathbf{x}) - q(T\mathbf{y})$ by linearity and polarization.
Thus $2\langle T\mathbf{x}, T\mathbf{y} \rangle = q(\mathbf{x}+\mathbf{y}) - q(\mathbf{x}) - q(\mathbf{y}) = 2\langle \mathbf{x}, \mathbf{y} \rangle$ by $q \circ T = q$ and polarization.
Hence $\langle T\mathbf{x}, T\mathbf{y} \rangle = \langle \mathbf{x}, \mathbf{y} \rangle$ by $\mathrm{char}(\mathbb{F}) \neq 2$, and $T \in \mathcal{O}(\mathcal{V})$ by $T \in \mathrm{GL}(\mathcal{V})$.

Structural Commentary: Diagonal preservation and polarization transfer quadratic invariance to every cross-pairing.
Key Insight: Invertibility of 2 makes the diagonal determine the symmetric form. □

Definition 3.8.2. *Special Orthogonal Group and Symmetries*
Let $\mathcal{V}$ be nonsingular orthogonal with $\mathrm{char}(\mathbb{F}) \neq 2$, and put $q(\mathbf{x}) := \langle \mathbf{x}, \mathbf{x} \rangle$.

(i) The *special orthogonal group* is $\mathrm{SO}(\mathcal{V}) := \{\sigma \in \mathcal{O}(\mathcal{V}) : \det(\sigma) = 1\}$; its elements are *rotations*.
(ii) If $q(\mathbf{u}) \neq 0$, the *symmetry* with normal line $\mathbb{F}\mathbf{u}$ is the map $\sigma_{\mathbf{u}} : \mathcal{V} \to \mathcal{V}$. It is defined by $(\forall\, \mathbf{x} \in \mathcal{V})\, \sigma_{\mathbf{u}}(\mathbf{x}) := \mathbf{x} - 2\frac{\langle \mathbf{x}, \mathbf{u} \rangle}{q(\mathbf{u})}\mathbf{u}$.

Proposition 3.8.3. *Symmetries and Equal Quadratic Values*
Let $\mathcal{V}$ be nonsingular orthogonal with $\mathrm{char}(\mathbb{F}) \neq 2$, and put $q(\mathbf{x}) := \langle \mathbf{x}, \mathbf{x} \rangle$.

(i) If $q(\mathbf{w}) \neq 0$, then $\sigma_{\mathbf{w}}\mathbf{w} = -\mathbf{w}$ and $\sigma_{\mathbf{w}}|_{(\mathbb{F}\mathbf{w})^\perp} = I$.
(ii) If $q(\mathbf{w}) \neq 0$, then $\sigma_{\mathbf{w}} \in \mathcal{O}(\mathcal{V})$ and $\sigma_{\mathbf{w}}^2 = I$.
(iii) If $q(\mathbf{u}) = q(\mathbf{v}) \neq 0$, then $q(\mathbf{u}-\mathbf{v}) \neq 0$ or $q(\mathbf{u}+\mathbf{v}) \neq 0$. In the respective cases, $\sigma_{\mathbf{u}-\mathbf{v}}\mathbf{u} = \mathbf{v}$ and $\sigma_{\mathbf{u}+\mathbf{v}}\mathbf{u} = -\mathbf{v}$.

Proof.
(i) If $q(\mathbf{w}) \neq 0$, then $\sigma_{\mathbf{w}}\mathbf{w} = \mathbf{w} - 2\mathbf{w} = -\mathbf{w}$. For $\mathbf{z} \in (\mathbb{F}\mathbf{w})^\perp$, $\langle \mathbf{z}, \mathbf{w} \rangle = 0$, so $\sigma_{\mathbf{w}}\mathbf{z} = \mathbf{z}$.
(ii) The formula for $\sigma_{\mathbf{w}}$ is linear, and $\mathcal{V} = \mathbb{F}\mathbf{w} \odot (\mathbb{F}\mathbf{w})^\perp$ by Theorem 3.4.2(ii).
Thus $\sigma_{\mathbf{w}}(\alpha\mathbf{w} + \mathbf{z}) = -\alpha\mathbf{w} + \mathbf{z}$ by (i), so $\sigma_{\mathbf{w}}^2 = I$ and $q \circ \sigma_{\mathbf{w}} = q$. Hence $\sigma_{\mathbf{w}} \in \mathcal{O}(\mathcal{V})$ by Proposition 3.8.1.
(iii) Put $\mathbf{a} = \mathbf{u} - \mathbf{v}$ and $\mathbf{b} = \mathbf{u} + \mathbf{v}$. Then $\langle \mathbf{a}, \mathbf{b} \rangle = q(\mathbf{u}) - q(\mathbf{v}) = 0$.
The conjunction $q(\mathbf{a}) = q(\mathbf{b}) = 0$ would imply $0 = q(\mathbf{a}+\mathbf{b}) = q(2\mathbf{u}) = 4q(\mathbf{u})$, a contradiction.
Therefore $q(\mathbf{a}) \neq 0$ or $q(\mathbf{b}) \neq 0$. If $q(\mathbf{a}) \neq 0$, then $q(\mathbf{a}) = 2\langle \mathbf{u}, \mathbf{a} \rangle$ and $\sigma_{\mathbf{a}}\mathbf{u} = \mathbf{u} - \mathbf{a} = \mathbf{v}$.
If $q(\mathbf{b}) \neq 0$, then $q(\mathbf{b}) = 2\langle \mathbf{u}, \mathbf{b} \rangle$ and $\sigma_{\mathbf{b}}\mathbf{u} = \mathbf{u} - \mathbf{b} = -\mathbf{v}$.

Structural Commentary: The normal-line decomposition verifies a symmetry; the sum-difference pair then aligns equal quadratic values.
Key Insight: Orthogonal sum-difference directions cannot both be isotropic. □

Theorem 3.8.4. *Orthogonal Transformations Are Products of Symmetries*
Let $\mathcal{V}$ be nonsingular orthogonal with $\mathrm{char}(\mathbb{F}) \neq 2$, and put $q(\mathbf{x}) := \langle \mathbf{x}, \mathbf{x} \rangle$. Then $\mathcal{O}(\mathcal{V}) = \langle \sigma_{\mathbf{u}} : \mathbf{u} \in \mathcal{V},\ q(\mathbf{u}) \neq 0 \rangle$.

Proof.
(i) *Induction Basis*: Induct on $n = \dim \mathcal{V}$. If $n = 0$, then $\mathcal{O}(\mathcal{V}) = \{I\}$, generated by the empty product.
If $n = 1$, fix $\mathbf{0} \neq \mathbf{u} \in \mathcal{V}$. For $\tau \in \mathcal{O}(\mathcal{V})$, write $\tau\mathbf{u} = \lambda\mathbf{u}$.
Nonsingularity implies $q(\mathbf{u}) \neq 0$, and $\lambda^2 = 1$ by $q(\tau\mathbf{u}) = q(\mathbf{u})$. Thus $\tau = I$ or $\tau = \sigma_{\mathbf{u}}$ by Proposition 3.8.3(i).
(ii) *Nonisotropic Line*: Assume $n > 1$. If $(\forall\, \mathbf{x} \in \mathcal{V})\, q(\mathbf{x}) = 0$, then the form is alternating.
It is zero by Proposition 3.1.2(ii), contrary to nonsingularity. Thus $(\exists\, \mathbf{u} \in \mathcal{V})\, q(\mathbf{u}) \neq 0$; fix such a $\mathbf{u}$.
(iii) *Line Alignment*: Fix $\tau \in \mathcal{O}(\mathcal{V})$.
Since $q(\tau\mathbf{u}) = q(\mathbf{u})$, fix a symmetry σ and $\varepsilon \in \{1, -1\}$ satisfying $\sigma\tau\mathbf{u} = \varepsilon\mathbf{u}$ by Proposition 3.8.3(iii).
Put $\rho = \sigma$ if $\varepsilon = 1$, and $\rho = \sigma_{\mathbf{u}}\sigma$ if $\varepsilon = -1$. Then $\rho\tau\mathbf{u} = \mathbf{u}$ by Proposition 3.8.3(i).
(iv) *Complement Reduction*: Put $\mathcal{W} = (\mathbb{F}\mathbf{u})^\perp$. For $\mathbf{x} \in \mathcal{W}$, $\langle \rho\tau\mathbf{x}, \mathbf{u} \rangle = \langle \rho\tau\mathbf{x}, \rho\tau\mathbf{u} \rangle = \langle \mathbf{x}, \mathbf{u} \rangle = 0$.
Hence $\rho\tau\mathcal{W} \subseteq \mathcal{W}$, and equality holds by injectivity and finite dimensionality.
$\mathcal{V} = \mathbb{F}\mathbf{u} \odot \mathcal{W}$ and $\dim \mathcal{W} = n - 1$ by Theorem 3.4.2(i),(ii). The space $\mathcal{W}$ is nonsingular by Theorem 3.4.2(iv).
(v) *Factor Lifting*: By induction, $(\rho\tau)|_{\mathcal{W}}$ is a product of symmetries of $\mathcal{W}$.
Each factor with normal $\mathbf{w} \in \mathcal{W}$ extends to $\sigma_{\mathbf{w}} \in \mathcal{O}(\mathcal{V})$, which fixes $\mathbb{F}\mathbf{u}$ and has the required restriction.
The lifted product equals $\rho\tau$ on $\mathbb{F}\mathbf{u} \odot \mathcal{W}$, so $\rho\tau$ is a product of symmetries.
The map ρ^{-1} is also such a product by Proposition 3.8.3(ii). Therefore $\tau = \rho^{-1}(\rho\tau)$ is a product of symmetries.

Structural Commentary: Symmetries align one nonisotropic line; induction factors the induced complement isometry.
Key Insight: A fixed nonisotropic line exposes a lower-dimensional nonsingular complement. □

Proposition 3.8.5. *Fixed Spaces of Isometries*
Let $\mathcal{V}$ be nonsingular and let $\tau \in \mathrm{Iso}(\mathcal{V})$. Then $\ker(I - \tau) = \mathrm{im}(I - \tau)^\perp$.

Proof. If $\mathbf{x} \in \ker(I - \tau)$, then $(\forall\, \mathbf{y} \in \mathcal{V})\ \langle \mathbf{x}, (I - \tau)\mathbf{y} \rangle = \langle \mathbf{x}, \mathbf{y} \rangle - \langle \tau\mathbf{x}, \tau\mathbf{y} \rangle = 0$. Hence $\ker(I - \tau) \subseteq \mathrm{im}(I - \tau)^\perp$.
$\dim(\mathrm{im}(I-\tau)^\perp) = \dim \mathcal{V} - \dim(\mathrm{im}(I-\tau)) = \dim(\ker(I-\tau))$ by Theorem 3.4.2(i) and Theorem 1.7.3(ii). Thus $\ker(I-\tau) = \mathrm{im}(I-\tau)^\perp$.
Structural Commentary: Form preservation makes fixed vectors orthogonal to displacements; dimension equality closes the inclusion.
Key Insight: Fixed directions are exactly those orthogonal to every displacement. □

Proposition 3.8.6. *Symmetries and Fixed Hyperplanes*
Let $\mathcal{V}$ be nonsingular orthogonal with $\mathrm{char}(\mathbb{F}) \neq 2$, put $q(\mathbf{x}) := \langle \mathbf{x}, \mathbf{x} \rangle$, and let $\tau \in \mathcal{O}(\mathcal{V})$ with $\tau \neq I$.

(i) If $q(\mathbf{u}) \neq 0$, then $\ker(I - \sigma_{\mathbf{u}}) = (\mathbb{F}\mathbf{u})^\perp$ is a nonsingular hyperplane.

(ii) The condition $(\exists\, \mathbf{u} \in \mathcal{V})\,(q(\mathbf{u}) \neq 0 \wedge \tau = \sigma_{\mathbf{u}})$ *holds if and only if* $\ker(I - \tau)$ *is a nonsingular hyperplane.*

Proof.

(i) The map $\sigma_{\mathbf{u}}$ fixes $(\mathbb{F}\mathbf{u})^{\perp}$ pointwise and sends $\mathbf{u}$ to $-\mathbf{u}$ by Proposition 3.8.3(i).
The decomposition $\mathcal{V} = \mathbb{F}\mathbf{u} \odot (\mathbb{F}\mathbf{u})^{\perp}$ holds by Theorem 3.4.2(ii). Thus $\ker(I - \sigma_{\mathbf{u}}) = (\mathbb{F}\mathbf{u})^{\perp}$ by $\operatorname{char}(\mathbb{F}) \neq 2$.
This complement is a nonsingular hyperplane by Theorem 3.4.2(i),(iv).
(ii) ($\Rightarrow$) If $\tau = \sigma_{\mathbf{u}}$ with $q(\mathbf{u}) \neq 0$, then $\ker(I - \tau)$ is a nonsingular hyperplane by (i).
(ii) ($\Leftarrow$) Suppose $\mathcal{H} := \ker(I - \tau)$ is a nonsingular hyperplane, and put $\mathcal{L} = \mathcal{H}^{\perp}$.
Then $\mathcal{V} = \mathcal{H} \odot \mathcal{L}$ and $\dim \mathcal{L} = 1$ by Theorem 3.4.2(i),(ii). The line $\mathcal{L}$ is nonsingular by Theorem 3.4.2(iv).
For $\mathbf{x} \in \mathcal{L}$ and $\mathbf{h} \in \mathcal{H}$, $\langle \tau\mathbf{x}, \mathbf{h}\rangle = \langle \tau\mathbf{x}, \tau\mathbf{h}\rangle = \langle \mathbf{x}, \mathbf{h}\rangle = 0$. Hence $\tau\mathcal{L} \subseteq \mathcal{L}$, and equality holds by injectivity.
Fix $\mathbf{0} \neq \mathbf{u} \in \mathcal{L}$ and write $\tau\mathbf{u} = \lambda\mathbf{u}$. Then $q(\mathbf{u}) \neq 0$ by nonsingularity of $\mathcal{L}$, while $q(\tau\mathbf{u}) = q(\mathbf{u})$ implies $\lambda^2 = 1$.
The alternative $\lambda = 1$ would imply $\tau = I$ on $\mathcal{H} \odot \mathcal{L}$, so $\lambda = -1$ by $\operatorname{char}(\mathbb{F}) \neq 2$. Finally, $\mathcal{H} = (\mathbb{F}\mathbf{u})^{\perp}$ by Theorem 3.4.2(iii).
The map $\sigma_{\mathbf{u}}$ acts as I on $\mathcal{H}$ and as $-I$ on $\mathcal{L}$ by Proposition 3.8.3(i), as does τ. Therefore $\tau = \sigma_{\mathbf{u}}$ by $\mathcal{V} = \mathcal{H} \odot \mathcal{L}$.

Structural Commentary: Item (i) reads the fixed space; item (ii) reconstructs the flipped orthogonal line.
Key Insight: A symmetry is determined by its fixed hyperplane and normal line. □

Proposition 3.8.7. *No Unipotent Isometries in Anisotropic Spaces*
Let $\mathcal{V}$ *be nonsingular anisotropic and let* $\tau \in \operatorname{Iso}(\mathcal{V})$. *If* $(\exists\, m \in \mathbb{Z}_{>0})\,(\tau - I)^m = 0$, *then* $\tau = I$.

Proof.

(i) *Top Displacement*: Put $N = \tau - I$ and suppose $N \neq 0$. By nilpotence, fix maximal $k \geq 1$ with $N^k \neq 0$.
Then $N^{k+1} = 0$; choose $\mathbf{x} \in \mathcal{V}$ with $\mathbf{u} := N^k\mathbf{x} \neq \mathbf{0}$.
(ii) *Adjoint Expansion*: $N^* = \tau^{-1} - I$ by the adjoint identity and Proposition 3.3.10(iv).
Since $\tau = I + N$ and $N^{k+1} = 0$, $N^* = -N + N^2 - \cdots + (-1)^k N^k$ by direct multiplication.
(iii) *Polynomial Annihilation*: Put $P(t) = -1 + t - \cdots + (-1)^k t^{k-1}$, so $N^* = NP(N)$.
Hence $(N^*)^k N^k = N^{2k} P(N)^k = 0$ by $2k \geq k + 1$ and $N^{k+1} = 0$.
(iv) *Contradiction*: By k iterations of the adjoint identity, $\langle \mathbf{u}, \mathbf{u}\rangle = \langle N^k\mathbf{x}, N^k\mathbf{x}\rangle = \langle \mathbf{x}, (N^*)^k N^k\mathbf{x}\rangle = 0$.
This contradicts anisotropy because $\mathbf{u} \neq \mathbf{0}$. Therefore $N = 0$ and $\tau = I$.

Structural Commentary: The adjoint polynomial annihilates the top displacement, forcing its self-pairing to vanish.
Key Insight: The terminal nilpotent image is forced to be isotropic. □

Ambient extension and orthogonal cancellation remain available by Theorem 3.4.12 and Corollary 3.4.13.

4 Affine, Projective, and Convex Geometry

4.1 Affine Flats, Hulls, and Incidence

Throughout, $\mathcal{V}$ is finite-dimensional over a fixed field $\mathbb{F}$; affine geometry treats translated subspaces without choosing an origin.

Definition 4.1.1. *Flats*
Let $\mathcal{S} \leq \mathcal{V}$ and $\mathbf{x} \in \mathcal{V}$, and put $\mathbf{x} + \mathcal{S} := \{\mathbf{x} + \mathbf{s} : \mathbf{s} \in \mathcal{S}\}$.

(i) The affine subset $\mathbf{x} + \mathcal{S}$ from Definition 2.2.1 is a *flat* in $\mathcal{V}$; $\mathcal{S}$ is its *base*, and $\mathbf{x}$ is a *representative*.
(ii) The *affine geometry* on $\mathcal{V}$ is $\mathcal{A}(\mathcal{V}) := \{\mathbf{y} + \mathcal{T} : \mathbf{y} \in \mathcal{V},\ \mathcal{T} \leq \mathcal{V}\}$, with $\dim(\mathcal{A}(\mathcal{V})) := \dim(\mathcal{V})$.
(iii) The *dimension* of $\mathbf{x} + \mathcal{S}$ is $\dim(\mathcal{S})$.
A 0-flat is a *point*, a 1-flat is a *line*, a 2-flat is a *plane*, and a codimension-one flat is a *hyperplane*.

Proposition 4.1.2. *Flat Bases and Representatives*
Let $\mathcal{S}, \mathcal{T} \leq \mathcal{V}$ *and* $\mathbf{x}, \mathbf{y} \in \mathcal{V}$.

(i) $\mathbf{x} + \mathcal{S} = \mathbf{y} + \mathcal{T} \Rightarrow \mathcal{S} = \mathcal{T}$.
(ii) If $X = \mathbf{x} + \mathcal{S}$ *and* $\mathbf{z} \in X$, *then* $X = \mathbf{z} + \mathcal{S}$.

Proof.

(i) Suppose $\mathbf{x} + \mathcal{S} = \mathbf{y} + \mathcal{T}$. Then $\mathbf{x} - \mathbf{y} \in \mathcal{T}$, and $(\forall\, \mathbf{s} \in \mathcal{S})\,(\mathbf{x} - \mathbf{y}) + \mathbf{s} \in \mathcal{T}$, so $\mathcal{S} \subseteq \mathcal{T}$. $\mathcal{T} \subseteq \mathcal{S}$ by interchanging the representations.
(ii) Write $\mathbf{z} = \mathbf{x} + \mathbf{s}_0$ with $\mathbf{s}_0 \in \mathcal{S}$. Then $\mathbf{z} + \mathcal{S} = \mathbf{x} + (\mathbf{s}_0 + \mathcal{S}) = \mathbf{x} + \mathcal{S} = X$.

Structural Commentary: Base equality holds by two inclusions; representative invariance holds by subspace translation.
Key Insight: A flat has one base but many representatives. □

Definition 4.1.3. *Parallel Flats*
For flats $X = \mathbf{x} + \mathcal{S}$ and $Y = \mathbf{y} + \mathcal{T}$, define $X \parallel Y \iff (\mathcal{S} \subseteq \mathcal{T} \vee \mathcal{T} \subseteq \mathcal{S})$. The relation is representation-independent by Proposition 4.1.2(i).

Proposition 4.1.4. *Basic Incidence of Flats*
Let $X = \mathbf{x} + \mathcal{S}$ *and* $Y = \mathbf{y} + \mathcal{T}$ *be flats in* $\mathcal{V}$, *and write* $\mathbf{w} + X := \{\mathbf{w} + \mathbf{u} : \mathbf{u} \in X\}$.

(i) $(\exists\, \mathbf{w} \in \mathcal{V})(\mathbf{w} + X \subseteq Y) \iff \mathcal{S} \subseteq \mathcal{T}$.
(ii) $(\exists\, \mathbf{w} \in \mathcal{V})(\mathbf{w} + X = Y) \iff \mathcal{S} = \mathcal{T}$.
(iii) $X \cap Y \neq \emptyset \Rightarrow (X \subseteq Y \iff \mathcal{S} \subseteq \mathcal{T})$.
(iv) $X \cap Y \neq \emptyset \Rightarrow (X = Y \iff \mathcal{S} = \mathcal{T})$.
(v) $X \parallel Y \Rightarrow (X \subseteq Y \vee Y \subseteq X \vee X \cap Y = \emptyset)$.
(vi) $X \parallel Y \iff [(\exists\, \mathbf{w} \in \mathcal{V})(\mathbf{w} + X \subseteq Y)] \vee [(\exists\, \mathbf{w} \in \mathcal{V})(\mathbf{w} + Y \subseteq X)]$.

Proof.

(i) ($\Rightarrow$) Fix $\mathbf{w}$ with $\mathbf{w} + X \subseteq Y$ and choose $\mathbf{z} \in \mathbf{w} + X$. Then $\mathbf{w} + X = \mathbf{z} + \mathcal{S}$ and $Y = \mathbf{z} + \mathcal{T}$ by Proposition 4.1.2(ii).
Hence $(\forall\, \mathbf{s} \in \mathcal{S})\,\mathbf{z} + \mathbf{s} \in \mathbf{z} + \mathcal{T}$, so $\mathcal{S} \subseteq \mathcal{T}$.
(i) ($\Leftarrow$) If $\mathcal{S} \subseteq \mathcal{T}$, then $(\mathbf{y} - \mathbf{x}) + X = \mathbf{y} + \mathcal{S} \subseteq Y$.
(ii) ($\Rightarrow$) If $\mathbf{w} + X = Y$, then $\mathcal{S} = \mathcal{T}$ by Proposition 4.1.2(i).

(*ii*) ($\Leftarrow$) If $\mathcal{S} = \mathcal{T}$, then $(\mathbf{y} - \mathbf{x}) + X = Y$.
(*iii*) ($\Rightarrow$) Fix $\mathbf{z} \in X \cap Y$. Then $X = \mathbf{z} + \mathcal{S}$, $Y = \mathbf{z} + \mathcal{T}$ by Proposition 4.1.2(ii). Thus $X \subseteq Y \Rightarrow (\forall\, \mathbf{s} \in \mathcal{S})\, \mathbf{z} + \mathbf{s} \in \mathbf{z} + \mathcal{T}$, so $\mathcal{S} \subseteq \mathcal{T}$.
(*iii*) ($\Leftarrow$) Fix $\mathbf{z} \in X \cap Y$. By Proposition 4.1.2(ii), $X = \mathbf{z} + \mathcal{S} \subseteq \mathbf{z} + \mathcal{T} = Y$ whenever $\mathcal{S} \subseteq \mathcal{T}$.
(*iv*) ($\Rightarrow$) If $X = Y$, then $\mathcal{S} = \mathcal{T}$ by Proposition 4.1.2(i).
(*iv*) ($\Leftarrow$) Fix $\mathbf{z} \in X \cap Y$. If $\mathcal{S} = \mathcal{T}$, then $X = \mathbf{z} + \mathcal{S} = \mathbf{z} + \mathcal{T} = Y$ by Proposition 4.1.2(ii).
(*v*) By Definition 4.1.3, $\mathcal{S} \subseteq \mathcal{T}$ or $\mathcal{T} \subseteq \mathcal{S}$. If $X \cap Y \neq \emptyset$, then $X \subseteq Y$ or $Y \subseteq X$ by (iii); otherwise $X \cap Y = \emptyset$.
(*vi*) ($\Rightarrow$) By Definition 4.1.3 and (i), a translate of X lies in Y or a translate of Y lies in X.
(*vi*) ($\Leftarrow$) By (i), either translate-containment condition implies $\mathcal{S} \subseteq \mathcal{T}$ or $\mathcal{T} \subseteq \mathcal{S}$, so $X \parallel Y$ by Definition 4.1.3.

Structural Commentary: Claims (i)–(iv) reduce incidence by common representatives; (v)–(vi) then characterize parallelism.
Key Insight: A common representative converts affine incidence into subspace incidence. □

Definition 4.1.5. *Affine Combinations*

(i) Let $n \in \mathbb{Z}_{>0}$, $\mathbf{p} = (\mathbf{p}_1, \dots, \mathbf{p}_n) \in \mathcal{V}^n$, and $\mathbf{r} = (r_1, \dots, r_n) \in \mathbb{F}^n$. The vector $\sum_{j=1}^{n} r_j \mathbf{p}_j$ is an *affine combination* of $\mathbf{p}$ iff $\sum_{j=1}^{n} r_j = 1$.

(ii) A nonempty $E \subseteq \mathcal{V}$ is *affine closed* iff $(\forall\, n \in \mathbb{Z}_{>0})(\forall\, (\mathbf{p}, \mathbf{r}) \in E^n \times \mathbb{F}^n)\, [\sum_{j=1}^{n} r_j = 1 \Rightarrow \sum_{j=1}^{n} r_j \mathbf{p}_j \in E]$.

(iii) A nonempty $E \subseteq \mathcal{V}$ is *two-affine closed* iff $(\forall\, \mathbf{x}, \mathbf{y} \in E)(\forall\, r \in \mathbb{F})\, r\mathbf{x} + (1 - r)\mathbf{y} \in E$.

(iv) If $\mathbf{x} \neq \mathbf{y}$, their affine line is $\overline{\mathbf{xy}} := \{r\mathbf{x} + (1 - r)\mathbf{y} : r \in \mathbb{F}\} = \mathbf{y} + \operatorname{span}(\mathbf{x} - \mathbf{y})$.
Thus a nonempty $E \subseteq \mathcal{V}$ is two-affine closed iff $(\forall\, \mathbf{x}, \mathbf{y} \in E)\, [\mathbf{x} \neq \mathbf{y} \Rightarrow \overline{\mathbf{xy}} \subseteq E]$.

Theorem 4.1.6. *Two-Point Affine Closure*
Let $\emptyset \neq E \subseteq \mathcal{V}$ and assume $\operatorname{char}(\mathbb{F}) \neq 2$. Then E is affine closed iff E is two-affine closed.

Proof.

($\Rightarrow$) Two-affine closure is the $n = 2$ instance of affine closure.
($\Leftarrow$) Assume that E is two-affine closed, fix $\mathbf{x}_0 \in E$, and put $\mathcal{S} := E - \mathbf{x}_0$. Fix $\mathbf{s}, \mathbf{t} \in \mathcal{S}$ and $c \in \mathbb{F}$.
Put $\mathbf{a} := \mathbf{x}_0 + c\mathbf{s} = c(\mathbf{x}_0 + \mathbf{s}) + (1 - c)\mathbf{x}_0$; then $\mathbf{a} \in E$ by two-affine closure.
Put $\mathbf{b} := \frac{1}{2}\mathbf{a} + \frac{1}{2}(\mathbf{x}_0 + \mathbf{t}) = \mathbf{x}_0 + \frac{1}{2}(c\mathbf{s} + \mathbf{t})$; then $\mathbf{b} \in E$ by two-affine closure.
The identity $2\mathbf{b} - \mathbf{x}_0 = \mathbf{x}_0 + c\mathbf{s} + \mathbf{t} \in E$ holds by two-affine closure with coefficient 2.
Hence $(\forall\, \mathbf{s}, \mathbf{t} \in \mathcal{S})(\forall\, c \in \mathbb{F})\, c\mathbf{s} + \mathbf{t} \in \mathcal{S}$, so $\mathcal{S} \leq \mathcal{V}$ by Theorem 1.2.2.

Fix $n \in \mathbb{Z}_{>0}$, $\mathbf{p} = (\mathbf{p}_j)_{j=1}^n \in E^n$, and $\mathbf{r} = (r_j)_{j=1}^n \in \mathbb{F}^n$ with $\sum_{j=1}^{n} r_j = 1$. Choose $\mathbf{s} = (\mathbf{s}_j)_{j=1}^n \in \mathcal{S}^n$ with $\mathbf{p} = (\mathbf{x}_0 + \mathbf{s}_j)_{j=1}^n$.

Then $\sum_{j=1}^{n} r_j \mathbf{p}_j = \mathbf{x}_0 + \sum_{j=1}^{n} r_j \mathbf{s}_j \in \mathbf{x}_0 + \mathcal{S} = E$. Thus E is affine closed.

Structural Commentary: Affine closure follows by translation, subspace closure, and reconstruction of finite combinations.
Key Insight: Midpoints and dilation by 2 recover vector addition. □

Counterexample 4.1.7. *Failure in Characteristic Two*
The characteristic restriction in Theorem 4.1.6 cannot be omitted. In $\mathbb{F}_2^2$, put $E := \{(0,0), (1,0), (0,1)\}$.
Since $r \in \{0, 1\}$, every two-point affine combination equals one of its endpoints, so E is two-affine closed.
However, $(1,1) = (0,0) + (1,0) + (0,1) \notin E$ is an affine combination because $1 + 1 + 1 = 1$ in $\mathbb{F}_2$.

Theorem 4.1.8. *Flats Are the Affine-Closed Sets*
Let $\emptyset \neq E \subseteq \mathcal{V}$. Then $E \in \mathcal{A}(\mathcal{V})$ iff E is affine closed.

Proof.

($\Rightarrow$) Write $E = \mathbf{x} + \mathcal{S}$ with $\mathcal{S} \leq \mathcal{V}$. Fix $n \in \mathbb{Z}_{>0}$, $\mathbf{p} = (\mathbf{p}_j)_{j=1}^n \in E^n$, and $\mathbf{r} = (r_j)_{j=1}^n \in \mathbb{F}^n$ with $\sum_{j=1}^{n} r_j = 1$.

Choose $\mathbf{s} = (\mathbf{s}_j)_{j=1}^n \in \mathcal{S}^n$ with $\mathbf{p} = (\mathbf{x} + \mathbf{s}_j)_{j=1}^n$. Then $\sum_{j=1}^{n} r_j \mathbf{p}_j = \mathbf{x} + \sum_{j=1}^{n} r_j \mathbf{s}_j \in E$, so E is affine closed.

($\Leftarrow$) Assume that E is affine closed, fix $\mathbf{x} \in E$, and put $\mathcal{S} := E - \mathbf{x}$. Fix $\mathbf{s}_1, \mathbf{s}_2 \in \mathcal{S}$ and $c \in \mathbb{F}$, and choose $\mathbf{x}_1, \mathbf{x}_2 \in E$ with $\mathbf{s}_j = \mathbf{x}_j - \mathbf{x}$.
Then $c\mathbf{s}_1 + \mathbf{s}_2 + \mathbf{x} = c\mathbf{x}_1 + \mathbf{x}_2 - c\mathbf{x} \in E$ by affine closure, so $c\mathbf{s}_1 + \mathbf{s}_2 \in \mathcal{S}$. Hence $\mathcal{S} \leq \mathcal{V}$ by Theorem 1.2.2, and $E = \mathbf{x} + \mathcal{S} \in \mathcal{A}(\mathcal{V})$.

Structural Commentary: Forward closure is inherited from the base; reverse closure becomes linear after translation.
Key Insight: Affine closure becomes linear closure after translation. □

Theorem 4.1.9. *Flats Are the Two-Affine-Closed Sets*
Let $\emptyset \neq E \subseteq \mathcal{V}$ and assume $\operatorname{char}(\mathbb{F}) \neq 2$. Then $E \in \mathcal{A}(\mathcal{V})$ iff E is two-affine closed.

Proof.

($\Rightarrow$) If $E \in \mathcal{A}(\mathcal{V})$, then E is affine closed by Theorem 4.1.8 and two-affine closed by Theorem 4.1.6.
($\Leftarrow$) If E is two-affine closed, then E is affine closed by Theorem 4.1.6 and $E \in \mathcal{A}(\mathcal{V})$ by Theorem 4.1.8.

Structural Commentary: Each direction follows by composing the preceding affine-closure characterizations.
Key Insight: Binary affine closure detects translated subspaces when 2 is invertible. □

Definition 4.1.10. *Affine Hull and Affine Span*
Let $\emptyset \neq E \subseteq \mathcal{V}$.

(i) The *affine hull* is $\operatorname{affhull}(E) := \bigcap \{X \in \mathcal{A}(\mathcal{V}) : E \subseteq X\}$; the defining family contains $\mathcal{V}$.

(ii) The *affine span* is $\operatorname{affspan}(E) := \{\sum_{j=1}^{n} r_j \mathbf{p}_j : n \in \mathbb{Z}_{>0},\ (\mathbf{p}, \mathbf{r}) \in E^n \times \mathbb{F}^n,\ \sum_{j=1}^{n} r_j = 1\}$.

Theorem 4.1.11. *Affine Hull Formula*
Let $\emptyset \neq E \subseteq \mathcal{V}$, fix $\mathbf{x} \in E$, and put $\mathcal{S}_{\mathbf{x}} := \operatorname{span}(E - \mathbf{x})$.

(i) $\operatorname{affhull}(E) = \operatorname{affspan}(E) = \mathbf{x} + \mathcal{S}_{\mathbf{x}}$.
(ii) $\dim(\operatorname{affhull}(E)) = \dim(\mathcal{S}_{\mathbf{x}})$.

Proof.

(i) Fix $\mathbf{z} \in \operatorname{affspan}(E)$ and choose an affine-combination representation $\mathbf{z} = \sum_{j=1}^{n} r_j \mathbf{e}_j$. Then $\mathbf{z} = \mathbf{x} + \sum_{j=1}^{n} r_j(\mathbf{e}_j - \mathbf{x}) \in \mathbf{x} + \mathcal{S}_{\mathbf{x}}$.

Conversely, write $\mathbf{z} \in \mathbf{x} + \mathcal{S}_{\mathbf{x}}$ as $\mathbf{z} = \mathbf{x} + \sum_{j=1}^{n} a_j(\mathbf{e}_j - \mathbf{x})$, where $\mathbf{e}_j \in E$.

Then $\mathbf{z} = (1 - \sum_{j=1}^{n} a_j)\mathbf{x} + \sum_{j=1}^{n} a_j \mathbf{e}_j \in \operatorname{affspan}(E)$. Hence $\operatorname{affspan}(E) = \mathbf{x} + \mathcal{S}_{\mathbf{x}}$, a flat containing E.

Every flat containing E contains $\operatorname{affspan}(E)$ by Theorem 4.1.8, so this flat equals $\operatorname{affhull}(E)$ by Definition 4.1.10(i).

(ii) By (i) and Definition 4.1.1(iii), $\dim(\operatorname{affhull}(E)) = \dim(\mathbf{x} + \mathcal{S}_{\mathbf{x}}) = \dim(\mathcal{S}_{\mathbf{x}})$.

Structural Commentary: The hull formula follows by two inclusions; its dimension is read from the common base.
Key Insight: Differences from one point encode every affine direction. □

Lemma 4.1.12. *Intersections of Flats*
Let $\emptyset \neq I$ and let $X_i = \mathbf{x}_i + \mathcal{S}_i$ be flats indexed by $i \in I$. If $\mathbf{z} \in \bigcap_{i\in I} X_i$, then $\bigcap_{i\in I} X_i = \mathbf{z} + \bigcap_{i\in I} \mathcal{S}_i$.

Proof. By Proposition 4.1.2(ii), $(\forall\, i \in I)\, X_i = \mathbf{z} + \mathcal{S}_i$. Hence $(\forall\, \mathbf{u} \in \mathcal{V})\,[\mathbf{u} \in \bigcap_{i\in I} X_i \iff \mathbf{u} - \mathbf{z} \in \bigcap_{i\in I} \mathcal{S}_i]$. Therefore $\bigcap_{i\in I} X_i = \mathbf{z} + \bigcap_{i\in I} \mathcal{S}_i$.

Structural Commentary: The intersection formula follows by synchronizing representatives and intersecting their bases.
Key Insight: Common incidence synchronizes all affine origins. □

Theorem 4.1.13. *Lattice of Flats*
Let $\mathcal{A}_0(\mathcal{V}) := \mathcal{A}(\mathcal{V}) \cup \{\emptyset\}$, ordered by inclusion.

(i) $(\forall\, \mathcal{C} \subseteq \mathcal{A}_0(\mathcal{V}))\ \bigwedge \mathcal{C} = \bigcap_{X\in\mathcal{C}} X$.

(ii) If $\mathcal{C} \subseteq \mathcal{A}_0(\mathcal{V})$ and $U := \bigcup_{X\in\mathcal{C}} X$, then $U \neq \emptyset \Rightarrow \bigvee \mathcal{C} = \operatorname{affhull}(U)$, while $U = \emptyset \Rightarrow \bigvee \mathcal{C} = \emptyset$.

(iii) $\mathcal{A}_0(\mathcal{V})$ is a complete lattice.

Proof.

(i) Fix $\mathcal{C} \subseteq \mathcal{A}_0(\mathcal{V})$ and put $M := \bigcap_{X\in\mathcal{C}} X$. If $\mathcal{C} = \emptyset$, then $M = \mathcal{V}$; if $M = \emptyset$, then $M \in \mathcal{A}_0(\mathcal{V})$.

If $\mathcal{C} \neq \emptyset$ and $M \neq \emptyset$, choose $\mathbf{z} \in M$ and let $\mathcal{S}_X$ be the unique base of X. Then $M = \mathbf{z} + \bigcap_{X\in\mathcal{C}} \mathcal{S}_X$ by Lemma 4.1.12, so M is a flat.

Thus $M \in \mathcal{A}_0(\mathcal{V})$. It is a lower bound of $\mathcal{C}$, and any lower bound is contained in M, so $M = \bigwedge \mathcal{C}$.

(ii) Fix $\mathcal{C} \subseteq \mathcal{A}_0(\mathcal{V})$ and put $U := \bigcup_{X\in\mathcal{C}} X$. If $U = \emptyset$, then $\emptyset$ is the least upper bound of $\mathcal{C}$.

Assume $U \neq \emptyset$. Then $\operatorname{affhull}(U)$ is a flat containing each $X \in \mathcal{C}$ by Theorem 4.1.11.
If $B \in \mathcal{A}_0(\mathcal{V})$ is an upper bound of $\mathcal{C}$, then $U \subseteq B$; since $U \neq \emptyset$, the set B is a flat.
Thus $\operatorname{affhull}(U) \subseteq B$ by Definition 4.1.10(i), so $\operatorname{affhull}(U) = \bigvee \mathcal{C}$.

(iii) $\mathcal{A}_0(\mathcal{V})$ is complete by (i)–(ii) and Definition 5.3.4(iv).

Structural Commentary: Completeness follows by arbitrary intersection meets and affine-hull joins.
Key Insight: Empty incidence must be adjoined to close arbitrary meets. □

Convention 4.1.14. *Empty Affine Hull Convention*
Within $\mathcal{A}_0(\mathcal{V})$, set $\operatorname{affhull}(\emptyset) := \emptyset$; then Theorem 4.1.13(ii) has the uniform form $\bigvee \mathcal{C} = \operatorname{affhull}(\bigcup_{X\in\mathcal{C}} X)$.

Corollary 4.1.15. *Join of Two Flats*
Let $X = \mathbf{x} + \mathcal{S}$ and $Y = \mathbf{y} + \mathcal{T}$ be flats.

(i) $X \vee Y = \mathbf{x} + \operatorname{span}(\{\mathbf{x} - \mathbf{y}\} \cup \mathcal{S} \cup \mathcal{T})$.

(ii) $X \cap Y \neq \emptyset \Rightarrow X \vee Y = \mathbf{x} + (\mathcal{S} + \mathcal{T})$.

Proof.

(i) Put $\mathcal{W} := \operatorname{span}((X \cup Y) - \mathbf{x})$. Then $X \vee Y = \mathbf{x} + \mathcal{W}$ by Theorems 4.1.13(ii) and 4.1.11(i).
Since $(X \cup Y) - \mathbf{x} = \mathcal{S} \cup ((\mathbf{y} - \mathbf{x}) + \mathcal{T})$, the space $\mathcal{W}$ contains $\mathcal{S}$ and $\mathbf{x} - \mathbf{y}$ by $\mathbf{0} \in \mathcal{T}$ and scalar closure.
$(\forall\, \mathbf{t} \in \mathcal{T})\, \mathbf{t} = ((\mathbf{y} - \mathbf{x}) + \mathbf{t}) - (\mathbf{y} - \mathbf{x}) \in \mathcal{W}$, so $\mathcal{T} \subseteq \mathcal{W}$. Hence $\operatorname{span}(\{\mathbf{x} - \mathbf{y}\} \cup \mathcal{S} \cup \mathcal{T}) \subseteq \mathcal{W}$ by Theorem 1.2.5(iii).
The reverse inclusion holds by $(X \cup Y) - \mathbf{x} \subseteq \operatorname{span}(\{\mathbf{x} - \mathbf{y}\} \cup \mathcal{S} \cup \mathcal{T})$ and Theorem 1.2.5(iii).

(ii) Fix $\mathbf{z} = \mathbf{x} + \mathbf{s} = \mathbf{y} + \mathbf{t} \in X \cap Y$. Then $\mathbf{x} - \mathbf{y} = \mathbf{t} - \mathbf{s} \in \mathcal{S} + \mathcal{T}$, so the span in (i) equals $\mathcal{S} + \mathcal{T}$.

Structural Commentary: The join formula follows by a hull expansion; intersection then absorbs the displacement.
Key Insight: Intersection absorbs the displacement into the two bases. □

Corollary 4.1.16. *Dimension of the Join of Two Flats*
Let $X = \mathbf{x} + \mathcal{S}$ and $Y = \mathbf{y} + \mathcal{T}$ be flats.

(i) $X \cap Y \neq \emptyset \Rightarrow \dim(X \vee Y) = \dim(X) + \dim(Y) - \dim(X \cap Y)$.

(ii) $X \cap Y = \emptyset \Rightarrow \dim(X \vee Y) = \dim(\mathcal{S} + \mathcal{T}) + 1$.

Proof.

(i) Fix $\mathbf{z} \in X \cap Y$. By Corollary 4.1.15(ii) and Lemma 4.1.12, the bases of $X \vee Y$ and $X \cap Y$ are $\mathcal{S} + \mathcal{T}$ and $\mathcal{S} \cap \mathcal{T}$, respectively.
Hence $\dim(X \vee Y) = \dim(\mathcal{S}) + \dim(\mathcal{T}) - \dim(\mathcal{S} \cap \mathcal{T})$ by Theorem 2.3.1, which is the stated identity by Definition 4.1.1(iii).

(ii) Assume $X \cap Y = \emptyset$ and put $\mathcal{W} := \mathcal{S} + \mathcal{T}$. By Corollary 4.1.15(i), the base of $X \vee Y$ is $\mathcal{U} := \operatorname{span}(\{\mathbf{x} - \mathbf{y}\} \cup \mathcal{W})$.
If $\mathbf{x} - \mathbf{y} \in \mathcal{W}$, choose $\mathbf{s} \in \mathcal{S}$ and $\mathbf{t} \in \mathcal{T}$ with $\mathbf{x} - \mathbf{y} = \mathbf{s} + \mathbf{t}$. Then $\mathbf{x} - \mathbf{s} = \mathbf{y} + \mathbf{t} \in X \cap Y$, a contradiction.
If $a(\mathbf{x} - \mathbf{y}) \in \mathcal{W}$ with $a \neq 0$, then $\mathbf{x} - \mathbf{y} \in \mathcal{W}$ by scalar closure. Thus $\operatorname{span}(\mathbf{x} - \mathbf{y}) \cap \mathcal{W} = \{\mathbf{0}\}$ and $\mathcal{U} = \mathcal{W} \oplus \operatorname{span}(\mathbf{x} - \mathbf{y})$.
Hence $\dim(X \vee Y) = \dim(\mathcal{W}) + 1 = \dim(\mathcal{S} + \mathcal{T}) + 1$ by Corollary 2.3.2.

Structural Commentary: The dimension formulas follow by the subspace sum formula or one independent displacement.
Key Insight: Disjointness makes the representative displacement linearly independent. □

4.2 Affine Independence and Barycentric Coordinates

Throughout this subsection, $\mathcal{V}$ is finite-dimensional over a fixed field $\mathbb{F}$.

Definition 4.2.1. *Affinely Independent Sets*
A set $E \subseteq \mathcal{V}$ is *affinely independent* iff $E \neq \emptyset$ and $(\forall\, \mathbf{x} \in E)\,(E - \mathbf{x}) \setminus \{\mathbf{0}\}$ is linearly independent.

Theorem 4.2.2. *Affine Independence Criteria*
Let $\emptyset \neq E \subseteq \mathcal{V}$ and, for $F \subseteq \mathcal{V}$ and $n \in \mathbb{Z}_{>0}$, put $F^n_{\neq} := \{\mathbf{x} \in F^n : \mathbf{x}_j \neq \mathbf{x}_k \ (1 \leq j < k \leq n)\}$.
The following conditions are equivalent.

(i) E *is affinely independent.*
(ii) $(\forall\, \mathbf{x} \in E)\, \mathbf{x} \notin \operatorname{affhull}(E \setminus \{\mathbf{x}\})$, *where* $\operatorname{affhull}(\emptyset) = \emptyset$.
(iii) $(\forall\, n \in \mathbb{Z}_{>0})(\forall\, (\mathbf{x}_1, \ldots, \mathbf{x}_n) \in E^n_{\neq})(\forall\, \mathbf{r} \in \mathbb{F}^n)\,[\sum_{j=1}^{n} r_j \mathbf{x}_j = \mathbf{0} \wedge \sum_{j=1}^{n} r_j = 0 \Rightarrow \mathbf{r} = \mathbf{0}]$.
(iv) $(\forall\, n \in \mathbb{Z}_{>0})(\forall\, (\mathbf{x}_1, \ldots, \mathbf{x}_n) \in E^n_{\neq})(\forall\, \mathbf{r}, \mathbf{s} \in \mathbb{F}^n)\,[\sum_{j=1}^{n} r_j \mathbf{x}_j = \sum_{j=1}^{n} s_j \mathbf{x}_j \wedge \sum_{j=1}^{n} r_j = \sum_{j=1}^{n} s_j = 1 \Rightarrow \mathbf{r} = \mathbf{s}]$.

Proof.

(i) $\Rightarrow$ *(ii)* Fix $\mathbf{x} \in E$. If $E = \{\mathbf{x}\}$, then $\mathbf{x} \notin \operatorname{affhull}(\emptyset)$ by the empty-hull convention. Suppose $E \neq \{\mathbf{x}\}$ and $\mathbf{x} \in \operatorname{affhull}(E \setminus \{\mathbf{x}\})$.
By Theorem 4.1.11(i), $\mathbf{x} \in \operatorname{affspan}(E \setminus \{\mathbf{x}\})$. Collect the repeated points in an affine representation of $\mathbf{x}$.
Fix $m \in \mathbb{Z}_{>0}$ and $(\mathbf{y}_1, \ldots, \mathbf{y}_m) \in (E \setminus \{\mathbf{x}\})^m_{\neq}$ as its distinct points.
The collected coefficients form $\mathbf{r} \in \mathbb{F}^m$ with $\mathbf{x} = \sum_{j=1}^{m} r_j \mathbf{y}_j$ and $\sum_{j=1}^{m} r_j = 1$.
The relation $\sum_{j=1}^{m} r_j (\mathbf{y}_j - \mathbf{x}) = \mathbf{0}$ with $\mathbf{r} \neq \mathbf{0}$ holds by these identities, contradicting (i).

(ii) $\Rightarrow$ *(iii)* Fix $n \in \mathbb{Z}_{>0}$ and $(\mathbf{x}_1, \ldots, \mathbf{x}_n) \in E^n_{\neq}$. Let $\mathbf{r} \in \mathbb{F}^n$ satisfy $\sum_{j=1}^{n} r_j \mathbf{x}_j = \mathbf{0}$ and $\sum_{j=1}^{n} r_j = 0$.
If $\mathbf{r} \neq \mathbf{0}$, choose k with $r_k \neq 0$. The inequality $n \geq 2$ holds by the contradiction $r_k = \sum_{j=1}^{n} r_j = 0$ when $n = 1$.
The identities $\mathbf{x}_k = \sum_{j \neq k} (-\frac{r_j}{r_k}) \mathbf{x}_j$ and $\sum_{j \neq k} -\frac{r_j}{r_k} = 1$ hold by rearrangement.
$\mathbf{x}_k \in \operatorname{affhull}(E \setminus \{\mathbf{x}_k\})$ by Theorem 4.1.11(i), contrary to (ii). $\mathbf{r} = \mathbf{0}$ by contradiction.

(iii) $\Rightarrow$ *(iv)* Subtraction produces $\sum_{j=1}^{n} (r_j - s_j) \mathbf{x}_j = \mathbf{0}$ and $\sum_{j=1}^{n} (r_j - s_j) = 0$. Thus $\mathbf{r} = \mathbf{s}$ by (iii).

(iv) $\Rightarrow$ *(i)* Fix $\mathbf{x} \in E$, $m \in \mathbb{Z}_{>0}$, and $(\mathbf{y}_1, \ldots, \mathbf{y}_m) \in (E \setminus \{\mathbf{x}\})^m_{\neq}$. Let $\mathbf{a} \in \mathbb{F}^m$ satisfy $\sum_{j=1}^{m} a_j (\mathbf{y}_j - \mathbf{x}) = \mathbf{0}$.
The tuple $(\mathbf{y}_1, \ldots, \mathbf{y}_m, \mathbf{x})$ lies in $E^{m+1}_{\neq}$. Put $\mathbf{c} := (a_1, \ldots, a_m, -\sum_{j=1}^{m} a_j)$ and $\mathbf{b} := (0, \ldots, 0, 1)$.
Both $\mathbf{b}$ and $\mathbf{b} + \mathbf{c}$ have coefficient sum 1 and represent $\mathbf{x}$, so $\mathbf{c} = \mathbf{0}$ by (iv).
$\mathbf{a} = \mathbf{0}$ by the definition of $\mathbf{c}$, and E is affinely independent by the arbitrariness of all choices.

Structural Commentary: Pass from excluded-point hulls to zero-sum relations, then identify them with coordinate differences.
Key Insight: Affine representations differ by a zero-sum linear relation. □

Corollary 4.2.3. *Dimension Criterion for Affine Independence*
Let $E \subseteq \mathcal{V}$ be finite and nonempty with $|E| = n$. Then E is affinely independent iff $\dim(\operatorname{affhull}(E)) = n - 1$.

Proof.

$(\Rightarrow)$ Fix $\mathbf{x} \in E$ and put $B_{\mathbf{x}} := (E - \mathbf{x}) \setminus \{\mathbf{0}\}$.
The set $B_{\mathbf{x}}$ has $n - 1$ elements, is linearly independent by the forward hypothesis, and spans $\operatorname{span}(E - \mathbf{x})$.
The identity $\dim(\operatorname{affhull}(E)) = \dim(\operatorname{span}(E - \mathbf{x})) = n - 1$ holds by Theorem 4.1.11(ii).
$(\Leftarrow)$ Fix $\mathbf{x} \in E$ and put $B_{\mathbf{x}} := (E - \mathbf{x}) \setminus \{\mathbf{0}\}$. By Theorem 4.1.11(ii), $\dim(\operatorname{span}(E - \mathbf{x})) = n - 1 = |B_{\mathbf{x}}|$.
Any ordering of $B_{\mathbf{x}}$ is a basis of $\operatorname{span}(E - \mathbf{x})$ by Proposition 1.4.4(i).
$B_{\mathbf{x}}$ is linearly independent by the basis property, and E is affinely independent by the arbitrariness of $\mathbf{x}$.

Structural Commentary: Compare each translated difference set's cardinality with the dimension of its span.
Key Insight: Translation removes one point but preserves all affine directions. □

Definition 4.2.4. *Affine Bases and Barycentric Coordinates*
Let $A = \mathbf{x} + \mathcal{S}$ be an n-flat.

(i) A finite subset $\mathcal{B} \subseteq A$ is an *affine basis* of A iff $\mathcal{B}$ is affinely independent and $\operatorname{affspan}(\mathcal{B}) = A$.
(ii) A tuple $(\mathbf{p}_1, \ldots, \mathbf{p}_m)$ is an *ordered affine basis* of A iff its entries are distinct and $\{\mathbf{p}_1, \ldots, \mathbf{p}_m\}$ is an affine basis of A.
(iii) Let $(\mathbf{p}_1, \ldots, \mathbf{p}_m)$ be an ordered affine basis of A and $\mathbf{v} \in A$.
A vector $\mathbf{r} = (r_1, \ldots, r_m) \in \mathbb{F}^m$ is a *barycentric coordinate vector* of $\mathbf{v}$ iff $\mathbf{v} = \sum_{j=1}^{m} r_j \mathbf{p}_j$ and $\sum_{j=1}^{m} r_j = 1$.

Theorem 4.2.5. *Affine Bases and Barycentric Coordinates*
Let $A = \mathbf{x} + \mathcal{S}$ be an n-flat.

(i) If $(\mathbf{s}_1, \ldots, \mathbf{s}_n)$ is an ordered basis of $\mathcal{S}$, then $(\mathbf{x} + \mathbf{s}_1, \ldots, \mathbf{x} + \mathbf{s}_n, \mathbf{x})$ is an ordered affine basis of A.
(ii) If $\mathcal{B}$ is an affine basis of A, then $|\mathcal{B}| = n + 1$.
(iii) If $(\mathbf{p}_1, \ldots, \mathbf{p}_{n+1})$ is an ordered affine basis of A, then $(\forall\, \mathbf{v} \in A)(\exists!\, \mathbf{r} \in \mathbb{F}^{n+1})\,[\mathbf{v} = \sum_{j=1}^{n+1} r_j \mathbf{p}_j \wedge \sum_{j=1}^{n+1} r_j = 1]$.

Proof.

(i) Put $\mathbf{p}_j := \mathbf{x} + \mathbf{s}_j$ for $1 \le j \le n$ and $\mathbf{p}_{n+1} := \mathbf{x}$. The entries of $(\mathbf{p}_1, \dots, \mathbf{p}_{n+1})$ are distinct by linear independence of $(\mathbf{s}_1, \dots, \mathbf{s}_n)$.
Every zero-sum relation on a subtuple extends by zero coefficients to the full tuple.
For $\mathbf{a} \in \mathbb{F}^{n+1}$ with $\sum_{j=1}^{n+1} a_j \mathbf{p}_j = \mathbf{0}$ and $\sum_{j=1}^{n+1} a_j = 0$, the relation $\sum_{j=1}^{n} a_j \mathbf{s}_j = \mathbf{0}$ holds by substitution.
The identities $a_1 = \cdots = a_n = 0$ and $a_{n+1} = 0$ hold by independence of the $\mathbf{s}_j$ and the coefficient sum, respectively.
The set $\{\mathbf{p}_1, \dots, \mathbf{p}_{n+1}\}$ is affinely independent by Theorem 4.2.2(iii).
By Theorem 4.1.11(i), $\operatorname{affspan}(\{\mathbf{p}_1, \dots, \mathbf{p}_{n+1}\}) = \mathbf{x} + \operatorname{span}(\mathbf{s}_1, \dots, \mathbf{s}_n) = A$.
The tuple $(\mathbf{p}_1, \dots, \mathbf{p}_{n+1})$ is an ordered affine basis of A by the preceding distinctness, independence, and spanning identities.

(ii) Put $m := |\mathcal{B}|$. By Corollary 4.2.3, $\dim(\operatorname{affhull}(\mathcal{B})) = m - 1$. The identity $\operatorname{affhull}(\mathcal{B}) = A$ holds by $\operatorname{affspan}(\mathcal{B}) = A$ and Theorem 4.1.11(i).
The equality $|\mathcal{B}| = m = n + 1$ holds by $n = \dim(A) = \dim(\operatorname{affhull}(\mathcal{B})) = m - 1$.

(iii) Fix $\mathbf{v} \in A$ and put $\mathcal{P} := \{\mathbf{p}_1, \dots, \mathbf{p}_{n+1}\}$. $\mathbf{v} \in \operatorname{affspan}(\mathcal{P})$ by $\operatorname{affspan}(\mathcal{P}) = A$.
Choose $\ell \in \mathbb{Z}_{>0}$, $\mathbf{q} \in \mathcal{P}^\ell$, and $\mathbf{c} \in \mathbb{F}^\ell$ from this affine representation.
The chosen data satisfy $\mathbf{v} = \sum_{k=1}^{\ell} c_k \mathbf{q}_k$ and $\sum_{k=1}^{\ell} c_k = 1$. For $1 \le j \le n+1$, put $I_j := \{k \in \{1, \dots, \ell\} : \mathbf{q}_k = \mathbf{p}_j\}$ and $r_j := \sum_{k \in I_j} c_k$.
The sets $I_1, \dots, I_{n+1}$ partition $\{1, \dots, \ell\}$. The identities $\mathbf{v} = \sum_{j=1}^{n+1} r_j \mathbf{p}_j$ and $\sum_{j=1}^{n+1} r_j = 1$ hold by this partition.
The vector $\mathbf{r} := (r_1, \dots, r_{n+1})$ is unique by Theorem 4.2.2(iv).

Structural Commentary: Adjoin an affine origin, compare dimensions, then group coefficients by basis point.
Key Insight: Barycentric uniqueness is the affine-independence uniqueness criterion. □

Example 4.2.6. *Barycentric Coordinates on a Plane*
Let $\mathbf{x}, \mathbf{v}_1, \mathbf{v}_2 \in \mathbb{R}^3$ with $(\mathbf{v}_1, \mathbf{v}_2)$ linearly independent, and put $A := \mathbf{x} + \operatorname{span}(\mathbf{v}_1, \mathbf{v}_2)$. Put $\mathbf{p}_1 := \mathbf{x} + \mathbf{v}_1$, $\mathbf{p}_2 := \mathbf{x} + \mathbf{v}_2$, and $\mathbf{p}_3 := \mathbf{x}$.
The tuple $(\mathbf{p}_1, \mathbf{p}_2, \mathbf{p}_3)$ is an ordered affine basis of A by Theorem 4.2.5(i). For $(t_1, t_2) \in \mathbb{R}^2$, put $\mathbf{a} := \mathbf{x} + t_1 \mathbf{v}_1 + t_2 \mathbf{v}_2$.
Then $\mathbf{a} = t_1 \mathbf{p}_1 + t_2 \mathbf{p}_2 + (1 - t_1 - t_2)\mathbf{p}_3$ and $t_1 + t_2 + (1 - t_1 - t_2) = 1$.
Thus $(t_1, t_2, 1 - t_1 - t_2)$ is the barycentric coordinate vector of $\mathbf{a}$ by Theorem 4.2.5(iii).

4.3 Affine Maps and Affine Groups

Throughout, $\mathcal{V}$ is finite-dimensional over a fixed field $\mathbb{F}$. For $n \in \mathbb{Z}_{>0}$, put $\mathcal{C}_n := \{\mathbf{r} = (r_1, \dots, r_n) \in \mathbb{F}^n : \sum_{j=1}^{n} r_j = 1\}$.

Definition 4.3.1. *Affine Transformation*
A map $f : \mathcal{V} \to \mathcal{V}$ is *affine* iff $(\forall\, n \in \mathbb{Z}_{>0})(\forall\, (\mathbf{x}_1, \dots, \mathbf{x}_n) \in \mathcal{V}^n)(\forall\, \mathbf{r} \in \mathcal{C}_n)\, f(\sum_{j=1}^{n} r_j \mathbf{x}_j) = \sum_{j=1}^{n} r_j f(\mathbf{x}_j)$.

Theorem 4.3.2. *Two-Point Test for Affine Maps*
Assume $\operatorname{char}(\mathbb{F}) \neq 2$. *A map $f : \mathcal{V} \to \mathcal{V}$ is affine iff* $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})(\forall\, r \in \mathbb{F})\, f(r\mathbf{x} + (1 - r)\mathbf{y}) = rf(\mathbf{x}) + (1 - r)f(\mathbf{y})$.

Proof.

(⇒) The identity holds by Definition 4.3.1 with $n = 2$ and $(r, 1 - r) \in \mathcal{C}_2$.

(⇐) Put $\Gamma_f := \{(\mathbf{x}, f(\mathbf{x})) : \mathbf{x} \in \mathcal{V}\} \subseteq \mathcal{V} \times \mathcal{V}$.
The relation $(\forall\, \mathbf{x}, \mathbf{y} \in \mathcal{V})(\forall\, r \in \mathbb{F})\, r(\mathbf{x}, f(\mathbf{x})) + (1 - r)(\mathbf{y}, f(\mathbf{y})) \in \Gamma_f$ holds by the hypothesis, so Γ_f is two-affine closed.
The nonempty set Γ_f is affine closed by Theorem 4.1.6 in $\mathcal{V} \times \mathcal{V}$.
Hence $(\forall\, n \in \mathbb{Z}_{>0})(\forall\, (\mathbf{x}_1, \dots, \mathbf{x}_n) \in \mathcal{V}^n)(\forall\, \mathbf{r} \in \mathcal{C}_n)\, (\sum_{j=1}^{n} r_j \mathbf{x}_j, \sum_{j=1}^{n} r_j f(\mathbf{x}_j)) \in \Gamma_f$.
By the definition of Γ_f, this membership is equivalent to the identity in Definition 4.3.1; hence f is affine.

Structural Commentary: Transfer binary preservation to the graph, then promote its two-affine closure to affine closure.
Key Insight: Binary preservation is two-affine closure of the graph. □

Definition 4.3.3. *Translations*
For $\mathbf{a} \in \mathcal{V}$, the *translation by* $\mathbf{a}$ is the map $T_{\mathbf{a}} : \mathcal{V} \to \mathcal{V}$ defined by $T_{\mathbf{a}}(\mathbf{x}) = \mathbf{x} + \mathbf{a}$.

Theorem 4.3.4. *Affine Maps Are Linear Maps Followed by Translations*
A map $f : \mathcal{V} \to \mathcal{V}$ is affine iff $(\exists!\, (\mathbf{a}, \tau) \in \mathcal{V} \times \mathcal{L}(\mathcal{V}))\, [\mathbf{a} = f(\mathbf{0}) \wedge \tau = T_{-\mathbf{a}} \circ f \wedge f = T_{\mathbf{a}} \circ \tau]$.

Proof.

(⇒) Put $\mathbf{a} := f(\mathbf{0})$ and $\tau := T_{-\mathbf{a}} \circ f$.
For $r, s \in \mathbb{F}$ and $\mathbf{x}, \mathbf{y} \in \mathcal{V}$, $\tau(r\mathbf{x} + s\mathbf{y}) = r\tau(\mathbf{x}) + s\tau(\mathbf{y})$ by Definition 4.3.1 with $(\mathbf{x}, \mathbf{y}, \mathbf{0})$ and $(r, s, 1 - r - s) \in \mathcal{C}_3$.
Thus $\tau \in \mathcal{L}(\mathcal{V})$, $\mathbf{a} = f(\mathbf{0})$, $\tau = T_{-\mathbf{a}} \circ f$, and $f = T_{\mathbf{a}} \circ \tau$.
If $f = T_{\mathbf{b}} \circ \sigma$ with $(\mathbf{b}, \sigma) \in \mathcal{V} \times \mathcal{L}(\mathcal{V})$, then $\mathbf{b} = f(\mathbf{0}) = \mathbf{a}$ and $\sigma = T_{-\mathbf{b}} \circ f = \tau$, so the pair is unique.

(⇐) Suppose $(\mathbf{a}, \tau) \in \mathcal{V} \times \mathcal{L}(\mathcal{V})$ satisfies $f = T_{\mathbf{a}} \circ \tau$.
For $n \in \mathbb{Z}_{>0}$, $(\mathbf{x}_1, \dots, \mathbf{x}_n) \in \mathcal{V}^n$, and $\mathbf{r} \in \mathcal{C}_n$, $f(\sum_{j=1}^{n} r_j \mathbf{x}_j) = \mathbf{a} + \sum_{j=1}^{n} r_j \tau(\mathbf{x}_j) = \sum_{j=1}^{n} r_j f(\mathbf{x}_j)$. Therefore f affine by Definition 4.3.1.

Structural Commentary: Translate $f(\mathbf{0})$ to zero, verify linearity, and identify both factors by evaluation at zero.
Key Insight: The value $f(\mathbf{0})$ determines the translation factor. □

Definition 4.3.5. *Affine Group Data*

(i) The *general linear group* is $\operatorname{GL}(\mathcal{V}) := \{\tau \in \mathcal{L}(\mathcal{V}) : (\exists\, \sigma \in \mathcal{L}(\mathcal{V}))\, [\sigma\tau = I_{\mathcal{V}} = \tau\sigma]\}$.
(ii) The *affine group* is $\operatorname{Aff}(\mathcal{V}) := \{T_{\mathbf{a}} \circ \tau : \mathbf{a} \in \mathcal{V},\ \tau \in \operatorname{GL}(\mathcal{V})\}$.
(iii) The *translation group* is $\operatorname{Trans}(\mathcal{V}) := \{T_{\mathbf{a}} : \mathbf{a} \in \mathcal{V}\}$.
(iv) The *linear-part map* is $\Lambda : \operatorname{Aff}(\mathcal{V}) \to \operatorname{GL}(\mathcal{V})$, defined by $\Lambda(T_{\mathbf{a}} \circ \tau) = \tau$.

Well-definedness holds by Theorem 4.3.4.

Corollary 4.3.6. *Bijective Affine Maps*
Let $\mathbf{a} \in \mathcal{V}$ and $\tau \in \mathcal{L}(\mathcal{V})$. Then $T_{\mathbf{a}} \circ \tau$ is bijective iff $\tau \in \mathrm{GL}(\mathcal{V})$.

Proof.
($\Rightarrow$) The map $T_{-\mathbf{a}}$ is bijective with inverse $T_{\mathbf{a}}$. Thus $\tau = T_{-\mathbf{a}} \circ (T_{\mathbf{a}} \circ \tau)$ is bijective, so $\tau \in \mathrm{GL}(\mathcal{V})$ by Proposition 1.6.7.
($\Leftarrow$) If $\tau \in \mathrm{GL}(\mathcal{V})$, then $\tau^{-1} \circ T_{-\mathbf{a}}$ is a two-sided inverse of $T_{\mathbf{a}} \circ \tau$. Hence $T_{\mathbf{a}} \circ \tau$ is bijective by Proposition 1.6.7.

Structural Commentary: Cancel the translation forward and compose the linear and translation inverses backward.
Key Insight: Translation does not affect bijectivity. □

Theorem 4.3.7. *Affine Group and Translations*
(i) $(\forall \mathbf{a}, \mathbf{b} \in \mathcal{V})(\forall \tau, \sigma \in \mathcal{L}(\mathcal{V}))\ (T_{\mathbf{a}} \circ \tau) \circ (T_{\mathbf{b}} \circ \sigma) = T_{\mathbf{a}+\tau(\mathbf{b})} \circ (\tau\sigma)$.
(ii) $\mathrm{GL}(\mathcal{V})$ *is a group under composition.*
(iii) $\mathrm{Aff}(\mathcal{V})$ *is a group under composition, with identity* $T_{\mathbf{0}} \circ I_{\mathcal{V}}$ *and* $(T_{\mathbf{a}} \circ \tau)^{-1} = T_{-\tau^{-1}(\mathbf{a})} \circ \tau^{-1}$.
(iv) $\mathrm{Trans}(\mathcal{V}) \trianglelefteq \mathrm{Aff}(\mathcal{V})$.
(v) Λ *is a group homomorphism.*
(vi) Λ *is surjective.*
(vii) $\ker \Lambda = \mathrm{Trans}(\mathcal{V})$.
(viii) $\mathrm{Aff}(\mathcal{V})/\mathrm{Trans}(\mathcal{V}) \cong \mathrm{GL}(\mathcal{V})$.

Proof.
(i) For $\mathbf{x} \in \mathcal{V}$, $((T_{\mathbf{a}} \circ \tau) \circ (T_{\mathbf{b}} \circ \sigma))(\mathbf{x}) = \mathbf{a} + \tau(\mathbf{b}) + (\tau\sigma)(\mathbf{x})$. Hence $(T_{\mathbf{a}} \circ \tau) \circ (T_{\mathbf{b}} \circ \sigma) = T_{\mathbf{a}+\tau(\mathbf{b})} \circ (\tau\sigma)$ by Assumption 3.1.2.
(ii) The identity $I_{\mathcal{V}}$ belongs to $\mathrm{GL}(\mathcal{V})$, and composition is associative. Closure holds by Proposition 1.6.6(i).
If $\tau \in \mathrm{GL}(\mathcal{V})$, then $\tau^{-1} \in \mathrm{GL}(\mathcal{V})$ by Definition 1.6.4 and Proposition 1.6.5. Thus $\mathrm{GL}(\mathcal{V})$ is a group under composition.
(iii) Closure holds by (i)–(ii), associativity is inherited from composition, and the identity is $T_{\mathbf{0}} \circ I_{\mathcal{V}}$.
For $g = T_{\mathbf{a}} \circ \tau$, put $h := T_{-\tau^{-1}(\mathbf{a})} \circ \tau^{-1} \in \mathrm{Aff}(\mathcal{V})$. The identity $gh = hg = T_{\mathbf{0}} \circ I_{\mathcal{V}}$ holds by (i), so $h = g^{-1}$ and $\mathrm{Aff}(\mathcal{V})$ is a group.
(iv) The identities $T_{\mathbf{a}}T_{\mathbf{b}} = T_{\mathbf{a}+\mathbf{b}}$, $T_{\mathbf{0}} = I_{\mathcal{V}}$, and $T_{\mathbf{a}}^{-1} = T_{-\mathbf{a}}$ hold by (i), so $\mathrm{Trans}(\mathcal{V}) \leq \mathrm{Aff}(\mathcal{V})$.
If $g = T_{\mathbf{a}} \circ \tau$, then $(\forall\, \mathbf{b} \in \mathcal{V})\, gT_{\mathbf{b}}g^{-1} = T_{\tau(\mathbf{b})}$ by (i). The map τ is bijective by Proposition 1.6.7, so $g\,\mathrm{Trans}(\mathcal{V})g^{-1} = \mathrm{Trans}(\mathcal{V})$.
(v) For $g = T_{\mathbf{a}} \circ \tau$ and $h = T_{\mathbf{b}} \circ \sigma$, $\Lambda(gh) = \tau\sigma = \Lambda(g)\Lambda(h)$ by (i).
(vi) $(\forall\, \tau \in \mathrm{GL}(\mathcal{V}))\, \Lambda(T_{\mathbf{0}} \circ \tau) = \tau$, so Λ is surjective.
(vii) The identity $\ker \Lambda = \{T_{\mathbf{a}} \circ I_{\mathcal{V}} : \mathbf{a} \in \mathcal{V}\} = \mathrm{Trans}(\mathcal{V})$ holds by Definition 4.3.5.
(viii) Put $N := \mathrm{Trans}(\mathcal{V})$ and define $\overline{\Lambda}(gN) := \Lambda(g)$. If $gN = hN$, then $h^{-1}g \in N = \ker \Lambda$.
The identities $\Lambda(h^{-1}) = \Lambda(h)^{-1}$ and $\Lambda(h)^{-1}\Lambda(g) = I_{\mathcal{V}}$ hold by (v), so $\Lambda(g) = \Lambda(h)$ and $\overline{\Lambda}$ is well defined.
For $g, h \in \mathrm{Aff}(\mathcal{V})$, $\overline{\Lambda}((gN)(hN)) = \Lambda(gh) = \Lambda(g)\Lambda(h) = \overline{\Lambda}(gN)\overline{\Lambda}(hN)$ by (v), so $\overline{\Lambda}$ is a homomorphism.
It is surjective by (vi). If $\overline{\Lambda}(gN) = \overline{\Lambda}(hN)$, then $\Lambda(h^{-1}g) = I_{\mathcal{V}}$ by (v), so $h^{-1}g \in N$ by (vii) and $gN = hN$.
Hence $\overline{\Lambda}$ is a bijective homomorphism and $\mathrm{Aff}(\mathcal{V})/N \cong \mathrm{GL}(\mathcal{V})$.

Structural Commentary: Product and inverse laws establish normal translations before Λ descends injectively to their quotient.
Key Insight: The kernel of the linear-part map is exactly translation. □

4.4 Linear Projective Geometry and Affine Completion

Throughout this subsection, $\mathcal{V}$ is finite-dimensional over a fixed field $\mathbb{F}$.

Definition 4.4.1. *Projective Geometry of a Vector Space*
(i) The *projective geometry* of $\mathcal{V}$ is the inclusion poset $\mathrm{Sub}(\mathcal{V})$; its elements are *projective subspaces*.
Their projective dimension is $\mathrm{pdim}(\mathcal{U}) := \dim(\mathcal{U}) - 1$ for $\mathcal{U} \leq \mathcal{V}$.
(ii) A *projective point* is a 1-dimensional projective subspace.
A *projective line* is a 2-dimensional projective subspace.

Theorem 4.4.2. *Linear Span Map from Affine to Projective Geometry*
Let $H = \mathbf{x} + \mathcal{K}$ be an affine hyperplane with $\mathbf{0} \notin H$. Put $\mathcal{A}(H) := \{X \in \mathcal{A}(\mathcal{V}) : X \subseteq H\}$.
Define $P : \mathcal{A}(H) \to \mathrm{Sub}(\mathcal{V})$ by $P(X) := \mathrm{span}(X)$. Define $D : \mathcal{A}(H) \to \mathrm{Sub}(\mathcal{K})$ by $D(X) := P(X) \cap \mathcal{K}$.
(i) $(\forall\, X \in \mathcal{A}(H))\, P(X) \cap H = X$. *Consequently, P is injective and* $(\forall \mathcal{U} \in \mathrm{im}\, P)\, P^{-1}(\mathcal{U}) = \mathcal{U} \cap H$.
(ii) $\mathrm{im}\, P = \{\mathcal{U} \leq \mathcal{V} : \mathcal{U} \not\subseteq \mathcal{K}\}$.
(iii) $(\forall\, X, Y \in \mathcal{A}(H))\, [X \subseteq Y \iff P(X) \subseteq P(Y)]$.
(iv) $(\forall\, \mathcal{C} \subseteq \mathcal{A}(H))\, [\mathcal{C} \neq \emptyset \wedge \bigcap \mathcal{C} \neq \emptyset \Rightarrow P(\bigcap \mathcal{C}) = \bigcap_{X \in \mathcal{C}} P(X)]$.
(v) $(\forall\, \mathcal{C} \subseteq \mathcal{A}(H))\, [\mathcal{C} \neq \emptyset \Rightarrow P(\bigvee \mathcal{C}) = \bigvee_{X \in \mathcal{C}} P(X) = \sum_{X \in \mathcal{C}} P(X)]$. *Here $\bigvee \mathcal{C}$ is computed in $\mathcal{A}_0(\mathcal{V})$.*
(vi) $(\forall\, X \in \mathcal{A}(H))\ \mathrm{pdim}(P(X)) = \dim(X)$.
(vii) $(\forall\, X, Y \in \mathcal{A}(H))\, [X \parallel Y \iff (D(X) \subseteq D(Y) \vee D(Y) \subseteq D(X))]$.

Proof.
(i) Fix $X = \mathbf{u} + \mathcal{S} \in \mathcal{A}(H)$. Then $\mathcal{S} \leq \mathcal{K}$ by Proposition 4.1.4(iii). If $\mathbf{z} \in H \cap \mathcal{K}$, then $\mathbf{x} = \mathbf{z} - (\mathbf{z} - \mathbf{x}) \in \mathcal{K}$ and $\mathbf{0} \in H$, a contradiction.
Thus $H \cap \mathcal{K} = \emptyset$ and $\mathbf{u} \notin \mathcal{K}$. Since $\mathbf{u} \in X$ and $(\forall\, \mathbf{s} \in \mathcal{S})\, \mathbf{s} = (\mathbf{u} + \mathbf{s}) - \mathbf{u}$, $P(X) = \mathbb{F}\mathbf{u} \oplus \mathcal{S}$.
If $\mathbf{z} \in P(X) \cap H$, write $\mathbf{z} = a\mathbf{u} + \mathbf{s}$ with $(a, \mathbf{s}) \in \mathbb{F} \times \mathcal{S}$. Then $(a-1)\mathbf{u} = (\mathbf{z} - \mathbf{u}) - \mathbf{s} \in \mathcal{K}$, so $a = 1$ and $\mathbf{z} \in X$.
Thus $P(X) \cap H = X$; hence P is injective. For $\mathcal{U} \in \mathrm{im}\, P$, the same identity is $P^{-1}(\mathcal{U}) = \mathcal{U} \cap H$.
(ii) The relation $(\forall\, X \in \mathcal{A}(H))\, P(X) \not\subseteq \mathcal{K}$ holds by the decomposition in (i). Conversely, fix $\mathcal{U} \leq \mathcal{V}$ with $\mathcal{U} \not\subseteq \mathcal{K}$ and choose $\mathbf{u} \in \mathcal{U} \setminus \mathcal{K}$.
Let $\pi : \mathcal{V} \to \mathcal{V}/\mathcal{K}$ be the quotient map. The quotient has dimension 1 by Theorem 2.2.9(ii), and $\pi(\mathbf{x}), \pi(\mathbf{u}) \neq \mathbf{0}$.
Choose $r \in \mathbb{F}^{\times}$ with $\pi(\mathbf{x}) = r\pi(\mathbf{u})$, and put $\mathbf{h} := r\mathbf{u} \in \mathcal{U} \cap H$. For $\mathbf{z} \in \mathcal{V}$, $\mathbf{z} \in \mathcal{U} \cap H \iff \mathbf{z} - \mathbf{h} \in \mathcal{U} \cap \mathcal{K}$.
Hence $\mathcal{U} \cap H = \mathbf{h} + (\mathcal{U} \cap \mathcal{K}) \in \mathcal{A}(H)$.Since $\pi(\mathbf{h}) \neq \mathbf{0}$ spans $\mathcal{V}/\mathcal{K}$, $(\forall\, \mathbf{w} \in \mathcal{U})(\exists\, a \in \mathbb{F})\, \pi(\mathbf{w}) = a\pi(\mathbf{h})$.
Thus $\mathcal{U} = \mathbb{F}\mathbf{h} + (\mathcal{U} \cap \mathcal{K})$ by the preceding quotient representation. This sum is direct by $\mathbf{h} \notin \mathcal{K}$.
Therefore $P(\mathcal{U} \cap H) = \mathcal{U}$, which proves the image formula.
(iii) ($\Rightarrow$) For $X, Y \in \mathcal{A}(H)$, $X \subseteq Y \Rightarrow P(X) \subseteq P(Y)$ by monotonicity of linear span.
(iii) ($\Leftarrow$) For $X, Y \in \mathcal{A}(H)$, $P(X) \subseteq P(Y) \Rightarrow X = P(X) \cap H \subseteq P(Y) \cap H = Y$ by (i).

(iv) Fix $\emptyset \neq \mathcal{C} \subseteq \mathcal{A}(H)$ with $\bigcap \mathcal{C} \neq \emptyset$. Choose $\mathbf{z} \in \bigcap \mathcal{C}$. For $X \in \mathcal{C}$, let $\mathcal{S}_X$ be its base. Then $X = \mathbf{z} + \mathcal{S}_X$ by Proposition 4.1.2(ii).
The identity $\bigcap \mathcal{C} = \mathbf{z} + \bigcap_{X \in \mathcal{C}} \mathcal{S}_X$ holds by Lemma 4.1.12. The identity $(\forall\, X \in \mathcal{C})\, P(X) = \mathbb{F}\mathbf{z} \oplus \mathcal{S}_X$ holds by (i).
Fix $\mathbf{w} \in \bigcap_{X \in \mathcal{C}} P(X)$ and choose $X_0 \in \mathcal{C}$. Write $\mathbf{w} = a\mathbf{z} + \mathbf{s}_0$ with $\mathbf{s}_0 \in \mathcal{S}_{X_0}$. For $X \in \mathcal{C}$, write $\mathbf{w} = b_X \mathbf{z} + \mathbf{s}_X$ with $\mathbf{s}_X \in \mathcal{S}_X$.
Then $(a - b_X)\mathbf{z} = \mathbf{s}_X - \mathbf{s}_0 \in \mathcal{K}$, so $a = b_X$. Hence $\mathbf{w} - a\mathbf{z} \in \bigcap_{X \in \mathcal{C}} \mathcal{S}_X$.
Conversely, $(\forall\, X \in \mathcal{C})\, \mathbb{F}\mathbf{z} \oplus \bigcap_{Y \in \mathcal{C}} \mathcal{S}_Y \subseteq P(X)$. Therefore $\bigcap_{X \in \mathcal{C}} P(X) = \mathbb{F}\mathbf{z} \oplus \bigcap_{X \in \mathcal{C}} \mathcal{S}_X = P(\bigcap \mathcal{C})$.

(v) Fix $\emptyset \neq \mathcal{C} \subseteq \mathcal{A}(H)$ and put $E := \bigcup \mathcal{C}$. Since H is an upper bound, $\bigvee \mathcal{C} = \operatorname{affhull}(E) \subseteq H$ by Theorem 4.1.13(ii).
The inclusion $\operatorname{affhull}(E) = \operatorname{affspan}(E) \subseteq \operatorname{span}(E)$ holds by Theorem 4.1.11(i) and Definition 4.1.10(ii).
Since $E \subseteq \operatorname{affhull}(E)$, the reverse inclusion holds after taking linear spans.
Thus $P(\bigvee \mathcal{C}) = \operatorname{span}(E) = \sum_{X \in \mathcal{C}} P(X)$. This sum is $\bigvee_{X \in \mathcal{C}} P(X)$ by Theorem 2.1.7(i).

(vi) If $X = \mathbf{u} + \mathcal{S} \in \mathcal{A}(H)$, then $P(X) = \mathbb{F}\mathbf{u} \oplus \mathcal{S}$ by (i). Hence $\operatorname{pdim}(P(X)) = \dim(\mathbb{F}\mathbf{u} \oplus \mathcal{S}) - 1 = \dim \mathcal{S} = \dim X$.

(vii) ($\Rightarrow$) Fix $X = \mathbf{u} + \mathcal{S}, Y = \mathbf{v} + \mathcal{T} \in \mathcal{A}(H)$. The identities $D(X) = \mathcal{S}$ and $D(Y) = \mathcal{T}$ hold by (i).
Hence $X \parallel Y \Rightarrow D(X) \subseteq D(Y) \vee D(Y) \subseteq D(X)$ by Definition 4.1.3.

(vii) ($\Leftarrow$) Fix $X = \mathbf{u} + \mathcal{S}, Y = \mathbf{v} + \mathcal{T} \in \mathcal{A}(H)$. The identities $D(X) = \mathcal{S}$ and $D(Y) = \mathcal{T}$ hold by (i).
Thus $D(X) \subseteq D(Y) \vee D(Y) \subseteq D(X)$ implies $\mathcal{S} \subseteq \mathcal{T} \vee \mathcal{T} \subseteq \mathcal{S}$. Hence $X \parallel Y$ by Definition 4.1.3.

Structural Commentary: Trace–span inversion transports incidence and joins; intersection with $\mathcal{K}$ extracts each affine direction.
Key Insight: Codimension-one transversality makes the quotient coordinate unique. □

Perspective 4.4.3. *Projective Completion of an Affine Hyperplane*
Let $H = \mathbf{x} + \mathcal{K}$ be an affine hyperplane with $\mathbf{0} \notin H$. By Theorem 4.4.2, each affine flat $X \subseteq H$ corresponds to $P(X) = \operatorname{span}(X)$.
Its direction is $D(X) = P(X) \cap \mathcal{K}$. If $\dim H = 2$, distinct parallel affine lines X, Y satisfy $\dim D(X) = 1$ and $D(X) = D(Y)$.
This common projective point is their direction at infinity.
This completion is an incidence dictionary; the theorem, not the geometric picture, owns its formal claims.

Figure 37 illustrates the plane case.
Parallel affine lines are disjoint in H; their projective spans meet in the shared direction $D \leq \mathcal{K}$.

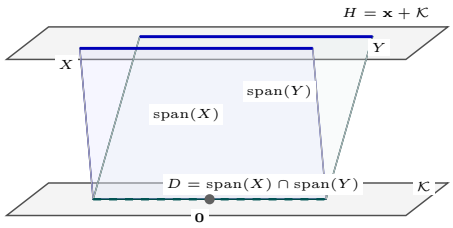

Figure 37: The affine plane $H = \mathbf{x} + \mathcal{K}$ contains the parallel lines X, Y. Their shaded spans meet along the dashed subspace $D = P(X) \cap \mathcal{K} = P(Y) \cap \mathcal{K}$. This projective point is their common direction at infinity.

4.5 Convex Combinations, Cones, and Hulls

Definition 4.5.1. *Convex Combinations, Cones, and Hulls*
Let $n, k \in \mathbb{Z}_{>0}$ and $\mathbf{x}_1, \dots, \mathbf{x}_k \in \mathbb{R}^n$. Put $\Delta_{k-1} := \{\mathbf{t} = (t_1, \dots, t_k) \in [0, \infty)^k : \sum_{i=1}^{k} t_i = 1\}$.

(i) The *convex combinations* of $\mathbf{x}_1, \dots, \mathbf{x}_k$ form $\{\sum_{i=1}^{k} t_i \mathbf{x}_i : \mathbf{t} \in \Delta_{k-1}\}$.
(ii) A set $C \subseteq \mathbb{R}^n$ is *convex* iff $(\forall\, \mathbf{x}, \mathbf{y} \in C)(\forall\, t \in [0,1])\, t\mathbf{x} + (1-t)\mathbf{y} \in C$.
(iii) A set $K \subseteq \mathbb{R}^n$ is a *cone* iff $(\forall\, \mathbf{x} \in K)(\forall\, a \in [0, \infty))\, a\mathbf{x} \in K$.
(iv) A *convex cone* is a subset of $\mathbb{R}^n$ that is both convex and a cone.
(v) For $S := \{\mathbf{x}_1, \dots, \mathbf{x}_k\}$, let $\mathcal{F}_S$ be the family of convex subsets of $\mathbb{R}^n$ containing S.
The *convex hull* of S is $\operatorname{conv}(S) := \bigcap \mathcal{F}_S$; the family $\mathcal{F}_S$ contains $\mathbb{R}^n$.

Definition 4.5.2. *Euclidean Topological Scope*
Let $d \in \mathbb{Z}_{>0}$.

(i) For $\mathbf{a} \in \mathbb{R}^d$ and $r > 0$, put $B_r(\mathbf{a}) := \{\mathbf{x} \in \mathbb{R}^d : \|\mathbf{x} - \mathbf{a}\| < r\}$.
(ii) A set $G \subseteq \mathbb{R}^d$ is *open* iff $(\forall\, \mathbf{x} \in G)(\exists\, r > 0)\, B_r(\mathbf{x}) \subseteq G$, and *closed* iff $\mathbb{R}^d \setminus G$ is open.
(iii) A set $K \subseteq \mathbb{R}^d$ is *compact* iff every cover of K by open subsets of $\mathbb{R}^d$ has a finite subcover.

Proposition 4.5.3. *Finite Convex Hulls*
Let $n, k \in \mathbb{Z}_{>0}$, $\mathbf{x}_1, \dots, \mathbf{x}_k \in \mathbb{R}^n$, and $S := \{\mathbf{x}_1, \dots, \mathbf{x}_k\}$.

(i) $\operatorname{conv}(S) = \left\{ \sum_{i=1}^{k} t_i \mathbf{x}_i : \mathbf{t} \in \Delta_{k-1} \right\}$.
(ii) $\operatorname{conv}(S)$ *is compact.*

Proof. Define $T : \mathbb{R}^k \to \mathbb{R}^n$ by $T(\mathbf{t}) := \sum_{i=1}^{k} t_i \mathbf{x}_i$, and put $C := T(\Delta_{k-1})$.

(i) $(\forall\, i \in \{1, \dots, k\})\, [\mathbf{e}_i \in \Delta_{k-1} \wedge T(\mathbf{e}_i) = \mathbf{x}_i]$, so $S \subseteq C$. Let $K \subseteq \mathbb{R}^n$ be convex with $S \subseteq K$.
For $1 \leq q \leq k$, put $C_q := \{\sum_{i=1}^{q} t_i \mathbf{x}_i : \mathbf{t} \in \Delta_{q-1}\}$. We prove $C_q \subseteq K$ by induction on q. The base case is $C_1 = \{\mathbf{x}_1\} \subseteq K$.
Fix $2 \leq q \leq k$ and assume $C_{q-1} \subseteq K$. Fix $\mathbf{t} \in \Delta_{q-1}$ and put $\mathbf{z} := \sum_{i=1}^{q} t_i \mathbf{x}_i \in C_q$.

If $t_q = 1$, then $(\forall\, i < q)\, t_i = 0$ by nonnegativity, and $\mathbf{z} = \mathbf{x}_q \in K$. If $t_q < 1$, put $s := 1 - t_q > 0$ and $\mathbf{y} := \sum_{i=1}^{q-1} \frac{t_i}{s}\mathbf{x}_i$.

Then $(\frac{t_1}{s}, \dots, \frac{t_{q-1}}{s}) \in \Delta_{q-2}$ by $\mathbf{t} \in \Delta_{q-1}$ and $s = 1 - t_q$, so $\mathbf{y} \in C_{q-1}$.
Then $\mathbf{z} = s\mathbf{y} + t_q\mathbf{x}_q \in K$ by the induction hypothesis and convexity. Hence $C = C_k \subseteq K$. Thus $C \subseteq \operatorname{conv}(S)$ by Definition 4.5.1(v).
Conversely, $t\mathbf{r} + (1-t)\mathbf{s} \in \Delta_{k-1}$ for $\mathbf{r}, \mathbf{s} \in \Delta_{k-1}$ and $t \in [0,1]$ by nonnegativity and coefficient sums.
For $\mathbf{r}, \mathbf{s} \in \Delta_{k-1}$ and $t \in [0,1]$, $T(t\mathbf{r} + (1-t)\mathbf{s}) = tT(\mathbf{r}) + (1-t)T(\mathbf{s}) \in C$; hence C is convex.
Since $S \subseteq C$, $\operatorname{conv}(S) \subseteq C$ by Definition 4.5.1(v), and therefore $\operatorname{conv}(S) = C$.

(ii)

(a) *Coefficient compactness*: Let $\mathcal{U}$ be an open cover of Δ_{k-1} with no finite subcover, and put $Q_0 := [0,1]^k$.
Recursively, after Q_m is chosen, partition it into 2^k equal closed subcubes.
Choose Q_{m+1} among them so that $\Delta_{k-1} \cap Q_{m+1}$ has no finite $\mathcal{U}$-subcover.
At least one such subcube exists; otherwise finite subcovers of the 2^k intersections combine into a finite subcover of $\Delta_{k-1} \cap Q_m$.
Thus $(Q_m)_{m\ge 0}$ is nested, Q_m has side length 2^{-m}, and $\Delta_{k-1} \cap Q_m \neq \emptyset$.

Write $Q_m = \prod_{i=1}^{k} [a_{m,i}, b_{m,i}]$ and put $t_i := \sup\{a_{m,i} : m \ge 0\}$.

Nestedness makes $(a_{m,i})_{m\ge 0}$ nondecreasing, and $b_{m,i}$ is an upper bound of $\{a_{\ell,i} : \ell \ge 0\}$.
Hence $a_{m,i} \le t_i \le b_{m,i}$, so $\mathbf{t} := (t_1, \dots, t_k) \in \bigcap_{m\ge 0} Q_m$. For $m \ge 0$, choose $\mathbf{t}_m \in \Delta_{k-1} \cap Q_m$.

Then $\|\mathbf{t}_m - \mathbf{t}\| \le \sqrt{k}\, 2^{-m}$, so $\mathbf{t}_m \to \mathbf{t}$. Since $\mathbf{t} \in Q_0$, its coordinates are nonnegative.

The equality $\sum_{i=1}^{k} t_i = 1$ holds by $\left|\sum_{i=1}^{k} t_i - 1\right| \le k\, 2^{-m} \to 0$, so $\mathbf{t} \in \Delta_{k-1}$. Choose $U \in \mathcal{U}$ and $r > 0$ with $\mathbf{t} \in B_r(\mathbf{t}) \subseteq U$.

Choose m with $\sqrt{k}\, 2^{-m} < r$; then $Q_m \subseteq B_r(\mathbf{t}) \subseteq U$, contrary to the choice of Q_m. Therefore Δ_{k-1} is compact.

(b) *Open inverse images*: Put $L := 1 + \sum_{i=1}^{k} \|\mathbf{x}_i\| > 0$. For $\mathbf{r}, \mathbf{s} \in \mathbb{R}^k$, $\|T(\mathbf{r}) - T(\mathbf{s})\| \le \sum_{i=1}^{k} |r_i - s_i|\, \|\mathbf{x}_i\| \le L\, \|\mathbf{r} - \mathbf{s}\|$.

If $V \subseteq \mathbb{R}^n$ is open and $\mathbf{t} \in T^{-1}(V)$, choose $r > 0$ with $B_r(T(\mathbf{t})) \subseteq V$. Then $B_{\frac{r}{L}}(\mathbf{t}) \subseteq T^{-1}(V)$, so $T^{-1}(V)$ is open.

(c) *Finite image cover*: Let $\mathcal{V}$ be an open cover of C. By (b), $\{T^{-1}(V) : V \in \mathcal{V}\}$ consists of open subsets of $\mathbb{R}^k$.

The family covers Δ_{k-1} by $C = T(\Delta_{k-1})$. By (a), choose $m \in \mathbb{Z}_{>0}$ and $V_1, \dots, V_m \in \mathcal{V}$ with $\Delta_{k-1} \subseteq \bigcup_{j=1}^{m} T^{-1}(V_j)$.

Then $C \subseteq \bigcup_{j=1}^{m} V_j$, so $C = \operatorname{conv}(S)$ is compact by (i).

Structural Commentary: Induction identifies the hull; cube bisection and the coefficient map establish compactness.
Key Insight: A finite convex hull is the image of a compact coefficient simplex. □

Proposition 4.5.4. *Sums of Convex and Closed Sets*
Let $n \in \mathbb{Z}_{>0}$ and $X, Y \subseteq \mathbb{R}^n$. Put $X + Y := \{\mathbf{x} + \mathbf{y} : \mathbf{x} \in X,\ \mathbf{y} \in Y\}$.

(i) If X and Y are convex, then $X + Y$ is convex.
(ii) If X is compact and Y is closed, then $X + Y$ is closed.

Proof.

(i) Assume X and Y are convex. Fix $\mathbf{z}_0, \mathbf{z}_1 \in X + Y$ and $t \in [0,1]$. For $r \in \{0,1\}$, choose $(\mathbf{x}_r, \mathbf{y}_r) \in X \times Y$ with $\mathbf{z}_r = \mathbf{x}_r + \mathbf{y}_r$.
By convexity, $t\mathbf{x}_0 + (1-t)\mathbf{x}_1 \in X$ and $t\mathbf{y}_0 + (1-t)\mathbf{y}_1 \in Y$. Hence $t\mathbf{z}_0 + (1-t)\mathbf{z}_1 = \big(t\mathbf{x}_0 + (1-t)\mathbf{x}_1\big) + \big(t\mathbf{y}_0 + (1-t)\mathbf{y}_1\big) \in X + Y$.

(ii) Assume X compact, Y closed. If $X = \emptyset$, then $X + Y = \emptyset$. Its complement $\mathbb{R}^n$ is open by $(\forall\, \mathbf{u} \in \mathbb{R}^n)\, B_1(\mathbf{u}) \subseteq \mathbb{R}^n$, so $\emptyset$ is closed.
Suppose $X \neq \emptyset$ and fix $\mathbf{z} \notin X + Y$. For $\mathbf{x} \in X$, choose $r_{\mathbf{x}} > 0$ with $B_{2r_{\mathbf{x}}}(\mathbf{z} - \mathbf{x}) \subseteq \mathbb{R}^n \setminus Y$ by openness of $\mathbb{R}^n \setminus Y$.
Fix $\mathbf{x} \in X$ and $\mathbf{u} \in B_{r_{\mathbf{x}}}(\mathbf{x})$, and put $\varepsilon := r_{\mathbf{x}} - \|\mathbf{u} - \mathbf{x}\| > 0$. Then $B_\varepsilon(\mathbf{u}) \subseteq B_{r_{\mathbf{x}}}(\mathbf{x})$ by Theorem 1.1.14(i).

Thus the balls $B_{r_{\mathbf{x}}}(\mathbf{x})$ form an open cover of X. Choose $m \in \mathbb{Z}_{>0}$ and $\mathbf{x}_1, \dots, \mathbf{x}_m \in X$ with $X \subseteq \bigcup_{j=1}^{m} B_{r_{\mathbf{x}_j}}(\mathbf{x}_j)$ by compactness.

Put $\delta := \min_{1\le j\le m} r_{\mathbf{x}_j} > 0$. Suppose $\mathbf{w} = \mathbf{x} + \mathbf{y} \in B_\delta(\mathbf{z}) \cap (X + Y)$ with $(\mathbf{x}, \mathbf{y}) \in X \times Y$. Choose j with $\mathbf{x} \in B_{r_{\mathbf{x}_j}}(\mathbf{x}_j)$.
By Theorem 1.1.14(i), $\|\mathbf{y} - (\mathbf{z} - \mathbf{x}_j)\| \le \|\mathbf{w} - \mathbf{z}\| + \|\mathbf{x} - \mathbf{x}_j\| < \delta + r_{\mathbf{x}_j} \le 2r_{\mathbf{x}_j}$. This contradicts $\mathbf{y} \in Y$, so $B_\delta(\mathbf{z}) \subseteq \mathbb{R}^n \setminus (X + Y)$.
Since $\mathbf{z} \notin X + Y$ was arbitrary, $\mathbb{R}^n \setminus (X + Y)$ is open and $X + Y$ is closed.

Structural Commentary: Part (i) separates summands; compactness makes the exclusion radii uniform in (ii).
Key Insight: A finite subcover converts local separation into one neighborhood radius. □

4.6 Hyperplanes, Nearest Points, and Separation

Definition 4.6.1. *Hyperplanes, Half-Spaces, and Separation*
Let $n \in \mathbb{Z}_{>0}$, $\mathbf{N} \in \mathbb{R}^n \setminus \{\mathbf{0}\}$, and $b \in \mathbb{R}$.

(i) The *affine hyperplane* with normal $\mathbf{N}$ and level b is $\mathcal{H}(\mathbf{N}, b) := \{\mathbf{x} \in \mathbb{R}^n : \langle \mathbf{N}, \mathbf{x}\rangle = b\}$.
Its affine decomposition is $\mathcal{H}(\mathbf{N}, b) = \frac{b}{\|\mathbf{N}\|^2}\mathbf{N} + \operatorname{span}(\mathbf{N})^\perp$.

(ii) The *linear hyperplane* with normal $\mathbf{N}$ is $\mathcal{H}(\mathbf{N}, 0) = \operatorname{span}(\mathbf{N})^\perp$.

(iii) The *closed positive half-space* is $\mathcal{H}_+(\mathbf{N}, b) := \{\mathbf{x} \in \mathbb{R}^n : \langle \mathbf{N}, \mathbf{x}\rangle \ge b\}$.
The *closed negative half-space* is $\mathcal{H}_-(\mathbf{N}, b) := \{\mathbf{x} \in \mathbb{R}^n : \langle \mathbf{N}, \mathbf{x}\rangle \le b\}$.
Replacing $\ge, \le$ by $>, <$ defines the corresponding open half-spaces.

(iv) For $X \subseteq \mathbb{R}^n$ and $\star \in \{<, \le, >, \ge\}$, the *set-inequality convention* is $\langle \mathbf{N}, X\rangle \star b \iff (\forall\, \mathbf{x} \in X)\ \langle \mathbf{N}, \mathbf{x}\rangle \star b$.
Symmetrically, $b \star \langle \mathbf{N}, X\rangle \iff (\forall\, \mathbf{x} \in X)\, b \star \langle \mathbf{N}, \mathbf{x}\rangle$.

(v) For $\sigma \in \{\pm 1\}$, $\sigma(\mathbf{N}, b) := (\sigma\mathbf{N}, \sigma b)$ is an *orientation* of $\mathcal{H}(\mathbf{N}, b)$.

(vi) Sets $X, Y \subseteq \mathbb{R}^n$ are *strictly separated* by $\mathcal{H}(\mathbf{N}, b)$ iff $(\exists\, \sigma \in \{\pm 1\})\ \langle \sigma\mathbf{N}, X\rangle < \sigma b < \langle \sigma\mathbf{N}, Y\rangle$.

(vii) Sets $X, Y \subseteq \mathbb{R}^n$ are *strongly separated* by $\mathcal{H}(\mathbf{N}, b)$ iff $(\exists\, \sigma \in \{\pm 1\})(\exists\, \varepsilon > 0)\ \langle \sigma\mathbf{N}, X\rangle < \sigma b - \varepsilon < \sigma b + \varepsilon < \langle \sigma\mathbf{N}, Y\rangle$.

Remark 4.6.2. *Basic Hyperplane Geometry*
The identity $\mathcal{H}_+(\mathbf{N}, b) \cap \mathcal{H}_-(\mathbf{N}, b) = \mathcal{H}(\mathbf{N}, b)$ holds.

$\mathbb{R}^n = \big(\mathcal{H}_-(\mathbf{N},b)\setminus\mathcal{H}(\mathbf{N},b)\big)\sqcup\mathcal{H}(\mathbf{N},b)\sqcup\big(\mathcal{H}_+(\mathbf{N},b)\setminus\mathcal{H}(\mathbf{N},b)\big)$.
The three terms are the negative open half-space, the hyperplane, and the positive open half-space.
Since $\mathbf{N}\in\mathcal{H}(\mathbf{N},\|\mathbf{N}\|^2)$, $(\forall\,\mathbf{x}\in\mathcal{H}(\mathbf{N},\|\mathbf{N}\|^2))\ \|\mathbf{N}\|^2=\langle\mathbf{N},\mathbf{x}\rangle\le\|\mathbf{N}\|\,\|\mathbf{x}\|$ by Theorem 1.1.13(i).
Hence $(\forall\,\mathbf{x}\in\mathcal{H}(\mathbf{N},\|\mathbf{N}\|^2))\ \|\mathbf{N}\|\le\|\mathbf{x}\|$, so $\mathbf{N}$ is a closest point of this hyperplane to $\mathbf{0}$.

Theorem 4.6.3. *Nearest Points and Separating a Point*
Let $C\subseteq\mathbb{R}^n$ be nonempty, closed, and convex.

(i) $(\exists!\,\mathbf{N}_C\in C)(\forall\,\mathbf{x}\in C)\ \|\mathbf{N}_C\|\le\|\mathbf{x}\|$.
(ii) If $\mathbf{b}\notin C$, put $D:=C-\mathbf{b}:=\{\mathbf{x}-\mathbf{b}:\mathbf{x}\in C\}$ and let $\mathbf{N}$ be its unique minimum-norm vector. Then $\mathbf{N}\neq\mathbf{0}$ and $\langle\mathbf{N},C\rangle\ge\|\mathbf{N}\|^2+\langle\mathbf{N},\mathbf{b}\rangle>\langle\mathbf{N},\mathbf{b}\rangle$.
(iii) Under the hypotheses and notation of (ii), set $\alpha:=\langle\mathbf{N},\mathbf{b}\rangle+\frac{1}{2}\|\mathbf{N}\|^2$. Then $\mathcal{H}(\mathbf{N},\alpha)$ strongly separates $\{\mathbf{b}\}$ and C.

Proof.

(i) Put $m:=\inf\{\|\mathbf{x}\|^2:\mathbf{x}\in C\}$. By the definition of infimum, choose $(\mathbf{x}_j)_{j\ge1}\subseteq C$ satisfying $m\le\|\mathbf{x}_j\|^2<m+\frac{1}{j}$.
For $j,\ell\ge1$, $\mathbf{w}_{j,\ell}:=\frac{1}{2}(\mathbf{x}_j+\mathbf{x}_\ell)\in C$ by convexity.
By Theorem 1.1.20, $\|\mathbf{x}_j-\mathbf{x}_\ell\|^2=2\|\mathbf{x}_j\|^2+2\|\mathbf{x}_\ell\|^2-4\|\mathbf{w}_{j,\ell}\|^2\le\frac{2}{j}+\frac{2}{\ell}$, so $(\mathbf{x}_j)_{j\ge1}$ is Cauchy.
Write $\mathbf{x}_j=(x_{j,1},\dots,x_{j,n})$. For $r\in\{1,\dots,n\}$ and $q\ge1$, put $a_{q,r}:=\inf\{x_{j,r}:j\ge q\}$ and $b_{q,r}:=\sup\{x_{j,r}:j\ge q\}$.
Since $(\forall\,j,\ell\ge1)\ |x_{j,r}-x_{\ell,r}|\le\|\mathbf{x}_j-\mathbf{x}_\ell\|$, each coordinate sequence is Cauchy.
Each coordinate sequence is bounded, so $a_{q,r},b_{q,r}\in\mathbb{R}$.
For $\eta>0$, choose $q_0\ge1$ with $(\forall\,q\ge q_0)\,0\le b_{q,r}-a_{q,r}\le\eta$ by the Cauchy property.
Thus $b_{q,r}-a_{q,r}\to0$, and the intervals $[a_{q,r},b_{q,r}]$ are nested. Put $N_r:=\sup\{a_{q,r}:q\ge1\}$.
Nestedness implies $(\forall\,q\ge1)\,[a_{q,r}\le N_r\le b_{q,r}\wedge(\forall\,j\ge q)\ |x_{j,r}-N_r|\le b_{q,r}-a_{q,r}]$, so $x_{j,r}\to N_r$.
For $\mathbf{N}_C:=(N_1,\dots,N_n)$, $\|\mathbf{x}_j-\mathbf{N}_C\|^2=\sum_{r=1}^{n}|x_{j,r}-N_r|^2\to0$.
If $\mathbf{N}_C\notin C$, choose $\rho>0$ with $B_\rho(\mathbf{N}_C)\subseteq\mathbb{R}^n\setminus C$ by openness of $\mathbb{R}^n\setminus C$.
$(\exists\,j\ge1)\,\mathbf{x}_j\in B_\rho(\mathbf{N}_C)\subseteq\mathbb{R}^n\setminus C$ by convergence. This contradicts $(\mathbf{x}_j)_{j\ge1}\subseteq C$, so $\mathbf{N}_C\in C$.
By Proposition 1.1.15, $\|\mathbf{x}_j\|\to\|\mathbf{N}_C\|$, and therefore $\|\mathbf{N}_C\|^2=m$.
If $\mathbf{u},\mathbf{v}\in C$ both have squared norm m, then $\mathbf{w}:=\frac{1}{2}(\mathbf{u}+\mathbf{v})\in C$ by convexity.
By Theorem 1.1.20, $m\le\|\mathbf{w}\|^2=m-\frac{1}{4}\|\mathbf{u}-\mathbf{v}\|^2$, so $\mathbf{u}=\mathbf{v}$.

(ii) The singleton $\{-\mathbf{b}\}$ is convex by definition and compact by Proposition 4.5.3(i),(ii).
Since $C\neq\emptyset$, $D=\{-\mathbf{b}\}+C\neq\emptyset$, and D is closed and convex by Proposition 4.5.4(i),(ii).
Fix its unique minimum-norm vector $\mathbf{N}$ by (i). Since $\mathbf{b}\notin C\iff\mathbf{0}\notin D$, $\mathbf{N}\neq\mathbf{0}$.
Fix $\mathbf{z}\in D$ and put $\mathbf{h}:=\mathbf{z}-\mathbf{N}$. By convexity, $(\forall\,t\in(0,1])\,\mathbf{N}+t\mathbf{h}\in D$.
By minimality, $(\forall\,t\in(0,1])\,0\le\|\mathbf{N}+t\mathbf{h}\|^2-\|\mathbf{N}\|^2=2t\langle\mathbf{N},\mathbf{h}\rangle+t^2\|\mathbf{h}\|^2$.
If $a:=\langle\mathbf{N},\mathbf{h}\rangle<0$, then $\mathbf{h}\neq\mathbf{0}$ and the right-hand side is negative for $t\in\left(0,\min\left\{1,\frac{-2a}{\|\mathbf{h}\|^2}\right\}\right)$, a contradiction.
Hence $\langle\mathbf{N},\mathbf{z}\rangle\ge\|\mathbf{N}\|^2$. Substituting $\mathbf{z}=\mathbf{x}-\mathbf{b}$ proves $\langle\mathbf{N},C\rangle\ge\|\mathbf{N}\|^2+\langle\mathbf{N},\mathbf{b}\rangle>\langle\mathbf{N},\mathbf{b}\rangle$.

(iii) Put $\varepsilon:=\frac{1}{4}\|\mathbf{N}\|^2>0$. By (ii), $(\forall\,\mathbf{x}\in C)\ \langle\mathbf{N},\mathbf{b}\rangle<\alpha-\varepsilon<\alpha+\varepsilon<\langle\mathbf{N},\mathbf{x}\rangle$.
Hence $\mathcal{H}(\mathbf{N},\alpha)$ strongly separates $\{\mathbf{b}\}$ and C by Definition 4.6.1(vii) with $\sigma=1$.

Structural Commentary: Parallelogram control constructs the minimizer; translation and one-sided variations construct the separator.
Key Insight: Minimum norm forces every feasible displacement into one supporting half-space. □

Figure 38 illustrates Theorem 4.6.3(ii),(iii).
Here $\mathbf{p}=\mathbf{b}+\mathbf{N}\in C$ is nearest to $\mathbf{b}$. The vector $\mathbf{N}\in C-\mathbf{b}$ is both the displacement and the separating normal.

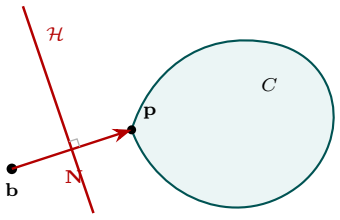

Figure 38: For $\mathbf{b}\notin C$, the labeled point $\mathbf{p}=\mathbf{b}+\mathbf{N}\in C$ is nearest to $\mathbf{b}$, the arrow $\mathbf{N}$ is the displacement from $\mathbf{b}$ to $\mathbf{p}$, and the labeled hyperplane lies strictly between $\mathbf{b}$ and the closed convex set C.

Theorem 4.6.4. *Separating a Compact Convex Set from a Subspace*
Let $C\subseteq\mathbb{R}^n$ be nonempty, compact, and convex, and let $S\le\mathbb{R}^n$ satisfy $C\cap S=\emptyset$. Then:

(i) $(\exists\,\mathbf{N}\in S^\perp\setminus\{\mathbf{0}\})\ \langle\mathbf{N},C\rangle\ge\|\mathbf{N}\|^2>0$.
(ii) For a vector $\mathbf{N}$ as in (i), $\mathcal{H}(\mathbf{N},\frac{1}{2}\|\mathbf{N}\|^2)$ strongly separates S and C.

Proof.

(i) The subspace S is convex. Put $Q:=P_{S^\perp}$. By Proposition 2.2.3(i),(vi) and Corollary 2.1.8, Q is linear and $\ker(Q)=S$.
By Proposition 2.2.3(viii), $(\forall\,\mathbf{v}\in\mathbb{R}^n)\ \|Q\mathbf{v}\|\le\|\mathbf{v}\|$. Fix $\mathbf{x}\notin S$ and put $\mathbf{q}:=Q\mathbf{x}\neq\mathbf{0}$.
If $\|\mathbf{y}-\mathbf{x}\|<\frac{1}{2}\|\mathbf{q}\|$, then $\|Q\mathbf{y}\|\ge\|\mathbf{q}\|-\|Q(\mathbf{y}-\mathbf{x})\|\ge\|\mathbf{q}\|-\|\mathbf{y}-\mathbf{x}\|>0$ by Proposition 1.1.15.
Thus $B_{\frac{1}{2}\|\mathbf{q}\|}(\mathbf{x})\subseteq\mathbb{R}^n\setminus S$, so S is closed. Put $D:=C+S$.
Since $\mathbf{0}\in S$, $C\subseteq D$ and $D\neq\emptyset$. The set D is closed and convex by Proposition 4.5.4(i),(ii).
If $\mathbf{0}\in D$, then $(\exists\,(\mathbf{c},\mathbf{s})\in C\times S)\,\mathbf{0}=\mathbf{c}+\mathbf{s}$, whence $\mathbf{c}=-\mathbf{s}\in C\cap S$, a contradiction.
Fix the unique minimum-norm vector $\mathbf{N}$ of D by Theorem 4.6.3(i).
By Theorem 4.6.3(ii) with D and $\mathbf{0}$, $\mathbf{N}\neq\mathbf{0}$ and $(\forall\,\mathbf{c}\in C)(\forall\,\mathbf{s}\in S)\ \langle\mathbf{N},\mathbf{c}+\mathbf{s}\rangle\ge\|\mathbf{N}\|^2$.
Fix $\mathbf{c}_0\in C$. For $\mathbf{s}\in S$, put $a:=\langle\mathbf{N},\mathbf{s}\rangle$. If $a\neq0$, set $\lambda:=\frac{\|\mathbf{N}\|^2-\langle\mathbf{N},\mathbf{c}_0\rangle-1}{a}$.

Then $\lambda\mathbf{s}+\mathbf{c}_0 \in D$ but $\langle \mathbf{N}, \lambda\mathbf{s}+\mathbf{c}_0\rangle = \|\mathbf{N}\|^2 - 1$, a contradiction.
Hence $(\forall\, \mathbf{s}\in S)\ \langle \mathbf{N},\mathbf{s}\rangle = 0$, so $\mathbf{N}\in S^\perp$. Taking $\mathbf{s}=\mathbf{0}$ in the preceding bound proves $\langle \mathbf{N}, C\rangle \geq \|\mathbf{N}\|^2 > 0$.

(ii) Put $\alpha := \frac{1}{2}\|\mathbf{N}\|^2$ and $\varepsilon := \frac{1}{4}\|\mathbf{N}\|^2$. By (i), $(\forall\, \mathbf{s}\in S)(\forall\, \mathbf{c}\in C)\ \langle \mathbf{N},\mathbf{s}\rangle = 0 < \alpha-\varepsilon < \alpha+\varepsilon < \|\mathbf{N}\|^2 \leq \langle \mathbf{N},\mathbf{c}\rangle$.
Hence $\mathcal{H}(\mathbf{N},\alpha)$ strongly separates S and C by Definition 4.6.1(vii) with $\sigma = 1$.

Structural Commentary: Minimum-norm separation of $C+S$ constructs the normal; unrestricted subspace scaling proves orthogonality.
Key Insight: Translation invariance along S forces the supporting normal into $S^\perp$. □

4.7 Positive Orthants, Alternatives, and Farkas's Lemma

This subsection uses real inner-product geometry to decide feasibility of positive linear systems.
A separating hyperplane converts infeasibility into a dual vector certificate.

Definition 4.7.1. *Positive Orthants*
Let $n\in\mathbb{Z}_{>0}$ and $\mathbf{x}=(x_1,\dots,x_n)\in\mathbb{R}^n$.

(i) $\mathbf{x}\geq\mathbf{0} \iff (\forall\, i\in\{1,\dots,n\})\, x_i\geq 0$ defines *coordinatewise nonnegativity*; $\mathbf{x}\leq\mathbf{0}\iff -\mathbf{x}\geq\mathbf{0}$.
(ii) $\mathbf{x}>\mathbf{0}\iff[\mathbf{x}\geq\mathbf{0}\wedge\mathbf{x}\neq\mathbf{0}]$ defines *nonzero nonnegativity*.
(iii) $\mathbf{x}\gg\mathbf{0}\iff(\forall\, i\in\{1,\dots,n\})\, x_i>0$ defines *coordinatewise positivity*.
(iv) $\mathbb{R}^n_{\geq 0} := \{\mathbf{y}\in\mathbb{R}^n : \mathbf{y}\geq\mathbf{0}\}$ is the *nonnegative orthant*.
(v) $\mathbb{R}^n_{+} := \{\mathbf{y}\in\mathbb{R}^n : \mathbf{y}>\mathbf{0}\} = \mathbb{R}^n_{\geq 0}\setminus\{\mathbf{0}\}$ is the *nonzero nonnegative orthant*.
(vi) $\mathbb{R}^n_{++} := \{\mathbf{y}\in\mathbb{R}^n : \mathbf{y}\gg\mathbf{0}\}$ is the *coordinatewise positive orthant*.

Motivation 4.7.2. *Positive Null Vectors as Probabilities*
Let $m,n\in\mathbb{Z}_{>0}$ and $A=[\mathbf{a}_1\ \cdots\ \mathbf{a}_n]\in\mathrm{Mat}(m,n,\mathbb{R})$. Suppose $\mathbf{x}=(x_1,\dots,x_n)>\mathbf{0}$ and $A\mathbf{x}=\mathbf{0}$.

(i) Set $s := x_1+\cdots+x_n>0$ and $\boldsymbol{\pi} := s^{-1}\mathbf{x}$.
(ii) $(\forall\, i\in\{1,\dots,n\})\,\pi_i\geq 0$ and $\sum_{i=1}^{n}\pi_i = 1$, so $\boldsymbol{\pi}$ is a probability vector.
(iii) The identity $A\boldsymbol{\pi} = s^{-1}A\mathbf{x} = \mathbf{0}$ is equivalent to $\sum_{i=1}^{n}\pi_i\mathbf{a}_i = \mathbf{0}$.
(iv) $\mathbf{x}\gg\mathbf{0}\Longrightarrow(\forall\, i\in\{1,\dots,n\})\,\pi_i>0$.

Thus a nonzero nonnegative null vector normalizes to a distribution whose probability-weighted column mean is $\mathbf{0}$.

Principle 4.7.3. *Positive Solutions Are Orthant Intersections*
Let $m,n\in\mathbb{Z}_{>0}$, $A\in\mathrm{Mat}(m,n,\mathbb{R})$, and $S := \mathrm{row}(A)$. Then $\ker(A) = S^\perp$ by Corollary 2.3.12(i).

(i) $\{\mathbf{x}\in\mathbb{R}^n : A\mathbf{x}=\mathbf{0}\wedge\mathbf{x}>\mathbf{0}\} = S^\perp\cap\mathbb{R}^n_{+}$.
(ii) $\{\mathbf{x}\in\mathbb{R}^n : A\mathbf{x}=\mathbf{0}\wedge\mathbf{x}\gg\mathbf{0}\} = S^\perp\cap\mathbb{R}^n_{++}$.

Thus positive null vectors are precisely the indicated orthant intersections with $\mathrm{row}(A)^\perp$.

Theorem 4.7.4. *Positive Orthant Alternatives for Subspaces*
Let $n\in\mathbb{Z}_{>0}$ and $S\leq\mathbb{R}^n$. Then:

(i) $S\cap\mathbb{R}^n_{+}=\emptyset\iff S^\perp\cap\mathbb{R}^n_{++}\neq\emptyset$.
(ii) $S\cap\mathbb{R}^n_{++}=\emptyset\iff S^\perp\cap\mathbb{R}^n_{+}\neq\emptyset$.

Proof.

(i) ($\Rightarrow$) Put $\Delta := \mathrm{conv}\{\mathbf{e}_1,\dots,\mathbf{e}_n\}$, which is convex by definition.
The identity $\Delta = \{(t_1,\dots,t_n)\in\mathbb{R}^n : (\forall\, i\in\{1,\dots,n\})\, t_i\geq 0,\ \sum_{i=1}^{n}t_i = 1\}$ holds by Proposition 4.5.3(i).
The set Δ is compact by Proposition 4.5.3(ii). Hence $\emptyset\neq\Delta\subseteq\mathbb{R}^n_{+}$ and $\Delta\cap S=\emptyset$.
Choose $\mathbf{N}\in S^\perp\setminus\{\mathbf{0}\}$ satisfying $(\forall\, i\in\{1,\dots,n\})\, N_i = \langle\mathbf{N},\mathbf{e}_i\rangle\geq\|\mathbf{N}\|^2>0$ by Theorem 4.6.4(i). Thus $\mathbf{N}\in S^\perp\cap\mathbb{R}^n_{++}$.

(i) ($\Leftarrow$) Suppose $\mathbf{N}\in S^\perp\cap\mathbb{R}^n_{++}$ and $\mathbf{x}\in S\cap\mathbb{R}^n_{+}$. Choose $j\in\{1,\dots,n\}$ with $x_j>0$ by $\mathbf{x}\geq\mathbf{0}$ and $\mathbf{x}\neq\mathbf{0}$.
Then $0=\langle\mathbf{N},\mathbf{x}\rangle = \sum_{i=1}^{n}N_ix_i\geq N_jx_j>0$, a contradiction. Hence $S\cap\mathbb{R}^n_{+}=\emptyset$.

(ii) ($\Rightarrow$) Suppose $S\cap\mathbb{R}^n_{++}=\emptyset$ and $S^\perp\cap\mathbb{R}^n_{+}=\emptyset$. Then $(S^\perp)^\perp\cap\mathbb{R}^n_{++}\neq\emptyset$ by (i) with $S^\perp$.
But $(S^\perp)^\perp = S$ by Corollary 2.1.8, contradicting $S\cap\mathbb{R}^n_{++}=\emptyset$.

(ii) ($\Leftarrow$) Suppose $\mathbf{N}\in S^\perp\cap\mathbb{R}^n_{+}$ and $\mathbf{x}\in S\cap\mathbb{R}^n_{++}$. Choose $j\in\{1,\dots,n\}$ with $N_j>0$ by $\mathbf{N}\geq\mathbf{0}$ and $\mathbf{N}\neq\mathbf{0}$.
Then $0=\langle\mathbf{N},\mathbf{x}\rangle = \sum_{i=1}^{n}N_ix_i\geq N_jx_j>0$, a contradiction. Hence $S\cap\mathbb{R}^n_{++}=\emptyset$.

Structural Commentary: Simplex separation proves (i); double orthogonal complementation converts (i) into (ii).
Key Insight: Orthant avoidance forces a strictly positive normal in the complementary subspace. □

Figure 39 illustrates Theorem 4.7.4(i) in $\mathbb{R}^2$.
The displayed $\mathbf{y}\in S^\perp\cap\mathbb{R}^2_{++}$ certifies $S\cap\mathbb{R}^2_{+}=\emptyset$; the theorem owns this implication.

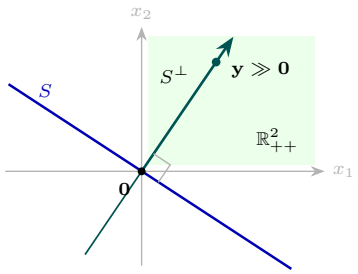

Figure 39: In $\mathbb{R}^2$, the negative-slope line S avoids $\mathbb{R}^2_+$, while $\mathbf{y} \in S^\perp \cap \mathbb{R}^2_{++}$.

Theorem 4.7.5. *Homogeneous Positive Alternatives*
Let $m, n \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(m, n, \mathbb{R})$. Exactly one alternative holds in each pair:
(i) $\ker(A) \cap \mathbb{R}^n_{++} \neq \emptyset$ *or* $\mathrm{col}(A^t) \cap \mathbb{R}^n_+ \neq \emptyset$.
(ii) $\ker(A) \cap \mathbb{R}^n_+ \neq \emptyset$ *or* $\mathrm{col}(A^t) \cap \mathbb{R}^n_{++} \neq \emptyset$.

Proof. Put $S := \mathrm{row}(A) = \mathrm{col}(A^t)$. Then $\ker(A) = S^\perp$ by Corollary 2.3.12(i).
(i) The pair in (i) is equivalent to $S^\perp \cap \mathbb{R}^n_{++} \neq \emptyset$ or $S \cap \mathbb{R}^n_+ \neq \emptyset$.
Exactly one alternative holds by Theorem 4.7.4(i).
(ii) The pair in (ii) is equivalent to $S^\perp \cap \mathbb{R}^n_+ \neq \emptyset$ or $S \cap \mathbb{R}^n_{++} \neq \emptyset$.
Exactly one alternative holds by Theorem 4.7.4(ii).
Structural Commentary: The fundamental-subspace identity translates both subspace alternatives into matrix feasibility tests.
Key Insight: Row space and nullspace meet complementary positive orthants. □

Computation Method 4.7.6. *Testing Positive Homogeneous Systems*
Given $m, n \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(m, n, \mathbb{R})$, set $S := \mathrm{row}(A) = \mathrm{col}(A^t)$. The following searches are exact by Theorem 4.7.5:
(i) Seek $\mathbf{v} \in \mathbb{R}^m$ with $A^t\mathbf{v} > \mathbf{0}$ to certify $\ker(A) \cap \mathbb{R}^n_{++} = \emptyset$.
(ii) Seek $\mathbf{v} \in \mathbb{R}^m$ with $A^t\mathbf{v} \gg \mathbf{0}$ to certify $\ker(A) \cap \mathbb{R}^n_+ = \emptyset$.
(iii) Seek $\mathbf{x} \in \ker(A) \cap \mathbb{R}^n_{++}$ to certify $S \cap \mathbb{R}^n_+ = \emptyset$.
(iv) Seek $\mathbf{x} \in \ker(A) \cap \mathbb{R}^n_+$ to certify $S \cap \mathbb{R}^n_{++} = \emptyset$.

Lemma 4.7.7. *Nonnegative Matrix Cone*
Let $m, n \in \mathbb{Z}_{>0}$ and $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_n] \in \mathrm{Mat}(m, n, \mathbb{R})$. Define $C_A := A(\mathbb{R}^n_{\geq 0}) = \left\{ \sum_{i=1}^n t_i \mathbf{a}_i : (t_1, \ldots, t_n) \in \mathbb{R}^n_{\geq 0} \right\}$.
(i) C_A is a convex cone in $\mathbb{R}^m$.
(ii) C_A is closed in $\mathbb{R}^m$.

Proof.
(i) Let $\mathbf{x}_r = A\mathbf{y}_r \in C_A$ with $\mathbf{y}_r \geq \mathbf{0}$ for $r \in \{1, 2\}$. For $t \in [0, 1]$, $t\mathbf{x}_1 + (1-t)\mathbf{x}_2 = A(t\mathbf{y}_1 + (1-t)\mathbf{y}_2) \in C_A$.
For $a \in [0, \infty)$, $a\mathbf{x}_1 = A(a\mathbf{y}_1) \in C_A$. Thus C_A is convex and a cone.
(ii) It suffices to express C_A as a finite union of closed cones.
(a) *Independent supports*: Let $\mathcal{I}$ contain $I \subseteq \{1, \ldots, n\}$ exactly when $\{\mathbf{a}_i : i \in I\}$ is linearly independent; then $\emptyset \in \mathcal{I}$.
For $I \in \mathcal{I}$, set $K_I := \left\{ \sum_{i \in I} t_i \mathbf{a}_i : (\forall\, i \in I)\, t_i \geq 0 \right\}$.
Fix $\mathbf{x} \in C_A \setminus \{\mathbf{0}\}$ and choose $I \subseteq \{1, \ldots, n\}$ with $\mathbf{x} = \sum_{i \in I} t_i \mathbf{a}_i$, $(\forall\, i \in I)\, t_i > 0$, and minimal $|I|$.
If the indexed columns are dependent, choose $(d_i)_{i \in I} \in \mathbb{R}^I \setminus \{\mathbf{0}\}$ with $\sum_{i \in I} d_i \mathbf{a}_i = \mathbf{0}$.
After replacing $(d_i)_{i \in I}$ by its negative if necessary, $J := \{i \in I : d_i < 0\} \neq \emptyset$. Put $\lambda := \min_{i \in J} \frac{t_i}{-d_i} > 0$.
Then $(\forall\, i \in I)\, t_i + \lambda d_i \geq 0$, $(\exists\, j \in J)\, t_j + \lambda d_j = 0$, and $\mathbf{x} = \sum_{i \in I} (t_i + \lambda d_i)\mathbf{a}_i$.
Deleting the zero coefficients contradicts minimality of $|I|$, so $I \in \mathcal{I}$. Since $\mathbf{0} \in K_\emptyset$, $C_A = \bigcup_{I \in \mathcal{I}} K_I$.
(b) *Closed simplicial cones*: Fix $I \in \mathcal{I}$. If $I = \emptyset$, then $K_I = \{\mathbf{0}\}$. For $\mathbf{x} \neq \mathbf{0}$, $B_{\frac{1}{2}\|\mathbf{x}\|}(\mathbf{x}) \subseteq \mathbb{R}^m \setminus K_I$ by Proposition 1.1.15.
Hence K_I is closed when $I = \emptyset$. Suppose $I \neq \emptyset$ and put $U_I := \mathrm{span}\{\mathbf{a}_i : i \in I\}$.
Then $(\mathbf{a}_i)_{i \in I}$ is a basis of U_I. Its dual basis $(\varphi_i)_{i \in I}$ exists by Proposition 1.5.8.
Choose $(\mathbf{d}_i)_{i \in I} \subseteq U_I$ satisfying $(\forall\, \mathbf{u} \in U_I)(\forall\, i \in I)\, \varphi_i(\mathbf{u}) = \langle \mathbf{u}, \mathbf{d}_i \rangle$ by Theorem 1.6.1(i).
Hence $K_I = \{\mathbf{u} \in U_I : (\forall\, i \in I)\ \langle \mathbf{u}, \mathbf{d}_i \rangle \geq 0\}$. Identity $\ker(P_{U_I^\perp}) = U_I$ holds by Proposition 2.2.3(vi) and Corollary 2.1.8.
Fix $\mathbf{x} \notin K_I$. If $\mathbf{x} \notin U_I$, put $\mathbf{q} := P_{U_I^\perp}\mathbf{x} \neq \mathbf{0}$. For $\|\mathbf{y} - \mathbf{x}\| < \frac{1}{2}\|\mathbf{q}\|$, $\left\|P_{U_I^\perp}(\mathbf{y} - \mathbf{x})\right\| \leq \|\mathbf{y} - \mathbf{x}\|$ by Proposition 2.2.3(i),(viii).
Thus $\left\|P_{U_I^\perp}\mathbf{y}\right\| \geq \|\mathbf{q}\| - \left\|P_{U_I^\perp}(\mathbf{y} - \mathbf{x})\right\| > 0$ by Proposition 1.1.15. Hence $\mathbf{y} \notin U_I$.
If $\mathbf{x} \in U_I \setminus K_I$, choose $j \in I$ with $\langle \mathbf{x}, \mathbf{d}_j \rangle < 0$. Then $\mathbf{d}_j \neq \mathbf{0}$ because $\langle \mathbf{a}_j, \mathbf{d}_j \rangle = 1$. Put $r_j := -\frac{\langle \mathbf{x}, \mathbf{d}_j \rangle}{2\|\mathbf{d}_j\|} > 0$.
For $\|\mathbf{y} - \mathbf{x}\| < r_j$, $\left|\langle \mathbf{y} - \mathbf{x}, \mathbf{d}_j \rangle\right| < -\frac{1}{2}\langle \mathbf{x}, \mathbf{d}_j \rangle$ by Theorem 1.1.13(i).
Hence $\langle \mathbf{y}, \mathbf{d}_j \rangle \leq \langle \mathbf{x}, \mathbf{d}_j \rangle + \left|\langle \mathbf{y} - \mathbf{x}, \mathbf{d}_j \rangle\right| < \frac{1}{2}\langle \mathbf{x}, \mathbf{d}_j \rangle < 0$, so $\mathbf{y} \notin K_I$. Thus $\mathbb{R}^m \setminus K_I$ is open, and K_I is closed.
(c) *Finite union*: Fix $\mathbf{x} \notin C_A$. Choose $(r_I)_{I \in \mathcal{I}} \subseteq (0, \infty)$ satisfying $(\forall\, I \in \mathcal{I})\, B_{r_I}(\mathbf{x}) \subseteq \mathbb{R}^m \setminus K_I$ by (b).
Since $\mathcal{I}$ is finite and nonempty, put $r := \min_{I \in \mathcal{I}} r_I > 0$. Then $B_r(\mathbf{x}) \subseteq \mathbb{R}^m \setminus C_A$ by (a). Thus $\mathbb{R}^m \setminus C_A$ is open, so C_A is closed.
Structural Commentary: Minimal supports form a finite simplicial cover; dual coordinates prove each cone closed.
Key Insight: Independent generators convert cone membership into closed coordinate inequalities. □

Theorem 4.7.8. *Farkas's Lemma*
Let $m, n \in \mathbb{Z}_{>0}$ and $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_n] \in \mathrm{Mat}(m, n, \mathbb{R})$. Fix $\mathbf{b} \in \mathbb{R}^m \setminus \{\mathbf{0}\}$ and set $C_A := \{A\mathbf{y} : \mathbf{y} \in \mathbb{R}^n \wedge \mathbf{y} \geq \mathbf{0}\}$.
Exactly one of the following alternatives holds:

(i) $\mathbf{b} \in C_A$, *equivalently* $(\exists\, \mathbf{u} \in \mathbb{R}^n)\,[\mathbf{u} > \mathbf{0} \wedge A\mathbf{u} = \mathbf{b}]$.
(ii) $(\exists\, \mathbf{v} \in \mathbb{R}^m)\,[A^t\mathbf{v} \leq \mathbf{0} \wedge \langle \mathbf{v}, \mathbf{b}\rangle > 0]$.

Proof.

(i) The equivalence $\mathbf{b} \in C_A \iff (\exists\, \mathbf{u} \in \mathbb{R}^n)\,[\mathbf{u} \geq \mathbf{0} \wedge A\mathbf{u} = \mathbf{b}]$ holds by the definition of C_A.
Every such $\mathbf{u}$ is nonzero by $\mathbf{b} \neq \mathbf{0}$, proving the equivalent formulation in (i). If (i) and (ii) both hold, choose witnesses $\mathbf{u}$ and $\mathbf{v}$.
Then $0 < \langle \mathbf{v}, \mathbf{b}\rangle = \langle \mathbf{v}, A\mathbf{u}\rangle = \langle A^t\mathbf{v}, \mathbf{u}\rangle = \sum_{i=1}^{n} (A^t\mathbf{v})_i u_i \leq 0$ by the coordinate inequalities, a contradiction.

(ii) Suppose $\mathbf{b} \notin C_A$. Then $\mathbf{0} \in C_A$, and C_A is closed and convex by Lemma 4.7.7(i),(ii).
Choose $\mathbf{N} \neq \mathbf{0}$ satisfying $(\forall\, \mathbf{c} \in C_A)\ \langle \mathbf{N}, \mathbf{c}\rangle \geq \|\mathbf{N}\|^2 + \langle \mathbf{N}, \mathbf{b}\rangle$ by Theorem 4.6.3(ii).
Set $\mathbf{v} := -\mathbf{N}$. Then $(\forall\, \mathbf{c} \in C_A)\ \langle \mathbf{v}, \mathbf{c}\rangle \leq \langle \mathbf{v}, \mathbf{b}\rangle - \|\mathbf{v}\|^2$. The choice $\mathbf{c} = \mathbf{0}$ proves $\langle \mathbf{v}, \mathbf{b}\rangle \geq \|\mathbf{v}\|^2 > 0$. Fix $i \in \{1, \ldots, n\}$.
Then $(\forall\, \lambda \in [0, \infty))\ \lambda\mathbf{a}_i \in C_A$. Hence $(\forall\, \lambda \in [0, \infty))\ \lambda\langle \mathbf{v}, \mathbf{a}_i\rangle \leq \langle \mathbf{v}, \mathbf{b}\rangle - \|\mathbf{v}\|^2$. If $\gamma := \langle \mathbf{v}, \mathbf{a}_i\rangle > 0$, set $\lambda := \frac{\langle \mathbf{v}, \mathbf{b}\rangle - \|\mathbf{v}\|^2}{\gamma} + 1 \geq 1$.
Then $\lambda\gamma > \langle \mathbf{v}, \mathbf{b}\rangle - \|\mathbf{v}\|^2$, a contradiction. Thus $(\forall\, i \in \{1, \ldots, n\})\ \langle \mathbf{v}, \mathbf{a}_i\rangle \leq 0$.
Equivalently, $A^t\mathbf{v} \leq \mathbf{0}$. Therefore (ii) holds whenever (i) fails, so exactly one alternative holds.

Structural Commentary: Nearest-point separation constructs $\mathbf{v}$; ray scaling tests every coordinate of $A^t\mathbf{v}$.
Key Insight: A separating functional must be nonpositive on each cone generator. □

Counterexample 4.7.9. *A Certificate Need Not Be Strict*
Certificate in Theorem 4.7.8 need not satisfy $-A^t\mathbf{v} \gg \mathbf{0}$. Take $A = \left(\begin{smallmatrix} 1 & 0 & 0 \\ 0 & 1 & -1 \end{smallmatrix}\right)$, $\mathbf{b} = \left(\begin{smallmatrix} -1 \\ 0 \end{smallmatrix}\right)$. If $\mathbf{u} \geq \mathbf{0}$, then $(A\mathbf{u})_1 = u_1 \geq 0$, so $A\mathbf{u} \neq \mathbf{b}$.
The vector $\mathbf{v} = \left(\begin{smallmatrix} -1 \\ 0 \end{smallmatrix}\right)$ satisfies $A^t\mathbf{v} = (-1, 0, 0)^t \leq \mathbf{0}$ and $\langle \mathbf{v}, \mathbf{b}\rangle = 1 > 0$. For $\mathbf{w} = (r, s)^t \in \mathbb{R}^2$, $A^t\mathbf{w} = (r, s, -s)^t$.
Thus $-A^t\mathbf{w} \gg \mathbf{0}$ would require both $s < 0$ and $s > 0$, which is impossible. The weak coordinate inequality is therefore sharp.

5 Eigenstructure and Invariant Subspaces

5.1 Eigenvalues, Eigenspaces, and Spectral Criteria

Eigenstructure begins by identifying the scalars for which a shifted operator has a nontrivial kernel.
Throughout this subsection, $\mathcal{V}$ is a vector space over $\mathbb{F}$, and $n \in \mathbb{Z}_{>0}$ whenever an $n \times n$ matrix occurs.

Definition 5.1.1. *Eigenvalue and Eigenvector*
Let $T \in \mathcal{L}(\mathcal{V})$.

(i) A scalar $\lambda \in \mathbb{F}$ is an *eigenvalue* of T iff $(\exists\, \mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\})\, T\mathbf{v} = \lambda\mathbf{v}$.
(ii) For $\lambda \in \mathbb{F}$, a vector $\mathbf{v} \in \mathcal{V}$ is an *eigenvector* of T corresponding to λ iff $\mathbf{v} \neq \mathbf{0} \wedge T\mathbf{v} = \lambda\mathbf{v}$.

Definition 5.1.2. *Eigenspace*
Let $T \in \mathcal{L}(\mathcal{V})$ and $\lambda \in \mathbb{F}$. The *eigenspace* of T corresponding to λ is $E_\lambda(T) := \ker(T - \lambda I_\mathcal{V}) = \{\mathbf{v} \in \mathcal{V} : T\mathbf{v} = \lambda\mathbf{v}\}$.
Equivalently, λ is an eigenvalue of T iff $E_\lambda(T) \neq \{\mathbf{0}\}$.

Definition 5.1.3. *Spectrum and Geometric Multiplicity*
Let $T \in \mathcal{L}(\mathcal{V})$.

(i) The *spectrum* of T is $\mathrm{spec}(T) := \{\lambda \in \mathbb{F} : E_\lambda(T) \neq \{\mathbf{0}\}\}$.
(ii) If $\mathcal{V}$ is finite-dimensional and $\lambda \in \mathrm{spec}(T)$, then the *geometric multiplicity* of λ is $\dim E_\lambda(T)$.
(iii) For $A \in \mathrm{Mat}(n, n, \mathbb{F})$ and $\lambda \in \mathbb{F}$, set $E_\lambda(A) := \ker(A - \lambda I_n)$. Define $\mathrm{spec}(A) := \{\mu \in \mathbb{F} : E_\mu(A) \neq \{\mathbf{0}\}\}$.

Theorem 5.1.4. *Equivalent Conditions for an Eigenvalue*
Let $\mathcal{V}$ be finite-dimensional, let $T \in \mathcal{L}(\mathcal{V})$, and let $\lambda \in \mathbb{F}$. The following are equivalent:

(i) λ *is an eigenvalue of* T;
(ii) $T - \lambda I_\mathcal{V}$ *is not injective;*
(iii) $T - \lambda I_\mathcal{V}$ *is not surjective;*
(iv) $T - \lambda I_\mathcal{V}$ *is not invertible.*

Proof. Set $S := T - \lambda I_\mathcal{V}$.

(i) $\Rightarrow$ *(ii)* Choose $\mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\}$ with $T\mathbf{v} = \lambda\mathbf{v}$ by (i).
The membership $\mathbf{v} \in \ker(S) \setminus \{\mathbf{0}\}$ holds by $S\mathbf{v} = T\mathbf{v} - \lambda\mathbf{v} = \mathbf{0}$, and S is not injective by Proposition 1.6.2.
(ii) $\Rightarrow$ *(iii)* The operator S is not surjective by Theorem 1.7.7(ii),(iii).
(iii) $\Rightarrow$ *(iv)* The operator S is not invertible by Theorem 1.7.7(iii),(i).
(iv) $\Rightarrow$ *(i)* The operator S is not injective by Theorem 1.7.7(i),(ii), and $\ker(S) \neq \{\mathbf{0}\}$ by Proposition 1.6.2.
Choose $\mathbf{v} \in \ker(S) \setminus \{\mathbf{0}\}$. The equality $T\mathbf{v} = \lambda\mathbf{v}$ holds by $S\mathbf{v} = \mathbf{0}$. The scalar λ is an eigenvalue of T by the choice of $\mathbf{v}$.

Structural Commentary: The kernel test links singular shifts to the finite-dimensional invertibility cycle.
Key Insight: A scalar is spectral exactly when its shifted operator has nonzero kernel. □

Theorem 5.1.5. *Eigenvectors for Distinct Eigenvalues Are Independent*
Let $m \in \mathbb{Z}_{>0}$ and $T \in \mathcal{L}(\mathcal{V})$. Suppose $\lambda_1, \ldots, \lambda_m$ are pairwise distinct eigenvalues of T with corresponding eigenvectors $\mathbf{v}_1, \ldots, \mathbf{v}_m$. Then $(\mathbf{v}_1, \ldots, \mathbf{v}_m)$ is linearly independent.

Proof. For $m = 1$, the list is independent by $\mathbf{v}_1 \neq \mathbf{0}$. Assume $m \geq 2$ and suppose $(\mathbf{v}_1, \ldots, \mathbf{v}_m)$ is dependent.
Let k be least index for which $(\mathbf{v}_1, \ldots, \mathbf{v}_k)$ is dependent. Bounds $k \leq m$ and $k \geq 2$ hold by choice of k and $\mathbf{v}_1 \neq \mathbf{0}$, respectively.
The list $(\mathbf{v}_1, \ldots, \mathbf{v}_{k-1})$ is independent by minimality of k. Choose $c_1, \ldots, c_k \in \mathbb{F}$, not all zero, with $\sum_{i=1}^{k} c_i\mathbf{v}_i = \mathbf{0}$ by dependence.
The coefficient $c_k \neq 0$ by independence of the preceding prefix: $c_k = 0$ would force $c_1 = \cdots = c_{k-1} = 0$.
Set $a_i := -\frac{c_i}{c_k}$ $(1 \leq i < k)$. The representation $\mathbf{v}_k = \sum_{i=1}^{k-1} a_i\mathbf{v}_i$ holds by the chosen dependence relation.

The equality $\mathbf{0} = (T - \lambda_k I_{\mathcal{V}})\mathbf{v}_k = \sum_{i=1}^{k-1} a_i(\lambda_i - \lambda_k)\mathbf{v}_i$ holds by linearity and the eigenvector identities.
The relation $(\forall\, i \in \{1, \dots, k-1\})\, a_i(\lambda_i - \lambda_k) = 0$ holds by independence of the preceding prefix.
The relation $(\forall\, i \in \{1, \dots, k-1\})\, a_i = 0$ holds by pairwise distinctness of the eigenvalues.
The equality $\mathbf{v}_k = \mathbf{0}$ holds by its representation and the preceding coefficient identities, contrary to the eigenvector hypothesis.
The original list is linearly independent by contradiction.
Structural Commentary: Minimal dependence exposes the last coefficient; the spectral shift isolates the rest.
Key Insight: The shift by λ_k rescales every earlier eigenvector nontrivially. □

Corollary 5.1.6. *Number of Distinct Eigenvalues*
If $\mathcal{V}$ is finite-dimensional and $T \in \mathcal{L}(\mathcal{V})$, then $|\operatorname{spec}(T)| \leq \dim(\mathcal{V})$.

Proof. Set $d := \dim(\mathcal{V})$, and choose a basis β of length d by finite dimensionality and the definition of d.
Suppose $|\operatorname{spec}(T)| > d$. Choose distinct $\lambda_1, \dots, \lambda_{d+1} \in \operatorname{spec}(T)$.
Choose corresponding eigenvectors $\mathbf{v}_1, \dots, \mathbf{v}_{d+1}$ by the definition of the spectrum.
The list $(\mathbf{v}_1, \dots, \mathbf{v}_{d+1})$ is independent by Theorem 5.1.5, while β spans $\mathcal{V}$.
The inequality $d + 1 \leq d$ holds by Theorem 1.3.11, a contradiction. The claimed bound holds by contradiction.
Structural Commentary: Spectral representatives form an independent list bounded in length by a basis.
Key Insight: Each distinct eigenvalue requires a separate independent direction. □

Corollary 5.1.7. *Invertibility and the Zero Eigenvalue*
Let $\mathcal{V}$ be finite-dimensional and let $T \in \mathcal{L}(\mathcal{V})$. Then T is invertible iff $0 \notin \operatorname{spec}(T)$.

Proof.
(⇒) Suppose T is invertible. The scalar 0 is not an eigenvalue of T by Theorem 5.1.4(iv),(i).
The exclusion $0 \notin \operatorname{spec}(T)$ holds by the definition of $\operatorname{spec}(T)$.
(⇐) Suppose $0 \notin \operatorname{spec}(T)$. The scalar 0 is not an eigenvalue of T by the definition of $\operatorname{spec}(T)$.
The operator $T = T - 0I_{\mathcal{V}}$ is invertible by Theorem 5.1.4(i),(iv).
Structural Commentary: At zero, the singular-shift criterion equates invertibility with spectral exclusion.
Key Insight: The zero eigenspace is $\ker(T)$. □

Corollary 5.1.8. *Matrix Invertibility and the Spectrum*
Let $A \in \operatorname{Mat}(n, n, \mathbb{F})$. Then A is invertible iff $0 \notin \operatorname{spec}(A)$.

Proof.
(⇒) Suppose A is invertible. The equality $\operatorname{rank}(A) = n$ holds by Corollary 3.6.2.
The equality $\dim(\ker(A)) = 0$ holds by Corollary 3.3.1(i).
The relations $\{\mathbf{0}\} \leq \ker(A)$ and $\dim(\{\mathbf{0}\}) = \dim(\ker(A)) = 0$ hold by $A\mathbf{0} = \mathbf{0}$ and the preceding equality.
The identity $\ker(A) = \{\mathbf{0}\}$ holds by Proposition 1.4.3(ii). The exclusion $0 \notin \operatorname{spec}(A)$ holds by the matrix-spectrum definition.
(⇐) Suppose $0 \notin \operatorname{spec}(A)$. The identity $\ker(A) = \{\mathbf{0}\}$ holds by the matrix-spectrum definition.
Equality $\dim(\ker(A)) = 0$ holds by $\ker(A) = \{\mathbf{0}\}$, $\operatorname{rank}(A) = n$ by Corollary 3.3.1(i). Matrix A is invertible by Corollary 3.6.2.
Structural Commentary: Rank–nullity carries full rank to the zero-kernel matrix-spectrum test.
Key Insight: Zero is spectral exactly when $\ker(A) \neq \{\mathbf{0}\}$. □

5.2 Invariant Subspaces, Reducing Pairs, and Quotient Operators

Throughout this subsection, $\mathcal{V}$ is a vector space over $\mathbb{F}$.
In statements involving inner products, adjoints, or unitary matrices, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.

Definition 5.2.1. *Invariant Subspace*
Let $T \in \mathcal{L}(\mathcal{V})$. A subspace $\mathcal{U} \leq \mathcal{V}$ is *invariant under T* iff $T\mathcal{U} \subseteq \mathcal{U}$. The set of all T-invariant subspaces is $\operatorname{Inv}(T) := \{\mathcal{U} \leq \mathcal{V} : T\mathcal{U} \subseteq \mathcal{U}\}$.

Definition 5.2.2. *Restriction and Quotient Operators*
Let $T \in \mathcal{L}(\mathcal{V})$ and $\mathcal{U} \in \operatorname{Inv}(T)$.
(i) The *restriction operator* is $T|_{\mathcal{U}} : \mathcal{U} \to \mathcal{U}$, $T|_{\mathcal{U}}(\mathbf{u}) := T\mathbf{u}$.
(ii) The *quotient operator* is $T/\mathcal{U} : \mathcal{V}/\mathcal{U} \to \mathcal{V}/\mathcal{U}$, $(T/\mathcal{U})(\mathbf{v} + \mathcal{U}) := T\mathbf{v} + \mathcal{U}$.

Proposition 5.2.3. *Restriction and Quotient Operators Are Well-Defined*
Let $T \in \mathcal{L}(\mathcal{V})$ and $\mathcal{U} \in \operatorname{Inv}(T)$.
(i) $T|_{\mathcal{U}} \in \mathcal{L}(\mathcal{U})$.
(ii) $T/\mathcal{U} \in \mathcal{L}(\mathcal{V}/\mathcal{U})$.

Proof.
(i) The inclusion $T\mathcal{U} \subseteq \mathcal{U}$ holds by Definition 5.2.1, so $T|_{\mathcal{U}}$ has codomain $\mathcal{U}$.
For $a, b \in \mathbb{F}$ and $\mathbf{u}, \mathbf{v} \in \mathcal{U}$, $T|_{\mathcal{U}}(a\mathbf{u} + b\mathbf{v}) = aT|_{\mathcal{U}}\mathbf{u} + bT|_{\mathcal{U}}\mathbf{v}$ by the linearity of T.
Therefore $T|_{\mathcal{U}} \in \mathcal{L}(\mathcal{U})$ by the codomain inclusion and linearity identity.
(ii) Suppose $\mathbf{v} + \mathcal{U} = \mathbf{w} + \mathcal{U}$. Then $\mathbf{v} - \mathbf{w} \in \mathcal{U}$ by Proposition 2.2.2.
The relation $T\mathbf{v} - T\mathbf{w} = T(\mathbf{v} - \mathbf{w}) \in \mathcal{U}$ holds by linearity and invariance.
Consequently, $T\mathbf{v} + \mathcal{U} = T\mathbf{w} + \mathcal{U}$ by Proposition 2.2.2, so the quotient rule is independent of the representative.
Set $S := T/\mathcal{U}$ and $[\mathbf{x}] := \mathbf{x} + \mathcal{U}$. For $a, b \in \mathbb{F}$ and $\mathbf{v}, \mathbf{w} \in \mathcal{V}$, $S(a[\mathbf{v}] + b[\mathbf{w}]) = [T(a\mathbf{v} + b\mathbf{w})]$ by Proposition 2.2.6(ii).
The identity $[T(a\mathbf{v} + b\mathbf{w})] = [aT\mathbf{v} + bT\mathbf{w}] = aS[\mathbf{v}] + bS[\mathbf{w}]$ holds by linearity of T and the quotient rule.
Therefore $T/\mathcal{U} \in \mathcal{L}(\mathcal{V}/\mathcal{U})$ by representative independence and the two linearity identities.
Structural Commentary: Invariance closes the restriction codomain and transports equality between quotient representatives.
Key Insight: Preserving $\mathcal{U}$ also preserves differences modulo $\mathcal{U}$. □

Proposition 5.2.4. *One-Dimensional Invariant Subspaces and Eigenvectors*
Let $T \in \mathcal{L}(\mathcal{V})$ and $\mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\}$. Then $\operatorname{span}(\mathbf{v}) \in \operatorname{Inv}(T)$ iff $\mathbf{v}$ is an eigenvector of T.

Proof.

(⇒) Suppose $\operatorname{span}(\mathbf{v}) \in \operatorname{Inv}(T)$. The relation $(\exists\, \lambda \in \mathbb{F})\, T\mathbf{v} = \lambda\mathbf{v}$ holds by $T\mathbf{v} \in \operatorname{span}(\mathbf{v})$.
Therefore $\mathbf{v}$ is an eigenvector of T by $\mathbf{v} \neq \mathbf{0}$ and Definition 5.1.1.

(⇐) Suppose $\mathbf{v}$ is an eigenvector of T. Choose $\lambda \in \mathbb{F}$ satisfying $T\mathbf{v} = \lambda\mathbf{v}$ by Definition 5.1.1.
The inclusion $T(\operatorname{span}(\mathbf{v})) \subseteq \operatorname{span}(\mathbf{v})$ holds by $(\forall\, a \in \mathbb{F})\, T(a\mathbf{v}) = a\lambda\mathbf{v}$. Hence $\operatorname{span}(\mathbf{v}) \in \operatorname{Inv}(T)$ by Definition 5.2.1.

Structural Commentary: The two directions translate line invariance into the image relation for its generator.
Key Insight: A line is invariant exactly when its generator is rescaled. □

Figure 40 illustrates Proposition 5.2.4: T rescales $\mathbf{v}$ within $\operatorname{span}(\mathbf{v})$.
The proposition, rather than the diagram, owns the equivalence.

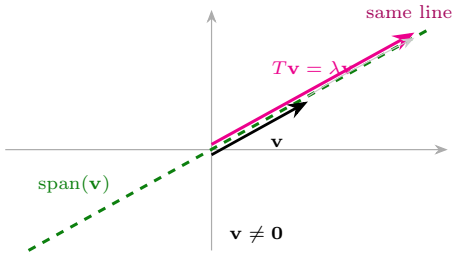

Figure 40: An eigenvector and its image lie on the same invariant line.

Proposition 5.2.5. *Invariant Subspaces and Block Form*
Let $\mathcal{V}$ be finite-dimensional, let $T \in \mathcal{L}(\mathcal{V})$, suppose $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$, and let β be a basis adapted to this decomposition.

(i) $\mathcal{U} \in \operatorname{Inv}(T) \Longrightarrow [T]_{\beta \leftarrow \beta}$ *is block upper triangular.*
(ii) $\mathcal{U}, \mathcal{W} \in \operatorname{Inv}(T) \Longrightarrow [T]_{\beta \leftarrow \beta}$ *is block diagonal.*

Proof. Write $\beta = (\mathbf{u}_1, \ldots, \mathbf{u}_p, \mathbf{w}_1, \ldots, \mathbf{w}_q)$, where $(\mathbf{u}_1, \ldots, \mathbf{u}_p)$ and $(\mathbf{w}_1, \ldots, \mathbf{w}_q)$ are bases of $\mathcal{U}$ and $\mathcal{W}$, respectively.

(i) Suppose $\mathcal{U} \in \operatorname{Inv}(T)$. The relation $(\forall\, j \in \{1, \ldots, p\})\, T\mathbf{u}_j \in \mathcal{U}$ holds by invariance.
Therefore the coordinates along $\mathbf{w}_1, \ldots, \mathbf{w}_q$ vanish, forming the zero lower-left block.

(ii) Suppose also that $\mathcal{W} \in \operatorname{Inv}(T)$. The relation $(\forall\, j \in \{1, \ldots, q\})\, T\mathbf{w}_j \in \mathcal{W}$ holds by invariance.
Therefore the coordinates along $\mathbf{u}_1, \ldots, \mathbf{u}_p$ vanish, forming the zero upper-right block.

Structural Commentary: Adapted-basis columns convert invariance of each summand into a vanishing off-diagonal block.
Key Insight: Each invariant summand eliminates the block pointing out of it. □

Definition 5.2.6. *Reducing Pair*
Let $T \in \mathcal{L}(\mathcal{V})$. A pair $(\mathcal{U}, \mathcal{W})$ of subspaces *reduces* T iff $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$ and $\mathcal{U}, \mathcal{W} \in \operatorname{Inv}(T)$.
For such a pair, $T = T|_{\mathcal{U}} \oplus T|_{\mathcal{W}}$ means $(\forall\, (\mathbf{u}, \mathbf{w}) \in \mathcal{U} \times \mathcal{W})\, T(\mathbf{u} + \mathbf{w}) = T|_{\mathcal{U}}\mathbf{u} + T|_{\mathcal{W}}\mathbf{w}$.

Theorem 5.2.7. *Adjoints and Invariant Orthogonal Complements*
Let $T \in \mathcal{L}(\mathcal{V})$ on a finite-dimensional inner-product space and let $\mathcal{U} \leq \mathcal{V}$.

(i) $\mathcal{U} \in \operatorname{Inv}(T) \Longleftrightarrow \mathcal{U}^{\perp} \in \operatorname{Inv}(T^*)$.
(ii) $(\mathcal{U}, \mathcal{U}^{\perp})$ *reduces* $T \Longleftrightarrow \mathcal{U} \in \operatorname{Inv}(T) \cap \operatorname{Inv}(T^*)$.
(iii) If $(\mathcal{U}, \mathcal{U}^{\perp})$ *reduces* T, *then* $(T|_{\mathcal{U}})^* = (T^*)|_{\mathcal{U}}$.

Proof.

(i) (⇒) Suppose $\mathcal{U} \in \operatorname{Inv}(T)$. For $\mathbf{z} \in \mathcal{U}^{\perp}$ and $\mathbf{u} \in \mathcal{U}$, $\langle T^*\mathbf{z}, \mathbf{u} \rangle = \langle \mathbf{z}, T\mathbf{u} \rangle = 0$ by conjugate symmetry, Definition 2.3.1, and $T\mathbf{u} \in \mathcal{U}$.
Thus $T^*\mathbf{z} \in \mathcal{U}^{\perp}$, and $\mathcal{U}^{\perp} \in \operatorname{Inv}(T^*)$ by Definition 5.2.1.

(i) (⇐) Suppose $\mathcal{U}^{\perp} \in \operatorname{Inv}(T^*)$. If $\mathbf{u} \in \mathcal{U}$ and $\mathbf{z} \in \mathcal{U}^{\perp}$, then $\langle T\mathbf{u}, \mathbf{z} \rangle = \langle \mathbf{u}, T^*\mathbf{z} \rangle = 0$ by Definition 2.3.1.
Therefore $T\mathbf{u} \in (\mathcal{U}^{\perp})^{\perp} = \mathcal{U}$ by Corollary 2.1.8, so $\mathcal{U} \in \operatorname{Inv}(T)$ by Definition 5.2.1.

(ii) (⇒) Suppose $(\mathcal{U}, \mathcal{U}^{\perp})$ reduces T. Then $\mathcal{U} \in \operatorname{Inv}(T)$ and $\mathcal{U}^{\perp} \in \operatorname{Inv}(T)$ by Definition 5.2.6.
Thus $\mathcal{U} \in \operatorname{Inv}(T^*)$ by (i) for T^* and Proposition 2.3.8(iii).

(ii) (⇐) Suppose $\mathcal{U} \in \operatorname{Inv}(T) \cap \operatorname{Inv}(T^*)$. Then $\mathcal{U}^{\perp} \in \operatorname{Inv}(T)$ by (i) for T^* and Proposition 2.3.8(iii).
The identity $\mathcal{V} = \mathcal{U} \oplus \mathcal{U}^{\perp}$ holds by Theorem 2.1.5. Hence $(\mathcal{U}, \mathcal{U}^{\perp})$ reduces T by Definition 5.2.6.

(iii) Suppose $(\mathcal{U}, \mathcal{U}^{\perp})$ reduces T. Then $\mathcal{U} \in \operatorname{Inv}(T) \cap \operatorname{Inv}(T^*)$ by (ii), and $T|_{\mathcal{U}}, (T^*)|_{\mathcal{U}} \in \mathcal{L}(\mathcal{U})$ by Proposition 5.2.3(i).
For $\mathbf{u}, \mathbf{v} \in \mathcal{U}$, $\langle T|_{\mathcal{U}}\mathbf{u}, \mathbf{v} \rangle_{\mathcal{U}} = \langle \mathbf{u}, (T^*)|_{\mathcal{U}}\mathbf{v} \rangle_{\mathcal{U}}$ by Definition 2.3.1. Identity $(T|_{\mathcal{U}})^* = (T^*)|_{\mathcal{U}}$ follows by Definition 2.3.1, Lemma 2.3.3.

Structural Commentary: Adjoint duality transfers invariance to $\mathcal{U}^{\perp}$; orthogonal decomposition then characterizes reduction.
Key Insight: Reducing $\mathcal{U}$ is joint invariance under T and T^*. □

Proposition 5.2.8. *Reducing Pairs and Projections*
Let $T \in \mathcal{L}(\mathcal{V})$, let $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$, and set $\rho := \rho_{\mathcal{U},\mathcal{W}}$. Then $(\mathcal{U}, \mathcal{W})$ reduces T iff $T\rho = \rho T$.

Proof.

(⇒) Suppose $(\mathcal{U}, \mathcal{W})$ reduces T. For $\mathbf{v} = \mathbf{u} + \mathbf{w}$ with $(\mathbf{u}, \mathbf{w}) \in \mathcal{U} \times \mathcal{W}$, $(T\rho)\mathbf{v} = T\mathbf{u} = (\rho T)\mathbf{v}$ by $T\mathbf{u} \in \mathcal{U}$ and $T\mathbf{w} \in \mathcal{W}$.
Therefore $T\rho = \rho T$ by pointwise equality.

(⇐) Suppose $T\rho = \rho T$. For $\mathbf{u} \in \mathcal{U}$, $\rho T\mathbf{u} = T\rho\mathbf{u} = T\mathbf{u}$, so $T\mathbf{u} \in \operatorname{range}(\rho) = \mathcal{U}$ by Proposition 2.4.2(iii).
For $\mathbf{w} \in \mathcal{W}$, $\rho T\mathbf{w} = T\rho\mathbf{w} = \mathbf{0}$, so $T\mathbf{w} \in \ker(\rho) = \mathcal{W}$ by Proposition 2.4.2(iii). Hence $(\mathcal{U}, \mathcal{W})$ reduces T by Definition 5.2.6.

Structural Commentary: Pointwise commutation preserves the range and kernel summands of the algebraic projection.
Key Insight: Commutation with ρ is simultaneous invariance of its range and kernel. □

Proposition 5.2.9. *Invariant Subspaces and Algebraic Projections*
Let $T \in \mathcal{L}(\mathcal{V})$, let $\mathcal{V} = \mathcal{U} \oplus \mathcal{W}$, and set $\rho := \rho_{\mathcal{U},\mathcal{W}}$.

(i) $\mathcal{U} \in \mathrm{Inv}(T) \iff \rho T \rho = T\rho$.
(ii) If $\mathcal{U} \in \mathrm{Inv}(T)$, *then* $(\forall\, \mathcal{Z} \leq \mathcal{V})\,[\mathcal{V} = \mathcal{U} \oplus \mathcal{Z} \implies \rho_{\mathcal{U},\mathcal{Z}} T \rho_{\mathcal{U},\mathcal{Z}} = T\rho_{\mathcal{U},\mathcal{Z}}]$.

Proof.

(i) ($\Rightarrow$) Suppose $\mathcal{U} \in \mathrm{Inv}(T)$, and write $\mathbf{v} = \mathbf{u} + \mathbf{w}$ with $(\mathbf{u}, \mathbf{w}) \in \mathcal{U} \times \mathcal{W}$.
The identity $(\rho T \rho)\mathbf{v} = \rho T \mathbf{u} = T\mathbf{u} = (T\rho)\mathbf{v}$ holds by $T\mathbf{u} \in \mathcal{U}$ and Definition 2.4.1. Therefore $\rho T \rho = T\rho$ by pointwise equality.
(i) ($\Leftarrow$) Suppose $\rho T \rho = T\rho$. If $\mathbf{u} \in \mathcal{U}$, then $\rho T \mathbf{u} = \rho T \rho \mathbf{u} = T\rho\mathbf{u} = T\mathbf{u}$.
Hence $T\mathbf{u} \in \mathrm{range}(\rho) = \mathcal{U}$ by Proposition 2.4.2(iii), so $\mathcal{U} \in \mathrm{Inv}(T)$ by Definition 5.2.1.
(ii) Suppose $\mathcal{U} \in \mathrm{Inv}(T)$ and fix $\mathcal{Z} \leq \mathcal{V}$ satisfying $\mathcal{V} = \mathcal{U} \oplus \mathcal{Z}$. Set $\sigma := \rho_{\mathcal{U},\mathcal{Z}}$.
The identity $\sigma T \sigma = T\sigma$ holds by the forward implication in (i) for $\mathcal{V} = \mathcal{U} \oplus \mathcal{Z}$. Claim (ii) follows by the arbitrary choice of $\mathcal{Z}$.

Structural Commentary: The compression identity tests range preservation and remains independent of the chosen complement.
Key Insight: $\rho T \rho = T\rho$ forbids T from leaving range(ρ). □

Theorem 5.2.10. *Invariant Subspaces, Blocks, and Projections*
Let $n \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$, and $\mathcal{U} \leq \mathbb{F}^n$, where $\dim(\mathcal{U}) = r$ and $1 \leq r \leq n-1$.
Let $Q = [Q_1\ Q_2]$ be unitary, where the columns of Q_1 and Q_2 are orthonormal bases of $\mathcal{U}$ and $\mathcal{U}^\perp$, respectively.
Set $P := Q_1 Q_1^*$. The following are equivalent:

(i) $A\mathcal{U} \subseteq \mathcal{U}$.
(ii) The lower-left $(n-r) \times r$ block of $Q^* A Q$ is zero.
(iii) $PAP = AP$.

Proof. The identities $Q_1^* Q_1 = I_r$, $Q_2^* Q_1 = 0$, $P^* = P$, and $P^2 = Q_1 (Q_1^* Q_1) Q_1^* = P$ hold by unitarity of Q.
For $\mathbf{x} \in \mathbb{F}^n$ and $\mathbf{c} \in \mathbb{F}^r$, $P\mathbf{x} \in \mathrm{col}(Q_1)$ and $P(Q_1\mathbf{c}) = Q_1\mathbf{c}$, so $\mathrm{range}(P) = \mathrm{col}(Q_1) = \mathcal{U}$.
For $\mathbf{z} \in \mathcal{U}^\perp$, $Q_1^*\mathbf{z} = \mathbf{0}$ and $P\mathbf{z} = \mathbf{0}$. Therefore $P = \rho_{\mathcal{U},\mathcal{U}^\perp}$ by Theorem 2.1.5 and Definition 2.4.1.
The matrix P is an orthogonal projection matrix by Definition 2.5.5.
Set $M := Q^* A Q = \left[\begin{smallmatrix} B & X \\ Y & C \end{smallmatrix}\right]$, so $Y = Q_2^* A Q_1$, and set $E := Q^* P Q = I_r \oplus 0_{n-r}$.

(i) $\Rightarrow$ *(ii)* Suppose $A\mathcal{U} \subseteq \mathcal{U}$. Every column of AQ_1 belongs to $\mathcal{U} = (\mathcal{U}^\perp)^\perp$ by Corollary 2.1.8.
Since the columns of Q_2 span $\mathcal{U}^\perp$, $Y = Q_2^* A Q_1 = 0$.
(ii) $\Rightarrow$ *(iii)* Suppose $Y = 0$. Then $EME = \left[\begin{smallmatrix} B & 0 \\ 0 & 0 \end{smallmatrix}\right] = ME$, so $Q^*(PAP)Q = Q^*(AP)Q$.
Therefore $PAP = AP$ by multiplication by Q and Q^*.
(iii) $\Rightarrow$ *(i)* Suppose $PAP = AP$. Since P is the algebraic projection onto $\mathcal{U}$ along $\mathcal{U}^\perp$, $A\mathcal{U} \subseteq \mathcal{U}$ by Proposition 5.2.9(i).

Structural Commentary: Unitary coordinates identify the escape block; projection compression tests the same range preservation.
Key Insight: The lower-left block records precisely the component leaving $\mathcal{U}$. □

Corollary 5.2.11. *Reducing Subspaces and Commuting Projections*
Let $n \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$, and $\mathcal{U} \leq \mathbb{F}^n$, where $\dim(\mathcal{U}) = r$ and $1 \leq r \leq n-1$.
Let $Q = [Q_1\ Q_2]$ be unitary with $\mathrm{col}(Q_1) = \mathcal{U}$ and $\mathrm{col}(Q_2) = \mathcal{U}^\perp$. Set $P := Q_1 Q_1^*$. The following are equivalent:

(i) $A\mathcal{U} \subseteq \mathcal{U}$ *and* $A^*\mathcal{U} \subseteq \mathcal{U}$.
(ii) $Q^* A Q$ is block diagonal relative to $\mathbb{F}^r \oplus \mathbb{F}^{n-r}$.
(iii) $PA = AP$.

Proof. Set $M := Q^* A Q = \left[\begin{smallmatrix} B & X \\ Y & C \end{smallmatrix}\right]$ and $E := Q^* P Q = I_r \oplus 0_{n-r}$. Then $Q^* A^* Q = M^*$, $Q^*(PA)Q = EM$, and $Q^*(AP)Q = ME$.

(i) $\Rightarrow$ *(ii)* Suppose $A\mathcal{U} \subseteq \mathcal{U}$ and $A^*\mathcal{U} \subseteq \mathcal{U}$. Then $Y = 0$ by Theorem 5.2.10, (i)$\Rightarrow$(ii), for A.
The relation $X^* = 0$ holds by the same implication for A^* because X^* is the lower-left block of M^*.
Therefore $X = Y = 0$, so $M = B \oplus C$.
(ii) $\Rightarrow$ *(iii)* Suppose $M = B \oplus C$. Then $EM = ME$ by block multiplication, and $PA = AP$ by conjugation with Q.
(iii) $\Rightarrow$ *(i)* Suppose $PA = AP$. Then $EM = ME$. The identities $EM = \left[\begin{smallmatrix} B & X \\ 0 & 0 \end{smallmatrix}\right]$ and $ME = \left[\begin{smallmatrix} B & 0 \\ Y & 0 \end{smallmatrix}\right]$ imply $X = Y = 0$.
Therefore $A\mathcal{U} \subseteq \mathcal{U}$ by Theorem 5.2.10, (ii)$\Rightarrow$(i), for A.
Since $X^* = 0$ is the lower-left block of M^*, $A^*\mathcal{U} \subseteq \mathcal{U}$ by the same implication for A^*.

Structural Commentary: The invariant-block criterion for A and A^* eliminates opposite off-diagonal blocks.
Key Insight: Projection commutation is equivalent to simultaneous A- and A^*-invariance. □

Figure 41 summarizes the preceding results: invariance removes the lower-left block.
Projection commutation removes both off-diagonal blocks. Proposition 5.2.5, Theorem 5.2.10, and Corollary 5.2.11 own these claims.

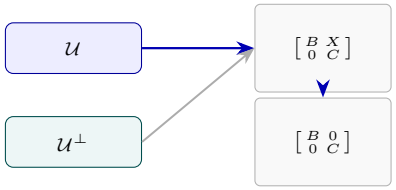

Figure 41: Adapted coordinates represent invariance by upper block form and reduction by block diagonal form.

Perspective 5.2.12. *Two Smaller Views of an Operator*
Let $T \in \mathcal{L}(\mathcal{V})$ and $\mathcal{U} \in \mathrm{Inv}(T)$. Definition 5.2.2 separates the action inside $\mathcal{U}$ from the action modulo $\mathcal{U}$.
Proposition 5.2.3 validates both operators. In an adapted block matrix from Proposition 5.2.5(i), they determine the two diagonal blocks but not the upper-right block. Thus restriction and quotient simplify the study of T without necessarily determining T.

5.3 Triangularization over Complex and Real Fields

Definition 5.3.1. *Diagonal and Upper-Triangular Matrices*
Let $n \in \mathbb{Z}_{>0}$ and $A = [a_{ij}]_{i,j=1}^{n} \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) The *diagonal* of A is $(a_{11}, \dots, a_{nn})$.
(ii) The matrix A is *diagonal* iff $(\forall\, i, j \in \{1, \dots, n\})\, (i \neq j \Rightarrow a_{ij} = 0)$.
(iii) The matrix A is *upper triangular* iff $(\forall\, i, j \in \{1, \dots, n\})\, (i > j \Rightarrow a_{ij} = 0)$.

Theorem 5.3.2. *Complex Operators Have Eigenvalues*
Let $\mathcal{V}$ be a nonzero finite-dimensional complex vector space. Every $T \in \mathcal{L}(\mathcal{V})$ has an eigenvalue.

Proof. Fix $T \in \mathcal{L}(\mathcal{V})$. Choose a nonconstant annihilating polynomial for T by Proposition 1.1.7.
One of its complex roots is an eigenvalue of T by Theorem 1.1.9(ii).
Structural Commentary: An annihilator and complex factorization reduce existence to a singular linear factor.
Key Insight: A zero product of shifted operators contains a singular factor. □

Theorem 5.3.3. *Criteria for an Upper-Triangular Operator Matrix*
Let $n \in \mathbb{Z}_{>0}$, let $T \in \mathcal{L}(\mathcal{V})$, and let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ be a basis of $\mathcal{V}$. The following are equivalent:

(i) $[T]_{\beta \leftarrow \beta}$ *is upper triangular;*
(ii) $(\forall\, j \in \{1, \dots, n\})\, T\mathbf{v}_j \in \mathrm{span}(\mathbf{v}_1, \dots, \mathbf{v}_j)$;
(iii) $(\forall\, j \in \{1, \dots, n\})\ \mathrm{span}(\mathbf{v}_1, \dots, \mathbf{v}_j) \in \mathrm{Inv}(T)$.

Proof.

(i) $\Rightarrow$ *(ii)* Fix $j \in \{1, \dots, n\}$. The jth column of $[T]_{\beta \leftarrow \beta}$ is $[T\mathbf{v}_j]_\beta$.
Its entries below row j vanish by (i), so $T\mathbf{v}_j \in \mathrm{span}(\mathbf{v}_1, \dots, \mathbf{v}_j)$. Thus (ii) holds by the arbitrariness of j.

(ii) $\Rightarrow$ *(iii)* Fix $j \in \{1, \dots, n\}$ and $\mathbf{u} \in \mathrm{span}(\mathbf{v}_1, \dots, \mathbf{v}_j)$.
Choose $a_1, \dots, a_j \in \mathbb{F}$ with $\mathbf{u} = \sum_{k=1}^{j} a_k \mathbf{v}_k$. Then $T\mathbf{u} = \sum_{k=1}^{j} a_k T\mathbf{v}_k \in \mathrm{span}(\mathbf{v}_1, \dots, \mathbf{v}_j)$ by (ii).
Hence the span is invariant under T by Definition 5.2.1, and (iii) follows.

(iii) $\Rightarrow$ *(i)* For $j \in \{1, \dots, n\}$, the vector $\mathbf{v}_j$ belongs to the T-invariant space $\mathrm{span}(\mathbf{v}_1, \dots, \mathbf{v}_j)$ by (iii).
Thus $T\mathbf{v}_j \in \mathrm{span}(\mathbf{v}_1, \dots, \mathbf{v}_j)$ by Definition 5.2.1. Every matrix entry below the diagonal therefore vanishes, so (i) holds.

Structural Commentary: The implication cycle translates column support into preservation of every initial span.
Key Insight: Upper triangularity is the coordinate form of an invariant flag. □

Corollary 5.3.4. *Upper-Triangular Form in an Orthonormal Basis*
Let $\mathcal{V}$ be a nonzero finite-dimensional inner-product space and let $T \in \mathcal{L}(\mathcal{V})$.
If T has an upper-triangular matrix relative to a basis of $\mathcal{V}$, then it has one relative to an orthonormal basis.

Proof. Choose a basis $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ for which $[T]_{\beta \leftarrow \beta}$ is upper triangular, and set $\mathcal{U}_j := \mathrm{span}(\mathbf{v}_1, \dots, \mathbf{v}_j)$.
Then $(\forall\, j \in \{1, \dots, n\})\, \mathcal{U}_j \in \mathrm{Inv}(T)$ by Theorem 5.3.3(i),(iii). Let $\gamma = (\mathbf{e}_1, \dots, \mathbf{e}_n)$ be the Gram–Schmidt output for β.
List γ is orthonormal by Theorem 1.3.6(ii). Prefix identities $(\forall\, j \in \{1, \dots, n\})\ \mathrm{span}(\mathbf{e}_1, \dots, \mathbf{e}_j) = \mathcal{U}_j$ hold by Theorem 1.3.6(i).
Since $\mathrm{span}(\gamma) = \mathcal{U}_n = \mathcal{V}$, γ is an orthonormal basis. Its matrix for T is upper triangular by Theorem 5.3.3(iii),(i).
Structural Commentary: Gram–Schmidt transports the invariant flag to an orthonormal basis.
Key Insight: Triangularity depends on initial spans, not their chosen generators. □

Theorem 5.3.5. *Complex Upper Triangularization*
Let $\mathcal{V}$ be a nonzero finite-dimensional complex vector space and let $T \in \mathcal{L}(\mathcal{V})$.
Then T has an upper-triangular matrix relative to a basis of $\mathcal{V}$.

Proof.

(i) *Induction*: Induct on $n := \dim_{\mathbb{C}}(\mathcal{V})$. For $n = 1$, every operator matrix is upper triangular. Assume $n > 1$ and that every operator on a nonzero complex vector space of dimension less than n has an upper-triangular matrix relative to a basis.
(ii) *Eigenline and Quotient*: Choose eigenvector $\mathbf{v}_1$ of T by Theorem 5.3.2, set $\mathcal{U} := \mathrm{span}(\mathbf{v}_1)$; $\mathcal{U} \in \mathrm{Inv}(T)$ by Proposition 5.2.4.
The relations $T/\mathcal{U} \in \mathcal{L}(\mathcal{V}/\mathcal{U})$ and $\dim_{\mathbb{C}}(\mathcal{V}/\mathcal{U}) = n - 1 > 0$ hold by Proposition 5.2.3(ii) and Theorem 2.2.9(ii).
By induction, choose a quotient basis $(\mathbf{v}_2 + \mathcal{U}, \dots, \mathbf{v}_n + \mathcal{U})$ in which $T/\mathcal{U}$ is upper triangular.
(iii) *Lifted Basis*: Choose representatives $\mathbf{v}_2, \dots, \mathbf{v}_n \in \mathcal{V}$.
A zero relation among $\mathbf{v}_1, \dots, \mathbf{v}_n$ descends to the quotient basis, so the coefficients of $\mathbf{v}_2, \dots, \mathbf{v}_n$ vanish.
The remaining coefficient vanishes because $\mathbf{v}_1 \neq \mathbf{0}$. Thus $\beta := (\mathbf{v}_1, \dots, \mathbf{v}_n)$ is a basis by Proposition 1.4.4(ii).
(iv) *Triangularity*: The relation $T\mathbf{v}_1 \in \mathrm{span}(\mathbf{v}_1)$ holds by $\mathcal{U} \in \mathrm{Inv}(T)$. Fix $j \in \{2, \dots, n\}$.
Choose $c_{2,j}, \dots, c_{j,j} \in \mathbb{C}$ satisfying $(T/\mathcal{U})(\mathbf{v}_j + \mathcal{U}) = \sum_{k=2}^{j} c_{k,j}(\mathbf{v}_k + \mathcal{U})$ by Theorem 5.3.3(i),(ii).
The relation $T\mathbf{v}_j - \sum_{k=2}^{j} c_{k,j}\mathbf{v}_k \in \mathcal{U} = \mathrm{span}(\mathbf{v}_1)$ holds by Definition 5.2.2(ii).
Thus $(\forall\, j \in \{1, \dots, n\})\, T\mathbf{v}_j \in \mathrm{span}(\mathbf{v}_1, \dots, \mathbf{v}_j)$, and $[T]_{\beta \leftarrow \beta}$ is upper triangular by Theorem 5.3.3(ii),(i).

Structural Commentary: Induction lifts a triangular quotient basis above a complex eigenline.
Key Insight: Each lifted quotient relation differs by a vector in the eigenline. □

Definition 5.3.6. *Complexification of a Real Vector Space*
Let $\mathcal{V}$ be a real vector space.

(i) The *complexification* of $\mathcal{V}$ is $\mathcal{V}_{\mathbb{C}} := \mathcal{V} \times \mathcal{V}$, with $(\mathbf{u}, \mathbf{v})$ denoted $\mathbf{u} + i\mathbf{v}$.
(ii) Addition is $(\mathbf{u}_1 + i\mathbf{v}_1) + (\mathbf{u}_2 + i\mathbf{v}_2) := (\mathbf{u}_1 + \mathbf{u}_2) + i(\mathbf{v}_1 + \mathbf{v}_2)$. For $a, b \in \mathbb{R}$, define $(a + bi)(\mathbf{u} + i\mathbf{v}) := (a\mathbf{u} - b\mathbf{v}) + i(b\mathbf{u} + a\mathbf{v})$.
(iii) The *complexification map* is $\mathrm{cpx} : \mathcal{V} \to \mathcal{V}_{\mathbb{C}}$, $\mathrm{cpx}(\mathbf{u}) := \mathbf{u} + i\mathbf{0}$. Its image is $\mathrm{im}(\mathrm{cpx}) = \{\mathbf{u} + i\mathbf{0} : \mathbf{u} \in \mathcal{V}\}$.
(iv) Define $\mathrm{Re}, \mathrm{Im} : \mathcal{V}_{\mathbb{C}} \to \mathcal{V}$ by $\mathrm{Re}(\mathbf{u} + i\mathbf{v}) := \mathbf{u}$ and $\mathrm{Im}(\mathbf{u} + i\mathbf{v}) := \mathbf{v}$. Then $\mathbf{z} = \mathbf{0}$ iff $\mathrm{Re}\,\mathbf{z} = \mathrm{Im}\,\mathbf{z} = \mathbf{0}$.

Proposition 5.3.7. *Complexification Preserves Bases*
Let $\mathcal{V}$ be a finite-dimensional real vector space and let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ be a real basis of $\mathcal{V}$. Set $\beta_{\mathbb{C}} := \operatorname{cpx}(\beta)$. Then:

(i) $\mathcal{V}_{\mathbb{C}}$ is a complex vector space;
(ii) $\beta_{\mathbb{C}}$ is a complex basis of $\mathcal{V}_{\mathbb{C}}$;
(iii) $\dim_{\mathbb{C}}(\mathcal{V}_{\mathbb{C}}) = \dim_{\mathbb{R}}(\mathcal{V})$.

Proof.

(i) Addition makes $\mathcal{V}_{\mathbb{C}}$ an abelian group with zero $\mathbf{0} + i\mathbf{0}$ and inverse $-(\mathbf{u} + i\mathbf{v}) = (-\mathbf{u}) + i(-\mathbf{v})$ by the real vector-space axioms. Fix $\alpha = a + bi$, $\eta = c + di \in \mathbb{C}$ and $\mathbf{z} = \mathbf{u} + i\mathbf{v} \in \mathcal{V}_{\mathbb{C}}$. The real parts of $\alpha(\eta\mathbf{z})$ and $(\alpha\eta)\mathbf{z}$ both equal $(ac - bd)\mathbf{u} - (ad + bc)\mathbf{v}$. Imaginary parts both equal $(ad + bc)\mathbf{u} + (ac - bd)\mathbf{v}$, so scalar multiplication is associative. The identity $1\mathbf{z} = \mathbf{z}$ follows directly. The two distributive laws hold by Definition 5.3.6(ii) and real vector-space distributivity. Hence $\mathcal{V}_{\mathbb{C}}$ is a complex vector space.

(ii) For $\mathbf{u}, \mathbf{v} \in \mathcal{V}$, choose real coefficients satisfying $\mathbf{u} = \sum_{j=1}^{n} a_j \mathbf{v}_j$ and $\mathbf{v} = \sum_{j=1}^{n} b_j \mathbf{v}_j$.

Then $\mathbf{u} + i\mathbf{v} = \sum_{j=1}^{n} (a_j + ib_j) \operatorname{cpx}(\mathbf{v}_j)$, so $\beta_{\mathbb{C}}$ spans $\mathcal{V}_{\mathbb{C}}$. Suppose $\sum_{j=1}^{n} (c_j + id_j) \operatorname{cpx}(\mathbf{v}_j) = \mathbf{0}$.

The equality $\sum_{j=1}^{n} c_j \mathbf{v}_j = \sum_{j=1}^{n} d_j \mathbf{v}_j = \mathbf{0}$ holds by Definition 5.3.6(ii),(iv).

Thus $(\forall\, j \in \{1, \dots, n\})\, c_j = d_j = 0$ by independence of β, and $\beta_{\mathbb{C}}$ is a complex basis.

(iii) The basis $\beta_{\mathbb{C}}$ has $n = \dim_{\mathbb{R}}(\mathcal{V})$ members. Hence $\dim_{\mathbb{C}}(\mathcal{V}_{\mathbb{C}}) = \dim_{\mathbb{R}}(\mathcal{V})$.

Structural Commentary: Component identities establish scalar action; coefficient separation transports the basis and dimension.
Key Insight: Each complex coefficient is two independent real coefficients. □

Corollary 5.3.8. *Coordinates Survive Complexification*
Let $\mathcal{V}$ be a finite-dimensional real vector space and let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ be a basis of $\mathcal{V}$.
Set $\beta_{\mathbb{C}} := \operatorname{cpx}(\beta)$. Then $(\forall\, \mathbf{v} \in \mathcal{V})\, [\operatorname{cpx}(\mathbf{v})]_{\beta_{\mathbb{C}}} = [\mathbf{v}]_{\beta} \in \mathbb{R}^n \subseteq \mathbb{C}^n$.

Proof. Fix $\mathbf{v} \in \mathcal{V}$ and write $[\mathbf{v}]_{\beta} = (a_1, \dots, a_n)^t \in \mathbb{R}^n$. Then $\operatorname{cpx}(\mathbf{v}) = \sum_{j=1}^{n} a_j \operatorname{cpx}(\mathbf{v}_j)$ by Definition 5.3.6(ii)–(iii).
Thus $[\operatorname{cpx}(\mathbf{v})]_{\beta_{\mathbb{C}}} = (a_1, \dots, a_n)^t = [\mathbf{v}]_{\beta}$ by Proposition 5.3.7(ii).
Structural Commentary: The embedding preserves one real expansion inside the complexified basis.
Key Insight: Embedded real vectors retain their real coordinate columns. □

Proposition 5.3.9. *Complexification as a Real Space*
Let $\mathcal{V}$ be finite-dimensional real vector space, $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ be basis of $\mathcal{V}$. Regard $\mathcal{V}_{\mathbb{C}}$ as real vector space by restriction of scalars.
Set $\mathbf{e}_j := \operatorname{cpx}(\mathbf{v}_j)$ $(j \in \{1, \dots, n\})$. Define $\delta := (\mathbf{e}_1, \dots, \mathbf{e}_n, i\mathbf{e}_1, \dots, i\mathbf{e}_n)$. Then:

(i) δ is a real basis of $\mathcal{V}_{\mathbb{C}}$;
(ii) $\dim_{\mathbb{R}}(\mathcal{V}_{\mathbb{C}}) = 2 \dim_{\mathbb{R}}(\mathcal{V})$;
(iii) $\operatorname{cpx} : \mathcal{V} \to \mathcal{V}_{\mathbb{C}}$ is real-linear and injective.

Proof.

(i) For $\mathbf{u} + i\mathbf{w} \in \mathcal{V}_{\mathbb{C}}$, choose real coefficients with $\mathbf{u} = \sum_{j=1}^{n} a_j \mathbf{v}_j$ and $\mathbf{w} = \sum_{j=1}^{n} b_j \mathbf{v}_j$.

Then $\mathbf{u} + i\mathbf{w} = \sum_{j=1}^{n} a_j \mathbf{e}_j + \sum_{j=1}^{n} b_j (i\mathbf{e}_j)$, so δ spans over $\mathbb{R}$.

If this right side is zero, its real and imaginary parts vanish by Definition 5.3.6(iv).

Thus $(\forall\, j \in \{1, \dots, n\})\, a_j = b_j = 0$ by independence of β, and δ is a real basis.

(ii) The basis δ has $2n = 2 \dim_{\mathbb{R}}(\mathcal{V})$ members.

(iii) For $r, s \in \mathbb{R}$ and $\mathbf{u}, \mathbf{v} \in \mathcal{V}$, $\operatorname{cpx}(r\mathbf{u} + s\mathbf{v}) = r \operatorname{cpx}(\mathbf{u}) + s \operatorname{cpx}(\mathbf{v})$ by Definition 5.3.6(ii)–(iii).
If $\operatorname{cpx}(\mathbf{u}) = \operatorname{cpx}(\mathbf{v})$, then $\operatorname{cpx}(\mathbf{u} - \mathbf{v}) = \mathbf{0}$ by linearity and $\mathbf{u} - \mathbf{v} = \mathbf{0}$ by Definition 5.3.6(iv). Hence cpx is real-linear and injective.

Structural Commentary: Real–imaginary separation builds the doubled basis and detects the embedding kernel.
Key Insight: Complexification is two independent real copies of $\mathcal{V}$. □

Definition 5.3.10. *Complexification of a Real Operator*
Let $\mathcal{V}$ be a real vector space and let $T \in \mathcal{L}(\mathcal{V})$. The *complexification* of T is $T_{\mathbb{C}} : \mathcal{V}_{\mathbb{C}} \to \mathcal{V}_{\mathbb{C}}$, defined by $T_{\mathbb{C}}(\mathbf{u} + i\mathbf{v}) := T\mathbf{u} + iT\mathbf{v}$.

Proposition 5.3.11. *Complexification Preserves Operator Data*
Let $\mathcal{V}$ be a real vector space and let $T \in \mathcal{L}(\mathcal{V})$.

(i) $T_{\mathbb{C}} \in \mathcal{L}(\mathcal{V}_{\mathbb{C}})$.
(ii) $(\forall\, k \in \mathbb{Z}_{\geq 0})(\forall\, \mathbf{u}, \mathbf{v} \in \mathcal{V})\, (T_{\mathbb{C}})^k(\mathbf{u} + i\mathbf{v}) = T^k\mathbf{u} + iT^k\mathbf{v}$;
(iii) For a real basis $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ of $\mathcal{V}$, set $\beta_{\mathbb{C}} := \operatorname{cpx}(\beta)$. Then $[T_{\mathbb{C}}]_{\beta_{\mathbb{C}} \leftarrow \beta_{\mathbb{C}}} = [T]_{\beta \leftarrow \beta}$ as complex matrices.

Proof.

(i) Let $\mathbf{z} = \mathbf{u} + i\mathbf{v}$, $\mathbf{w} = \mathbf{x} + i\mathbf{y}$, and $\alpha = a + bi \in \mathbb{C}$. Then $T_{\mathbb{C}}(\mathbf{z} + \mathbf{w}) = T_{\mathbb{C}}\mathbf{z} + T_{\mathbb{C}}\mathbf{w}$ by the additivity of T.
By the real linearity of T, $T_{\mathbb{C}}(\alpha\mathbf{z}) = T(a\mathbf{u} - b\mathbf{v}) + iT(b\mathbf{u} + a\mathbf{v}) = (aT\mathbf{u} - bT\mathbf{v}) + i(bT\mathbf{u} + aT\mathbf{v})$.
The last term equals $\alpha T_{\mathbb{C}}\mathbf{z}$ by Definition 5.3.6(ii). Hence $T_{\mathbb{C}}$ is complex-linear.

(ii) Fix $\mathbf{u}, \mathbf{v} \in \mathcal{V}$. The identity holds for $k = 0$. If it holds at k, then $(T_{\mathbb{C}})^{k+1}(\mathbf{u} + i\mathbf{v}) = T_{\mathbb{C}}(T^k\mathbf{u} + iT^k\mathbf{v}) = T^{k+1}\mathbf{u} + iT^{k+1}\mathbf{v}$.
Thus $(\forall\, k \in \mathbb{Z}_{\geq 0})\, (T_{\mathbb{C}})^k(\mathbf{u} + i\mathbf{v}) = T^k\mathbf{u} + iT^k\mathbf{v}$ by induction, and claim (ii) follows by the arbitrariness of $\mathbf{u}, \mathbf{v}$.

(iii) The list $\beta_{\mathbb{C}}$ is a complex basis by Proposition 5.3.7(ii). Fix $j \in \{1, \dots, n\}$ and write $T\mathbf{v}_j = \sum_{r=1}^{n} a_{r,j} \mathbf{v}_r$ with $a_{r,j} \in \mathbb{R}$.

Then $T_{\mathbb{C}} \operatorname{cpx}(\mathbf{v}_j) = \sum_{r=1}^{n} a_{r,j} \operatorname{cpx}(\mathbf{v}_r)$ by Definition 5.3.10. Hence these matrices have same columns by arbitrariness of j.

Structural Commentary: Scalar expansion proves linearity, induction controls powers, and basis images identify columns.
Key Insight: Complexification changes the scalar field without changing real coordinate columns. □

Figure 42 illustrates the componentwise action established in Proposition 5.3.11.
The proposition, rather than the diagram, owns complex linearity and coordinate compatibility.

Figure 42: Complexification packages two real vectors: $T_{\mathbb{C}}(\mathbf{u} + i\mathbf{v}) = T\mathbf{u} + iT\mathbf{v}$.

Proposition 5.3.12. *Real Eigenvalues of a Complexification*
Let $\mathcal{V}$ be a finite-dimensional real vector space, let $T \in \mathcal{L}(\mathcal{V})$, and let $\lambda \in \mathbb{R}$. Then λ is an eigenvalue of T iff it is an eigenvalue of $T_{\mathbb{C}}$.

Proof.

($\Rightarrow$) Suppose $T\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$. Then $\operatorname{cpx}(\mathbf{v}) \neq \mathbf{0}$ by Proposition 5.3.9(iii).
The identity $T_{\mathbb{C}} \operatorname{cpx}(\mathbf{v}) = \lambda \operatorname{cpx}(\mathbf{v})$ holds by Definition 5.3.10.
Hence λ is an eigenvalue of $T_{\mathbb{C}}$ by Definition 5.1.1.

($\Leftarrow$) Suppose $\mathbf{u}, \mathbf{v} \in \mathcal{V}$ satisfy $T_{\mathbb{C}}(\mathbf{u} + i\mathbf{v}) = \lambda(\mathbf{u} + i\mathbf{v})$ and $\mathbf{u} + i\mathbf{v} \neq \mathbf{0}$.
Then $T\mathbf{u} = \lambda\mathbf{u}$ and $T\mathbf{v} = \lambda\mathbf{v}$ by Definitions 5.3.6(ii),(iv) and 5.3.10.
The relation $\mathbf{u} \neq \mathbf{0} \vee \mathbf{v} \neq \mathbf{0}$ holds by Definition 5.3.6(iv).
Thus one of $\mathbf{u}, \mathbf{v}$ is an eigenvector of T for λ by Definition 5.1.1.

Structural Commentary: The embedding preserves a real eigenvector; component separation recovers one from its complexification.
Key Insight: A real eigenvalue acts identically on both real components. □

Computation Method 5.3.13. *Real Invariant Subspace from a Complex Eigenpair*
Given $n \in \mathbb{Z}_{>0}$ and $A \in \operatorname{Mat}(n, n, \mathbb{R})$, construct a nonzero subspace $\mathcal{U} \leq \mathbb{R}^n$ satisfying $A\mathcal{U} \subseteq \mathcal{U}$ and $\dim(\mathcal{U}) \in \{1, 2\}$:

(i) Let $T_A \in \mathcal{L}(\mathbb{C}^n)$ be defined by $T_A\mathbf{z} := A\mathbf{z}$.
(ii) Choose an eigenvalue $a + bi \in \mathbb{C}$ of T_A by Theorem 5.3.2.
Choose an associated eigenvector $\mathbf{0} \neq \mathbf{u} + i\mathbf{v} \in \mathbb{C}^n$ by Definition 5.1.1.
Then $A(\mathbf{u} + i\mathbf{v}) = (a + bi)(\mathbf{u} + i\mathbf{v})$ by the definition of T_A.
(iii) Separate components to obtain $A\mathbf{u} = a\mathbf{u} - b\mathbf{v}$ and $A\mathbf{v} = b\mathbf{u} + a\mathbf{v}$.
(iv) Set $\mathcal{U} := \operatorname{span}(\mathbf{u}, \mathbf{v})$. Then $\mathcal{U} \neq \{\mathbf{0}\}$ by step (ii), and $A\mathcal{U} \subseteq \mathcal{U}$ by step (iii) and linearity.
A basis sublist of $(\mathbf{u}, \mathbf{v})$ exists by Theorem 1.3.12, so $\dim(\mathcal{U}) \in \{1, 2\}$.

Theorem 5.3.14. *Invariant Line or Plane over $\mathbb{R}$*
Let $\mathcal{V}$ be a nonzero finite-dimensional real vector space and let $T \in \mathcal{L}(\mathcal{V})$.
Then $(\exists \mathcal{U} \in \operatorname{Inv}(T))\ \dim(\mathcal{U}) \in \{1, 2\}$.

Proof.

(i) *Complex Eigenpair*: The space $\mathcal{V}_{\mathbb{C}}$ is nonzero and finite-dimensional over $\mathbb{C}$ by Proposition 5.3.7(i),(iii).
The complexified operator satisfies $T_{\mathbb{C}} \in \mathcal{L}(\mathcal{V}_{\mathbb{C}})$ by Proposition 5.3.11(i). Choose an eigenvalue $\lambda := a + bi \in \mathbb{C}$ by Theorem 5.3.2.
Choose $\mathbf{z} := \mathbf{u} + i\mathbf{v} \in \mathcal{V}_{\mathbb{C}} \setminus \{\mathbf{0}\}$ satisfying $T_{\mathbb{C}}\mathbf{z} = \lambda\mathbf{z}$ by Definition 5.1.1.
(ii) *Invariant Real Span*: The component identities $T\mathbf{u} = a\mathbf{u} - b\mathbf{v}$ and $T\mathbf{v} = b\mathbf{u} + a\mathbf{v}$ hold by Definitions 5.3.6(ii),(iv) and 5.3.10.
Set $\mathcal{U} := \operatorname{span}(\mathbf{u}, \mathbf{v})$. For $c, d \in \mathbb{R}$, $T(c\mathbf{u} + d\mathbf{v}) = (ca + db)\mathbf{u} + (-cb + da)\mathbf{v} \in \mathcal{U}$ by the component identities.
Thus $\mathcal{U} \in \operatorname{Inv}(T)$ by Definition 5.2.1.
(iii) *Dimension*: The relation $\mathcal{U} \neq \{\mathbf{0}\}$ holds by $\mathbf{u} + i\mathbf{v} \neq \mathbf{0}$ and Definition 5.3.6(iv).
A basis sublist of $(\mathbf{u}, \mathbf{v})$ exists by Theorem 1.3.12. Consequently, $\dim(\mathcal{U}) \in \{1, 2\}$.

Structural Commentary: A complex eigenpair separates into two generators whose span is closed under T.
Key Insight: The real and imaginary components form a nonzero invariant span. □

Figure 43 depicts the component separation in Theorem 5.3.14.
The theorem, rather than the diagram, owns the invariant-subspace conclusion.

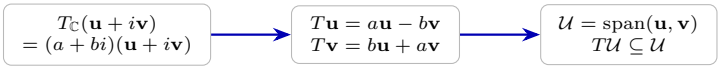

Figure 43: A complex eigenpair determines a nonzero invariant real line or plane.

Definition 5.3.15. *Almost Upper-Triangular Real Matrices*
Let $n \in \mathbb{Z}_{>0}$, $A \in \operatorname{Mat}(n, n, \mathbb{R})$. Matrix A is *almost upper triangular* iff it admits a block representation with following properties:

(i) The block count and sizes satisfy $m \in \mathbb{Z}_{>0}$ and $(d_1, \ldots, d_m) \in \{1, 2\}^m$.
(ii) One has $A = [A_{ij}]_{i,j=1}^{m}$, $A_{ij} \in \operatorname{Mat}(d_i, d_j, \mathbb{R})$, and $\sum_{j=1}^{m} d_j = n$.
(iii) $(\forall\, i, j \in \{1, \ldots, m\})\,(i > j \Rightarrow A_{ij} = 0)$.
(iv) Every diagonal block is either $A_{jj} = [\lambda_j]$ with $\lambda_j \in \mathbb{R}$, or $A_{jj} = \left[\begin{smallmatrix} a_j & -b_j \\ b_j & a_j \end{smallmatrix}\right]$ with $a_j, b_j \in \mathbb{R}$ and $b_j \neq 0$.

The matrix A is in *real Schur block form* iff it admits a block representation satisfying (i)–(iii), with no restriction beyond the prescribed sizes on its diagonal blocks.

Theorem 5.3.16. *Real Almost Upper Triangularization*
Let $\mathcal{V}$ be nonzero finite-dimensional real vector space, $T \in \mathcal{L}(\mathcal{V})$. Then T has almost-upper-triangular matrix relative to basis of $\mathcal{V}$.

Proof.

(i) *Induction*: Induct on $n := \dim_{\mathbb{R}}(\mathcal{V})$. If $n = 1$, every operator matrix is an admissible real 1×1 block. Assume $n \geq 2$ and that every operator on a nonzero real vector space of dimension less than n has an almost-upper-triangular matrix relative to a basis.

(ii) *Complex Eigenpair*: The space $\mathcal{V}_{\mathbb{C}}$ is a nonzero n-dimensional complex vector space by Proposition 5.3.7(i),(iii).
The complexified operator satisfies $T_{\mathbb{C}} \in \mathcal{L}(\mathcal{V}_{\mathbb{C}})$ by Proposition 5.3.11(i). Choose an eigenvalue $\lambda := a + bi \in \mathbb{C}$ by Theorem 5.3.2.
Choose $\mathbf{z} := \mathbf{u} + i\mathbf{v} \in \mathcal{V}_{\mathbb{C}} \setminus \{\mathbf{0}\}$ satisfying $T_{\mathbb{C}}\mathbf{z} = \lambda\mathbf{z}$ by Definition 5.1.1.
Then $T\mathbf{u} = a\mathbf{u} - b\mathbf{v}$ and $T\mathbf{v} = b\mathbf{u} + a\mathbf{v}$ by Definitions 5.3.6(ii),(iv) and 5.3.10.

(iii) *Initial Invariant Block*: Construct $\mathcal{U}$ and its basis α by cases.

(a) If $b = 0$, then $\mathbf{u} \neq \mathbf{0} \vee \mathbf{v} \neq \mathbf{0}$ by Definition 5.3.6(iv). Choose $\mathbf{x} \in \{\mathbf{u}, \mathbf{v}\} \setminus \{\mathbf{0}\}$. Set $\mathcal{U} := \operatorname{span}(\mathbf{x})$ and $\alpha := (\mathbf{x})$.
The component identities imply $T\mathbf{x} = a\mathbf{x}$, so $\mathcal{U} \in \operatorname{Inv}(T)$ and $[T|_{\mathcal{U}}]_{\alpha\leftarrow\alpha} = [a]$.

(b) Suppose $b \neq 0$. Implication $\mathbf{u} = \mathbf{0} \Rightarrow b\mathbf{v} = \mathbf{0} \Rightarrow \mathbf{v} = \mathbf{0}$ contradicts chosen eigenvector by first component identity.
Hence $\mathbf{u} \neq \mathbf{0}$. If $\mathbf{v} = c\mathbf{u}$ for $c \in \mathbb{R}$, then $c(a - bc)\mathbf{u} = cT\mathbf{u} = T\mathbf{v} = (b + ac)\mathbf{u}$ by linearity and the component identities.
Thus $b(c^2 + 1) = 0$ by $\mathbf{u} \neq \mathbf{0}$, contrary to $b \neq 0$. Therefore $\mathbf{u}, \mathbf{v}$ are independent. Set $\mathcal{U} := \operatorname{span}(\mathbf{u}, \mathbf{v})$ and $\alpha := (\mathbf{u}, -\mathbf{v})$.
Then $\mathcal{U} \in \operatorname{Inv}(T)$ and $[T|_{\mathcal{U}}]_{\alpha\leftarrow\alpha} = \left[\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right]$ by the component identities.

In both cases, α is a basis of $\mathcal{U}$, $\dim(\mathcal{U}) \in \{1, 2\}$, and $[T|_{\mathcal{U}}]_{\alpha\leftarrow\alpha}$ is an admissible first diagonal block.

(iv) *Quotient Induction*: If $\mathcal{U} = \mathcal{V}$, the basis α proves the claim. Suppose $\mathcal{U} \neq \mathcal{V}$. Then $T/\mathcal{U} \in \mathcal{L}(\mathcal{V}/\mathcal{U})$ by Proposition 5.2.3(ii).
The inequality $0 < \dim_{\mathbb{R}}(\mathcal{V}/\mathcal{U}) = n - \dim_{\mathbb{R}}(\mathcal{U}) < n$ holds by Theorem 2.2.9(ii). Set $q := n - \dim_{\mathbb{R}}(\mathcal{U})$.
By induction, choose a quotient basis $\overline{\gamma} := (\mathbf{w}_1 + \mathcal{U}, \ldots, \mathbf{w}_q + \mathcal{U})$ in which $T/\mathcal{U}$ is almost upper triangular.

(v) *Lifted Block Form*: Set $\gamma := (\mathbf{w}_1, \ldots, \mathbf{w}_q)$ and $\beta := (\alpha, \gamma)$.
A zero relation in β descends to the quotient basis, so every coefficient of γ vanishes.
The coefficients of α then vanish because α is a basis of $\mathcal{U}$. Thus β is independent and has n members.
Hence β is a basis by Proposition 1.4.4(ii), and $\mathcal{V} = \mathcal{U} \oplus \operatorname{span}(\gamma)$.
The matrix of T in β is block upper triangular by Proposition 5.2.5(i).
Its first diagonal block is $[T|_{\mathcal{U}}]_{\alpha\leftarrow\alpha}$. Its lower-right block is $[T/\mathcal{U}]_{\overline{\gamma}\leftarrow\overline{\gamma}}$ by Definition 5.2.2(i)–(ii).
Therefore $[T]_{\beta\leftarrow\beta}$ is almost upper triangular by Definition 5.3.15.

Structural Commentary: Induction lifts an almost-triangular quotient above an invariant line or plane.
Key Insight: Complex eigenpairs supply the admissible real diagonal blocks. □

Corollary 5.3.17. *Orthonormal Real Schur Block Form*
Let $\mathcal{V}$ be nonzero finite-dimensional real inner-product space, $T \in \mathcal{L}(\mathcal{V})$.
Then T has real Schur block form relative to an orthonormal basis of $\mathcal{V}$.

Proof.

(i) *Invariant Block Flag*: Choose a basis $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ in which T is almost upper triangular by Theorem 5.3.16.
Fix its block sizes $(d_1, \ldots, d_m) \in \{1, 2\}^m$. Set $s_k := \sum_{j=1}^{k} d_j$ and $\mathcal{U}_k := \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_{s_k})$.
The zero blocks below the block diagonal imply $(\forall\, k \in \{1, \ldots, m\})\, \mathcal{U}_k \in \operatorname{Inv}(T)$ by Definitions 5.3.15(iii) and 5.2.1.

(ii) *Orthonormal Flag*: Let $\gamma = (\mathbf{e}_1, \ldots, \mathbf{e}_n)$ be the Gram–Schmidt output for β. The list γ is orthonormal by Theorem 1.3.6(ii).
The prefix identities $(\forall\, k \in \{1, \ldots, m\})\ \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_{s_k}) = \mathcal{U}_k$ hold by Theorem 1.3.6(i).
Since $\operatorname{span}(\gamma) = \mathcal{U}_m = \mathcal{V}$, γ is an orthonormal basis.

(iii) *Block Form*: Relations $(\forall\, k \in \{1, \ldots, m\})\ \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_{s_k}) \in \operatorname{Inv}(T)$ make $[T]_{\gamma\leftarrow\gamma}$ block upper triangular for sizes $(d_1, \ldots, d_m)$.
Hence it is in real Schur block form by Definition 5.3.15.

Structural Commentary: Gram–Schmidt preserves each subspace in the invariant block flag.
Key Insight: Orthonormalization changes block entries without changing block boundaries. □

Proposition 5.3.18. *Invertibility from an Upper-Triangular Matrix*
Let $\dim(\mathcal{V}) = n \in \mathbb{Z}_{>0}$ and $T \in \mathcal{L}(\mathcal{V})$. Suppose T has an upper-triangular matrix with diagonal $(\lambda_1, \ldots, \lambda_n)$ relative to a basis of $\mathcal{V}$.
Then T is invertible iff $(\forall\, j \in \{1, \ldots, n\})\ \lambda_j \neq 0$.

Proof. Let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ be such a basis.

($\Rightarrow$) Suppose T is invertible and $(\exists\, j \in \{1, \ldots, n\})\ \lambda_j = 0$; fix such a j. Set $\mathcal{U}_k := \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$ and $\mathcal{U}_0 := \{\mathbf{0}\}$.
The first j matrix columns have zero entries in rows $j, \ldots, n$ by upper triangularity and $\lambda_j = 0$, so $T\mathcal{U}_j \subseteq \mathcal{U}_{j-1}$.
Map $S : \mathcal{U}_j \to \mathcal{U}_{j-1}$, $S\mathbf{u} := T\mathbf{u}$, is therefore linear. Since $\dim(\mathcal{U}_j) = j > j - 1 = \dim(\mathcal{U}_{j-1})$, S is not injective by Corollary 1.7.4.
Thus $(\exists\, \mathbf{u} \in \mathcal{U}_j \setminus \{\mathbf{0}\})\, T\mathbf{u} = \mathbf{0}$, contrary to the injectivity of T by Theorem 1.7.7(i),(ii). Hence $(\forall\, j \in \{1, \ldots, n\})\ \lambda_j \neq 0$.

($\Leftarrow$) Suppose $(\forall\, j \in \{1, \ldots, n\})\ \lambda_j \neq 0$, and set $M := [T]_{\beta\leftarrow\beta}$. Then M is invertible by Theorem 3.8.9(i).
Choose $S \in \mathcal{L}(\mathcal{V})$ satisfying $[S]_{\beta\leftarrow\beta} = M^{-1}$ by Theorem 3.4.5(i).
The identity $[ST]_{\beta\leftarrow\beta} = M^{-1}M = I_n = [I_{\mathcal{V}}]_{\beta\leftarrow\beta}$ holds by Proposition 3.4.4.
The identity $[TS]_{\beta\leftarrow\beta} = MM^{-1} = I_n = [I_{\mathcal{V}}]_{\beta\leftarrow\beta}$ holds by the same proposition.
Hence $ST = TS = I_{\mathcal{V}}$ by Theorem 3.4.5(i), so T is invertible by Definition 1.6.4.

Structural Commentary: A zero diagonal compresses an initial span; nonzero diagonals transport a matrix inverse.
Key Insight: Nonzero diagonal entries are exactly the invertible triangular layers. □

Proposition 5.3.19. *Eigenvalues from an Upper-Triangular Matrix*
Let $\dim(\mathcal{V}) = n \in \mathbb{Z}_{>0}$ and $T \in \mathcal{L}(\mathcal{V})$. Suppose T has an upper-triangular matrix with diagonal $(\lambda_1, \ldots, \lambda_n)$ relative to a basis of $\mathcal{V}$.
Then $\operatorname{spec}(T) = \{\lambda_1, \ldots, \lambda_n\}$.

Proof. Fix $\lambda \in \mathbb{F}$. The matrix of $T - \lambda I_{\mathcal{V}}$ in the same basis is upper triangular with diagonal $(\lambda_1 - \lambda, \ldots, \lambda_n - \lambda)$.
Thus $T - \lambda I_{\mathcal{V}}$ is not invertible iff $(\exists\, j \in \{1, \ldots, n\})\ \lambda = \lambda_j$ by Proposition 5.3.18.
The left condition is equivalent to $\lambda \in \operatorname{spec}(T)$ by Theorem 5.1.4(i),(iv) and Definition 5.1.3(i).
Hence $\operatorname{spec}(T) = \{\lambda_1, \ldots, \lambda_n\}$ by the arbitrariness of λ.
Structural Commentary: Scalar shifting reduces the spectrum calculation to triangular invertibility.
Key Insight: A shifted diagonal entry vanishes exactly at an eigenvalue. □

Perspective 5.3.20. *Why Triangular Form Matters*
Theorems 5.3.5 and 5.3.16 encode an operator by a basis-adapted flag.
Proposition 5.3.19 reads the spectrum from diagonal entries whenever triangular form exists.
Upper-block coupling records interactions that diagonalization would remove.
This viewpoint organizes spectral data without asserting diagonalizability.

5.4 Diagonalization, Commutants, and Simultaneous Forms

Definition 5.4.1. *Diagonalizable Operator*
Let $\mathcal{V}$ be a finite-dimensional vector space over $\mathbb{F}$. An operator $T \in \mathcal{L}(\mathcal{V})$ is *diagonalizable* iff $(\exists$ a basis β of $\mathcal{V})\,[T]_{\beta \leftarrow \beta}$ is diagonal.

Proposition 5.4.2. *Eigenspaces for Distinct Eigenvalues Form a Direct Sum*
Let $\mathcal{V}$ be finite-dimensional, $T \in \mathcal{L}(\mathcal{V})$, and let $\lambda_1, \dots, \lambda_m$ be distinct eigenvalues of T, where $m \geq 1$. The following hold:

(i) The sum $E_{\lambda_1}(T) + \cdots + E_{\lambda_m}(T)$ is direct.

(ii) $\sum_{j=1}^{m} \dim E_{\lambda_j}(T) \leq \dim(\mathcal{V})$.

Proof.

(i) Suppose $(\mathbf{u}_j)_{j=1}^m \in \prod_{j=1}^{m} E_{\lambda_j}(T)$ and $\sum_{j=1}^{m} \mathbf{u}_j = \mathbf{0}$. Set $J := \{j \in \{1, \dots, m\} : \mathbf{u}_j \neq \mathbf{0}\}$.
If $J \neq \emptyset$, then $(\mathbf{u}_j)_{j \in J}$ is linearly independent by Theorem 5.1.5. This contradicts its zero relation with coefficients 1.
Thus $J = \emptyset$, so the sum is direct by Proposition 2.1.23(ii),(i).

(ii) $\dim(E_{\lambda_1}(T) \oplus \cdots \oplus E_{\lambda_m}(T)) = \sum_{j=1}^{m} \dim E_{\lambda_j}(T)$ by Theorem 2.3.4(i). The left side is at most $\dim(\mathcal{V})$ by Proposition 1.4.3(i).

Structural Commentary: Removing zero components reduces every mixed relation to distinct-eigenvalue independence.
Key Insight: Distinct-eigenvalue independence forbids cross-eigenspace cancellation. □

Theorem 5.4.3. *Conditions Equivalent to Diagonalizability*
Let $\mathcal{V}$ be finite-dimensional, $T \in \mathcal{L}(\mathcal{V})$, and $n := \dim(\mathcal{V})$.
Let $(\lambda_1, \dots, \lambda_m)$ list the distinct elements of $\operatorname{spec}(T)$*, where $m \geq 0$. The following are equivalent:*

(i) T is diagonalizable;

(ii) $\mathcal{V}$ has a basis consisting of eigenvectors of T;

(iii) $(\exists\, (\mathcal{U}_j)_{j=1}^n \in \operatorname{Inv}(T)^n)\,[(\forall j \in \{1, \dots, n\})\ \dim(\mathcal{U}_j) = 1 \wedge \mathcal{V} = \bigoplus_{j=1}^{n} \mathcal{U}_j]$;

(iv) $\mathcal{V} = \bigoplus_{j=1}^{m} E_{\lambda_j}(T)$;

(v) $\dim(\mathcal{V}) = \sum_{j=1}^{m} \dim E_{\lambda_j}(T)$.

Proof.

(i) $\Rightarrow$ *(ii)* Choose a basis $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ such that $[T]_{\beta \leftarrow \beta}$ is diagonal.
Writing its jth column as $a_j \mathbf{e}_j$, $T\mathbf{v}_j = a_j \mathbf{v}_j$ by the matrix representation. Thus β is an eigenbasis.

(ii) $\Rightarrow$ *(iii)* Let $(\mathbf{v}_1, \dots, \mathbf{v}_n)$ be an eigenbasis and set $\mathcal{U}_j := \operatorname{span}(\mathbf{v}_j)$.
Each $\mathcal{U}_j$ is one-dimensional and T-invariant by Proposition 5.2.4. The equality $\mathcal{V} = \sum_{j=1}^{n} \mathcal{U}_j$ holds by spanning.
Every zero relation across the summands is a basis relation, so the sum is direct by Proposition 2.1.23(ii),(i).

(iii) $\Rightarrow$ *(iv)* Choose $(\mathbf{v}_j)_{j=1}^n \in \prod_{j=1}^{n} (\mathcal{U}_j \setminus \{\mathbf{0}\})$. Each $\mathbf{v}_j$ is an eigenvector by Proposition 5.2.4.
Thus every $\mathcal{U}_j$ lies in an eigenspace of T, and the listed eigenspaces span $\mathcal{V}$.
If $m = 0$ and $n \geq 1$, then $\mathbf{v}_1$ contradicts $\operatorname{spec}(T) = \emptyset$; hence $m = 0 \Rightarrow n = 0$.
If $m = 0$, the asserted empty direct sum is $\mathcal{V} = \{\mathbf{0}\}$. If $m \geq 1$, the sum is direct by Proposition 5.4.2(i).

(iv) $\Rightarrow$ *(v)* If $m = 0$, condition (iv) states $\mathcal{V} = \{\mathbf{0}\}$, so both sides of (v) vanish. If $m \geq 1$, the dimensions add by Theorem 2.3.4(i).

(v) $\Rightarrow$ *(i)* If $m = 0$, then $n = 0$ by condition (v), and the empty basis diagonalizes T. Suppose $m \geq 1$.
Choose bases $(\beta_j)_{j=1}^m$ with β_j a basis of $E_{\lambda_j}(T)$, and let β be their concatenation.
The eigenspace sum is direct by Proposition 5.4.2(i). Hence β is a basis of that sum by Theorem 2.3.4(ii).
Its length is n by (v), so it is a basis of $\mathcal{V}$ by Proposition 1.4.4(ii).
Each member of β is an eigenvector; hence $[T]_{\beta \leftarrow \beta}$ is diagonal, and T is diagonalizable.

Structural Commentary: The implication cycle converts diagonal coordinates into invariant lines and exhaustive eigenspace dimension.
Key Insight: Diagonalizability is exactly exhaustion by distinct eigenspaces. □

Corollary 5.4.4. *Enough Eigenvalues Imply Diagonalizability*
Let $\mathcal{V}$ be finite-dimensional and let $T \in \mathcal{L}(\mathcal{V})$. If $|\operatorname{spec}(T)| = \dim(\mathcal{V})$, then T is diagonalizable.

Proof. Set $n := \dim(\mathcal{V})$. If $n = 0$, the empty basis diagonalizes T. Suppose $n \geq 1$ and list $\operatorname{spec}(T)$ as $\lambda_1, \dots, \lambda_n$.
Choose $(\mathbf{v}_j)_{j=1}^n \in \prod_{j=1}^{n} (E_{\lambda_j}(T) \setminus \{\mathbf{0}\})$. The list $(\mathbf{v}_1, \dots, \mathbf{v}_n)$ is linearly independent by Theorem 5.1.5.
Its length is n, so it is a basis by Proposition 1.4.4(ii). Thus T is diagonalizable by Theorem 5.4.3(ii),(i).
Structural Commentary: Distinct eigenvalues supply an independent eigenvector list whose cardinality reaches the ambient dimension.
Key Insight: A full-length independent eigenvector list is already a diagonalizing basis. □

Perspective 5.4.5. *Diagonalization as Exhaustion by Eigenspaces*
Separation holds by Proposition 5.4.2(i). Spanning is the remaining condition by Theorem 5.4.3.
Diagonalization therefore records exhaustion of $\mathcal{V}$ by its distinct eigenspaces.

Theorem 5.4.6. *Algebraic Spectral Resolution*
Let $\mathcal{V}$ be nonzero and finite-dimensional, $T \in \mathcal{L}(\mathcal{V})$, and let $\lambda_1, \dots, \lambda_m \in \mathbb{F}$ be distinct, where $m \geq 1$.
Set $\Lambda := \{\lambda_1, \dots, \lambda_m\}$, and interpret an empty product below as $I_{\mathcal{V}}$. The following hold:

(i) T is diagonalizable with $\operatorname{spec}(T) = \Lambda$ *iff* $(\exists\, (\rho_i)_{i=1}^m \in (\mathcal{L}(\mathcal{V}) \setminus \{0\})^m)$ *such that* $(\forall i \in \{1, \dots, m\})\ \rho_i^2 = \rho_i$,
$(\forall i, j \in \{1, \dots, m\})\,[i \neq j \Rightarrow \rho_i \rho_j = 0]$, $\sum_{i=1}^{m} \rho_i = I_{\mathcal{V}}$, *and* $T = \sum_{i=1}^{m} \lambda_i \rho_i$.

(ii) *Every family* $(\rho_i)_{i=1}^m$ *satisfying the right side of part (i) obeys* $(\forall i \in \{1,\dots,m\})\ \operatorname{range}(\rho_i) = E_{\lambda_i}(T)$.
(iii) *Every such family obeys* $(\forall i \in \{1,\dots,m\})\ \ker(\rho_i) = \bigoplus_{j\in\{1,\dots,m\}\setminus\{i\}} E_{\lambda_j}(T)$.
(iv) *Every such family obeys* $(\forall i \in \{1,\dots,m\})\ \rho_i = \prod_{j\in\{1,\dots,m\}\setminus\{i\}} \frac{T-\lambda_j I_{\mathcal{V}}}{\lambda_i-\lambda_j}$.

Proof.

(*i*) ($\Rightarrow$) The decomposition $\mathcal{V} = \bigoplus_{i=1}^m E_{\lambda_i}(T)$ holds by Theorem 5.4.3(i),(iv).
For $i \in \{1,\dots,m\}$, set $\mathcal{W}_i := \bigoplus_{j\in\{1,\dots,m\}\setminus\{i\}} E_{\lambda_j}(T)$ and $\rho_i := \rho_{E_{\lambda_i}(T),\mathcal{W}_i}$.
Each ρ_i is idempotent by Proposition 2.4.2(ii), and $\rho_i \neq 0$ because $E_{\lambda_i}(T) \neq \{\mathbf{0}\}$.
If $\mathbf{x} = \sum_{k=1}^m \mathbf{x}_k$ with $\mathbf{x}_k \in E_{\lambda_k}(T)$, then $(\forall i \in \{1,\dots,m\})\ \rho_i\mathbf{x} = \mathbf{x}_i$ by the projection rule.
Thus $(\forall i,j \in \{1,\dots,m\})\ [i \neq j \Rightarrow \rho_i\rho_j = 0]$ and $\sum_{i=1}^m \rho_i = I_{\mathcal{V}}$.
The identity $(\forall \mathbf{x} \in \mathcal{V})\ T\mathbf{x} = \sum_{i=1}^m \lambda_i\mathbf{x}_i = \sum_{i=1}^m \lambda_i\rho_i\mathbf{x}$ holds by the eigenspace identities and projection rule, so $T = \sum_{i=1}^m \lambda_i\rho_i$.

(*i*) ($\Leftarrow$) Fix a family satisfying the right side, and set $\mathcal{V}_i := \operatorname{range}(\rho_i)$ for $i \in \{1,\dots,m\}$. The equality $\mathcal{V} = \sum_{i=1}^m \mathcal{V}_i$ holds by $\sum_{i=1}^m \rho_i = I_{\mathcal{V}}$.
Suppose $(\mathbf{x}_i)_{i=1}^m \in \prod_{i=1}^m \mathcal{V}_i$ and $\sum_{i=1}^m \mathbf{x}_i = \mathbf{0}$. Then $(\forall k \in \{1,\dots,m\})\ \mathbf{x}_k = \rho_k \sum_{i=1}^m \mathbf{x}_i = \mathbf{0}$ by idempotence and pairwise annihilation.
Hence $\mathcal{V} = \bigoplus_{i=1}^m \mathcal{V}_i$ by Proposition 2.1.23(ii),(i). For $i \in \{1,\dots,m\}$ and $\mathbf{x} \in \mathcal{V}_i$, $T\mathbf{x} = \lambda_i\mathbf{x}$ by idempotence and pairwise annihilation.
Thus $\mathcal{V}_i \subseteq E_{\lambda_i}(T)$. $\mathcal{V}_i \neq \{\mathbf{0}\}$ and $\lambda_i \in \operatorname{spec}(T)$ by $\rho_i \neq 0$ and $\mathcal{V}_i \subseteq E_{\lambda_i}(T)$.
Conversely, if $T\mathbf{x} = \mu\mathbf{x}$ with $\mathbf{x} \neq \mathbf{0}$, write $\mathbf{x} = \sum_{i=1}^m \mathbf{x}_i$ with $\mathbf{x}_i \in \mathcal{V}_i$.
Then $(\forall i \in \{1,\dots,m\})\ (\lambda_i - \mu)\mathbf{x}_i = \mathbf{0}$ by directness of the decomposition. Since some $\mathbf{x}_i \neq \mathbf{0}$, $\mu \in \Lambda$.
Thus $\operatorname{spec}(T) = \Lambda$. The eigenspaces span $\mathcal{V}$ by $\mathcal{V}_i \subseteq E_{\lambda_i}(T)$ and the direct-sum decomposition.
Hence T is diagonalizable by Theorem 5.4.3(iv),(i).

(*ii*) Fix a family satisfying the right side of part (i), set $\mathcal{V}_j := \operatorname{range}(\rho_j)$ for $j \in \{1,\dots,m\}$, and fix $i \in \{1,\dots,m\}$.
By the reverse direction of part (i), $\mathcal{V} = \bigoplus_{j=1}^m \mathcal{V}_j$ and $\mathcal{V}_i \subseteq E_{\lambda_i}(T)$. If $\mathbf{x} \in E_{\lambda_i}(T)$, write $\mathbf{x} = \sum_{j=1}^m \mathbf{x}_j$ with $\mathbf{x}_j \in \mathcal{V}_j$.
Then $(\forall j \in \{1,\dots,m\} \setminus \{i\})\ \mathbf{x}_j = \mathbf{0}$ by directness of $\sum_{j=1}^m (\lambda_j - \lambda_i)\mathbf{x}_j = \mathbf{0}$ and distinctness.
Hence $\mathbf{x} = \mathbf{x}_i \in \mathcal{V}_i$, and $\mathcal{V}_i = E_{\lambda_i}(T)$ by the two inclusions.

(*iii*) Fix a family satisfying the right side of part (i), set $\mathcal{V}_j := \operatorname{range}(\rho_j)$, and fix $i \in \{1,\dots,m\}$.
For $\mathbf{x} \in \mathcal{V}$, $\mathbf{x} = \sum_{j=1}^m \mathbf{x}_j$ with $\mathbf{x}_j \in \mathcal{V}_j$ by reverse direction of part (i). Then $\rho_i\mathbf{x} = \mathbf{x}_i$ by idempotence, pairwise annihilation.
Hence $\mathbf{x} \in \ker(\rho_i) \iff \mathbf{x}_i = \mathbf{0}$, so $\ker(\rho_i) = \bigoplus_{j\in\{1,\dots,m\}\setminus\{i\}} \mathcal{V}_j$. The stated identity holds by part (ii).

(*iv*) Fix a family satisfying the right side of part (i). For $i \in \{1,\dots,m\}$, set $\ell_i(z) := \prod_{j\in\{1,\dots,m\}\setminus\{i\}} \frac{z-\lambda_j}{\lambda_i-\lambda_j}$.
If $k \in \{1,\dots,m\}$ and $\mathbf{x} \in E_{\lambda_k}(T)$, then $\ell_i(T)\mathbf{x} = \ell_i(\lambda_k)\mathbf{x} = \delta_{ik}\mathbf{x} = \rho_i\mathbf{x}$ by part (ii), idempotence, and pairwise annihilation.
The eigenspaces span $\mathcal{V}$ by parts (i)–(ii), so $\ell_i(T) = \rho_i$ by equality on a spanning family.

Structural Commentary: Direct-sum coordinates construct the idempotents; Lagrange interpolation recovers them from T.
Key Insight: Lagrange polynomials isolate the individual eigenspaces. □

Lemma 5.4.7. *Diagonalizable Restrictions to Invariant Subspaces*
Let $\mathcal{V}$ *be a nonzero finite-dimensional vector space, let* $T \in \mathcal{L}(\mathcal{V})$ *be diagonalizable, and let* $\mathcal{U} \in \operatorname{Inv}(T)$.
For $\lambda \in \operatorname{spec}(T)$, *set* $\mathcal{U}_\lambda := \mathcal{U} \cap E_\lambda(T)$. *The following hold:*
(i) $\mathcal{U} = \bigoplus_{\lambda\in\operatorname{spec}(T)} \mathcal{U}_\lambda$.
(ii) *The restriction* $T|_{\mathcal{U}}$ *is diagonalizable.*

Proof. The family of polynomial spectral projections $(\rho_\lambda)_{\lambda\in\operatorname{spec}(T)}$ exists by Theorem 5.4.6(i),(iv); fix it.
The inclusion $T^0(\mathcal{U}) = \mathcal{U}$ is immediate. If $T^k(\mathcal{U}) \subseteq \mathcal{U}$, then $T^{k+1}(\mathcal{U}) \subseteq T(\mathcal{U}) \subseteq \mathcal{U}$ by T-invariance.
Thus $(\forall k \in \mathbb{Z}_{\geq 0})\ T^k(\mathcal{U}) \subseteq \mathcal{U}$ by induction, and $\rho_\lambda(\mathcal{U}) \subseteq \mathcal{U}$ by its polynomial formula.

(i) If $\mathbf{u} \in \mathcal{U}$, then $\mathbf{u} = \sum_{\lambda\in\operatorname{spec}(T)} \rho_\lambda\mathbf{u}$ by Theorem 5.4.6(i).
The membership $\rho_\lambda\mathbf{u} \in \mathcal{U}_\lambda$ holds by the preceding inclusion and Theorem 5.4.6(ii).
Hence $\mathcal{U} = \sum_{\lambda\in\operatorname{spec}(T)} \mathcal{U}_\lambda$. The sum is direct by Proposition 5.4.2(i).

(ii) If $\mathcal{U} = \{\mathbf{0}\}$, the empty basis diagonalizes $T|_{\mathcal{U}}$. Suppose $\mathcal{U} \neq \{\mathbf{0}\}$.
Concatenating bases of the nonzero summands forms a basis of $\mathcal{U}$ by part (i) and Theorem 2.3.4(ii).
Its members are eigenvectors of $T|_{\mathcal{U}}$, so the restriction is diagonalizable by Theorem 5.4.3(ii),(i).

Structural Commentary: Polynomial spectral projections preserve $\mathcal{U}$ and split it across the ambient eigenspaces.
Key Insight: T-invariance propagates to every polynomial in T. □

Theorem 5.4.8. *Simultaneous Diagonalization of Commuting Diagonalizable Operators*
Let $\mathcal{V}$ *be a nonzero finite-dimensional vector space, and let* $\emptyset \neq \mathcal{F} \subseteq \mathcal{L}(\mathcal{V})$ *be finite with each member diagonalizable.*
Then $(\forall S,T \in \mathcal{F})\ ST = TS$ *iff* $(\exists$ *a basis* β *of* $\mathcal{V})$ *such that* $(\forall T \in \mathcal{F})\ [T]_{\beta\leftarrow\beta}$ *is diagonal.*

Proof.

($\Rightarrow$) Assume $(\forall S,T\in\mathcal{F})\,ST=TS$, and proceed by strong induction on $n:=\dim(\mathcal{V})$.
If $n=1$, every member of $\mathcal{F}$ is scalar, so any basis is common. Suppose $n>1$ and result holds in every smaller positive dimension.
If all members of $\mathcal{F}$ are scalar, any basis is common. Otherwise choose a nonscalar $S\in\mathcal{F}$.
By Theorem 5.4.3(i),(iv), $\mathcal{V}=\bigoplus_{\lambda\in\operatorname{spec}(S)} E_\lambda(S)$.
If this decomposition had one summand, then $\mathcal{V}=E_\lambda(S)$ and $S=\lambda I_\mathcal{V}$, contrary to the choice of S.
Hence $(\forall\lambda\in\operatorname{spec}(S))\,1\le\dim E_\lambda(S)<n$. Fix $\lambda\in\operatorname{spec}(S)$.
If $T\in\mathcal{F}$ and $\mathbf{x}\in E_\lambda(S)$, then $S(T\mathbf{x})=T(S\mathbf{x})=\lambda T\mathbf{x}$ by commutation. Thus $E_\lambda(S)\in\operatorname{Inv}(T)$.
Set $\mathcal{F}_\lambda:=\{T|_{E_\lambda(S)}:T\in\mathcal{F}\}$. This family is finite, nonempty, and commuting.
Its members are diagonalizable by Lemma 5.4.7(ii). By induction, $E_\lambda(S)$ has a common eigenbasis for $\mathcal{F}_\lambda$.
Concatenating these bases over $\lambda\in\operatorname{spec}(S)$ forms a basis of $\mathcal{V}$ by Theorem 2.3.4(ii).
The concatenated basis diagonalizes every member of $\mathcal{F}$.

($\Leftarrow$) Choose a basis β satisfying the right side. For $S,T\in\mathcal{F}$, set $D_S:=[S]_{\beta\leftarrow\beta}$ and $D_T:=[T]_{\beta\leftarrow\beta}$.
As D_S and D_T are diagonal, $[ST]_{\beta\leftarrow\beta}=D_SD_T=D_TD_S=[TS]_{\beta\leftarrow\beta}$ by Proposition 3.4.4; $ST=TS$ by Theorem 3.4.5(i).

Structural Commentary: A nonscalar member supplies proper common invariant eigenspaces for dimensional induction.
Key Insight: Commutation preserves every eigenspace in the diagonalizable splitting. □

Definition 5.4.9. *Commutant*
Let $n\ge1$ and $\emptyset\ne\mathcal{F}\subseteq\operatorname{Mat}(n,n,\mathbb{F})$. The *commutant* of $\mathcal{F}$ is $\operatorname{Comm}(\mathcal{F}):=\{X\in\operatorname{Mat}(n,n,\mathbb{F}):(\forall A\in\mathcal{F})\,XA=AX\}$.
For a singleton family $\{A\}$, write $\operatorname{Comm}(A)$.

Lemma 5.4.10. *Commuting with a Block Scalar Diagonal Matrix*
Let $k,n_1,\dots,n_k\ge1$, $n:=\sum_{i=1}^k n_i$, and $\lambda_1,\dots,\lambda_k\in\mathbb{F}$. Set $\Lambda:=\lambda_1I_{n_1}\oplus\cdots\oplus\lambda_kI_{n_k}$.
Let $A=[A_{ij}]\in\operatorname{Mat}(n,n,\mathbb{F})$ be partitioned conformally, where $A_{ij}\in\operatorname{Mat}(n_i,n_j,\mathbb{F})$.

(i) If A is block diagonal, then $A\Lambda=\Lambda A$.
(ii) If $A\Lambda=\Lambda A$ and $\lambda_1,\dots,\lambda_k$ are distinct, then A is block diagonal.

Proof. By block multiplication, $(A\Lambda)_{ij}=\lambda_jA_{ij}$ and $(\Lambda A)_{ij}=\lambda_iA_{ij}$.

(i) If A is block diagonal, then $(\forall i,j\in\{1,\dots,k\})\,[i\ne j\Rightarrow A_{ij}=0]$. The two diagonal-block expressions coincide, so $A\Lambda=\Lambda A$.
(ii) If $A\Lambda=\Lambda A$, then $(\forall i,j\in\{1,\dots,k\})\,(\lambda_j-\lambda_i)A_{ij}=0$.
The relation $(\forall i,j\in\{1,\dots,k\})\,[i\ne j\Rightarrow A_{ij}=0]$ holds by distinctness, so A is block diagonal.

Structural Commentary: Block comparison reduces commutation to scalar off-diagonal equations.
Key Insight: Distinct block scalars force every off-diagonal block to vanish. □

Counterexample 5.4.11. *Repeated Block Scalars Do Not Force Block Diagonality*
Set $k=2$, $n_1=n_2=1$, $\lambda_1=\lambda_2=1$, and $A=\left[\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right]$. Then $\Lambda=I_2$, so $A\Lambda=\Lambda A$, but A is not block diagonal.
Thus the distinctness hypothesis in Lemma 5.4.10(ii) is necessary.

Theorem 5.4.12. *Commutant of a Diagonalizable Matrix*
Let $n\ge1$, $A\in\operatorname{Mat}(n,n,\mathbb{C})$ be diagonalizable. List its distinct eigenvalues as $\mu_1,\dots,\mu_d$, where $d\ge1$, set $n_i:=\dim_{\mathbb{C}}E_{\mu_i}(A)$.
Choose $S\in\operatorname{Mat}(n,n,\mathbb{C})^\times$ satisfying $A=S(\mu_1I_{n_1}\oplus\cdots\oplus\mu_dI_{n_d})S^{-1}$. Set $\mathcal{D}:=\{X_1\oplus\cdots\oplus X_d:(X_i)_{i=1}^d\in\prod_{i=1}^d\operatorname{Mat}(n_i,n_i,\mathbb{C})\}$. Then:

(i) $(\forall B\in\operatorname{Mat}(n,n,\mathbb{C}))\,[B\in\operatorname{Comm}(A)\iff S^{-1}BS\in\mathcal{D}]$.
(ii) $\dim_{\mathbb{C}}\operatorname{Comm}(A)=\sum_{i=1}^d n_i^2$.

Proof. Set $\Lambda:=\mu_1I_{n_1}\oplus\cdots\oplus\mu_dI_{n_d}$.

(*i*) ($\Rightarrow$) Suppose $B\in\operatorname{Comm}(A)$. Then $(S^{-1}BS)\Lambda=\Lambda(S^{-1}BS)$ by multiplying $BA=AB$ on the left by S^{-1} and on the right by S.
Thus $S^{-1}BS\in\mathcal{D}$ by Lemma 5.4.10(ii).
(*i*) ($\Leftarrow$) Suppose $S^{-1}BS\in\mathcal{D}$. Then $S^{-1}BS$ commutes with Λ by Lemma 5.4.10(i).
Thus $BA=AB$ by conjugating this equality by S, so $B\in\operatorname{Comm}(A)$.
(*ii*) Conjugation by S is a linear bijection from $\mathcal{D}$ onto $\operatorname{Comm}(A)$ by part (i), with inverse conjugation by S^{-1}.
Embedding the canonical matrix-unit bases of the d diagonal blocks forms a basis of $\mathcal{D}$.

Hence $\dim_{\mathbb{C}}\operatorname{Comm}(A)=\dim_{\mathbb{C}}\mathcal{D}=\sum_{i=1}^d n_i^2$ by Proposition 3.1.5(ii).

Structural Commentary: Conjugation identifies the commutant with freely chosen endomorphisms on the eigenspaces.
Key Insight: Commuting matrices preserve eigenspaces but act freely within each one. □

Theorem 5.4.13. *Common Eigenvector for a Commuting Family*
Let $\mathcal{V}$ be a nonzero finite-dimensional complex vector space, and let $\emptyset\ne\mathcal{F}\subseteq\mathcal{L}(\mathcal{V})$ satisfy $(\forall S,T\in\mathcal{F})\,ST=TS$.
Then $(\exists\,(\mathbf{v},(\lambda_T)_{T\in\mathcal{F}})\in(\mathcal{V}\setminus\{\mathbf{0}\})\times\mathbb{C}^{\mathcal{F}})\,(\forall T\in\mathcal{F})\,T\mathbf{v}=\lambda_T\mathbf{v}$.

Proof.

(i) *Finite family*: Suppose $\mathcal{F}=\{T_1,\dots,T_m\}$, and induct on $m\ge1$. The case $m=1$ holds by Theorem 5.3.2. Suppose $m>1$.
Choose $\lambda\in\operatorname{spec}(T_1)$ by Theorem 5.3.2, and set $\mathcal{U}:=E_\lambda(T_1)\ne\{\mathbf{0}\}$.
If $\mathbf{u}\in\mathcal{U}$ and $j\in\{2,\dots,m\}$, then $(T_1-\lambda I_\mathcal{V})T_j\mathbf{u}=T_j(T_1-\lambda I_\mathcal{V})\mathbf{u}=\mathbf{0}$ by commutation.
Thus $\mathcal{U}$ is invariant under $T_2,\dots,T_m$. The restrictions to $\mathcal{U}$ commute and form a nonempty family of cardinality at most $m-1$.
They have a common eigenvector $\mathbf{v}\in\mathcal{U}\setminus\{\mathbf{0}\}$ by induction, and $\mathbf{v}$ is an eigenvector of T_1 by $\mathbf{v}\in E_\lambda(T_1)$.
(ii) *Finite reduction*: Set $\mathcal{W}:=\operatorname{span}(\mathcal{F})$. This space is finite-dimensional by Theorem 3.4.5(ii).
If $\mathcal{W}=\{0\}$, then $(\forall T\in\mathcal{F})\,T=0$ by $\mathcal{F}\subseteq\mathcal{W}$. Thus any $\mathbf{v}\in\mathcal{V}\setminus\{\mathbf{0}\}$ is common with eigenvalues $\lambda_T=0$. Suppose $\mathcal{W}\ne\{0\}$.
Choose a basis $(R_1,\dots,R_q)$ of $\mathcal{W}$ by Corollary 1.3.14. Each R_j is a finite linear combination of members of $\mathcal{F}$.
The union of their finite supports is a finite nonempty set $\mathcal{F}_0\subseteq\mathcal{F}$ satisfying $\operatorname{span}(\mathcal{F}_0)=\mathcal{W}$.

(iii) *Spanning extension*: Suppose $\mathcal{W} \neq \{0\}$ and let $\mathcal{F}_0$ be as in part (ii).
By part (i), choose $\mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\}$ and $(\mu_T)_{T\in\mathcal{F}_0}$ satisfying $(\forall T \in \mathcal{F}_0)\, T\mathbf{v} = \mu_T \mathbf{v}$.
For $S \in \mathcal{F} \subseteq \mathcal{W}$, write $S = \sum_{T\in\mathcal{F}_0} a_T T$ and define $\lambda_S := \sum_{T\in\mathcal{F}_0} a_T \mu_T$.
Then $S\mathbf{v} = \lambda_S \mathbf{v}$, and λ_S is independent of the representation by $\mathbf{v} \neq \mathbf{0}$.

Structural Commentary: Finite induction finds a common eigenline; a finite spanning subfamily handles arbitrary $\mathcal{F}$.
Key Insight: Commutation preserves the first operator's chosen eigenspace. □

Theorem 5.4.14. *Simultaneous Schur Triangularization*
Let $n \geq 1$ and let $\emptyset \neq \mathcal{F} \subseteq \mathrm{Mat}(n,n,\mathbb{C})$ satisfy $(\forall A, B \in \mathcal{F})\, AB = BA$. The following hold:
(i) $(\exists$ *a unitary* $U \in \mathrm{Mat}(n,n,\mathbb{C}))$ *such that* $(\forall A \in \mathcal{F})\, U^*AU$ *is upper triangular.*
(ii) Suppose $\mathcal{F} \subseteq \mathrm{Mat}(n,n,\mathbb{R})$ *and* $(\forall A \in \mathcal{F})\ \mathrm{spec}(A) \subseteq \mathbb{R}$.
Then $(\exists$ *an orthogonal* $U \in \mathrm{Mat}(n,n,\mathbb{R}))$ *such that* $(\forall A \in \mathcal{F})\, U^tAU$ *is upper triangular.*

Proof. Proceed by strong induction on n. Both conclusions hold with $U = I_1$ when $n = 1$.
Suppose $n > 1$ and both conclusions hold in each smaller positive dimension.

(i) By Theorem 5.4.13, the operators on $\mathbb{C}^n$ have a common eigenvector.
Normalize it to $\mathbf{x}$ and extend it to a unitary matrix $V = [\mathbf{x}\ V_2]$ by Theorem 2.6.13(ii).
For $A \in \mathcal{F}$, write $M_A := V^*AV = \begin{bmatrix} \lambda_A & \mathbf{r}_A \\ 0 & \widehat{A} \end{bmatrix}$. The lower-left block vanishes by $A\mathbf{x} = \lambda_A \mathbf{x}$.
If $A, B \in \mathcal{F}$, then $M_AM_B = V^*ABV = V^*BAV = M_BM_A$, so $\widehat{A}\widehat{B} = \widehat{B}\widehat{A}$ by comparison of the lower-right blocks.
Thus $\widehat{\mathcal{F}} := \{\widehat{A} : A \in \mathcal{F}\}$ is nonempty and commuting.
By induction, a unitary W simultaneously upper triangularizes its members. Set $U := V(I_1 \oplus W)$.
The matrix U is unitary by Proposition 2.6.12(i)–(ii), and $(\forall A \in \mathcal{F})\, U^*AU$ is upper triangular.

(ii) Regard $\mathcal{F}$ as a commuting family on $\mathbb{C}^n$. A common eigenvector $\mathbf{z} \in \mathbb{C}^n \setminus \{\mathbf{0}\}$ exists by Theorem 5.4.13; fix it.
Fix $(\lambda_A)_{A\in\mathcal{F}}$ satisfying $(\forall A \in \mathcal{F})\, A\mathbf{z} = \lambda_A \mathbf{z}$, and write $\mathbf{z} = \mathbf{u} + i\mathbf{v}$.
The relation $(\forall A \in \mathcal{F})\, \lambda_A \in \mathrm{spec}(A) \subseteq \mathbb{R}$ holds by the eigenvector identities and spectral hypothesis.
Because each A is real, $A\mathbf{u} = \lambda_A \mathbf{u}$ and $A\mathbf{v} = \lambda_A \mathbf{v}$ by comparison of real and imaginary parts.
At least one of $\mathbf{u}, \mathbf{v}$ is nonzero, so a common real unit eigenvector $\mathbf{x}$ exists by normalization.
Extend $\mathbf{x}$ to a real orthogonal matrix $V = [\mathbf{x}\ V_2]$ by Theorem 2.6.13(ii).
For $A \in \mathcal{F}$, write $M_A := V^tAV = \begin{bmatrix} \lambda_A & \mathbf{r}_A \\ 0 & \widehat{A} \end{bmatrix}$. The lower-right blocks are real and commute by the calculation in part (i).
Fix $A \in \mathcal{F}$ and $\mu \in \mathrm{spec}(\widehat{A})$, and choose $\mathbf{y} \in \mathbb{C}^{n-1} \setminus \{\mathbf{0}\}$ satisfying $\widehat{A}\mathbf{y} = \mu\mathbf{y}$.
If $\mu = \lambda_A$, then $\mu \in \mathbb{R}$. If $\mu \neq \lambda_A$, set $c := \frac{\mathbf{r}_A\mathbf{y}}{\mu - \lambda_A}$ and $\mathbf{w} := (c, \mathbf{y})^t$.
Then $\mathbf{w} \neq \mathbf{0}$ and $M_A\mathbf{w} = (\mu c, \mu\mathbf{y})^t = \mu\mathbf{w}$. Since $V\mathbf{w} \neq \mathbf{0}$ by orthogonality of V, it is an eigenvector of A for μ.
Hence $\mu \in \mathbb{R}$ by the spectral hypothesis. Thus $(\forall A \in \mathcal{F})\ \mathrm{spec}(\widehat{A}) \subseteq \mathbb{R}$.
By induction, a real orthogonal W simultaneously upper triangularizes $\widehat{\mathcal{F}}$.
Then $U := V(I_1 \oplus W)$ is real orthogonal by Proposition 2.6.12(i)–(ii), and $(\forall A \in \mathcal{F})\, U^tAU$ is upper triangular.

Structural Commentary: A common eigenline creates the first block, and commutation descends to the compression.
Key Insight: Real spectra turn a complex common eigenvector into a real one. □

Figure 44 depicts the complex induction in Theorem 5.4.14.
A common eigenline creates the first block, and pairwise commutation passes to the lower-right blocks.
The theorem, rather than the diagram, owns the simultaneous triangularization conclusion.

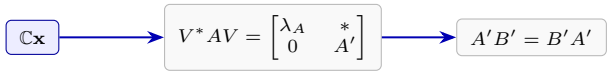

Figure 44: A shared eigenline determines a simultaneous first block; lower-right compressions remain commuting.

Corollary 5.4.15. *Eigenvalues of Sums and Products of Commuting Matrices*
Let $n \geq 1$ and let $A, B \in \mathrm{Mat}(n,n,\mathbb{C})$ satisfy $AB = BA$. Then $(\exists\, ((\lambda_i)_{i=1}^n, (\mu_i)_{i=1}^n) \in (\mathbb{C}^n)^2)$ such that the following hold:
(i) $\mathrm{spec}(A) = \{\lambda_1, \ldots, \lambda_n\}$ *and* $\mathrm{spec}(B) = \{\mu_1, \ldots, \mu_n\}$;
(ii) $\mathrm{spec}(A + B) = \{\lambda_i + \mu_i : i \in \{1, \ldots, n\}\}$;
(iii) $\mathrm{spec}(AB) = \{\lambda_i\mu_i : i \in \{1, \ldots, n\}\}$.

Proof. Choose a unitary U by Theorem 5.4.14(i). Set $T := U^*AU$, $R := U^*BU$, $\lambda_i := t_{ii}$, $\mu_i := r_{ii}$. Fix $M \in \mathrm{Mat}(n,n,\mathbb{C})$ and $\theta \in \mathbb{C}$.
If $\mathbf{x} \neq \mathbf{0}$, then $(U^*MU)\mathbf{x} = \theta\mathbf{x} \iff M(U\mathbf{x}) = \theta(U\mathbf{x})$ and $U\mathbf{x} \neq \mathbf{0}$ by unitarity of U. Hence $\mathrm{spec}(U^*MU) = \mathrm{spec}(M)$.

(i) The matrices T and R are upper triangular with diagonals $(\lambda_i)_{i=1}^n$ and $(\mu_i)_{i=1}^n$.
Their spectra are underlying sets of these lists by Proposition 5.3.19. Identities in part (i) hold by preceding similarity calculation.
(ii) The matrix $T + R = U^*(A + B)U$ is upper triangular with diagonal $(\lambda_i + \mu_i)_{i=1}^n$.
Its spectrum is the asserted set by Proposition 5.3.19. The identity in part (ii) holds by the preceding similarity calculation.
(iii) The matrix $TR = U^*ABU$ is upper triangular with diagonal $(\lambda_i\mu_i)_{i=1}^n$.
Its spectrum is the asserted set by Proposition 5.3.19. The identity in part (iii) holds by the preceding similarity calculation.

Structural Commentary: Common triangular coordinates reduce both spectra to diagonal arithmetic.
Key Insight: A common diagonal pairing controls both resulting spectra. □

6 Spectral Theorems and Operator Functions

6.1 Normal, Self-Adjoint, and Spectral Theorems

Structured spectral theory studies operators whose geometry and spectrum align.
This subsection derives orthonormal eigenbases and spectral resolutions from normality and self-adjointness.
All inner-product spaces below are finite-dimensional over $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$ unless stated otherwise.

Definition 6.1.1. *Normal Operator*

(i) An operator $T \in \mathcal{L}(\mathcal{V})$ is *normal* iff $T^*T = TT^*$.
(ii) For $n \geq 1$, a matrix $A \in \mathrm{Mat}(n, n, \mathbb{F})$ is *normal* iff $A^*A = AA^*$.

Theorem 6.1.2. *Normal Operators and Equal Adjoint Norms*
Let $T \in \mathcal{L}(\mathcal{V})$. Then T is normal iff $(\forall \mathbf{v} \in \mathcal{V})\ \|T\mathbf{v}\| = \|T^*\mathbf{v}\|$.

Proof. Set $C := T^*T - TT^*$. Then $C^* = C$ by Proposition 2.3.8(i)–(iii).
The identity $(\forall \mathbf{v} \in \mathcal{V})\ \langle C\mathbf{v}, \mathbf{v}\rangle = \|T\mathbf{v}\|^2 - \|T^*\mathbf{v}\|^2$ holds by the adjoint identity and Proposition 2.3.8(iii).
($\Rightarrow$) If T is normal, then $C = 0$ by Definition 6.1.1(i), so the quadratic identity implies the norm identity.
($\Leftarrow$) The norm identity implies $(\forall \mathbf{v} \in \mathcal{V})\ \langle C\mathbf{v}, \mathbf{v}\rangle = 0$. Hence $C = 0$ by Proposition 2.5.4, and T is normal by Definition 6.1.1(i).
Structural Commentary: The adjoint defect becomes a quadratic form and is recovered from its diagonal values.
Key Insight: Equal norm functions detect $T^*T - TT^* = 0$. □

Theorem 6.1.3. *Normal Operators Share Eigenvectors with Their Adjoints*
Let $T \in \mathcal{L}(\mathcal{V})$ be normal, let $\lambda \in \mathbb{F}$, and let $\mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\}$. If $T\mathbf{v} = \lambda\mathbf{v}$, then $T^*\mathbf{v} = \overline{\lambda}\mathbf{v}$.

Proof. Set $S := T - \lambda I_{\mathcal{V}}$. Then $S^* = T^* - \overline{\lambda} I_{\mathcal{V}}$ by Proposition 2.3.8(i),(iv).
The identity $S^*S - SS^* = T^*T - TT^* = 0$ holds by direct expansion and normality of T, so S is normal.
Since $S\mathbf{v} = \mathbf{0}$, $\|S^*\mathbf{v}\| = \|S\mathbf{v}\| = 0$ by Theorem 6.1.2. Thus $S^*\mathbf{v} = \mathbf{0}$ by positive definiteness, equivalently $T^*\mathbf{v} = \overline{\lambda}\mathbf{v}$.
Structural Commentary: Scalar shifting preserves normality, and the equal-norm criterion transfers the shifted kernel.
Key Insight: $\ker(T - \lambda I_{\mathcal{V}}) \subseteq \ker(T^* - \overline{\lambda} I_{\mathcal{V}})$. □

Figure 45 depicts the common eigenline in Theorem 6.1.3.

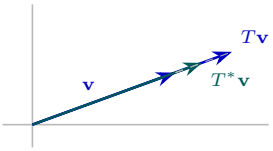

Figure 45: A normal operator and its adjoint preserve the same eigenline with conjugate eigenvalues.

Theorem 6.1.4. *Orthogonal Eigenvectors for Normal Operators*
Let $T \in \mathcal{L}(\mathcal{V})$ be normal and let $\alpha, \beta \in \mathrm{spec}(T)$ satisfy $\alpha \neq \beta$. Then $(\forall \mathbf{u} \in E_\alpha(T) \setminus \{\mathbf{0}\})(\forall \mathbf{v} \in E_\beta(T) \setminus \{\mathbf{0}\})\ \langle \mathbf{u}, \mathbf{v}\rangle = 0$.

Proof. Fix $\mathbf{u} \in E_\alpha(T) \setminus \{\mathbf{0}\}$ and $\mathbf{v} \in E_\beta(T) \setminus \{\mathbf{0}\}$. Then $T\mathbf{u} = \alpha\mathbf{u}$ by eigenspace membership and $T^*\mathbf{v} = \overline{\beta}\mathbf{v}$ by Theorem 6.1.3.
Hence $\alpha\langle \mathbf{u}, \mathbf{v}\rangle = \langle T\mathbf{u}, \mathbf{v}\rangle = \langle \mathbf{u}, T^*\mathbf{v}\rangle = \beta\langle \mathbf{u}, \mathbf{v}\rangle$, so $\langle \mathbf{u}, \mathbf{v}\rangle = 0$ by $\alpha \neq \beta$.
Structural Commentary: The adjoint eigenvalue transports T across the inner product and isolates $\alpha - \beta$.
Key Insight: $(\alpha - \beta)\langle \mathbf{u}, \mathbf{v}\rangle = 0$ forces orthogonality. □

Theorem 6.1.5. *Eigenvalues of Self-Adjoint Operators Are Real*
Let $T \in \mathcal{L}(\mathcal{V})$ be self-adjoint. Then $\mathrm{spec}(T) \subseteq \mathbb{R}$.

Proof. Fix $\lambda \in \mathrm{spec}(T)$ and $\mathbf{v} \in E_\lambda(T) \setminus \{\mathbf{0}\}$.
The identity $\lambda\|\mathbf{v}\|^2 = \langle T\mathbf{v}, \mathbf{v}\rangle = \langle \mathbf{v}, T\mathbf{v}\rangle = \overline{\lambda}\|\mathbf{v}\|^2$ holds by the eigenvector relation and $T = T^*$. Thus $\lambda = \overline{\lambda}$ by $\|\mathbf{v}\|^2 > 0$, so $\lambda \in \mathbb{R}$.
Structural Commentary: Self-adjointness compares an eigenvalue with its conjugate on a nonzero eigenvector.
Key Insight: $\|\mathbf{v}\|^2 > 0$ forces $\lambda = \overline{\lambda}$. □

Proposition 6.1.6. *Invertible Quadratic Expressions*
Let $T \in \mathcal{L}(\mathcal{V})$ be self-adjoint. If $b, c \in \mathbb{R}$ and $b^2 < 4c$, then $T^2 + bT + cI_{\mathcal{V}}$ is invertible.

Proof. Set $S := T^2 + bT + cI_{\mathcal{V}}$ and fix $\mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\}$. Set $x := \|T\mathbf{v}\|$, $y := \|\mathbf{v}\|$, and $a := \langle T\mathbf{v}, \mathbf{v}\rangle$.
The relations $a = \overline{a}$ and $\langle T^2\mathbf{v}, \mathbf{v}\rangle = x^2$ hold by self-adjointness, conjugate symmetry, and the adjoint identity, so $a \in \mathbb{R}$.
The bound $|a| \leq xy$ holds by Theorem 1.1.13(i), and $ba \geq -|b|\,|a| \geq -|b|\,xy$ by $a, b \in \mathbb{R}$.
Consequently, $\langle S\mathbf{v}, \mathbf{v}\rangle \geq x^2 - |b|\,xy + cy^2 = \left(x - \frac{|b|}{2}y\right)^2 + \left(c - \frac{b^2}{4}\right)y^2 > 0$ by $c - \frac{b^2}{4} > 0$ and $y > 0$.
Thus $S\mathbf{v} \neq \mathbf{0}$. Since $\mathbf{v}$ was arbitrary, S is injective and hence invertible by Theorem 1.7.7(ii),(i).
Structural Commentary: The quadratic form of S becomes a completed square in $\|T\mathbf{v}\|$ and $\|\mathbf{v}\|$.
Key Insight: The negative discriminant makes the completed square strictly positive. □

Lemma 6.1.7. *Self-Adjoint Operators Have Eigenvalues*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be a finite-dimensional real inner-product space. Every self-adjoint $T \in \mathcal{L}(\mathcal{V})$ has an eigenvalue.

Proof.

(i) *Hermitian Extension*: For $\mathbf{z} = \mathbf{u} + i\mathbf{y}$ and $\mathbf{w} = \mathbf{x} + i\mathbf{y}$ in $\mathcal{V}_{\mathbb{C}}$, define $B(\mathbf{z}, \mathbf{w}) := \langle \mathbf{u}, \mathbf{x}\rangle_{\mathcal{V}} + \langle \mathbf{v}, \mathbf{y}\rangle_{\mathcal{V}} + i\big(\langle \mathbf{v}, \mathbf{x}\rangle_{\mathcal{V}} - \langle \mathbf{u}, \mathbf{y}\rangle_{\mathcal{V}}\big)$.
Additivity and real homogeneity in the first slot hold componentwise, while $B(i\mathbf{z}, \mathbf{w}) = iB(\mathbf{z}, \mathbf{w})$ by $i\mathbf{z} = -\mathbf{v} + i\mathbf{u}$.
Thus the first slot is complex-linear, and $B(\mathbf{w}, \mathbf{z}) = \overline{B(\mathbf{z}, \mathbf{w})}$ by symmetry of the real inner product.
$B(\mathbf{z}, \mathbf{z}) = \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2 \geq 0$ holds by direct substitution, with equality iff $\mathbf{z} = \mathbf{0}$. Hence B is complex inner product on $\mathcal{V}_{\mathbb{C}}$.
This space is finite-dimensional over $\mathbb{C}$ by Proposition 5.3.7(i)–(iii), and it is nonzero by the hypothesis and Proposition 5.3.9(iii).
(ii) *Adjoint Preservation*: The operator $T_{\mathbb{C}}$ is complex-linear by Proposition 5.3.11(i). Fix $\mathbf{z} = \mathbf{u} + i\mathbf{v}$ and $\mathbf{w} = \mathbf{x} + i\mathbf{y}$ in $\mathcal{V}_{\mathbb{C}}$.
Identity $B(T_{\mathbb{C}}\mathbf{z}, \mathbf{w}) = B(\mathbf{z}, T_{\mathbb{C}}\mathbf{w})$ holds by self-adjointness of T in each real component. Thus $T_{\mathbb{C}}$ self-adjoint by adjoint definition.
(iii) *Spectral Descent*: Fix $\lambda \in \mathrm{spec}(T_{\mathbb{C}})$ by Theorem 5.3.2. Then $\lambda \in \mathbb{R}$ by Theorem 6.1.5, and $\lambda \in \mathrm{spec}(T)$ by Proposition 5.3.12.

Structural Commentary: The Hermitian extension preserves the adjoint relation before complex eigenvalue existence descends.
Key Insight: Self-adjoint complexification forces a real eigenvalue shared by T. □

Proposition 6.1.8. *Self-Adjoint Operators and Invariant Subspaces*
Let $T \in \mathcal{L}(\mathcal{V})$ be self-adjoint, and let $\mathcal{U} \in \mathrm{Inv}(T)$. Then:
(i) $\mathcal{U}^\perp$ is invariant under T;
(ii) $T|_{\mathcal{U}} \in \mathcal{L}(\mathcal{U})$ is self-adjoint;
(iii) $T|_{\mathcal{U}^\perp} \in \mathcal{L}(\mathcal{U}^\perp)$ is self-adjoint.

Proof.
(i) The subspace $\mathcal{U}^\perp$ is invariant under $T^* = T$ by the hypothesis and Theorem 5.2.7(i).
(ii) Pair $(\mathcal{U},\mathcal{U}^\perp)$ reduces T by (i), hypothesis, Theorem 2.1.5, Definition 5.2.6. Hence $(T|_{\mathcal{U}})^* = (T^*)|_{\mathcal{U}} = T|_{\mathcal{U}}$ by Theorem 5.2.7(iii).
(iii) The restriction $T|_{\mathcal{U}^\perp}$ is self-adjoint by (ii) with the invariant subspace $\mathcal{U}^\perp$ from (i).
Structural Commentary: Adjoint-complement invariance reduces T and transfers self-adjointness to both restrictions.
Key Insight: $T = T^*$ preserves both summands of $\mathcal{U} \oplus \mathcal{U}^\perp$. □

Theorem 6.1.9. *Schur Triangularization*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space and let $T \in \mathcal{L}(\mathcal{V})$.
The space $\mathcal{V}$ has an orthonormal basis γ for which $[T]_{\gamma\leftarrow\gamma}$ is upper triangular.

Proof. If $\mathcal{V} = \{\mathbf{0}\}$, the empty orthonormal basis has the required property. Assume $n := \dim(\mathcal{V}) \geq 1$.
(i) *Coordinate Reduction*: Fix an orthonormal basis β by Corollary 1.3.11 and set $A := [T]_{\beta\leftarrow\beta}$.
(ii) *Unitary Triangularization*: Fix a unitary U with U^*AU upper triangular by Theorem 5.4.14(i) for $\{A\}$.
(iii) *Basis Transport*: Let γ be the ordered list whose β-coordinate columns are the columns of U.
These columns form an orthonormal basis of $\mathbb{C}^n$ by Theorems 2.6.8(i),(ii),(vi) and 3.4.1.
The coordinate map is an isomorphism by Proposition 3.2.2(iii), so γ is a basis by Proposition 1.7.8.
The basis γ is orthonormal by Theorem 1.4.7(ii).
(iv) *Matrix Identification*: The identity $C_{\beta\leftarrow\gamma} = U$ holds by Definition 3.5.1.
The identity $C_{\gamma\leftarrow\beta} = U^{-1} = U^*$ holds by Theorems 3.5.2(i) and 2.6.8(vi). Thus $[T]_{\gamma\leftarrow\gamma} = U^*AU$ by Theorem 3.5.3, so this matrix is upper triangular.
Structural Commentary: Unitary matrix triangularization is transported through coordinate columns to an orthonormal basis.
Key Insight: $C_{\beta\leftarrow\gamma} = U$ converts unitary similarity into basis change. □

Lemma 6.1.10. *Upper-Triangular Normal Matrices Are Diagonal*
Let $n \geq 1$. If $A \in \mathrm{Mat}(n, n, \mathbb{C})$ is upper triangular and normal, then A is diagonal.

Proof. Induct on n. If $n = 1$, then A is diagonal. Suppose $n \geq 2$ and the claim holds in dimension $n - 1$.
The $(1,1)$ entries of $A^*A = AA^*$ are $|a_{11}|^2$ and $|a_{11}|^2 + \sum_{j=2}^{n} |a_{1j}|^2$, respectively.
Hence $(\forall j \in \{2, \ldots, n\})\, a_{1j} = 0$, so $A = a_{11} \oplus B$ with B upper triangular.
The identity $B^*B = BB^*$ holds by comparison of the lower-right blocks, so B is normal.
Thus B is diagonal by the induction hypothesis, and A is diagonal.
Structural Commentary: The $(1,1)$ identity removes the first-row tail and exposes a smaller normal block.
Key Insight: Once $a_{12}, \ldots, a_{1n}$ vanish, block normality closes the induction. □

Theorem 6.1.11. *Complex Spectral Theorem*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space and let $T \in \mathcal{L}(\mathcal{V})$. The following are equivalent:
(i) T is normal;
(ii) $\mathcal{V}$ has an orthonormal basis consisting of eigenvectors of T;
(iii) T has a diagonal matrix in an orthonormal basis of $\mathcal{V}$.

Proof. If $\mathcal{V} = \{\mathbf{0}\}$, the unique operator is normal and the empty basis is an orthonormal eigenbasis with an empty diagonal matrix.
Assume $n := \dim(\mathcal{V}) \geq 1$.
(*i*) $\Rightarrow$ (*ii*) Fix an orthonormal basis γ such that $A := [T]_{\gamma\leftarrow\gamma}$ is upper triangular by Theorem 6.1.9.
The identities $[T^*]_{\gamma\leftarrow\gamma} = A^*$, $[T^*T]_{\gamma\leftarrow\gamma} = A^*A$, and $[TT^*]_{\gamma\leftarrow\gamma} = AA^*$ hold by Theorem 2.3.7 and Proposition 3.4.4.
Thus $A^*A = AA^*$ by normality of T, so A is normal by Definition 6.1.1(ii).
The matrix A is diagonal by Lemma 6.1.10; hence γ consists of eigenvectors of T.
(*ii*) $\Rightarrow$ (*iii*) The matrix of T in an orthonormal eigenbasis is diagonal by Definition 3.2.3.
(*iii*) $\Rightarrow$ (*i*) Fix an orthonormal basis γ in which $A := [T]_{\gamma\leftarrow\gamma}$ is diagonal. Then $[T^*]_{\gamma\leftarrow\gamma} = A^*$ by Theorem 2.3.7.
Since $AA^* = A^*A$, $[TT^*]_{\gamma\leftarrow\gamma} = [T^*T]_{\gamma\leftarrow\gamma}$ by Proposition 3.4.4.
Therefore $TT^* = T^*T$ by Theorem 3.4.5(i), and T is normal by Definition 6.1.1(i).
Structural Commentary: Schur form reduces normality to the triangular lemma; diagonal coordinates verify the converse.
Key Insight: An upper-triangular normal matrix has no off-diagonal entries. □

Figure 46 depicts the forward mechanism in Theorem 6.1.11.

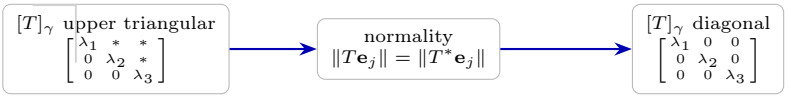

Figure 46: Normality turns Schur triangular form into diagonal form by forcing row tails to vanish.

Theorem 6.1.12. *Real Spectral Theorem*
Let $\mathcal{V}$ be a finite-dimensional real inner-product space and let $T \in \mathcal{L}(\mathcal{V})$. The following are equivalent:
(i) T is self-adjoint;
(ii) $\mathcal{V}$ has an orthonormal basis consisting of eigenvectors of T;
(iii) T has a diagonal matrix in an orthonormal basis of $\mathcal{V}$.

Proof.

(*i*) $\Rightarrow$ (*ii*) Suppose $T = T^*$ and induct on $n := \dim(\mathcal{V})$. For $n = 0$, the empty basis suffices. For $n = 1$, fix $\mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\}$.
Then $\operatorname{span}(\mathbf{v}) = \mathcal{V} \in \operatorname{Inv}(T)$, so $\mathbf{v}$ is an eigenvector by Proposition 5.2.4. Hence $\frac{\mathbf{v}}{\|\mathbf{v}\|}$ is an orthonormal eigenbasis.
Suppose $n \geq 2$ and assume the implication in dimension $n-1$.
Fix $\lambda \in \operatorname{spec}(T)$ by Lemma 6.1.7, choose a unit $\mathbf{u} \in E_\lambda(T)$ by normalization, and set $\mathcal{U} := \operatorname{span}(\mathbf{u})$.
Then $\mathcal{U} \in \operatorname{Inv}(T)$ by Proposition 5.2.4, while $\mathcal{U}^\perp \in \operatorname{Inv}(T)$ and $T|_{\mathcal{U}^\perp}$ is self-adjoint by Proposition 6.1.8(i),(iii).
The identity $\dim(\mathcal{U}^\perp) = n - 1$ holds by Corollary 2.1.7, so $\mathcal{U}^\perp$ has an orthonormal eigenbasis by the induction hypothesis.
Adjoining $\mathbf{u}$ forms an orthonormal eigenbasis of $\mathcal{V} = \mathcal{U} \oplus \mathcal{U}^\perp$ by Theorem 2.1.5.

(*ii*) $\Rightarrow$ (*iii*) The matrix of T in an orthonormal eigenbasis is diagonal by Definition 3.2.3.

(*iii*) $\Rightarrow$ (*i*) Fix an orthonormal basis γ in which $A := [T]_{\gamma \leftarrow \gamma}$ is real diagonal. Then $[T^*]_{\gamma \leftarrow \gamma} = A^t = A$ by Theorem 2.3.7.
If $\mathcal{V} \neq \{\mathbf{0}\}$, then $T^* = T$ by Theorem 3.4.5(i).
If $\mathcal{V} = \{\mathbf{0}\}$, then T and T^* are both the unique operator on the zero space, so again $T^* = T$.

Structural Commentary: Real eigenvalue existence starts induction on the invariant self-adjoint orthogonal complement.
Key Insight: Removing one eigenline preserves self-adjointness on its complement. □

Theorem 6.1.13. *Spectral Resolution of a Normal Operator*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space, $d \geq 1$, let $\mu_1, \dots, \mu_d \in \mathbb{C}$ be distinct. For $T \in \mathcal{L}(\mathcal{V})$, the following hold:

(i) T is normal with $\operatorname{spec}(T) \subseteq \{\mu_1, \dots, \mu_d\}$ iff $(\exists (P_j)_{j=1}^d \in \mathcal{L}(\mathcal{V})^d)$ such that $(\forall j \in \{1, \dots, d\})\, P_j^* = P_j = P_j^2$,
$(\forall i, j \in \{1, \dots, d\})\, [i \neq j \Longrightarrow P_i P_j = 0]$, $\sum_{j=1}^d P_j = I_{\mathcal{V}}$, and $T = \sum_{j=1}^d \mu_j P_j$.

(ii) Every family $(P_1, \dots, P_d)$ satisfying the right side of (i) obeys $(\forall j \in \{1, \dots, d\})\, \operatorname{range}(P_j) = E_{\mu_j}(T)$.

Proof.

(*i*) ($\Rightarrow$) Fix an orthonormal eigenbasis of T by Theorem 6.1.11(i),(ii).
Decomposition $\mathcal{V} = \bigoplus_{j=1}^d E_{\mu_j}(T)$ holds by grouping basis by eigenvalue and assigning the zero subspace to absent eigenvalues.
Its summands are pairwise orthogonal by Theorem 6.1.4.
Set $P_j := P_{E_{\mu_j}(T)}$ by Definition 2.2.2. Then $(\forall j \in \{1, \dots, d\})\, \operatorname{range}(P_j) = E_{\mu_j}(T)$ by Proposition 2.2.3(iv).
Thus $(\forall j \in \{1, \dots, d\})\, P_j^* = P_j = P_j^2$ by Theorem 2.5.6.
Fix $\mathbf{x} \in \mathcal{V}$ and write $\mathbf{x} = \sum_{j=1}^d \mathbf{x}_j$ with $(\forall j \in \{1, \dots, d\})\, \mathbf{x}_j \in E_{\mu_j}(T)$. Then $(\forall j \in \{1, \dots, d\})\, P_j \mathbf{x} = \mathbf{x}_j$.
Consequently, $(\forall i, j \in \{1, \dots, d\})\, [i \neq j \Longrightarrow P_i P_j \mathbf{x} = \mathbf{0}]$ and $\sum_{j=1}^d P_j \mathbf{x} = \mathbf{x}$.
The identity $T\mathbf{x} = \sum_{j=1}^d \mu_j \mathbf{x}_j = \sum_{j=1}^d \mu_j P_j \mathbf{x}$ holds by $\mathbf{x}_j \in E_{\mu_j}(T)$. Since $\mathbf{x}$ was arbitrary, the required operator identities hold.

(*i*) ($\Leftarrow$) Fix a family satisfying the right side of (i).
The identities $T^* = \sum_{j=1}^d \overline{\mu_j} P_j$ and $T^* T = T T^* = \sum_{j=1}^d |\mu_j|^2 P_j$ hold by Proposition 2.3.8(i) and the product relations.
Thus T is normal by Definition 6.1.1(i). Fix $\lambda \in \operatorname{spec}(T)$ and $\mathbf{x} \in E_\lambda(T) \setminus \{\mathbf{0}\}$.
Then $\mathbf{0} = (T - \lambda I_{\mathcal{V}})\mathbf{x} = \sum_{j=1}^d (\mu_j - \lambda) P_j \mathbf{x}$. If $i \neq j$, then $\langle P_i \mathbf{x}, P_j \mathbf{x} \rangle = \langle \mathbf{x}, P_i P_j \mathbf{x} \rangle = 0$ by self-adjointness and pairwise annihilation.
Hence $0 = \sum_{j=1}^d |\mu_j - \lambda|^2 \|P_j \mathbf{x}\|^2$. Since $\sum_{j=1}^d P_j \mathbf{x} = \mathbf{x} \neq \mathbf{0}$, $(\exists k \in \{1, \dots, d\})\, P_k \mathbf{x} \neq \mathbf{0}$.
$\lambda = \mu_k$ by the nonnegative sum and $P_k \mathbf{x} \neq \mathbf{0}$, so $\operatorname{spec}(T) \subseteq \{\mu_1, \dots, \mu_d\}$.

(*ii*) Fix a family satisfying the right side of (i), $j \in \{1, \dots, d\}$, and $\mathbf{x} \in \mathcal{V}$. Then $\mathbf{x} = \sum_{i=1}^d P_i \mathbf{x}$ and $(T - \mu_j I_{\mathcal{V}})\mathbf{x} = \sum_{i \neq j} (\mu_i - \mu_j) P_i \mathbf{x}$.
The vectors $P_i \mathbf{x}$ are pairwise orthogonal by self-adjointness and pairwise annihilation, so $\|(T - \mu_j I_{\mathcal{V}})\mathbf{x}\|^2 = \sum_{i \neq j} |\mu_i - \mu_j|^2 \|P_i \mathbf{x}\|^2$.
The equivalence $\mathbf{x} \in E_{\mu_j}(T) \Longleftrightarrow (\forall i \neq j)\, P_i \mathbf{x} = \mathbf{0} \Longleftrightarrow \mathbf{x} = P_j \mathbf{x}$ holds by distinctness and $\sum_{i=1}^d P_i = I_{\mathcal{V}}$.
The equivalence $\mathbf{x} = P_j \mathbf{x} \Longleftrightarrow \mathbf{x} \in \operatorname{range}(P_j)$ holds by $P_j^2 = P_j$.

Structural Commentary: Eigenspaces construct the projections; weighted norms recover normality, spectrum, and ranges.
Key Insight: The weighted norm identity separates every spectral coordinate. □

Figure 47 depicts the eigenspace resolution in Theorem 6.1.13.

Figure 47: Pairwise orthogonal spectral projections resolve $I_{\mathcal{V}}$ and reconstruct T by eigenvalue weights.

Perspective 6.1.14. *Spectral Resolutions Are Orthogonal Resolutions*
Part (ii) of Theorem 6.1.13 identifies $\operatorname{range}(P_j) = E_{\mu_j}(T)$.
Together with Theorem 2.5.6, this makes P_j the orthogonal projection onto $E_{\mu_j}(T)$.
Thus a spectral resolution records the orthogonal eigenspace decomposition without choosing bases in its summands. This viewpoint is confined here to finite-dimensional normal operators.

Corollary 6.1.15. *Functional Calculus from Spectral Resolution*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space, let $d \geq 1$, and let $\mu_1, \dots, \mu_d \in \mathbb{C}$ be distinct.
Let $P_1, \dots, P_d \in \mathcal{L}(\mathcal{V})$ be orthogonal projections satisfying $(\forall i, j \in \{1, \dots, d\})\,[i \neq j \implies P_i P_j = 0]$, $\sum_{j=1}^{d} P_j = I_{\mathcal{V}}$; $T := \sum_{j=1}^{d} \mu_j P_j$. Then:

(i) $(\forall f \in \mathbb{C}[z])\, f(T) = \sum_{j=1}^{d} f(\mu_j) P_j$;
(ii) $(\forall j \in \{1, \dots, d\})(\exists p_j \in \mathbb{C}[z])\, p_j(T) = P_j$.

Proof. Each P_j is idempotent by Theorem 2.5.6.

(i) We prove $(\forall m \in \mathbb{Z}_{\geq 0})\, T^m = \sum_{j=1}^{d} \mu_j^m P_j$ by induction. The case $m = 0$ is $I_{\mathcal{V}} = \sum_{j=1}^{d} P_j$.

If the identity holds at m, then $T^{m+1} = \sum_{i,j=1}^{d} \mu_i^m \mu_j P_i P_j = \sum_{j=1}^{d} \mu_j^{m+1} P_j$ by the product relations.

Thus the power identity holds by induction. For $f(z) = \sum_{m=0}^{r} a_m z^m$, $f(T) = \sum_{m=0}^{r} a_m \sum_{j=1}^{d} \mu_j^m P_j = \sum_{j=1}^{d} f(\mu_j) P_j$.

(ii) Fix $j \in \{1, \dots, d\}$ and define $p_j(z) := \prod_{1 \leq i \leq d,\ i \neq j} \frac{z - \mu_i}{\mu_j - \mu_i}$, with the empty product interpreted as 1.

Then $p_j(\mu_i) = \delta_{ij}$ by distinctness of the μ_i. Hence $p_j(T) = \sum_{i=1}^{d} \delta_{ij} P_i = P_j$ by part (i).

Structural Commentary: Projector multiplication determines all powers; Lagrange interpolation then isolates each projection.
Key Insight: $p_j(\mu_i) = \delta_{ij}$ selects exactly P_j. □

6.2 Normal Operator Consequences

All inner-product spaces in this subsection are finite-dimensional over the stated field.

Perspective 6.2.1. *Normal Means Diagonal in Orthogonal Coordinates*
Theorem 6.1.11 identifies complex normality with orthonormal diagonal form.
Thus normality is the coordinate-free form of orthogonal diagonalizability.
Over $\mathbb{R}$, invariant planes replace the missing nonreal eigenvectors.

Proposition 6.2.2. *Basic Spectral Properties of Normal Operators*
Let $\mathcal{V}$ be a complex inner-product space, $T \in \mathcal{L}(\mathcal{V})$ be normal, and $p \in \mathbb{C}[z]$.

(i) $p(T)$ *is normal and commutes with* T.
(ii) T^* *is normal and* $(\forall \lambda \in \mathbb{C})\ E_\lambda(T) = E_{\overline{\lambda}}(T^*)$.
(iii) $\ker T = \ker T^*$ *and* $\operatorname{range}(T) = \operatorname{range}(T^*)$.

Proof. Set $n := \dim(\mathcal{V})$. By Theorem 6.1.11(i),(ii), fix an orthonormal basis $(\mathbf{e}_j)_{j=1}^n$ satisfying $(\forall j \in J_n)\, T\mathbf{e}_j = \mu_j \mathbf{e}_j$.

(i) $(\forall j \in J_n)\, p(T)\mathbf{e}_j = p(\mu_j)\mathbf{e}_j$ by polynomial evaluation. The operator $p(T)$ is normal by Theorem 6.1.11(iii),(i).
The identity $Tp(T) = p(T)T$ holds by Proposition 1.1.6.

(ii) $(\forall j \in J_n)\, T^*\mathbf{e}_j = \overline{\mu_j}\mathbf{e}_j$ by Theorem 6.1.3. Thus T^* is normal by Theorem 6.1.11(iii),(i).
For $\lambda \in \mathbb{C}$, $E_\lambda(T) \subseteq E_{\overline{\lambda}}(T^*)$ by Theorem 6.1.3.
The reverse inclusion holds by the same theorem for T^* and $(T^*)^* = T$ by Proposition 2.3.8(iii); hence equality.

(iii) $\ker T = E_0(T) = E_0(T^*) = \ker T^*$ by (ii).
$\operatorname{range}(T) = \operatorname{span}\{\mathbf{e}_j : \mu_j \neq 0\} = \operatorname{range}(T^*)$ by the common eigenbasis and $\mu_j \neq 0 \iff \overline{\mu_j} \neq 0$.

Structural Commentary: The spectral theorem transfers polynomial, adjoint, kernel, and range claims to one diagonal basis.
Key Insight: Adjunction conjugates eigenvalues while preserving the zero eigenspace. □

Lemma 6.2.3. *Adjoints of Normal Matrices as One Polynomial*
Let $k \in \mathbb{Z}_{\geq 1}$ and $(n_j)_{j=1}^k \in \mathbb{Z}_{\geq 1}^k$. Let $(A_j)_{j=1}^k$ satisfy $(\forall j \in J_k)\,[A_j \in \operatorname{Mat}(n_j, n_j, \mathbb{C}) \wedge A_j^* A_j = A_j A_j^*]$.
Then $(\exists p \in \mathbb{C}[z])(\forall j \in J_k)\, p(A_j) = A_j^*$.

Proof.

(i) *Spectral Set*: Set $\Omega := \bigcup_{j=1}^{k} \operatorname{spec}(A_j)$. By Theorem 5.3.2 and Corollary 5.1.6, $(\forall j \in J_k)\, 1 \leq \#\operatorname{spec}(A_j) \leq n_j$; hence $0 < \#\Omega < \infty$.

(ii) *Interpolation*: Define $p(z) := \sum_{\lambda \in \Omega} \overline{\lambda} \prod_{\nu \in \Omega \setminus \{\lambda\}} \frac{z - \nu}{\lambda - \nu}$. Then $(\forall \lambda \in \Omega)\, p(\lambda) = \overline{\lambda}$ by direct evaluation of the Lagrange factors.

(iii) *Spectral Evaluation*: Fix $j \in J_k$. The matrix A_j induces a normal operator on $\mathbb{C}^{n_j}$ by Theorem 2.3.7 and Proposition 3.4.4.
Fix $A_j = \sum_{\mu \in \operatorname{spec}(A_j)} \mu P_{j,\mu}$ by Theorem 6.1.13(i). By Corollary 6.1.15 and the interpolation identity, $p(A_j) = \sum_{\mu \in \operatorname{spec}(A_j)} \overline{\mu} P_{j,\mu}$.
By Proposition 2.3.8(i) and Theorem 2.5.6, $A_j^* = \sum_{\mu \in \operatorname{spec}(A_j)} \overline{\mu} P_{j,\mu}$. Thus $(\forall j \in J_k)\, p(A_j) = A_j^*$.

Structural Commentary: Spectral union and Lagrange interpolation precede evaluation on each normal matrix.
Key Insight: A finite spectral union admits one conjugating polynomial. □

Theorem 6.2.4. *Fuglede–Putnam Theorem*
Let $m, n \geq 1$, and let $A \in \operatorname{Mat}(m, m, \mathbb{C})$ and $B \in \operatorname{Mat}(n, n, \mathbb{C})$ be normal. Let $X \in \operatorname{Mat}(m, n, \mathbb{C})$. Then $AX = XB \iff A^*X = XB^*$.

Proof.

($\Rightarrow$) Assume $AX = XB$. Then $(\forall r \in \mathbb{Z}_{\geq 0})\, A^r X = XB^r$ by induction, so $(\forall p \in \mathbb{C}[z])\, p(A)X = Xp(B)$ by linearity.
Fix p with $p(A) = A^*$ and $p(B) = B^*$ by Lemma 6.2.3. Then $A^*X = p(A)X = Xp(B) = XB^*$.

($\Leftarrow$) Assume $A^*X = XB^*$. The matrices A^* and B^* are normal by $(A^*)^*A^* = AA^* = A^*A = A^*(A^*)^*$ and its analogue for B^*.
Thus $(\forall q \in \mathbb{C}[z])\, q(A^*)X = Xq(B^*)$ by induction on powers and linearity.
Fix q with $q(A^*) = A$ and $q(B^*) = B$ by Lemma 6.2.3 and Proposition 2.3.8(iii). Then $AX = q(A^*)X = Xq(B^*) = XB$.

Structural Commentary: Polynomial propagation and common interpolation form symmetric directional arguments.
Key Insight: Normal adjoints are polynomial functions of their matrices. □

Computation Method 6.2.5. *Finding a Spectral Decomposition of a Normal Matrix*
Let $n \geq 1$ and let $A \in \mathrm{Mat}(n, n, \mathbb{C})$ be normal. Its eigenspaces span $\mathbb{C}^n$ by Theorem 6.1.11(i),(ii).
Distinct eigenspaces are orthogonal by Theorem 6.1.4. The output is a unitary diagonalization $A = U\Lambda U^*$.

i. Find the distinct eigenvalues $\mu_1, \ldots, \mu_d$.
ii. Compute $(E_{\mu_j}(A))_{j=1}^d$ by solving $(A - \mu_j I_n)\mathbf{x} = 0$ for $j \in J_d$.
iii. Orthonormalize bases of $(E_{\mu_j}(A))_{j=1}^d$.
iv. Concatenate these bases as the columns of U, and set $\Lambda := U^*AU$.
v. Verify $U^*U = UU^* = I_n$ and $AU = U\Lambda$. Check that the diagonal of Λ repeats μ_j exactly $\dim E_{\mu_j}(A)$ times for $j \in J_d$.

Theorem 6.2.6. *Spectral Classification of Normal Operators*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space and let $T \in \mathcal{L}(\mathcal{V})$ be normal.

(i) T is unitary if and only if $(\forall \lambda \in \mathrm{spec}(T))\ |\lambda| = 1$.
(ii) T is self-adjoint if and only if $\mathrm{spec}(T) \subseteq \mathbb{R}$.
(iii) T is an orthogonal projection if and only if $\mathrm{spec}(T) \subseteq \{0, 1\}$.
(iv) $T^* = -T$ if and only if $\mathrm{spec}(T) \subseteq i\mathbb{R}$.

Proof. If $\mathcal{V} = \{\mathbf{0}\}$, its unique operator satisfies all four operator conditions.
Its empty spectrum satisfies all four spectral conditions. Assume $\mathcal{V} \neq \{\mathbf{0}\}$.

List the distinct eigenvalues as $\mu_1, \ldots, \mu_d$, and fix $T = \sum_{j=1}^d \mu_j P_j$ by Theorem 6.1.13(i).

The identity $I_\mathcal{V} = \sum_{j=1}^d P_j$ holds by Theorem 6.1.13(i). The formula $T^* = \sum_{j=1}^d \overline{\mu_j} P_j$ holds by Proposition 2.3.8(i) and Theorem 2.5.6.

The formulas $T^*T = \sum_{j=1}^d |\mu_j|^2 P_j$ and $T^2 = \sum_{j=1}^d \mu_j^2 P_j$ hold by direct multiplication.

To verify linear independence, suppose $\sum_{j=1}^d \alpha_j P_j = 0$ and fix $k \in J_d$.

Fix $\mathbf{0} \neq \mathbf{x} \in E_{\mu_k}(T) = \mathrm{range}(P_k)$ by $\mu_k \in \mathrm{spec}(T)$ and Theorem 6.1.13(ii).

Then $0 = \sum_{j=1}^d \alpha_j P_j \mathbf{x} = \alpha_k \mathbf{x}$, so $\alpha_k = 0$. Thus $(P_j)_{j=1}^d$ is linearly independent.

(i) ($\Rightarrow$) If T is unitary, then $T^*T = I_\mathcal{V}$ by unitarity.
Hence $(\forall j \in J_d)\ |\mu_j|^2 = 1$ by linear independence of the P_j, and therefore $(\forall j \in J_d)\ |\mu_j| = 1$.

(i) ($\Leftarrow$) If $(\forall j \in J_d)\ |\mu_j| = 1$, then $T^*T = TT^* = \sum_{j=1}^d P_j = I_\mathcal{V}$. Thus T is unitary by the definition of unitarity.

(ii) ($\Rightarrow$) If $T = T^*$, then $\sum_{j=1}^d (\mu_j - \overline{\mu_j})P_j = 0$. Hence $(\forall j \in J_d)\, \mu_j = \overline{\mu_j}$ by linear independence of the P_j, so $\mathrm{spec}(T) \subseteq \mathbb{R}$.

(ii) ($\Leftarrow$) If $\mathrm{spec}(T) \subseteq \mathbb{R}$, then $T^* = \sum_{j=1}^d \overline{\mu_j} P_j = \sum_{j=1}^d \mu_j P_j = T$.

(iii) ($\Rightarrow$) If T is an orthogonal projection, then $T^* = T$ and $T^2 = T$ by Theorem 2.5.6.
Hence $(\forall j \in J_d)\, \mu_j = \overline{\mu_j}$ and $\mu_j^2 = \mu_j$ by linear independence of the P_j. Therefore $\mathrm{spec}(T) \subseteq \{0, 1\}$.

(iii) ($\Leftarrow$) If $\mathrm{spec}(T) \subseteq \{0, 1\}$, then $(\forall j \in J_d)\, \overline{\mu_j} = \mu_j^2 = \mu_j$. Hence $T^* = T^2 = T$ by the spectral formulas.
Thus T is an orthogonal projection by Theorem 2.5.6.

(iv) ($\Rightarrow$) If $T^* = -T$, then $\sum_{j=1}^d (\overline{\mu_j} + \mu_j)P_j = 0$. Hence $(\forall j \in J_d)\, \overline{\mu_j} = -\mu_j$ by linear independence of the P_j, so $\mathrm{spec}(T) \subseteq i\mathbb{R}$.

(iv) ($\Leftarrow$) If $\mathrm{spec}(T) \subseteq i\mathbb{R}$, then $(\forall j \in J_d)\, \overline{\mu_j} = -\mu_j$. Consequently, $T^* = \sum_{j=1}^d \overline{\mu_j} P_j = -\sum_{j=1}^d \mu_j P_j = -T$.

Structural Commentary: One spectral resolution converts four operator identities into coefficient comparisons.
Key Insight: Orthogonal spectral projections are linearly independent. □

Proposition 6.2.7. *Cartesian Decomposition and Normality*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space and let $T \in \mathcal{L}(\mathcal{V})$.

(i) The operator T has a unique decomposition $T = H + iK$ with self-adjoint $H, K \in \mathcal{L}(\mathcal{V})$.
Its terms are $H = \frac{1}{2}(T + T^*)$ and $K = \frac{1}{2i}(T - T^*)$.
(ii) For these operators, T is normal if and only if $HK = KH$.

Proof.

(i) Set $H := \frac{1}{2}(T + T^*)$ and $K := \frac{1}{2i}(T - T^*)$. Then $H^* = H$, $K^* = K$, and $T = H + iK$ by Proposition 2.3.8(i),(iii).
If $T = X + iY$ for self-adjoint X, Y, then $T^* = X - iY$ by Proposition 2.3.8(i).
Consequently, $X = \frac{1}{2}(T + T^*) = H$ and $Y = \frac{1}{2i}(T - T^*) = K$.
(ii) ($\Rightarrow$) Suppose T is normal.
Then $HK = KH$ by the identities $T^*T = H^2 + K^2 + i(HK - KH)$, $TT^* = H^2 + K^2 - i(HK - KH)$, and $T^*T = TT^*$.
(ii) ($\Leftarrow$) If $HK = KH$, the same product identities satisfy $T^*T = TT^*$, so T is normal.

Structural Commentary: Adjoint symmetrization precedes a direct product comparison.
Key Insight: The normality defect is $2i(HK - KH)$. □

Figure 48 summarizes Proposition 6.2.7.

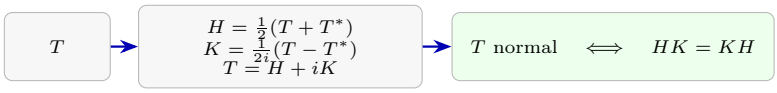

Figure 48: Cartesian decomposition: T is normal exactly when $HK = KH$.

Proposition 6.2.8. *Normal Block Upper-Triangular Matrices Collapse*
Let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$ and $r, s \geq 1$. Let $(B, C, X) \in \mathrm{Mat}(r, r, \mathbb{F}) \times \mathrm{Mat}(s, s, \mathbb{F}) \times \mathrm{Mat}(r, s, \mathbb{F})$.
Set $A := \left(\begin{smallmatrix} B & X \\ 0 & C \end{smallmatrix}\right) \in \mathrm{Mat}(r+s, r+s, \mathbb{F})$. Then A is normal if and only if $X = 0$ and both B and C are normal.

Proof.
($\Rightarrow$) Suppose A is normal; regard all matrices as complex when $\mathbb{F} = \mathbb{R}$.
By Theorem 6.1.9, fix unitary U_B, U_C such that $U_B^* B U_B$ and $U_C^* C U_C$ are upper triangular.
Set $Q := U_B \oplus U_C$, which is unitary by Proposition 2.6.12(ii). Then $Q^*Q = QQ^* = I_{r+s}$ by Theorem 2.6.8(i),(iii).
The matrix $Q^*AQ = \left(\begin{smallmatrix} U_B^* B U_B & U_B^* X U_C \\ 0 & U_C^* C U_C \end{smallmatrix}\right)$ is upper triangular.
The matrix Q^*AQ is normal by $(Q^*AQ)^*(Q^*AQ) = Q^*A^*AQ = Q^*AA^*Q = (Q^*AQ)(Q^*AQ)^*$.
Thus Q^*AQ is diagonal by Lemma 6.1.10. Hence $U_B^* X U_C = 0$ and $X = U_B(U_B^* X U_C)U_C^* = 0$.
Now $A = B \oplus C$, so $B^*B = BB^*$ and $C^*C = CC^*$ by blockwise normality.
($\Leftarrow$) If $X = 0$ and B, C are normal, then $A = B \oplus C$ and $A^*A = AA^*$ by blockwise multiplication.

Structural Commentary: Blockwise Schur reduction converts normality into the triangular-collapse lemma.
Key Insight: A normal triangular coupling cannot survive diagonalization. □

Figure 49 summarizes Proposition 6.2.8. Block-diagonal Schur coordinates reduce the claim to the earlier triangular normal-matrix lemma.

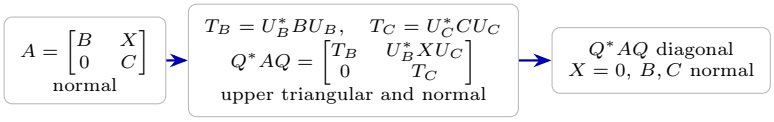

Figure 49: Normality removes the upper-right block in a block upper-triangular matrix.

Theorem 6.2.9. *Invariant Subspaces of Normal Matrices Reduce*
Let $n \geq 1$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and $A \in \mathrm{Mat}(n, n, \mathbb{F})$ be normal. Let $\mathcal{U} \leq \mathbb{F}^n$ be invariant under A, and let P be its orthogonal projection.
(i) The subspace $\mathcal{U}$ is invariant under A^*.
(ii) The identity $AP = PA$ holds.

Proof. If $\mathcal{U} = \{\mathbf{0}\}$, then $A^*\mathcal{U} \subseteq \mathcal{U}$ and $P = 0$, so both claims hold. If $\mathcal{U} = \mathbb{F}^n$, then $A^*\mathcal{U} \subseteq \mathcal{U}$ and $P = I_n$, so both claims hold.
Assume $r := \dim(\mathcal{U}) \in \{1, \ldots, n-1\}$. Choose orthonormal bases of $\mathcal{U}$ and $\mathcal{U}^\perp$ by Corollary 1.3.11.
Let $Q = [Q_1 \; Q_2]$ be the unitary matrix obtained by concatenating these bases.
The identity $Q_2^* A Q_1 = 0$ holds by invariance of $\mathcal{U}$, so $Q^*AQ = \left(\begin{smallmatrix} B & X \\ 0 & C \end{smallmatrix}\right)$.
The matrix Q^*AQ is normal by $(Q^*AQ)^*(Q^*AQ) = Q^*A^*AQ$ and $(Q^*AQ)(Q^*AQ)^* = Q^*AA^*Q$. Hence $X = 0$ by Proposition 6.2.8.
(i) The inclusion $A^*\mathcal{U} \subseteq \mathcal{U}$ holds by $Q^*A^*Q = (Q^*AQ)^* = B^* \oplus C^*$.
(ii) The identity $Q^*PQ = I_r \oplus 0$ holds by Proposition 2.2.3(ii)–(iii).
The matrices Q^*AQ and Q^*PQ commute by blockwise multiplication; hence $AP = PA$ by conjugation with Q.

Structural Commentary: An adapted unitary basis reduces both conclusions to block multiplication.
Key Insight: Normality eliminates the off-diagonal coupling block. □

Corollary 6.2.10. *Invariant Subspaces of Normal Operators Reduce*
Let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, let $\mathcal{V}$ be an inner-product space over $\mathbb{F}$, and let $T \in \mathcal{L}(\mathcal{V})$ be normal. Let $\mathcal{U} \leq \mathcal{V}$ be invariant under T.
(i) $\mathcal{U}^\perp$ is invariant under T;
(ii) $\mathcal{U}$ is invariant under T^*;
(iii) $(T|_{\mathcal{U}})^* = (T^*)|_{\mathcal{U}}$;
(iv) $T|_{\mathcal{U}}$ and $T|_{\mathcal{U}^\perp}$ are normal.

Proof. If $\mathcal{U} = \{\mathbf{0}\}$ or $\mathcal{U} = \mathcal{V}$, all four claims hold by $T\mathbf{0} = T^*\mathbf{0} = \mathbf{0}$ and normality of the restrictions.
Assume $0 < r := \dim(\mathcal{U}) < n := \dim(\mathcal{V})$. Choose an orthonormal basis β adapted to $\mathcal{U} \oplus \mathcal{U}^\perp$ by Corollary 1.3.11 and Theorem 2.1.5.
Set $A := [T]_{\beta \leftarrow \beta}$ and $R := I_r \oplus 0_{n-r}$. The matrix A is normal by Theorem 2.3.7 and Proposition 3.4.4.
The coordinate subspace $\mathbb{F}^r \oplus \{\mathbf{0}\}$ is invariant under A, and R is its orthogonal projection.
Hence $AR = RA$ by Theorem 6.2.9(ii). The identity $A = B \oplus C$ holds by direct block multiplication with R.
(i) The inclusion $T(\mathcal{U}^\perp) \subseteq \mathcal{U}^\perp$ holds by $A = B \oplus C$.
(ii) The identity $[T^*]_{\beta \leftarrow \beta} = A^* = B^* \oplus C^*$ holds by Theorem 2.3.7. Hence $\mathcal{U}$ is invariant under T^*.
(iii) The subspaces $\mathcal{U}$ and $\mathcal{U}^\perp$ are invariant under T by the hypothesis and part (i).
The identity $\mathcal{V} = \mathcal{U} \oplus \mathcal{U}^\perp$ holds by Theorem 2.1.5. Thus $(\mathcal{U}, \mathcal{U}^\perp)$ reduces T, and $(T|_{\mathcal{U}})^* = (T^*)|_{\mathcal{U}}$ by Theorem 5.2.7(iii).
(iv) The identity $A^*A = AA^*$ is equivalent blockwise to $B^*B = BB^*$ and $C^*C = CC^*$.
By Theorem 2.3.7 and Proposition 3.4.4, these are the adjoint-product identities for both restrictions.
Hence both restrictions are normal by Theorem 3.4.5(i).

Structural Commentary: Matrix reduction transfers four operator claims to two diagonal blocks.
Key Insight: Commutation with the projection is the reducing criterion. □

Theorem 6.2.11. *Simultaneous Unitary Diagonalization of Commuting Normal Operators*
Let $\mathcal{V}$ be a complex inner-product space, and let $\emptyset \neq \mathcal{F} \subseteq \mathcal{L}(\mathcal{V})$ consist of normal operators.
Then $\mathcal{F}$ is pairwise commuting if and only if $\mathcal{V}$ has an orthonormal basis of common eigenvectors for $\mathcal{F}$.

Proof.
($\Rightarrow$) Assume $\mathcal{F}$ is pairwise commuting and induct on $\dim(\mathcal{V})$.
If $(\forall A \in \mathcal{F})(\exists c_A \in \mathbb{C})\, A = c_A I_{\mathcal{V}}$, fix any orthonormal basis by Corollary 1.3.11.
It is common by the scalar condition, including the empty basis when $\mathcal{V} = \{\mathbf{0}\}$.
Otherwise, fix a nonscalar $A_0 \in \mathcal{F}$ and its spectral resolution $A_0 = \sum_{j=1}^{d} \mu_j P_j$ by Theorem 6.1.13(i).
The inequality $d \geq 2$ holds by nonscalarity. $(\forall j \in J_d)\, 0 < \dim(\text{range}(P_j)) < \dim(\mathcal{V})$ by Theorem 6.1.13(i)–(ii) and $d \geq 2$.
Each P_j is a polynomial in A_0 by Corollary 6.1.15(ii).
Fix $B \in \mathcal{F}$. Then $(\forall p \in \mathbb{C}[z])\, Bp(A_0) = p(A_0)B$ by $BA_0 = A_0B$, induction on powers, and linearity.
Hence $(\forall j \in J_d)\, BP_j = P_jB$. Fix $j \in J_d$ and $\mathbf{x} \in \text{range}(P_j)$. Then $P_jB\mathbf{x} = BP_j\mathbf{x} = B\mathbf{x}$, so $B\mathbf{x} \in \text{range}(P_j)$.
Thus $B|_{\text{range}(P_j)}$ is normal by Corollary 6.2.10(iv). The restricted family on each range is pairwise commuting and normal.
Fix a common orthonormal eigenbasis on each range by the induction hypothesis.
The identity $\mathcal{V} = \bigoplus_{j=1}^{d} \text{range}(P_j)$ holds by Theorem 6.1.13(i)–(ii).
Concatenating the restricted bases produces a common orthonormal eigenbasis of $\mathcal{V}$.
($\Leftarrow$) If $\mathcal{V} = \{\mathbf{0}\}$, its unique operator commutes with itself.
Otherwise, every $A \in \mathcal{F}$ has a diagonal matrix in the common orthonormal eigenbasis.
Hence the operators commute by Proposition 3.4.4 and Theorem 3.4.5(i).
Structural Commentary: Spectral reduction turns dimension induction into independent restricted families.
Key Insight: Commutants preserve all spectral subspaces. □

Figure 50 illustrates the spectral-subspace reduction in Theorem 6.2.11.

Figure 50: The spectral ranges of $A_0 = \sum_j \mu_j P_j$ reduce the commuting family for dimension induction.

Corollary 6.2.12. *Sums and Products of Commuting Normal Operators*
Let $\mathcal{V}$ be a complex inner-product space, and let $S, T \in \mathcal{L}(\mathcal{V})$ be commuting normal operators. Then $S+T$ and ST are normal.

Proof. Fix a common orthonormal eigenbasis for S and T by Theorem 6.2.11.
The operators $S+T$ and ST are diagonal in that basis and therefore normal by Theorem 6.1.11(iii),(i).
Structural Commentary: Simultaneous diagonalization reduces both constructions to scalar arithmetic.
Key Insight: Common diagonal coordinates are closed under sums and products. □

Perspective 6.2.13. *Real Normal Operators Use Planes*
Theorem 5.3.14 replaces complex eigenlines by invariant real lines and planes.
For normal operators, orthogonal reduction turns a nonreal conjugate pair into a rotation-dilation block.
This viewpoint is the real substitute for diagonalization; it does not make every invariant plane irreducible.

Proposition 6.2.14. *Two-Dimensional Real Normal Blocks*
Let $\mathcal{V}$ be a two-dimensional real inner-product space and let $T \in \mathcal{L}(\mathcal{V})$.
(i) T is normal and not self-adjoint if and only if every orthonormal-basis matrix has the form $\left(\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right)$. The corresponding parameters satisfy $a \in \mathbb{R}$ and $b \in \mathbb{R} \setminus \{0\}$.
(ii) If the equivalent conditions in (i) hold, then an orthonormal basis exists for which $b > 0$.

Proof.
(*i*) ($\Rightarrow$) Fix an arbitrary orthonormal basis and write $A = [T] = \left(\begin{smallmatrix} a & c \\ b & d \end{smallmatrix}\right)$.
The identities $A^tA = AA^t$ and $A \neq A^t$ hold by Theorem 2.3.7 and Proposition 3.4.4.
Equality of the $(1,1)$ entries is $b^2 = c^2$. The relation $c \neq b$ holds by $A \neq A^t$, so $c = -b$ and $b \neq 0$.
Equality of the off-diagonal entries is $-ab + bd = ab - bd$, so $d = a$.
The stated form holds in every orthonormal basis by arbitrariness of the basis.
(*i*) ($\Leftarrow$) Fix an orthonormal basis with $A = [T] = \left(\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right)$ and $b \neq 0$.
The identities $A^tA = AA^t$ and $A \neq A^t$ hold by direct multiplication and $b \neq 0$.
Thus T is normal and not self-adjoint by Theorem 2.3.7 and Proposition 3.4.4.
(*ii*) Fix an orthonormal basis and its nonzero parameter b by part (i).
If $b < 0$, negate the second basis vector; the new parameter is $-b > 0$. If $b > 0$, retain the basis.
Structural Commentary: Entrywise normality determines the block, followed by an orientation choice.
Key Insight: Nonsymmetry selects $c = -b$ from $c^2 = b^2$. □

Theorem 6.2.15. *Real Normal Operator Block Form*
Let $\mathcal{V}$ be a real inner-product space and let $T \in \mathcal{L}(\mathcal{V})$. For $a \in \mathbb{R}$ and $b > 0$, set $N_{a,b} := \left(\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right)$.
Then T is normal if and only if some orthonormal basis makes $[T]$ a direct sum of scalar blocks and blocks $N_{a,b}$.

Proof.
($\Rightarrow$) Induct on $n := \dim(\mathcal{V})$. For $n = 0$, the empty orthonormal basis has the required form.
For $n = 1$, any unit vector produces a scalar block. Suppose $n \geq 2$. Fix a T-invariant $\mathcal{U}$ with $\dim(\mathcal{U}) \in \{1, 2\}$ by Theorem 5.3.14.
The subspace $\mathcal{U}^{\perp}$ is T-invariant, and both restrictions are normal, by Corollary 6.2.10(i),(iv).
If $\dim(\mathcal{U}) = 1$, a unit vector in $\mathcal{U}$ determines a scalar block.

If $\dim(\mathcal{U}) = 2$ and $T|_{\mathcal{U}}$ is self-adjoint, fix an orthonormal eigenbasis by Theorem 6.1.12(i),(ii). Its two blocks are scalar.
If $T|_{\mathcal{U}}$ is not self-adjoint, fix an orthonormal basis with matrix $N_{a,b}$ by Proposition 6.2.14(ii).
Fix the required basis on $\mathcal{U}^{\perp}$ by the induction hypothesis.
Their concatenation is an orthonormal basis of $\mathcal{V} = \mathcal{U} \oplus \mathcal{U}^{\perp}$ by Theorem 2.1.5.

($\Leftarrow$) Fix an orthonormal basis with the stated block form and set $A := [T]$.
Every allowed block D satisfies $D^*D = DD^*$ by direct multiplication, so $A^*A = AA^*$ blockwise.
The identity $T^*T = TT^*$ holds by Theorem 2.3.7, Proposition 3.4.4, and Theorem 3.4.5(i).
Thus T is normal by its defining identity.

Structural Commentary: Orthogonal reduction supports induction over invariant lines and planes.
Key Insight: Two-dimensional nonsymmetric blocks have rotation-dilation form. □

Figure 51 summarizes Theorem 6.2.15.

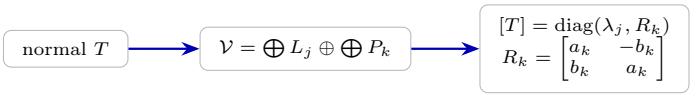

Figure 51: Orthogonal line/plane split into scalar and rotation blocks.

Theorem 6.2.16. *Description of Complex Isometries*
Let $\mathcal{V}$ be a complex inner-product space, $n := \dim(\mathcal{V})$, and $S \in \mathcal{L}(\mathcal{V})$.
Then S is an isometry if and only if $\mathcal{V}$ has an orthonormal eigenbasis $(\mathbf{e}_j)_{j=1}^n$ with eigenvalues $(\lambda_j)_{j=1}^n$ satisfying $(\forall j \in J_n)\ |\lambda_j| = 1$.

Proof. If $\mathcal{V} = \{\mathbf{0}\}$, both conditions hold for the unique operator and empty orthonormal basis. Assume $\mathcal{V} \neq \{\mathbf{0}\}$.

($\Rightarrow$) Suppose S is an isometry. Then $S^*S = I_{\mathcal{V}}$ by Theorem 2.6.6.
The map S is injective by norm preservation and invertible by Theorem 1.7.7(ii),(i). Thus $S^* = S^{-1}$ and $SS^* = I_{\mathcal{V}}$, so S is normal.
Fix an orthonormal eigenbasis $S\mathbf{e}_j = \lambda_j \mathbf{e}_j$ by Theorem 6.1.11(i),(ii).
Then $(\forall j \in J_n)\ |\lambda_j| = \|S\mathbf{e}_j\| = 1$ by norm preservation.

($\Leftarrow$) Suppose $(\mathbf{e}_j)_{j=1}^n$ is an orthonormal eigenbasis with eigenvalues $(\lambda_j)_{j=1}^n$ satisfying $(\forall j \in J_n)\ |\lambda_j| = 1$.
For $\mathbf{v} = \sum_{j=1}^n c_j \mathbf{e}_j$, $\|S\mathbf{v}\|^2 = \sum_{j=1}^n |\lambda_j c_j|^2 = \sum_{j=1}^n |c_j|^2 = \|\mathbf{v}\|^2$ by Theorem 1.4.7(i). Hence S is an isometry.

Structural Commentary: A forward normality reduction pairs with a reverse Parseval calculation.
Key Insight: Isometry becomes coefficientwise unit modulus. □

Example 6.2.17. *Plane Rotations*
For $\theta \in \mathbb{R}$, set $R_\theta := \left(\begin{smallmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{smallmatrix}\right)$. The identity $R_\theta^t R_\theta = I_2$ holds by direct multiplication.
Thus R_θ is an isometry of $\mathbb{R}^2$ by Theorem 2.3.7, Proposition 3.4.4, and Theorem 2.6.6.
If $\theta \notin \pi\mathbb{Z}$, its characteristic polynomial $x^2 - 2(\cos\theta)x + 1$ has discriminant $-4\sin^2\theta < 0$.
Hence R_θ has no real eigenvalue, which motivates two-dimensional blocks in the real isometry form.

Theorem 6.2.18. *Real Isometry Block Form*
Let $\mathcal{V}$ be a real inner-product space and let $S \in \mathcal{L}(\mathcal{V})$. For $\theta \in (0, \pi)$, set $R_\theta := \left(\begin{smallmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{smallmatrix}\right)$.
Then S is an isometry if and only if some orthonormal basis makes $[S]$ a direct sum of $[1]$, $[-1]$, and blocks R_θ.

Proof. If $\mathcal{V} = \{\mathbf{0}\}$, both conditions hold for the unique operator and empty orthonormal basis. Assume $\dim(\mathcal{V}) \geq 1$.

($\Rightarrow$) Suppose S is an isometry. Then $S^*S = I_{\mathcal{V}}$ by Theorem 2.6.6.
The map S is injective by norm preservation and invertible by Theorem 1.7.7(ii),(i).
Hence $S^* = S^{-1}$, so $SS^* = I_{\mathcal{V}}$ and S is normal. Fix a block basis by Theorem 6.2.15.
In this basis, $[S]^t[S] = I$ by Theorem 2.3.7 and Proposition 3.4.4. Every scalar block $[\lambda]$ satisfies $\lambda^2 = 1$, so $\lambda = \pm 1$.
Every two-dimensional block $\left(\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right)$ satisfies $a^2 + b^2 = 1$ with $b > 0$.
Hence a unique $\theta \in (0, \pi)$ satisfies $a = \cos\theta$ and $b = \sin\theta$, so the block equals R_θ.

($\Leftarrow$) Fix a basis with the stated block form. Every block D satisfies $D^tD = I$.
Thus $[S]^t[S] = I$, and $S^*S = I_{\mathcal{V}}$ by Theorem 2.3.7, Proposition 3.4.4, and Theorem 3.4.5(i).
Hence S is an isometry by Theorem 2.6.6.

Structural Commentary: The real normal form is filtered blockwise by the isometry identity.
Key Insight: Unit-length normal blocks are signs or rotations. □

Figure 52 illustrates the three block types in Theorem 6.2.18.

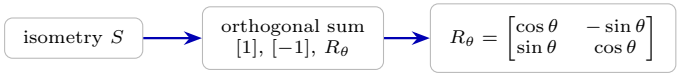

Figure 52: Normal form: fixed/flipped lines and rotation planes.

6.3 Operator Functions

This subsection develops finite spectral functions of normal operators and positive square roots.
It then characterizes commutativity through spectral projections and a single normal generator.

Definition 6.3.1. *Spectral Resolution Notation*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space, and let $T \in \mathcal{L}(\mathcal{V})$ be normal. The associated spectral notation is:

(i) *Spectral Set*: $\Omega_T := \operatorname{spec}(T)$.
(ii) *Spectral Projections*: For $\lambda \in \Omega_T$, P_λ is the orthogonal projection onto $E_\lambda(T)$.

(iii) *Spectral Resolution*: $(P_\lambda)_{\lambda\in\Omega_T}$, with $T = \sum_{\lambda\in\Omega_T} \lambda P_\lambda$ and $I_\mathcal{V} = \sum_{\lambda\in\Omega_T} P_\lambda$.

For $\mathcal{V} = \{\mathbf{0}\}$, the spectral set and projection family are empty, and both sums are the unique zero operator.

Theorem 6.3.2. *Finite Spectral Functional Calculus for Normal Operators*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space, and let $T \in \mathcal{L}(\mathcal{V})$ be normal.
Define $\Phi_T : \mathbb{C}^{\Omega_T} \to \mathcal{L}(\mathcal{V})$ by $\Phi_T(f) := f(T) := \sum_{\lambda\in\Omega_T} f(\lambda)P_\lambda$.

(i) $(\forall f \in \mathbb{C}^{\Omega_T})(\forall p \in \mathbb{C}[z])\,[p|_{\Omega_T} = f \implies p(T) = f(T)]$.
(ii) $(\forall f \in \mathbb{C}^{\Omega_T})(\exists p_f \in \mathbb{C}[z])\,[p_f|_{\Omega_T} = f \wedge p_f(T) = f(T)]$.

Proof. If $\Omega_T = \emptyset$, then $\mathcal{V} = \{\mathbf{0}\}$ by Theorem 6.1.11(i)–(ii).
The zero polynomial represents the unique $f \in \mathbb{C}^{\Omega_T}$, and all operator sums vanish; hence (i)–(ii).
Otherwise $\Omega_T \neq \emptyset$, and the following arguments apply.

(i) Fix $f \in \mathbb{C}^{\Omega_T}$ and $p \in \mathbb{C}[z]$ with $p|_{\Omega_T} = f$.
Then $p(T) = \sum_{\lambda\in\Omega_T} p(\lambda)P_\lambda = \sum_{\lambda\in\Omega_T} f(\lambda)P_\lambda = f(T)$ by Corollary 6.1.15(i) and the restriction identity.

(ii) Fix $f \in \mathbb{C}^{\Omega_T}$. For $\lambda \in \Omega_T$, set $\ell_\lambda(z) := \prod_{\mu\in\Omega_T\setminus\{\lambda\}} \frac{z-\mu}{\lambda-\mu}$.
Set $p_f(z) := \sum_{\lambda\in\Omega_T} f(\lambda)\ell_\lambda(z)$. For $\lambda_0 \in \Omega_T$, $(\forall \lambda \in \Omega_T)\,\ell_\lambda(\lambda_0) = \delta_{\lambda,\lambda_0}$ by distinctness.
Thus $p_f(\lambda_0) = f(\lambda_0)$, so $p_f|_{\Omega_T} = f$; moreover, $p_f(T) = f(T)$ by (i).

Structural Commentary: Polynomial spectral evaluation feeds an explicit Lagrange interpolation on Ω_T.
Key Insight: $\ell_\lambda(\mu) = \delta_{\lambda,\mu}$ encodes arbitrary finite spectral data. □

Theorem 6.3.3. *Rules for Normal Spectral Functions*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space, and let $T \in \mathcal{L}(\mathcal{V})$ be normal.
For $f, g : \Omega_T \to \mathbb{C}$, the following identities and properties hold:

(i) $(f+g)(T) = f(T) + g(T)$;
(ii) $(fg)(T) = f(T)g(T)$;
(iii) $f(T)^* = \overline{f}(T)$, *where* $(\forall \lambda \in \Omega_T)\,\overline{f}(\lambda) := \overline{f(\lambda)}$;
(iv) $f(T)$ *is normal;*
(v) $\operatorname{spec}(f(T)) = f(\Omega_T)$.

Proof. If $\mathcal{V} = \{\mathbf{0}\}$, all spectral sums and spectra are empty, so (i)–(v) hold. Assume $\mathcal{V} \neq \{\mathbf{0}\}$.

(i) $(f+g)(T) = \sum_{\lambda\in\Omega_T} (f(\lambda)+g(\lambda))P_\lambda = f(T) + g(T)$ by the definition of the spectral functional calculus.

(ii) The relations $P_\lambda P_\mu = 0$ for $\lambda \neq \mu$ and $P_\lambda^2 = P_\lambda$ hold by Theorem 6.1.13(i)–(ii). Hence $f(T)g(T) = \sum_{\lambda\in\Omega_T} f(\lambda)g(\lambda)P_\lambda = (fg)(T)$.

(iii) $(\forall \lambda \in \Omega_T)\,P_\lambda^* = P_\lambda$ by Theorem 2.5.6. Thus $f(T)^* = \sum_{\lambda\in\Omega_T} \overline{f(\lambda)}P_\lambda = \overline{f}(T)$ by Proposition 2.3.8(i).

(iv) $f(T)^*f(T) = (\overline{f}f)(T) = (f\overline{f})(T) = f(T)f(T)^*$ by (ii)–(iii). Therefore $f(T)$ is normal by Definition 6.1.1(i).

(v) Set $n := \dim(\mathcal{V})$. Fix an orthonormal eigenbasis $(\mathbf{e}_j)_{j=1}^n$ for T by Theorem 6.1.11(i)–(ii), and write $T\mathbf{e}_j = \lambda_j\mathbf{e}_j$.
Then $f(T)\mathbf{e}_j = f(\lambda_j)\mathbf{e}_j$ by the spectral resolution. Thus $f(T)$ is diagonal, with diagonal-value set $f(\Omega_T)$, so $\operatorname{spec}(f(T)) = f(\Omega_T)$.

Structural Commentary: Projection arithmetic transfers pointwise algebra and conjugation before the eigenbasis reads the spectrum.
Key Insight: Every $E_\lambda(T)$ converts $f(T)$ into multiplication by $f(\lambda)$. □

Definition 6.3.4. *Positive Operator*
Let $\mathcal{V}$ be finite-dimensional inner-product space over $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$. For $T \in \mathcal{L}(\mathcal{V})$, $T \geq 0$, T *positive* if $T = T^*$ and $(\forall \mathbf{v} \in \mathcal{V})\ \langle T\mathbf{v}, \mathbf{v}\rangle \geq 0$.

Definition 6.3.5. *Square Root of an Operator*
Let $\mathcal{V}$ be a finite-dimensional inner-product space over $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, $T \in \mathcal{L}(\mathcal{V})$. An operator $R \in \mathcal{L}(\mathcal{V})$ is a *square root* of T if $R^2 = T$.

Theorem 6.3.6. *Characterization of Positive Operators*
Let $\mathcal{V}$ be a finite-dimensional inner-product space over $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, $T \in \mathcal{L}(\mathcal{V})$. The following are equivalent:

(i) T *is positive;*
(ii) $T = T^*$ *and* $\operatorname{spec}(T) \subseteq [0, \infty)$;
(iii) $(\exists S \in \mathcal{L}(\mathcal{V}))\,[S \geq 0 \wedge S^2 = T]$;
(iv) $(\exists R \in \mathcal{L}(\mathcal{V}))\,[R = R^* \wedge R^2 = T]$;
(v) $(\exists R \in \mathcal{L}(\mathcal{V}))\,T = R^*R$.

Proof. If $\mathcal{V} = \{\mathbf{0}\}$, its unique operator satisfies all five conditions. Assume $\mathcal{V} \neq \{\mathbf{0}\}$.

(i) $\Rightarrow$ (ii) The identity $T = T^*$ holds by Definition 6.3.4. Fix $\lambda \in \operatorname{spec}(T)$ and $\mathbf{v} \in E_\lambda(T) \setminus \{\mathbf{0}\}$.
Then $\lambda \in \mathbb{R}$ by Theorem 6.1.5, while $0 \leq \langle T\mathbf{v}, \mathbf{v}\rangle = \lambda\|\mathbf{v}\|^2$. Hence $\lambda \geq 0$.

(ii) $\Rightarrow$ (iii) Set $n := \dim(\mathcal{V})$. In the complex case, $T^*T = T^2 = TT^*$ by $T = T^*$, so T is normal.
Fix an orthonormal eigenbasis $(\mathbf{e}_j)_{j=1}^n$ by Theorem 6.1.12(i)–(ii) when $\mathbb{F} = \mathbb{R}$ and by Theorem 6.1.11(i)–(ii) when $\mathbb{F} = \mathbb{C}$.
Write $T\mathbf{e}_j = \lambda_j\mathbf{e}_j$, where $(\forall j \in \{1, \ldots, n\})\,\lambda_j \geq 0$. Fix $S \in \mathcal{L}(\mathcal{V})$ satisfying $(\forall j \in \{1, \ldots, n\})\,S\mathbf{e}_j = \sqrt{\lambda_j}\mathbf{e}_j$ by Proposition 1.5.8.
For $\mathbf{u} = \sum_{j=1}^n c_j\mathbf{e}_j$ and $\mathbf{v} = \sum_{j=1}^n d_j\mathbf{e}_j$, $\langle S\mathbf{u}, \mathbf{v}\rangle = \sum_{j=1}^n \sqrt{\lambda_j}c_j\overline{d_j} = \langle \mathbf{u}, S\mathbf{v}\rangle$.
$S = S^*$ by the preceding adjoint identity, and $\langle S\mathbf{v}, \mathbf{v}\rangle = \sum_{j=1}^n \sqrt{\lambda_j}\,|d_j|^2 \geq 0$. Hence $S \geq 0$ by Definition 6.3.4.
The identity $S^2 = T$ holds by Proposition 1.5.8 and the equality $(\forall j \in \{1, \ldots, n\})\,S^2\mathbf{e}_j = T\mathbf{e}_j$.

(iii) $\Rightarrow$ (iv) The relation $S = S^*$ holds by $S \geq 0$ and Definition 6.3.4, so S is a self-adjoint square root.

(iv) $\Rightarrow$ (v) The identity $T = R^*R$ holds by $T = R^2$ and $R = R^*$.

(v) $\Rightarrow$ (i) The identity $T^* = (R^*R)^* = R^*(R^*)^* = R^*R = T$ holds by Proposition 2.3.8(ii)–(iii).
The inequality $(\forall \mathbf{v} \in \mathcal{V})\ \langle T\mathbf{v}, \mathbf{v}\rangle = \|R\mathbf{v}\|^2 \geq 0$ holds by $T = R^*R$ and the defining adjoint identity.
Thus $T \geq 0$ by Definition 6.3.4 and $T^* = T$.

Structural Commentary: Spectral coordinates construct the positive root, and adjoint factorization closes the implication cycle.
Key Insight: $\lambda_j \geq 0$ permits the canonical multiplier $\sqrt{\lambda_j}$. □

Proposition 6.3.7. *Unique Positive Square Root*
Let $\mathcal{V}$ be a finite-dimensional inner-product space over $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$. For $T \in \mathcal{L}(\mathcal{V})$ with $T \geq 0$, $(\exists! R \in \mathcal{L}(\mathcal{V}))\,[R \geq 0 \wedge R^2 = T]$.

Proof.

(i) *Existence and Degenerate Case*: A positive square root exists by Theorem 6.3.6(i),(iii).
If $\mathcal{V} = \{\mathbf{0}\}$, its unique operator is its unique positive square root. Assume $\mathcal{V} \neq \{\mathbf{0}\}$.

(ii) *Spectral Reduction*: Let $\lambda_1, \ldots, \lambda_m$ be the distinct eigenvalues of T.
Then $T = T^*$ and $(\forall j \in \{1, \ldots, m\})\ \lambda_j \geq 0$ by Theorem 6.3.6(i),(ii). In the complex case, $T^*T = T^2 = TT^*$, so T is normal.
Hence $\mathcal{V} = E_{\lambda_1}(T) \odot \cdots \odot E_{\lambda_m}(T)$ by Theorem 6.1.12(i)–(ii) when $\mathbb{F} = \mathbb{R}$ and by Theorem 6.1.11(i)–(ii) when $\mathbb{F} = \mathbb{C}$.

(iii) *Restriction to One Eigenspace*: Let R be a positive square root of T.
The identity $RT = R^3 = TR$ holds by $R^2 = T$, so $(\forall j \in \{1, \ldots, m\})\ E_{\lambda_j}(T) \in \mathrm{Inv}(R)$.
For $j \in \{1, \ldots, m\}$, set $R_j := R|_{E_{\lambda_j}(T)}$. Then $R_j = R_j^*$ by Proposition 6.1.8(ii), and $(\forall \mathbf{x} \in E_{\lambda_j}(T))\ \langle R_j\mathbf{x}, \mathbf{x}\rangle \geq 0$ by $R \geq 0$.
Thus $R_j \geq 0$ by Definition 6.3.4, while $R_j^2 = \lambda_j I_{E_{\lambda_j}(T)}$ by $R^2 = T$. In the complex case, $R_j^*R_j = R_j^2 = R_jR_j^*$.
Fix an orthonormal eigenbasis of R_j by Theorem 6.1.12(i)–(ii) when $\mathbb{F} = \mathbb{R}$ and by Theorem 6.1.11(i)–(ii) when $\mathbb{F} = \mathbb{C}$.
Every corresponding eigenvalue ρ satisfies $\rho \geq 0$ by Theorem 6.3.6(i),(ii) and $\rho^2 = \lambda_j$ by the restriction identity.
Therefore $\rho = \sqrt{\lambda_j}$, so $R_j = \sqrt{\lambda_j} I_{E_{\lambda_j}(T)}$ by Proposition 1.5.8.

(iv) *Uniqueness*: Every positive square root R satisfies $(\forall j \in \{1, \ldots, m\})\ R|_{E_{\lambda_j}(T)} = \sqrt{\lambda_j} I_{E_{\lambda_j}(T)}$ by (iii).
Any two positive square roots agree on every summand by this identity and are therefore equal on $\mathcal{V}$ by the decomposition in (ii).

Structural Commentary: Spectral reduction localizes uniqueness to the restriction equation $R_j^2 = \lambda_j I$.
Key Insight: Positivity selects $\sqrt{\lambda_j}$ rather than $-\sqrt{\lambda_j}$. □

Definition 6.3.8. *Positive Square Root Notation*
Let $\mathcal{V}$ be finite-dimensional inner-product space over $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$. For $T \in \mathcal{L}(\mathcal{V})$, $T \geq 0$, $\sqrt{T}$ denotes its unique positive square root.

Corollary 6.3.9. *Basic Functions from the Spectral Calculus*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space, and let $T \in \mathcal{L}(\mathcal{V})$ be normal.

(i) $T^* = \sum_{\lambda \in \Omega_T} \overline{\lambda} P_\lambda$.

(ii) *If* $0 \notin \Omega_T$, *then* $T^{-1} = \sum_{\lambda \in \Omega_T} \lambda^{-1} P_\lambda$.

(iii) *If* $T \geq 0$, *then* $\sqrt{T} = \sum_{\lambda \in \Omega_T} \sqrt{\lambda} P_\lambda$.

Proof.

(i) $T^* = \sum_{\lambda \in \Omega_T} \overline{\lambda} P_\lambda$ by Theorem 6.3.3(iii) with the identity function on Ω_T.

(ii) Set $f(\lambda) := \lambda^{-1}$. Then $Tf(T) = f(T)T = \sum_{\lambda \in \Omega_T} P_\lambda = I_{\mathcal{V}}$ by the projection product relations and the resolution of $I_{\mathcal{V}}$.
Thus $T^{-1} = f(T) = \sum_{\lambda \in \Omega_T} \lambda^{-1} P_\lambda$ by uniqueness of the inverse.

(iii) The inclusion $\Omega_T \subseteq [0, \infty)$ holds by Theorem 6.3.6(i),(ii). Set $g(\lambda) := \sqrt{\lambda}$.
Then $g(T)^* = g(T)$, $g(T)^2 = T$, and $\mathrm{spec}(g(T)) = g(\Omega_T) \subseteq [0, \infty)$ by Theorem 6.3.3(ii)–(v).
Hence $g(T) \geq 0$ by Theorem 6.3.6(ii),(i), and $\sqrt{T} = g(T) = \sum_{\lambda \in \Omega_T} \sqrt{\lambda} P_\lambda$ by Proposition 6.3.7.

Structural Commentary: Conjugation, inversion, and positive square roots transfer pointwise through the spectral calculus.
Key Insight: Each scalar function acts independently on every spectral block. □

Theorem 6.3.10. *Commutativity via Spectral Projections*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space, and let $T, S \in \mathcal{L}(\mathcal{V})$ be normal. Write $T = \sum_{\lambda \in \Omega_T} \lambda P_\lambda$ and $S = \sum_{\mu \in \Omega_S} \mu Q_\mu$.

(i) *For* $R \in \mathcal{L}(\mathcal{V})$, $RT = TR \iff (\forall \lambda \in \Omega_T)\ RP_\lambda = P_\lambda R$.

(ii) $TS = ST \iff (\forall \lambda \in \Omega_T)(\forall \mu \in \Omega_S)\ P_\lambda Q_\mu = Q_\mu P_\lambda$.

(iii) *If* $f : \Omega_T \to \mathbb{C}$ *and* $g : \Omega_S \to \mathbb{C}$ *are injective, then* $f(T)g(S) = g(S)f(T) \iff TS = ST$.

Proof. If $\mathcal{V} = \{\mathbf{0}\}$, both sides of every equivalence hold. Assume $\mathcal{V} \neq \{\mathbf{0}\}$.

(*i*) ($\Rightarrow$) If $RT = TR$, then $(\forall p \in \mathbb{C}[z])\ Rp(T) = p(T)R$ by induction on powers and linearity.
Each P_λ is a polynomial in T by Corollary 6.1.15(ii), so $(\forall \lambda \in \Omega_T)\ RP_\lambda = P_\lambda R$.

(*i*) ($\Leftarrow$) If $(\forall \lambda \in \Omega_T)\ RP_\lambda = P_\lambda R$, then $RT = \sum_{\lambda \in \Omega_T} \lambda RP_\lambda = \sum_{\lambda \in \Omega_T} \lambda P_\lambda R = TR$.

(*ii*) ($\Rightarrow$) If $TS = ST$, then $(\forall \lambda \in \Omega_T)\ SP_\lambda = P_\lambda S$ by (i) with $R = S$. Hence $(\forall \lambda \in \Omega_T)(\forall \mu \in \Omega_S)\ P_\lambda Q_\mu = Q_\mu P_\lambda$ by (i) for S with $R = P_\lambda$.

(*ii*) ($\Leftarrow$) If all spectral projections commute pairwise, then $TS = \sum_{\lambda \in \Omega_T,\, \mu \in \Omega_S} \lambda\mu P_\lambda Q_\mu = \sum_{\lambda \in \Omega_T,\, \mu \in \Omega_S} \lambda\mu Q_\mu P_\lambda = ST$.

(*iii*) ($\Rightarrow$) Suppose $f(T)g(S) = g(S)f(T)$. Then $f(T)$ and $g(S)$ are normal by Theorem 6.3.3(iv).
Spectral coefficients are distinct by injectivity, so spectral projections are $(P_\lambda)_{\lambda \in \Omega_T}$ and $(Q_\mu)_{\mu \in \Omega_S}$ by Theorem 6.1.13(ii).
These projections commute by (ii) for $f(T)$ and $g(S)$; hence $TS = ST$ by (ii) for T and S.

(*iii*) ($\Leftarrow$) If $TS = ST$, then all P_λ commute with all Q_μ by (ii).
Thus $f(T)g(S) = \sum_{\lambda \in \Omega_T,\, \mu \in \Omega_S} f(\lambda)g(\mu) P_\lambda Q_\mu = \sum_{\lambda \in \Omega_T,\, \mu \in \Omega_S} f(\lambda)g(\mu) Q_\mu P_\lambda = g(S)f(T)$.

Structural Commentary: Polynomial recovery transfers operator commutation to pairwise commutation of spectral projections.
Key Insight: Commutation is equivalent to preserving every spectral block. □

Corollary 6.3.11. *A Commuting Normal Pair Comes from One Normal Operator*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space, and let $T, S \in \mathcal{L}(\mathcal{V})$ be normal.
Let $\mathbb{C}[T,S]$ denote the finite sums of $c_{a,b}T^aS^b$ with $c_{a,b} \in \mathbb{C}$ and $a, b \in \mathbb{Z}_{\geq 0}$.
Then $TS = ST \iff (\exists H \in \mathbb{C}[T,S])(\exists p, q \in \mathbb{C}[z])\,[H^*H = HH^* \wedge T = p(H) \wedge S = q(H)]$.

Proof.
($\Rightarrow$) Suppose $TS = ST$. If $\mathcal{V} = \{\mathbf{0}\}$, the choices $H = T = S = 0$ and $p = q = 0$ satisfy the conclusion. Assume $\mathcal{V} \neq \{\mathbf{0}\}$.

(a) *Joint Spectral Blocks*: Write $T = \sum_{\lambda \in \Omega_T} \lambda P_\lambda$ and $S = \sum_{\mu \in \Omega_S} \mu Q_\mu$.
The projections commute by Theorem 6.3.10(ii). Set $\mathcal{I} := \{(\lambda, \mu) \in \Omega_T \times \Omega_S : P_\lambda Q_\mu \neq 0\}$.
For $(\lambda, \mu) \in \mathcal{I}$, $(P_\lambda Q_\mu)^2 = P_\lambda Q_\mu$ and $(P_\lambda Q_\mu)^* = P_\lambda Q_\mu$ by projection commutation and self-adjoint idempotence.
Thus $P_\lambda Q_\mu$ is an orthogonal projection by Theorem 2.5.6.
Distinct joint projections are orthogonal by pairwise annihilation and commutation.
After insertion of the zero products, $\sum_{(\lambda,\mu)\in\mathcal{I}} P_\lambda Q_\mu = \sum_{\lambda \in \Omega_T,\, \mu \in \Omega_S} P_\lambda Q_\mu$.
The latter sum equals $(\sum_{\lambda \in \Omega_T} P_\lambda)(\sum_{\mu \in \Omega_S} Q_\mu) = I_\mathcal{V}$ by the spectral resolutions.

(b) *Separating Operator*: Choose pairwise distinct $\alpha_{\lambda,\mu} \in \mathbb{C}$ for $(\lambda, \mu) \in \mathcal{I}$ and set $H := \sum_{(\lambda,\mu)\in\mathcal{I}} \alpha_{\lambda,\mu} P_\lambda Q_\mu$.
Then H is normal, with $\operatorname{spec}(H) = \{\alpha_{\lambda,\mu} : (\lambda, \mu) \in \mathcal{I}\}$, by Theorem 6.1.13(i)–(ii).

(c) *Generated Algebra*: Each P_λ is a polynomial in T and each Q_μ is a polynomial in S by Corollary 6.1.15(ii).
Therefore H is a finite sum of terms $c_{a,b}T^aS^b$, so $H \in \mathbb{C}[T,S]$.

(d) *Recovery of the Pair*: Define $f, g : \operatorname{spec}(H) \to \mathbb{C}$ by $f(\alpha_{\lambda,\mu}) := \lambda$ and $g(\alpha_{\lambda,\mu}) := \mu$.
Fix $p, q \in \mathbb{C}[z]$ satisfying $p|_{\operatorname{spec}(H)} = f$ and $q|_{\operatorname{spec}(H)} = g$ by Theorem 6.3.2(ii).
Then $p(H) = \sum_{(\lambda,\mu)\in\mathcal{I}} \lambda P_\lambda Q_\mu = T$ by the spectral resolution of T.
The identity $q(H) = \sum_{(\lambda,\mu)\in\mathcal{I}} \mu P_\lambda Q_\mu = S$ holds by the spectral resolution of S.

($\Leftarrow$) Suppose $T = p(H)$ and $S = q(H)$. Then $p(H)q(H) = q(H)p(H)$ by $H^aH^b = H^{a+b} = H^bH^a$ and distributivity, so $TS = ST$.

Structural Commentary: Joint spectral blocks build a separating normal generator before polynomial recovery of T and S.
Key Insight: Distinct labels encode both eigenvalue coordinates on each joint block. □

Part V
Polynomial Structure and Canonical Forms

1 Operator Polynomials

1.1 Polynomial Functional Calculus

Theorem 1.1.1. *Polynomial Functional Calculus for Diagonalizable Matrices*
Let $n \geq 1$, $\lambda_1, \dots, \lambda_n \in \mathbb{F}$, and set $\Lambda := \operatorname{diag}(\lambda_1, \dots, \lambda_n)$. Let $A \in \operatorname{Mat}(n, n, \mathbb{F})$ and $S \in \operatorname{Mat}(n, n, \mathbb{F})^\times$.
If $A = S\Lambda S^{-1}$, then $(\forall\, p \in \mathbb{F}[z])\, p(A) = S \operatorname{diag}(p(\lambda_1), \dots, p(\lambda_n))S^{-1}$.

Proof. Set $P_j := (A^j = S\Lambda^j S^{-1})$, $j \in \mathbb{Z}_{\geq 0}$. Base case P_0 holds by Definition 3.8.5 and inverse relations: $A^0 = I_n = SI_nS^{-1} = S\Lambda^0 S^{-1}$.
Fix $j \in \mathbb{Z}_{\geq 0}$ and suppose P_j. The identity $A^{j+1} = A^j A = S\Lambda^j S^{-1} S\Lambda S^{-1}$ holds by Definition 3.8.5 and P_j.
The identity $S\Lambda^j S^{-1} S\Lambda S^{-1} = S\Lambda^{j+1} S^{-1}$ holds by Proposition 3.1.2(i),(ii) and $S^{-1}S = I_n$.

Thus P_{j+1} holds, so $(\forall\, j \in \mathbb{Z}_{\geq 0})\, P_j$ by Theorem 2.6.2. Fix $p \in \mathbb{F}[z]$ and write $p(z) = \sum_{j=0}^{d} c_j z^j$ with $d \in \mathbb{Z}_{\geq 0}$ and $c_0, \dots, c_d \in \mathbb{F}$.

The identity $p(A) = \sum_{j=0}^{d} c_j S\Lambda^j S^{-1}$ holds by Definition 3.8.5 and the power identity.

The identity $\sum_{j=0}^{d} c_j S\Lambda^j S^{-1} = S\left(\sum_{j=0}^{d} c_j \Lambda^j\right) S^{-1}$ holds by Proposition 3.1.2(iii),(iv). Hence $p(A) = Sp(\Lambda)S^{-1}$ by Definition 3.8.5.
The identity $(\forall\, j \in \mathbb{Z}_{\geq 0})(\forall\, i, k \in J_n)\, (\Lambda^j)_{ik} = \delta_{ik}\lambda_i^j$ holds by induction on j and Definition 3.1.1(iv),(ix),(xii).
Hence $(\forall\, i, k \in J_n)\, p(\Lambda)_{ik} = \delta_{ik} p(\lambda_i)$ by Definition 3.8.5. Therefore $p(\Lambda) = \operatorname{diag}(p(\lambda_1), \dots, p(\lambda_n))$ by Definition 3.1.1(i),(iv).
The claimed identity holds by substituting this formula into $p(A) = Sp(\Lambda)S^{-1}$.
Structural Commentary: Power induction transfers conjugation to polynomial sums; diagonal powers reduce entrywise.
Key Insight: Conjugation cancels between powers, while diagonal entries evolve independently. □

2 Characteristic and Minimal Polynomials

2.1 Characteristic Polynomial Foundations

Motivation 2.1.1. *Two Spectral Polynomials*
Eigenvalues alone do not record algebraic repetition, and a matrix can satisfy many polynomial relations.
The characteristic polynomial records root multiplicities; the minimal polynomial selects the least-degree monic relation.

Definition 2.1.2. *Characteristic Polynomial*
Let $n \geq 1$ and $A \in \operatorname{Mat}(n, n, \mathbb{F})$. The *characteristic polynomial* of A is $p_A(z) := \det(zI_n - A) \in \mathbb{F}[z]$.

Theorem 2.1.3. *Basic Form of the Characteristic Polynomial*
Let $n \geq 1$ and $A = [a_{ij}] \in \operatorname{Mat}(n, n, \mathbb{F})$. The following hold:
(i) $p_A(z) = z^n - (\operatorname{tr} A)z^{n-1} + \cdots + (-1)^n \det A$*; in particular, p_A is monic of degree n.*
(ii) $\operatorname{spec}(A) = \{\lambda \in \mathbb{F} : p_A(\lambda) = 0\}$.

Proof.

(i) By Definitions 2.1.2 and 3.8.1, $p_A(z) = \sum_{\sigma \in \mathfrak{S}_n} \operatorname{sign}(\sigma) \prod_{j=1}^{n} (z\delta_{\sigma(j),j} - a_{\sigma(j),j})$.
A nonidentity permutation moves at least two indices, so its summand has degree at most $n-2$.
The identity summand is $\prod_{j=1}^{n} (z - a_{jj}) = z^n - (\operatorname{tr} A)z^{n-1} + \cdots$ by Definition 3.8.1(i).
$p_A(0) = \det(-A) = (-1)^n \det A$ by Definition 2.1.2 and repeated column linearity from Theorem 3.8.2(ii). Thus (i) holds.

(ii) Fix $\lambda \in \mathbb{F}$. By Definition 2.1.2 and Theorem 3.8.2(vii), $p_A(\lambda) = 0 \iff \lambda I_n - A$ is singular.
By Corollary 5.1.8 and Definition 5.1.3(iii), this is equivalent to $\lambda \in \operatorname{spec}(A)$.

Structural Commentary: Permutation degrees determine the coefficients; shifted singularity identifies the root set.
Key Insight: The determinant vanishes exactly when the spectral shift has nonzero kernel. □

Definition 2.1.4. *Algebraic Multiplicity*
Let $n \geq 1$, $A \in \operatorname{Mat}(n, n, \mathbb{F})$, and $\lambda \in \mathbb{F}$. The *algebraic multiplicity* $m_A(\lambda)$ is the multiplicity of λ as a root of p_A.
If $\lambda \notin \operatorname{spec}(A)$, set $m_A(\lambda) := 0$. Unqualified multiplicity means algebraic multiplicity.

Figure 53 summarizes the passage from a matrix to its characteristic polynomial and roots.

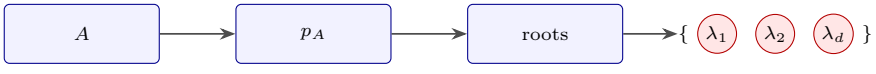

Figure 53: The chain $A \mapsto p_A \mapsto \{\lambda_1, \dots, \lambda_d\}$; m_A retains each root multiplicity.

Computation Method 2.1.5. *Characteristic Equation and Eigenspace Computation*
Given $n \geq 1$ and $A \in \operatorname{Mat}(n, n, \mathbb{F})$, compute its spectral data as follows:
(i) Form $p_A(z) = \det(zI_n - A)$ by Definition 2.1.2.
(ii) Compute $\{\lambda \in \mathbb{F} : p_A(\lambda) = 0\} = \operatorname{spec}(A)$ by Theorem 2.1.3(ii), recording each $m_A(\lambda)$.
(iii) $(\forall\, \lambda \in \operatorname{spec}(A))$, row-reduce $A - \lambda I_n$ and compute $E_\lambda(A) = \ker(A - \lambda I_n)$.
(iv) Choose a basis of each $E_\lambda(A)$ and return its dimension as the geometric multiplicity.
The output separates algebraic multiplicity from the nullspace dimension.

Proposition 2.1.6. *Upper-Triangular Eigenvalues*
Let $n \geq 1$, let $A = [a_{ij}] \in \mathrm{Mat}(n, n, \mathbb{F})$ be upper triangular, and set $J_n := \{1, \ldots, n\}$. Then:

(i) $p_A(z) = \prod_{j=1}^{n} (z - a_{jj})$;
(ii) $\mathrm{spec}(A) = \{a_{jj} : j \in J_n\}$;
(iii) $(\forall\, \lambda \in \mathbb{F})$, $m_A(\lambda) = \#\{j \in J_n : a_{jj} = \lambda\}$.

Proof.

(i) Matrix $zI_n - A$ is upper triangular with diagonal entries $z - a_{jj}$. By Theorem 3.8.2(v) and Definition 2.1.2, $p_A(z) = \prod_{j=1}^{n} (z - a_{jj})$.
(ii) By (i) and Theorem 2.1.3(ii), the roots of p_A and the elements of $\mathrm{spec}(A)$ are exactly the diagonal entries.
(iii) Fix $\lambda \in \mathbb{F}$. In the factorization from (i), the exponent of $z - \lambda$ is $\#\{j \in J_n : a_{jj} = \lambda\}$. This equals $m_A(\lambda)$ by Definition 2.1.4, including when $\lambda \notin \mathrm{spec}(A)$. Thus (iii) holds.

Structural Commentary: Triangularity reduces the determinant to diagonal factors; repeated factors encode algebraic multiplicity.
Key Insight: For an upper-triangular matrix, the entire characteristic root multiset is visible on the diagonal. □

Theorem 2.1.7. *Similarity Preserves Characteristic Data*
Let $n \geq 1$, let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$, and let $S \in \mathrm{Mat}(n, n, \mathbb{F})^{\times}$ satisfy $B = SAS^{-1}$. Then:

(i) $p_B = p_A$;
(ii) $(\forall\, \lambda \in \mathbb{F})$, $m_B(\lambda) = m_A(\lambda)$;
(iii) $(\forall\, \lambda \in \mathbb{F})$, *the restriction* $S|_{E_\lambda(A)} : E_\lambda(A) \to E_\lambda(B)$ *is an isomorphism, so* $\dim E_\lambda(B) = \dim E_\lambda(A)$.

Proof.

(i) By $zI_n - B = S(zI_n - A)S^{-1}$ and Theorem 3.8.2(vi),(viii), $p_B(z) = \det(S)\det(zI_n - A)\det(S^{-1}) = p_A(z)$.
(ii) Equal polynomials have the same roots with the same multiplicities. By (i) and Definition 2.1.4, $(\forall\, \lambda \in \mathbb{F})\, m_B(\lambda) = m_A(\lambda)$.
(iii) Fix $\lambda \in \mathbb{F}$. If $\mathbf{x} \in E_\lambda(A)$, then $(B - \lambda I_n)S\mathbf{x} = S(A - \lambda I_n)\mathbf{x} = \mathbf{0}$, so $S(E_\lambda(A)) \subseteq E_\lambda(B)$. The same calculation for $A = S^{-1}BS$ proves the reverse inclusion. Thus $S|_{E_\lambda(A)}$ is an isomorphism onto $E_\lambda(B)$, and the dimensions agree.

Structural Commentary: Conjugation preserves the shifted determinant and transports shifted kernels through one coordinate change.
Key Insight: Similarity preserves both algebraic multiplicity and geometric multiplicity. □

Proposition 2.1.8. *Block Upper-Triangular Characteristic Polynomial*
Let $r, s \geq 1$, let $B \in \mathrm{Mat}(r, r, \mathbb{F})$, $C \in \mathrm{Mat}(r, s, \mathbb{F})$, and $D \in \mathrm{Mat}(s, s, \mathbb{F})$, and set $A := \left(\begin{smallmatrix} B & C \\ 0 & D \end{smallmatrix}\right)$. Then:

(i) $p_A = p_B p_D$;
(ii) $(\forall\, \lambda \in \mathbb{F})$, $m_A(\lambda) = m_B(\lambda) + m_D(\lambda)$.

Proof.

(i) The shifted matrix is $zI_{r+s} - A = \left(\begin{smallmatrix} zI_r - B & -C \\ 0 & zI_s - D \end{smallmatrix}\right)$. By Theorem 3.8.4 and Definition 2.1.2, $p_A = p_B p_D$.
(ii) Fix $\lambda \in \mathbb{F}$. By (i) and Definition 2.1.4, the multiplicity of λ in p_A is the sum of its multiplicities in p_B and p_D, including when λ is absent from one or both spectra.

Structural Commentary: The determinant splits across the diagonal blocks, so root orders add across the two characteristic factors.
Key Insight: The off-diagonal block affects eigenvectors but not the characteristic polynomial. □

Theorem 2.1.9. *Matrix Schur Triangularisation with Ordered Diagonal*
Let $n \geq 1$, let $A \in \mathrm{Mat}(n, n, \mathbb{C})$ have eigenvalues $\lambda_1, \ldots, \lambda_n$, counted with algebraic multiplicity and listed in a prescribed order, and let $A\mathbf{x} = \lambda_1 \mathbf{x}$ with $\|\mathbf{x}\|_2 = 1$. Then:

(i) $(\exists\, U_2 \in \mathrm{Mat}(n, n-1, \mathbb{C}))$ *such that* $[\mathbf{x}\ U_2]$ *is unitary and* $[\mathbf{x}\ U_2]^* A [\mathbf{x}\ U_2]$ *is upper triangular with diagonal* $\lambda_1, \ldots, \lambda_n$;
(ii) if $A \in \mathrm{Mat}(n, n, \mathbb{R})$, $\lambda_1, \ldots, \lambda_n \in \mathbb{R}$, *and* $\mathbf{x} \in \mathbb{R}^n$, *then the matrix in (i) may be chosen real orthogonal.*

Proof.

(i) We induct on n. The case $n = 1$ follows by taking $U = [\mathbf{x}]$.
Assume $n > 1$. Extend $\mathbf{x}$ to an orthonormal basis by Corollary 1.3.12, and write the resulting unitary matrix as $V = [\mathbf{x}\ V_2]$.
Since $A\mathbf{x} = \lambda_1 \mathbf{x}$, the first column of V^*AV is $\lambda_1 \mathbf{e}_1$, so write $V^*AV = \left(\begin{smallmatrix} \lambda_1 & \mathbf{b}^* \\ 0 & A' \end{smallmatrix}\right)$ with $\mathbf{b} \in \mathbb{C}^{n-1}$ and $A' \in \mathrm{Mat}(n-1, n-1, \mathbb{C})$.
By Theorem 2.1.7(i) and Proposition 2.1.8(i), $p_A(z) = (z - \lambda_1) p_{A'}(z)$. Thus $\lambda_2, \ldots, \lambda_n$ is the prescribed eigenvalue list of A'.
By the induction hypothesis, choose a unitary $W \in \mathrm{Mat}(n-1, n-1, \mathbb{C})$ such that $T' := W^* A' W$ is upper triangular with diagonal $\lambda_2, \ldots, \lambda_n$. Set $U := V(I_1 \oplus W)$. Then U is unitary, its first column is $\mathbf{x}$, and $U^*AU = \left(\begin{smallmatrix} \lambda_1 & \mathbf{b}^* W \\ 0 & T' \end{smallmatrix}\right)$ has the required form.

(ii) We repeat the induction within $\mathbb{R}^n$. The case $n = 1$ is immediate. For $n > 1$, extend the real unit vector $\mathbf{x}$ to a real orthonormal basis by Corollary 1.3.12. The resulting real orthogonal $V = [\mathbf{x}\ V_2]$ satisfies $V^{\mathsf{T}}AV = \left(\begin{smallmatrix} \lambda_1 & \mathbf{b}^{\mathsf{T}} \\ 0 & A' \end{smallmatrix}\right)$ with real blocks.
By the factorization in (i), the real matrix A' has the prescribed real eigenvalue list $\lambda_2, \ldots, \lambda_n$.
By the real induction hypothesis, choose a real orthogonal W with $W^{\mathsf{T}} A' W$ upper triangular in that order. Thus $U := V(I_1 \oplus W)$ is real orthogonal, begins with $\mathbf{x}$, and has the required triangularization.

Structural Commentary: Schur induction isolates the prescribed eigenline and passes the remaining ordered roots to the trailing block.
Key Insight: The first eigenvector fixes the first diagonal entry and leaves the remaining multiplicities for the next step. □

Figure 54 summarizes the induction by isolating the prescribed first eigenline.

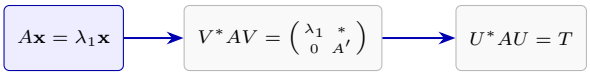

Figure 54: Schur induction: isolate an eigenline, then triangularise the compressed block.

Corollary 2.1.10. *Eigenvalues of the Inverse*
Let $n \geq 1$ and let $A \in \mathrm{Mat}(n,n,\mathbb{C})$ be invertible with eigenvalues $\lambda_1,\dots,\lambda_n$, counted with algebraic multiplicity. Then A^{-1} has eigenvalues $\lambda_1^{-1},\dots,\lambda_n^{-1}$, counted with algebraic multiplicity.

Proof. By Corollary 5.1.8, $(\forall\, j \in \{1,\dots,n\})\ \lambda_j \neq 0$. Choose $\mathbf{0} \neq \mathbf{y} \in E_{\lambda_1}(A)$ and set $\mathbf{x} := \frac{\mathbf{y}}{\|\mathbf{y}\|_2}$, so $\|\mathbf{x}\|_2 = 1$.
By Theorem 2.1.9(i), $A = UTU^*$ for a unitary U and an upper-triangular T with diagonal $\lambda_1,\dots,\lambda_n$.
Hence $A^{-1} = UT^{-1}U^*$, while T^{-1} is upper triangular with diagonal $\lambda_1^{-1},\dots,\lambda_n^{-1}$ by Theorem 3.8.9.
By Proposition 2.1.6(iii) and Theorem 2.1.7(ii), this reciprocal diagonal list is the eigenvalue multiset of A^{-1}.
Structural Commentary: Schur form turns inversion into inversion of a triangular matrix, whose diagonal entries invert individually.
Key Insight: Algebraic multiplicities are preserved when the nonzero spectral multiset is sent through $\lambda \mapsto \lambda^{-1}$. □

Theorem 2.1.11. *Geometric Multiplicity Is at Most Algebraic Multiplicity*
Let $n \geq 1$, let $A \in \mathrm{Mat}(n,n,\mathbb{F})$, and let $\lambda \in \mathrm{spec}(A)$. Then $\dim E_\lambda(A) \leq m_A(\lambda)$.

Proof. Set $k := \dim E_\lambda(A)$ and choose a basis $(\mathbf{x}_1,\dots,\mathbf{x}_k)$ of $E_\lambda(A)$.
If $k = n$, then $E_\lambda(A) = \mathbb{F}^n$, so $A = \lambda I_n$. By Proposition 2.1.6(i),(iii), $p_A(z) = (z-\lambda)^n$ and $m_A(\lambda) = n = k$. Suppose $k < n$.
Extend eigenspace basis to basis of $\mathbb{F}^n$ by Theorem 1.3.17, let S be invertible matrix whose columns are resulting basis vectors.
Since the first k columns are λ-eigenvectors, write $S^{-1}AS = \begin{pmatrix} \lambda I_k & C \\ 0 & D \end{pmatrix}$ with $C \in \mathrm{Mat}(k, n-k, \mathbb{F})$ and $D \in \mathrm{Mat}(n-k, n-k, \mathbb{F})$.
By Theorem 2.1.7(i) and Proposition 2.1.8(i), $p_A(z) = (z-\lambda)^k p_D(z)$. Hence $m_A(\lambda) \geq k = \dim E_\lambda(A)$ by Definition 2.1.4.
Structural Commentary: An eigenspace-first basis exposes $(z-\lambda)^k$, including the endpoint $k = n$.
Key Insight: Geometric multiplicity supplies a visible lower bound on the order of the corresponding characteristic root. □

Theorem 2.1.12. *Diagonalizability and Multiplicity*
Let $n \geq 1$ and let $A \in \mathrm{Mat}(n,n,\mathbb{C})$. Then A is similar to a diagonal matrix if and only if $(\forall\, \lambda \in \mathrm{spec}(A))\ \dim E_\lambda(A) = m_A(\lambda)$.

Proof.
(⇒) Suppose A is similar to a diagonal matrix D. By Theorem 2.1.7(ii),(iii), $(\forall\, \lambda \in \mathbb{C})\ m_A(\lambda) = m_D(\lambda)$ and $\dim E_\lambda(A) = \dim E_\lambda(D)$. By Proposition 2.1.6(iii), $m_D(\lambda)$ counts the diagonal entries equal to λ, and the corresponding standard basis vectors form a basis of $E_\lambda(D)$. Thus the required equality holds.
(⇐) Assume the stated equality and let $T_A : \mathbb{C}^n \to \mathbb{C}^n$ be defined by $T_A(\mathbf{v}) = A\mathbf{v}$. By Theorem 5.3.5, T_A has an upper-triangular matrix B relative to a basis. By Corollary 6.2.4 and Theorem 2.1.7(ii), A and B have the same algebraic multiplicities.
List the distinct eigenvalues as $\mu_1,\dots,\mu_d$. By Proposition 2.1.6(ii),(iii), the n diagonal positions of B are partitioned by these eigenvalues and $\sum_{i=1}^{d} m_A(\mu_i) = n$. Thus the hypothesis implies $\sum_{i=1}^{d} \dim E_{\mu_i}(T_A) = \sum_{i=1}^{d} \dim E_{\mu_i}(A) = n$.
By Theorem 5.4.3(v),(i), T_A is diagonalizable. Its matrices in the standard basis and in a diagonalizing basis are therefore similar by Corollary 6.2.4, so A is similar to a diagonal matrix.
Structural Commentary: Triangularization accounts for the complete algebraic-multiplicity total, while the hypothesis converts it into a full eigenspace dimension count.
Key Insight: A complex matrix is diagonalizable exactly when no algebraic multiplicity is lost as an eigenspace dimension. □

Proposition 2.1.13. *Permutation Similarity Reorders Diagonal Entries*
Let $n \geq 1$, let $\lambda_1,\dots,\lambda_n \in \mathbb{C}$, and let $\sigma \in \mathfrak{S}_n$. Set $\Lambda := \mathrm{diag}(\lambda_1,\dots,\lambda_n)$ and $P := [\mathbf{e}_{\sigma(1)}\ \cdots\ \mathbf{e}_{\sigma(n)}]$. Then $P^*\Lambda P = \mathrm{diag}(\lambda_{\sigma(1)},\dots,\lambda_{\sigma(n)})$.

Proof. For $i,j \in \{1,\dots,n\}$, the (i,j) entry of $P^*\Lambda P$ is $\mathbf{e}_{\sigma(i)}^*\Lambda\mathbf{e}_{\sigma(j)} = \lambda_{\sigma(j)}\mathbf{e}_{\sigma(i)}^*\mathbf{e}_{\sigma(j)} = \lambda_{\sigma(j)}\delta_{ij}$.
Hence all off-diagonal entries vanish and the jth diagonal entry is $\lambda_{\sigma(j)}$, which proves the matrix identity.
Structural Commentary: The entry calculation tracks both the row and column reordering induced by the same permutation.
Key Insight: Permutation similarity reorders a diagonal list without changing its entries. □

Corollary 2.1.14. *Normal Matrices with the Same Spectrum Are Unitarily Similar*
Let $n \geq 1$. If $A, B \in \mathrm{Mat}(n,n,\mathbb{C})$ are normal and have the same eigenvalue multiset, then A and B are unitarily similar.

Proof. By Theorem 6.1.11(i),(iii), write $A = U\Lambda U^*$ and $B = V\Gamma V^*$ with U, V unitary and Λ, Γ diagonal.
Since the eigenvalue multisets agree, choose $\sigma \in \mathfrak{S}_n$ that matches the diagonal of Λ to that of Γ, and set $P := [\mathbf{e}_{\sigma(1)}\ \cdots\ \mathbf{e}_{\sigma(n)}]$.
By Proposition 2.1.13, $\Gamma = P^*\Lambda P$. Set $Q := UPV^*$.
Then Q is unitary by Proposition 2.6.12, and $Q^*AQ = VP^*U^*(U\Lambda U^*)UPV^* = V\Gamma V^* = B$. Thus A and B are unitarily similar.
Structural Commentary: Spectral diagonalizations reduce the comparison to a unitary permutation of equal eigenvalue multisets.
Key Insight: For normal matrices, the eigenvalue multiset completely determines the unitary-similarity class. □

Definition 2.1.15. *Characteristic Polynomial of an Operator*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{F}$, let $n := \dim(\mathcal{V})$, and let $T \in \mathcal{L}(\mathcal{V})$.
For a basis β of $\mathcal{V}$, set $q_{T,\beta}(z) := p_{[T]_{\beta\leftarrow\beta}}(z) = \det(zI_n - [T]_{\beta\leftarrow\beta})$.
This value is independent of β by Theorems 5.1.1 and 2.1.7(i). It is the *characteristic polynomial* of T and is denoted by q_T.

Proposition 2.1.16. *Degree and Roots of q_T*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{F}$, let $T \in \mathcal{L}(\mathcal{V})$, and let q_T be the characteristic polynomial of T.
(i) $\deg q_T = \dim(\mathcal{V})$.
(ii) The roots of q_T are precisely the eigenvalues of T.

Proof. Choose a basis β of $\mathcal{V}$ and set $A = [T]_{\beta\leftarrow\beta}$.
(i) By Definition 2.1.15, $q_T = p_A$. Hence $\deg q_T = \dim(\mathcal{V})$ by Theorem 2.1.3(i).
(ii) Fix $\lambda \in \mathbb{F}$. By Proposition 3.2.5, $(\forall\, \mathbf{v} \in \mathcal{V})\ [T\mathbf{v}]_\beta = A[\mathbf{v}]_\beta$.
By Proposition 3.2.2(ii),(iii), $\lambda \in \mathrm{spec}(T) \iff \lambda \in \mathrm{spec}(A)$. By Theorem 2.1.3(ii), the latter set is the root set of $p_A = q_T$.
Structural Commentary: Coordinates transfer polynomial degree and the nonzero eigenvector equation between T and its matrix.
Key Insight: The operator characteristic polynomial has the expected dimension and detects exactly the operator eigenvalues. □

2.2 Minimal Polynomial Foundations

Theorem 2.2.1. *Existence of the Minimal Polynomial*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{F}$ and let $T \in \mathcal{L}(\mathcal{V})$. Then:

(i) T has a monic annihilator of positive least degree;
(ii) the annihilator in (i) is unique.

Proof.

(i) By Proposition 1.1.7, choose a nonconstant annihilator h and replace it by its monic normalization.
Let $\mathcal{M}_T$ be the monic annihilators of T and set $\mathcal{D}_T := \{\deg p : p \in \mathcal{M}_T\}$; then $\varnothing \neq \mathcal{D}_T \subseteq \mathbb{N}$.
By well-ordering, set $d := \min \mathcal{D}_T$ and choose a monic annihilator p with $\deg p = d$.
A nonzero constant c cannot annihilate T because $c(T) = cI_{\mathcal{V}} \neq 0$ on $\mathcal{V} \neq \{\mathbf{0}\}$. Thus $d \geq 1$.

(ii) Let p and q be monic annihilators of degree d. If $p \neq q$, then $(p-q)(T) = p(T) - q(T) = 0$ by Definition 1.1.2.
Their leading terms cancel, so $\deg(p-q) < d$. Normalizing the nonzero polynomial $p - q$ therefore produces a monic annihilator of degree less than d, contrary to the definition of d. Hence $p = q$.

Structural Commentary: Well-ordering selects a least normalized annihilator; leading-term cancellation forces uniqueness.
Key Insight: Two minimal monic annihilators would differ by a smaller annihilator. □

Definition 2.2.2. *Minimal Polynomial of an Operator*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{F}$ and let $T \in \mathcal{L}(\mathcal{V})$. The *minimal polynomial* μ_T is the unique monic polynomial of least degree satisfying $\mu_T(T) = 0$; it exists by Theorem 2.2.1.

Definition 2.2.3. *Minimal Polynomial of a Matrix*
Let $n \geq 1$, let $A \in \mathrm{Mat}(n, n, \mathbb{F})$, and let $T_A \in \mathcal{L}(\mathbb{F}^n)$ be induced by A as in Definition 3.1.7. The *minimal polynomial* of A is $\mu_A := \mu_{T_A}$.
For $j \in \mathbb{Z}_{\geq 0}$, set $P_j := ((\forall\, \mathbf{v} \in \mathbb{F}^n)\, T_A^j \mathbf{v} = A^j \mathbf{v})$. Then P_0 holds by Definitions 1.1.1 and 3.1.7.
If P_j holds, then $(\forall\, \mathbf{v} \in \mathbb{F}^n)\, T_A^{j+1}\mathbf{v} = T_A(A^j\mathbf{v}) = A^{j+1}\mathbf{v}$ by Definition 3.1.7, so P_{j+1} holds. Hence $(\forall\, j \in \mathbb{Z}_{\geq 0})\, P_j$ by Theorem 2.6.2.
If $p(z) = \sum_{j=0}^{d} c_j z^j \in \mathbb{F}[z]$, then $(\forall\, \mathbf{v} \in \mathbb{F}^n)\, p(T_A)\mathbf{v} = \sum_{j=0}^{d} c_j A^j \mathbf{v} = p(A)\mathbf{v}$ by Definitions 1.1.2 and 3.8.5.
Thus μ_A is equivalently the unique monic polynomial of least positive degree satisfying $\mu_A(A) = 0$.

Theorem 2.2.4. *Annihilators Are Multiples of μ_T*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{F}$, let $T \in \mathcal{L}(\mathcal{V})$, and let $f \in \mathbb{F}[z]$ be nonzero. Then $f(T) = 0$ if and only if μ_T divides f.

Proof.

($\Rightarrow$) Suppose $f(T) = 0$ and set $d := \deg \mu_T$. Starting from $r_0 := f$ and $s_0 := 0$, suppose $\deg r_k \geq d$, set $e_k := \deg r_k - d$, and let $a_k \in \mathbb{F}^\times$ be the leading coefficient of r_k. Set $r_{k+1} := r_k - a_k z^{e_k}\mu_T$ and $s_{k+1} := s_k + a_k z^{e_k}$.
The identity $f = s_k\mu_T + r_k$ holds for $k = 0$ and is preserved by the recurrence.
Monicity of μ_T implies $r_{k+1} = 0$ or $\deg r_{k+1} < \deg r_k$. Degree descent terminates with $f = s\mu_T + r$, where $r = 0$ or $\deg r < d$.
By Definition 1.1.2 and Proposition 1.1.6(i), $r(T) = f(T) - s(T)\mu_T(T) = 0$. If $r \neq 0$, its monic normalization is an annihilator of degree less than d, which is impossible by Definition 2.2.2. Thus $r = 0$ and μ_T divides f.

($\Leftarrow$) If $f = \mu_T s$, then $f(T) = \mu_T(T)s(T) = 0$ by Proposition 1.1.6(i).

Structural Commentary: Leading-term cancellation constructs a remainder; minimality eliminates every nonzero remainder.
Key Insight: A nonzero remainder would normalize below $\deg \mu_T$. □

Theorem 2.2.5. *Similarity Preserves the Minimal Polynomial*
Let $n \geq 1$ and let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$ be similar. Then:

(i) $p_A = p_B$;
(ii) $\mu_A = \mu_B$.

Proof. Choose $S \in \mathrm{Mat}(n, n, \mathbb{F})^\times$ satisfying $B = SAS^{-1}$ by Definition 6.2.1.

(i) $p_A = p_B$ by Theorem 2.1.7(i).

(ii) Set $P_j := (B^j = SA^jS^{-1})$ for $j \in \mathbb{Z}_{\geq 0}$. The identity P_0 holds because $B^0 = I_n = SI_nS^{-1} = SA^0S^{-1}$. If P_j holds, then $B^{j+1} = B^jB = SA^jS^{-1}SAS^{-1} = SA^{j+1}S^{-1}$, so P_{j+1} holds. Hence $(\forall\, j \in \mathbb{Z}_{\geq 0})\, P_j$ by Theorem 2.6.2.
By Definition 3.8.5, $(\forall\, f \in \mathbb{F}[z])\, f(B) = Sf(A)S^{-1}$. Therefore $f(B) = 0 \iff f(A) = 0$, so A and B have the same monic least-degree annihilator by Definition 2.2.3.

Structural Commentary: Power induction transports characteristic and minimal polynomial data across one conjugation.
Key Insight: Conjugation preserves every polynomial equation. □

3 Cayley-Hamilton and Annihilators

3.1 Cayley-Hamilton and Minimal Polynomials

Theorem 3.1.1. *Cayley–Hamilton Theorem*
Let $n \geq 1$ and let $A \in \mathrm{Mat}(n, n, \mathbb{C})$ have characteristic polynomial $p_A(z) = \det(zI_n - A)$. Then $p_A(A) = 0$.

Proof.

(i) *Triangular Reduction*: By Theorem 5.4.14(i) for $\{A\}$, choose a unitary U such that $T := U^*AU = [t_{ij}]$ is upper triangular.
Then $A = UTU^*$ by unitarity of U. Set $\lambda_j := t_{jj}$ for $j \in \{1, \ldots, n\}$.
Then $p_A = p_T = \prod_{j=1}^{n} (z - \lambda_j)$ by Theorem 2.1.7(i) and Proposition 2.1.6(i).

(ii) *Polynomial Transfer*: For $k \in \mathbb{Z}_{\geq 0}$, set $P_k := (A^k = UT^kU^*)$. The identity P_0 holds by unitarity of U.
If P_k holds, then $A^{k+1} = A^kA = UT^kU^*UTU^* = UT^{k+1}U^*$, so P_{k+1} holds. Hence $(\forall\, k \in \mathbb{Z}_{\geq 0})\, P_k$ by Theorem 2.6.2.
For $j \in \{1, \ldots, n\}$, set $Q_j := \prod_{i=1}^{j} (T - \lambda_i I_n)$. By Definition 3.8.5, part (i), and the identities P_k, $p_A(A) = Up_A(T)U^* = UQ_nU^*$.

(iii) *Column Induction*: For $j \in \{1, \dots, n\}$, set $R_j := ((\forall\, \ell \in \{1, \dots, j\})\, Q_j \mathbf{e}_\ell = \mathbf{0})$.
The predicate R_1 holds because the first column of $T - \lambda_1 I_n$ is zero. Suppose $j \in \{1, \dots, n-1\}$ and R_j holds.
By upper triangularity and the zero $(j+1, j+1)$ entry, $(\forall\, \ell \in \{1, \dots, j+1\})\, (T - \lambda_{j+1} I_n)\mathbf{e}_\ell \in \operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_j)$.
By R_j and linearity of Q_j, $(\forall\, \ell \in \{1, \dots, j+1\})\, Q_{j+1}\mathbf{e}_\ell = Q_j(T - \lambda_{j+1} I_n)\mathbf{e}_\ell = \mathbf{0}$, so R_{j+1} holds.
Hence $(\forall\, j \in \{1, \dots, n\})\, R_j$ by Theorem 2.6.2.
(iv) *Conclusion*: By R_n, every column of Q_n is zero, so $Q_n = 0$. Therefore $p_A(A) = U Q_n U^* = 0$ by part (ii).

Structural Commentary: Unitary triangularization transfers Cayley–Hamilton to a column-killing induction.
Key Insight: The jth factor extends the zero leading-column block from $j-1$ to j. □

Figure 55 depicts the invariant R_j: each new factor extends the zero leading-column block by one column.

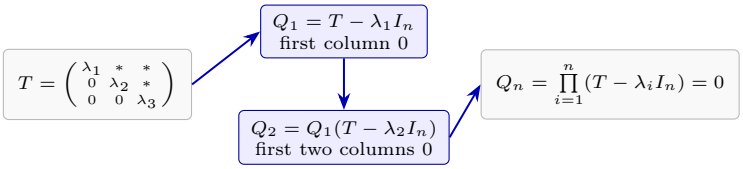

Figure 55: For upper-triangular T, the factors $T - \lambda_i I_n$ make the first j columns of Q_j vanish successively.

Theorem 3.1.2. *Cayley–Hamilton Theorem for Operators*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{C}$, let $T \in \mathcal{L}(\mathcal{V})$, and let q_T be the characteristic polynomial of T. Then $q_T(T) = 0$.

Proof. Choose a basis β of $\mathcal{V}$ and set $A = [T]_{\beta \leftarrow \beta}$. The identity $q_T = p_A$ holds by Definition 2.1.15.
The identity $[q_T(T)]_{\beta \leftarrow \beta} = q_T(A)$ holds by Propositions 3.2.4 and 3.4.4. Hence $[q_T(T)]_{\beta \leftarrow \beta} = p_A(A) = 0$ by Theorem 3.1.1.
Therefore $q_T(T) = 0$ by Theorem 3.4.5.
Structural Commentary: Matrix representation transfers operator polynomial evaluation to the matrix Cayley–Hamilton identity.
Key Insight: The coordinate matrix of $q_T(T)$ is exactly $q_T(A)$. □

Corollary 3.1.3. *Reduction Modulo the Characteristic Polynomial*
Let $n \geq 1$, let $A \in \operatorname{Mat}(n, n, \mathbb{C})$, and let $f, q, r \in \mathbb{C}[z]$. If $f = p_A q + r$ with $r = 0$ or $\deg r < n$, then $f(A) = r(A)$.

Proof. By the polynomial identity in the hypothesis, $f(A) = p_A(A)q(A) + r(A)$. Since $p_A(A) = 0$ by Theorem 3.1.1, $f(A) = r(A)$.
Structural Commentary: Evaluation transfers division by p_A to equality of the corresponding matrix polynomials.
Key Insight: The characteristic-polynomial term vanishes at A. □

Corollary 3.1.4. *Powers Span at Most n Dimensions*
Let $n \geq 1$, let $A \in \operatorname{Mat}(n, n, \mathbb{C})$, and set $\mathcal{W}_A := \operatorname{span}(I_n, A, \dots, A^{n-1})$. Then:
(i) $\operatorname{span}(I_n, A, A^2, \dots) = \mathcal{W}_A$;
(ii) $\dim(\mathcal{W}_A) \leq n$.

Proof.
(i) Write $p_A(z) = z^n + \sum_{j=0}^{n-1} c_j z^j$ by Theorem 2.1.3(i). Then $A^n = -\sum_{j=0}^{n-1} c_j A^j \in \mathcal{W}_A$ by Theorem 3.1.1.
If $0 \leq j < n-1$, then $AA^j = A^{j+1} \in \mathcal{W}_A$; the remaining generator satisfies $AA^{n-1} = A^n \in \mathcal{W}_A$.
Hence $A\mathcal{W}_A \subseteq \mathcal{W}_A$ by linearity. Set $P_k := (A^k \in \mathcal{W}_A)$ for $k \in \mathbb{Z}_{\geq 0}$.
The predicate P_0 holds by $A^0 = I_n \in \mathcal{W}_A$, and $P_k \Rightarrow P_{k+1}$ by $A\mathcal{W}_A \subseteq \mathcal{W}_A$. Thus $(\forall\, k \in \mathbb{Z}_{\geq 0})\, P_k$ by Theorem 2.6.2.
Therefore $\operatorname{span}(I_n, A, A^2, \dots) \subseteq \mathcal{W}_A$; the reverse inclusion holds by the definition of $\mathcal{W}_A$.
(ii) The list $(I_n, A, \dots, A^{n-1})$ spans $\mathcal{W}_A$ and has length n. It contains a basis of $\mathcal{W}_A$ by Theorem 1.3.12, so $\dim(\mathcal{W}_A) \leq n$.

Structural Commentary: The characteristic recurrence makes $\mathcal{W}_A$ invariant; a basis sublist supplies the dimension bound.
Key Insight: $A\mathcal{W}_A \subseteq \mathcal{W}_A$ propagates containment to every matrix power. □

Corollary 3.1.5. *Inverse from the Characteristic Polynomial*
Let $n \geq 1$, let $A \in \operatorname{Mat}(n, n, \mathbb{C})$, and write $p_A(z) = \sum_{j=0}^{n} c_j z^j$ with $c_n = 1$. If A is invertible, then $A^{-1} = -c_0^{-1} \sum_{j=1}^{n} c_j A^{j-1}$.

Proof. Since A is invertible, $0 \notin \operatorname{spec}(A)$ by Corollary 5.1.8. Hence $c_0 = p_A(0) \neq 0$ by Theorem 2.1.3(ii).
By Theorem 3.1.1, $c_0 I_n = -\sum_{j=1}^{n} c_j A^j$. By left multiplication by $c_0^{-1} A^{-1}$, $A^{-1} = -c_0^{-1} \sum_{j=1}^{n} c_j A^{j-1}$.
Structural Commentary: Cayley–Hamilton separates the constant term, while invertibility permits multiplication by $c_0^{-1} A^{-1}$.
Key Insight: The nonzero constant coefficient permits solving the characteristic identity for A^{-1}. □

Theorem 3.1.6. *Basic Properties of the Minimal Polynomial*
Let $n, d \geq 1$, let $A \in \operatorname{Mat}(n, n, \mathbb{C})$, and let $\lambda_1, \dots, \lambda_d$ be the distinct eigenvalues of A.
(i) $\mu_A \mid p_A$;
(ii) $\deg \mu_A \leq n$;
(iii) $(\exists\, q_1, \dots, q_d \in \mathbb{Z}_{>0})[(\forall\, i \in \{1, \dots, d\})\, q_i \leq m_A(\lambda_i) \ \wedge \ \mu_A(z) = \prod_{i=1}^{d} (z - \lambda_i)^{q_i}]$.

Proof.
(i) The polynomial p_A is nonzero by Theorem 2.1.3(i), and $p_A(A) = 0$ by Theorem 3.1.1.
Hence $\mu_A \mid p_A$ by Theorem 2.2.4 and Definition 2.2.3.
(ii) By (i) and $\deg p_A = n$ from Theorem 2.1.3(i), $\deg \mu_A \leq n$.

(iii) By Theorem 5.4.14(i) for $\{A\}$, choose a unitary U such that $R := U^*AU$ is upper triangular.

By Theorem 2.1.7(i),(ii) and Proposition 2.1.6(i),(iii), $p_A(z) = \prod_{i=1}^{d} (z-\lambda_i)^{m_A(\lambda_i)}$.

By factorization over $\mathbb{C}$ and monicity of μ_A, write μ_A as a product of monic linear factors.

By (i), each factor occurs in p_A with no greater exponent, so $\mu_A(z) = \prod_{i=1}^{d} (z-\lambda_i)^{q_i}$ for integers $0 \le q_i \le m_A(\lambda_i)$.

Fix $i \in \{1,\dots,d\}$ and choose $\mathbf{v} \neq \mathbf{0}$ satisfying $A\mathbf{v} = \lambda_i\mathbf{v}$ by the eigenvalue hypothesis.
Then $\mathbf{0} = \mu_A(A)\mathbf{v} = \mu_A(\lambda_i)\mathbf{v}$ by Proposition 1.1.8, so $\mu_A(\lambda_i) = 0$ and $q_i \ge 1$.
Since i was arbitrary, $(\forall\, i \in \{1,\dots,d\})\, q_i \ge 1$, which proves (iii).

Structural Commentary: Cayley–Hamilton supplies divisibility; Schur form and eigenvectors determine the exponents.
Key Insight: Every eigenvalue must occur in μ_A, but never above its multiplicity in p_A. □

Figure 56 depicts μ_A as a common divisor of p_A and every polynomial f satisfying $f(A) = 0$.

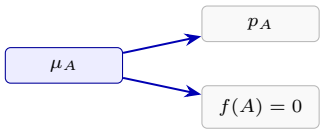

Figure 56: μ_A is the least monic annihilator; arrows indicate that μ_A divides p_A and every annihilator f.

3.2 Diagonalizability and Minimal Polynomial Tests

Theorem 3.2.1. *Diagonalizability and the Minimal Polynomial*
Let $n \ge 1$ and let $A \in \mathrm{Mat}(n,n,\mathbb{C})$ have the distinct eigenvalues $\lambda_1,\dots,\lambda_d$, where $d \ge 1$. Interpret empty products below as 1 for scalars and as the identity operator for operators. Set $p(z) := \prod_{i=1}^{d}(z-\lambda_i)$. The following are equivalent:

(i) A is similar to a diagonal matrix;
(ii) $\mu_A = p$;
(iii) μ_A has no repeated root, or is square-free.

Proof.

(i) $\Rightarrow$ (ii) Suppose $A = S\Lambda S^{-1}$ for some $S \in \mathrm{Mat}(n,n,\mathbb{C})^\times$ and diagonal $\Lambda = \mathrm{diag}(\nu_1,\dots,\nu_n)$.
For each k, the nonzero vector $S\mathbf{e}_k$ is an eigenvector of A with eigenvalue ν_k, so $p(\nu_k) = 0$.
Hence $p(A) = S\,\mathrm{diag}(p(\nu_1),\dots,p(\nu_n))S^{-1} = 0$ by Theorem 1.1.1. Divisibility $\mu_A \mid p$ holds by Theorem 2.2.4 and Definition 2.2.3.
By Theorem 3.1.6(iii), $\deg(\mu_A) \ge d$. Since $\mu_A \mid p$, $\deg(\mu_A) \le d$. Thus the monic polynomials μ_A and p are equal.

(ii) $\Rightarrow$ (iii) The roots $\lambda_1,\dots,\lambda_d$ are distinct, so $p = \prod_{i=1}^{d}(z-\lambda_i)$ has no repeated root.

(iii) $\Rightarrow$ (i) By Theorem 3.1.6(iii), there are integers $q_1,\dots,q_d \ge 1$ such that $\mu_A(z) = \prod_{i=1}^{d}(z-\lambda_i)^{q_i}$.
The absence of repeated roots forces $q_i = 1$ for every i, so $\mu_A = p$.
Let $T_A \in \mathcal{L}(\mathbb{C}^n)$ be the operator induced by A from Definition 3.1.7. Then $\mu_{T_A} = p$ and $p(T_A) = 0$ by Definition 2.2.3.
First, suppose $g \in \mathbb{C}[z]$ vanishes at every λ_i. Write $g(z) = \sum_{r=0}^{m} c_r z^r$.
If $g(\lambda) = 0$, then $g(z) = g(z) - g(\lambda)$; the identity $z^r - \lambda^r = (z-\lambda)\sum_{s=0}^{r-1} z^{r-1-s}\lambda^s$ therefore writes $g = (z-\lambda)h$ for some $h \in \mathbb{C}[z]$.
Write $g = (z-\lambda_1)g_1$. For $k \ge 2$, $0 = g(\lambda_k) = (\lambda_k - \lambda_1)g_1(\lambda_k)$ and $\lambda_k - \lambda_1 \neq 0$, so $g_1(\lambda_k) = 0$.
After d such factorizations, $g = ph$ for some $h \in \mathbb{C}[z]$, so $p \mid g$. For $i \in \{1,\dots,d\}$, set $\ell_i(z) := \prod_{j\neq i} \frac{z-\lambda_j}{\lambda_i-\lambda_j}$ and $\rho_i := \ell_i(T_A)$. Since $\ell_i(\lambda_k) = \delta_{ik}$, each polynomial $\ell_i\ell_j$ with $i \neq j$, $\sum_{i=1}^{d}\ell_i - 1$, and $z - \sum_{i=1}^{d}\lambda_i\ell_i$ vanishes at every λ_k and is therefore divisible by p.
Since $p(T_A) = 0$, the identities $\rho_i\rho_j = 0$ for $i \neq j$, $\sum_{i=1}^{d}\rho_i = I_{\mathbb{C}^n}$, and $T_A = \sum_{i=1}^{d}\lambda_i\rho_i$ hold by Definition 1.1.2 and Proposition 1.1.6.
Hence $\rho_i = \rho_i \sum_{j=1}^{d}\rho_j = \rho_i^2$ for every i. If $\rho_i = 0$, multiplication by the nonzero scalar $\prod_{j\neq i}(\lambda_i - \lambda_j)$ shows that the monic polynomial $\prod_{j\neq i}(z-\lambda_j)$ annihilates T_A, contradicting the degree-d minimality of $\mu_{T_A} = p$. Thus every ρ_i is nonzero.
By Theorem 5.4.6(i), T_A is diagonalizable. By Definition 5.4.1, choose a basis β of $\mathbb{C}^n$ for which $D := [T_A]_{\beta\leftarrow\beta}$ is diagonal.
Since A and D represent T_A in two bases, they are similar by Corollary 6.2.4.

Structural Commentary: Diagonal form plus degree bounds identify $\mu_A = p$; Lagrange projections transfer $\mu_A = p$ to diagonalization.
Key Insight: Multiplicity one in μ_A is exactly what makes the polynomial spectral projections complementary. □

Corollary 3.2.2. *Square-Free Annihilator Criterion*
Let $n \ge 1$ and $A \in \mathrm{Mat}(n,n,\mathbb{C})$. If $0 \neq f \in \mathbb{C}[z]$ is square-free and $f(A) = 0$, then A is similar to a diagonal matrix.

Proof. The divisibility $\mu_A \mid f$ holds by Theorem 2.2.4 and Definition 2.2.3. If μ_A had a repeated root λ, then $(z-\lambda)^2 \mid \mu_A$ and hence $(z-\lambda)^2 \mid f$, contrary to the hypothesis. Thus μ_A is square-free. By Theorem 3.2.1(iii),(i), A is similar to a diagonal matrix.
Structural Commentary: Divisibility transfers any repeated linear factor of the minimal polynomial to every annihilator.
Key Insight: A square-free annihilator excludes repeated roots from μ_A. □

Computation Method 3.2.3. *Computing μ_T from a Matrix*
Given an n-dimensional vector space $\mathcal{V}$ over $\mathbb{F}$, where $n \geq 1$, an operator $T \in \mathcal{L}(\mathcal{V})$, and a basis β, set $A := [T]_{\beta \leftarrow \beta} \in \mathrm{Mat}(n, n, \mathbb{F})$.
The output is μ_T. For every $p \in \mathbb{F}[z]$, the identity $[p(T)]_{\beta \leftarrow \beta} = p(A)$ holds by Proposition 3.2.4 and Proposition 3.4.4.
Hence $p(T) = 0$ if and only if $p(A) = 0$ by Theorem 3.4.5. Therefore $\mu_T = \mu_A$ by Definition 2.2.2 and Definition 2.2.3.

(i) For $1 \leq m \leq n^2$, set $p_m(z) := a_0 + a_1 z + \cdots + a_{m-1} z^{m-1} + z^m$, where $(a_0, \ldots, a_{m-1}) \in \mathbb{F}^m$ is unknown.
(ii) Compare matrix entries in $a_0 I_n + a_1 A + \cdots + a_{m-1} A^{m-1} = -A^m$ and solve the resulting linear system.
(iii) If the system is inconsistent, increase m. At the first solvable degree, choose a solution and return the corresponding p_m.

By Proposition 1.1.7 and Theorem 2.2.1, the search terminates by $m = n^2$. The returned polynomial is the least-degree monic annihilator of A and hence equals μ_T by the preceding equivalence and Definition 2.2.2.

Figure 57 summarizes the linear-system search for the least-degree monic annihilator.

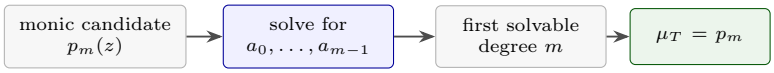

Figure 57: Solve $a_0 I_n + \cdots + a_{m-1} A^{m-1} = -A^m$; the first solvable monic candidate is μ_T.

Computation Method 3.2.4. *Testing a Minimal Polynomial from p_A*
Given $n, d \geq 1$, $A \in \mathrm{Mat}(n, n, \mathbb{C})$, known factorization $p_A(z) = \prod_{i=1}^{d} (z - \lambda_i)^{a_i}$, with distinct $\lambda_1, \ldots, \lambda_d$ and $a_1, \ldots, a_d \geq 1$, return μ_A.

i. Form the finite candidate family $m_{\mathbf{q}}(z) = \prod_{i=1}^{d} (z - \lambda_i)^{q_i}$, where $1 \leq q_i \leq a_i$.
ii. Test exponent vectors $\mathbf{q} = (q_i)_{i=1}^{d}$ in increasing total degree $\sum_{i=1}^{d} q_i$, using any order among vectors of equal total degree.
iii. For each $\mathbf{q}$, compute $m_{\mathbf{q}}(A) = \prod_{i=1}^{d} (A - \lambda_i I_n)^{q_i}$.
iv. Stop at the first candidate satisfying $m_{\mathbf{q}}(A) = 0$ and return it.

The search terminates because p_A is a candidate and $p_A(A) = 0$ by Theorem 3.1.1.
Since μ_A is a candidate by Theorem 3.1.6(iii), degree ordering and Definition 2.2.3 imply $\deg(m) = \deg(\mu_A)$ for returned candidate m.
The annihilator $m - \mu_A$ then has lower degree unless it is zero; hence $m = \mu_A$.

3.3 Annihilators and Spectral Control

Corollary 3.3.1. *q_T Is a Multiple of μ_T*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{C}$ and let $T \in \mathcal{L}(\mathcal{V})$.
Then the characteristic polynomial q_T is a polynomial multiple of the minimal polynomial μ_T.

Proof. The polynomial q_T is nonzero because $\deg q_T = \dim(\mathcal{V}) \geq 1$ by Proposition 2.1.16(i).
The identity $q_T(T) = 0$ holds by Theorem 3.1.2. Hence $\mu_T \mid q_T$ by Theorem 2.2.4.
Structural Commentary: Cayley–Hamilton turns the characteristic polynomial into an annihilator.
Key Insight: The minimal polynomial divides every annihilator, hence divides q_T. □

Theorem 3.3.2. *Roots of μ_T Are Eigenvalues*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{F}$ and let $T \in \mathcal{L}(\mathcal{V})$. Then $(\forall\, \lambda \in \mathbb{F})\, [\mu_T(\lambda) = 0 \iff \lambda \in \mathrm{spec}(T)]$.

Proof.

(⇒) Fix $\lambda \in \mathbb{F}$ with $\mu_T(\lambda) = 0$. Termwise, $\mu_T(z) - \mu_T(\lambda) \in (z - \lambda)\mathbb{F}[z]$ by $z^r - \lambda^r = (z - \lambda) \sum_{s=0}^{r-1} z^{r-1-s} \lambda^s$.
Thus $\mu_T(z) = (z - \lambda) g(z)$ for a monic g with $\deg g = \deg \mu_T - 1$.
Hence $g(T) \neq 0$ by Definition 2.2.2; choose $\mathbf{v} \in \mathcal{V}$ with $\mathbf{u} := g(T)\mathbf{v} \neq \mathbf{0}$.
Then $(T - \lambda I_{\mathcal{V}})\mathbf{u} = \mu_T(T)\mathbf{v} = \mathbf{0}$ by Proposition 1.1.6 and Definition 2.2.2. Thus $\lambda \in \mathrm{spec}(T)$ by Definition 5.1.3.
(⇐) Fix $\lambda \in \mathbb{F}$ and suppose $\lambda \in \mathrm{spec}(T)$. By Definition 5.1.3, choose $\mathbf{v} \neq \mathbf{0}$ satisfying $T\mathbf{v} = \lambda \mathbf{v}$.
Then $\mathbf{0} = \mu_T(T)\mathbf{v} = \mu_T(\lambda)\mathbf{v}$ by Definition 2.2.2 and Proposition 1.1.8. Since $\mathbf{v} \neq \mathbf{0}$, $\mu_T(\lambda) = 0$.

Structural Commentary: Root factorization supplies the forward eigenvector; evaluation proves the converse.
Key Insight: Minimality keeps the quotient operator nonzero. □

Theorem 3.3.3. *Minimal Polynomial of a Spectrally Disjoint Direct Sum*
Let $d, n_1, \ldots, n_d \geq 1$, let $A_i \in \mathrm{Mat}(n_i, n_i, \mathbb{C})$ for $i \in \{1, \ldots, d\}$, and set $A := A_1 \oplus \cdots \oplus A_d$.
If the spectra of $A_1, \ldots, A_d$ are pairwise disjoint, then $\mu_A = \mu_{A_1} \mu_{A_2} \cdots \mu_{A_d}$.

Proof. Set $f := \prod_{i=1}^{d} \mu_{A_i}$. The polynomial f is monic and hence nonzero.

(i) *Block Annihilation*: Since $\mu_{A_i} \mid f$, $(\forall\, i \in \{1, \ldots, d\})\, f(A_i) = 0$ by Theorem 2.2.4 and Definition 2.2.3.
Hence $f(A) = f(A_1) \oplus \cdots \oplus f(A_d) = 0$ by Proposition 3.8.6(iv), and $\mu_A \mid f$ by the same criterion.
(ii) *Block Restriction*: The identity $\mu_A(A) = \mu_A(A_1) \oplus \cdots \oplus \mu_A(A_d) = 0$ holds by Definition 2.2.3 and Proposition 3.8.6(iv).
Thus $(\forall\, i \in \{1, \ldots, d\})\, \mu_{A_i} \mid \mu_A$ by Theorem 2.2.4 and Definition 2.2.3.
(iii) *Coprime Factors*: The roots of μ_{A_i} are $\mathrm{spec}(A_i)$ by Theorem 3.3.2, so the polynomials $\mu_{A_1}, \ldots, \mu_{A_d}$ are pairwise coprime.
Hence $f \mid \mu_A$ by part (ii) and factorization over $\mathbb{C}$.
(iv) *Conclusion*: By parts (i) and (iii), $\mu_A \mid f$ and $f \mid \mu_A$. Monicity forces $\mu_A = f$.

Structural Commentary: Block evaluation establishes $\mu_A \mid f$; spectral disjointness establishes $f \mid \mu_A$.
Key Insight: Every spectral block contributes a distinct collection of factors to μ_A. □

Corollary 3.3.4. *Minimal and Characteristic Polynomials Have the Same Roots*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{C}$ and let $T \in \mathcal{L}(\mathcal{V})$. Then $\{\lambda \in \mathbb{C} : \mu_T(\lambda) = 0\} = \{\lambda \in \mathbb{C} : q_T(\lambda) = 0\} = \mathrm{spec}(T)$.

Proof. By Theorem 3.3.2, $\{\lambda \in \mathbb{C} : \mu_T(\lambda) = 0\} = \operatorname{spec}(T)$. By Proposition 2.1.16, $\{\lambda \in \mathbb{C} : q_T(\lambda) = 0\} = \operatorname{spec}(T)$.
Structural Commentary: Different multiplicities, same spectral scalars.
Key Insight: Minimal polynomial roots and characteristic polynomial roots are both just eigenvalues. □

Perspective 3.3.5. *Characteristic vs. Minimal Polynomial*
By Corollary 3.3.4, q_T and μ_T have the same roots.
They encode multiplicity differently: q_T records algebraic multiplicity, whereas μ_T uses the least exponents that annihilate T.

3.4 Polynomial Spectral Mapping

Proposition 3.4.1. *Eigenvalues of a Polynomial in a Matrix*
Let $n \geq 1$, $A \in \operatorname{Mat}(n, n, \mathbb{C})$, and $p \in \mathbb{C}[z]$.
If $(\lambda_i)_{i=1}^n$ lists the eigenvalues of A with algebraic multiplicity, then $(p(\lambda_i))_{i=1}^n$ lists the eigenvalues of $p(A)$ with algebraic multiplicity.

Proof.
(i) *Ordered Schur Form*: Choose a unit vector $\mathbf{x} \in E_{\lambda_1}(A)$.
By Theorem 2.1.9(i), $A = UTU^*$ for a unitary U and an upper-triangular T with diagonal $\lambda_1, \ldots, \lambda_n$.
(ii) *Polynomial Transfer*: By induction on k using $U^*U = UU^* = I_n$, $(\forall\, k \in \mathbb{Z}_{\geq 0})\, A^k = UT^kU^*$.
Hence $p(A) = Up(T)U^*$ by Definition 3.8.5.
(iii) *Triangular Evaluation*: By induction on k using Proposition 3.1.6, T^k is upper triangular with diagonal $\lambda_1^k, \ldots, \lambda_n^k$.
Hence $p(T)$ is upper triangular with diagonal $p(\lambda_1), \ldots, p(\lambda_n)$ by Definition 3.8.5.
(iv) *Spectral Multiplicities*: The diagonal of $p(T)$ is its eigenvalue list with algebraic multiplicity by Proposition 2.1.6(iii).
The same list applies to $p(A)$ by item (ii) and Theorem 2.1.7(ii).
Structural Commentary: Schur similarity transfers $p(A)$ to $p(T)$; triangularity determines its eigenvalue multiset.
Key Insight: Applying p to a triangular matrix applies p to every diagonal entry with its multiplicity. □

Corollary 3.4.2. *Polynomial Spectral Mapping*
Let $n \geq 1$, let $A \in \operatorname{Mat}(n, n, \mathbb{C})$, and let $p \in \mathbb{C}[z]$. Then $\operatorname{spec}(p(A)) = \{p(\lambda) : \lambda \in \operatorname{spec}(A)\}$.

Proof. Let $\lambda_1, \ldots, \lambda_n$ be the eigenvalues of A, counted with algebraic multiplicity.
By Proposition 3.4.1, the eigenvalues of $p(A)$, counted with algebraic multiplicity, are $p(\lambda_1), \ldots, p(\lambda_n)$.
The claimed equality of the underlying spectral sets follows by Definition 5.1.3.
Structural Commentary: Polynomial evaluation pushes the spectrum forward through the scalar polynomial.
Key Insight: Once Schur form has exposed the diagonal, p acts entry by entry there. □

Corollary 3.4.3. *Polynomial Spectral Mapping for Operators*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{C}$, let $T \in \mathcal{L}(\mathcal{V})$, and let $p \in \mathbb{C}[z]$. Then $\operatorname{spec}(p(T)) = \{p(\lambda) : \lambda \in \operatorname{spec}(T)\}$.

Proof. Choose a basis β and set $A = [T]_{\beta \leftarrow \beta}$.
By Proposition 3.2.4 and Proposition 3.4.4, $[p(T)]_{\beta \leftarrow \beta} = p(A)$.
For every $S \in \mathcal{L}(\mathcal{V})$, $\operatorname{spec}(S) = \operatorname{spec}([S]_{\beta \leftarrow \beta})$ by Definition 3.2.3, Proposition 3.2.2, and Definition 5.1.3.
Thus $\operatorname{spec}(T) = \operatorname{spec}(A)$ and $\operatorname{spec}(p(T)) = \operatorname{spec}(p(A))$; hence $\operatorname{spec}(p(T)) = \{p(\lambda) : \lambda \in \operatorname{spec}(T)\}$ by Corollary 3.4.2.
Structural Commentary: Coordinates reduce the operator statement to the matrix statement.
Key Insight: Polynomial spectral mapping is an operator fact seen through any convenient basis. □

Corollary 3.4.4. *Polynomial Invertibility Test*
Let $n \geq 1$, let $A \in \operatorname{Mat}(n, n, \mathbb{C})$, and let $p \in \mathbb{C}[z]$. If $p(\lambda) \neq 0$ for every $\lambda \in \operatorname{spec}(A)$, then $p(A)$ is invertible.

Proof. By Corollary 3.4.2, $0 \notin \operatorname{spec}(p(A))$. By Corollary 5.1.8, $p(A)$ is invertible.
Structural Commentary: Invertibility of $p(A)$ is checked on spectral values of A.
Key Insight: Avoiding zero on the spectrum prevents $p(A)$ from having a kernel. □

3.5 Polynomial Invariance and Block Separation

Proposition 3.5.1. *Kernel and Range of a Polynomial in an Operator Are Invariant*
Let $\mathcal{V}$ be a vector space over $\mathbb{F}$, let $T \in \mathcal{L}(\mathcal{V})$, and let $p \in \mathbb{F}[z]$. Then:
(i) $\ker(p(T))$ is invariant under T;
(ii) $\operatorname{range}(p(T))$ is invariant under T.

Proof. By Proposition 1.1.6(ii), with p and the polynomial z, the operators $p(T)$ and T commute.
(i) Let $\mathbf{v} \in \ker(p(T))$, so $p(T)\mathbf{v} = \mathbf{0}$. By commutativity, $p(T)(T\mathbf{v}) = T(p(T)\mathbf{v}) = \mathbf{0}$; $T\mathbf{v} \in \ker(p(T))$, so $\ker(p(T))$ invariant under T.
(ii) Let $\mathbf{v} \in \operatorname{range}(p(T))$. By this membership, choose $\mathbf{u} \in \mathcal{V}$ such that $\mathbf{v} = p(T)\mathbf{u}$.
By commutativity, $T\mathbf{v} = Tp(T)\mathbf{u} = p(T)(T\mathbf{u}) \in \operatorname{range}(p(T))$. Hence $\operatorname{range}(p(T))$ is invariant under T.
Structural Commentary: Commutativity transfers T-stability separately to the polynomial kernel and range.
Key Insight: The identity $Tp(T) = p(T)T$ preserves both subspaces. □

Theorem 3.5.2. *Sylvester Linear Matrix Equation*
Let $m, n \geq 1$, let $A \in \operatorname{Mat}(m, m, \mathbb{C})$, and let $B \in \operatorname{Mat}(n, n, \mathbb{C})$.
If $\operatorname{spec}(A) \cap \operatorname{spec}(B) = \emptyset$, then $(\forall C \in \operatorname{Mat}(m, n, \mathbb{C}))(\exists! X \in \operatorname{Mat}(m, n, \mathbb{C}))\, AX - XB = C$.

Proof.
(i) *Sylvester Map*: Set $\mathcal{M} := \operatorname{Mat}(m, n, \mathbb{C})$ and define $L : \mathcal{M} \to \mathcal{M}$ by $L(X) := AX - XB$.
The map L is linear by Proposition 3.1.2(iii)–(iv), and $\dim_{\mathbb{C}}(\mathcal{M}) = mn$ by Proposition 3.1.5.
It suffices to prove $\ker(L) = \{0\}$ by Proposition 1.6.2 and Corollary 1.7.6.
(ii) *Polynomial Intertwining*: Suppose $X \in \ker(L)$, so $AX = XB$. We prove $(\forall k \in \mathbb{Z}_{\geq 0})\, A^kX = XB^k$. For $k = 0$, this is $I_mX = XI_n$.
If $A^kX = XB^k$, then, by Proposition 3.1.2 and $AX = XB$, $A^{k+1}X = A(A^kX) = A(XB^k) = (AX)B^k = (XB)B^k = XB^{k+1}$.
The claim follows by mathematical induction. Therefore $(\forall p \in \mathbb{C}[z])\, p(A)X = Xp(B)$ by Definition 3.8.5.

(iii) *Kernel Vanishing*: By Theorem 3.1.1 and the polynomial-intertwining identity from (ii), $p_B(A)X = Xp_B(B) = 0$.
If $\lambda \in \operatorname{spec}(A)$, then $\lambda \notin \operatorname{spec}(B)$ by the disjointness hypothesis, so $p_B(\lambda) \neq 0$ by Theorem 2.1.3(ii).
Thus $p_B(A)$ is invertible by Corollary 3.4.4, and $X = p_B(A)^{-1}p_B(A)X = 0$. Hence $\ker(L) = \{0\}$.
(iv) *Existence and Uniqueness*: The map L is injective by (iii) and Proposition 1.6.2.
The map L is surjective by Corollary 1.7.6 and invertible by Proposition 1.6.7.
Consequently, $(\forall C \in \mathcal{M})(\exists! X \in \mathcal{M})\, L(X) = C$, equivalently, $(\forall C \in \mathcal{M})(\exists! X \in \mathcal{M})\, AX - XB = C$.

Structural Commentary: Polynomial intertwining combines Cayley–Hamilton for B with spectral invertibility for $p_B(A)$.
Key Insight: Disjoint spectra force every homogeneous Sylvester solution to vanish. □

Figure 58 summarizes the spectral-separation argument behind invertibility of the Sylvester map.

Figure 58: Disjoint spectra make $p_B(A)$ invertible, so the Sylvester map $L(X) = AX - XB$ is invertible.

Corollary 3.5.3. *Removing a Spectrally Separated Off-Diagonal Block*
Let $m, n \geq 1$, let $A \in \operatorname{Mat}(m, m, \mathbb{C})$, let $B \in \operatorname{Mat}(n, n, \mathbb{C})$, and let $C \in \operatorname{Mat}(m, n, \mathbb{C})$. Set $M := \left(\begin{smallmatrix} A & C \\ 0 & B \end{smallmatrix}\right) \in \operatorname{Mat}(m+n, m+n, \mathbb{C})$.
If $\operatorname{spec}(A) \cap \operatorname{spec}(B) = \emptyset$, then M is similar to $A \oplus B$.

Proof. By Theorem 3.5.2, choose $X \in \operatorname{Mat}(m, n, \mathbb{C})$ such that $AX - XB = -C$. Set $P := \left(\begin{smallmatrix} I_m & -X \\ 0 & I_n \end{smallmatrix}\right)$ and $Q := \left(\begin{smallmatrix} I_m & X \\ 0 & I_n \end{smallmatrix}\right)$.
By Proposition 3.7.3(ii), $PQ = QP = I_{m+n}$, so P is invertible and $P^{-1} = Q$. By same proposition, $PMQ = \left(\begin{smallmatrix} A & AX+C-XB \\ 0 & B \end{smallmatrix}\right)$.
By $AX - XB = -C$, $PMQ = \left(\begin{smallmatrix} A & 0 \\ 0 & B \end{smallmatrix}\right) = A \oplus B$. Thus $PMP^{-1} = A \oplus B$ by $P^{-1} = Q$, and M is similar to $A \oplus B$ by Definition 6.2.1.
Structural Commentary: A Sylvester solution determines the block shear that removes the coupling.
Key Insight: Spectral separation makes the upper-right block removable by similarity. □

Theorem 3.5.4. *Schur Form Grouped by Eigenvalues*
Let $n, d, n_1, \ldots, n_d \geq 1$, let $\lambda_1, \ldots, \lambda_d \in \mathbb{C}$ be distinct, and let $A \in \operatorname{Mat}(n, n, \mathbb{C})$.
Suppose $\sum_{i=1}^{d} n_i = n$, $\operatorname{spec}(A) = \{\lambda_1, \ldots, \lambda_d\}$, and $(\forall i \in \{1, \ldots, d\})\, m_A(\lambda_i) = n_i$.

(i) The matrix A is unitarily similar to a block upper-triangular matrix

$$T = \begin{bmatrix} T_{11} & T_{12} & \cdots & T_{1d} \\ 0 & T_{22} & \cdots & T_{2d} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & T_{dd} \end{bmatrix}, \qquad T_{ii} \in \operatorname{Mat}(n_i, n_i, \mathbb{C}),$$

where each T_{ii} is upper triangular with every diagonal entry equal to λ_i.
(ii) The matrix A is similar to $T_{11} \oplus \cdots \oplus T_{dd}$.

Proof.
(i) Order the eigenvalue multiset of A by listing λ_i exactly n_i times, $i \in \{1, \ldots, d\}$. Choose a unit vector $\mathbf{x} \in E_{\lambda_1}(A)$.
By Theorem 2.1.9(i), $T := U^*AU$ is upper triangular with this ordered diagonal for some unitary U.
After grouping consecutive rows and columns according to $(n_1, \ldots, n_d)$, T has the stated block form and each T_{ii} has constant diagonal λ_i. Thus A is unitarily similar to T by Definition 2.6.9.
(ii) By part (i), Theorem 2.6.8(vi), and Definition 6.2.1, A is similar to T. If $d = 1$, then $T = T_{11}$.
Suppose $d \geq 2$. Set $R_0 := T$, and for $k \in \{1, \ldots, d-1\}$ let R_k be the trailing principal block with block indices $k+1, \ldots, d$.
Then $R_{k-1} = \left(\begin{smallmatrix} T_{kk} & C_k \\ 0 & R_k \end{smallmatrix}\right)$. By Proposition 2.1.6, $\operatorname{spec}(T_{kk}) = \{\lambda_k\}$ and $\operatorname{spec}(R_k) = \{\lambda_{k+1}, \ldots, \lambda_d\}$.
Hence R_{k-1} is similar to $T_{kk} \oplus R_k$ by Corollary 3.5.3.
Consequently, for every $k \in \{1, \ldots, d-1\}$, T is similar to $T_{11} \oplus \cdots \oplus T_{kk} \oplus R_k$ by mathematical induction, Proposition 3.8.6(ii), and transitivity in Proposition 6.2.2. Since $R_{d-1} = T_{dd}$, the conclusion follows by transitivity in Proposition 6.2.2.

Structural Commentary: Ordered Schur form groups eigenvalues; Sylvester shears then split successive spectral blocks.
Key Insight: Cross-group blocks are coordinate-dependent and removable by similarity. □

Corollary 3.5.5. *Commuting with Disjoint Blocks*
Let $d, n_1, \ldots, n_d \geq 1$ and let $A_{ii} \in \operatorname{Mat}(n_i, n_i, \mathbb{C})$, $i \in \{1, \ldots, d\}$, have pairwise disjoint spectra.
Set $n := \sum_{i=1}^{d} n_i$ and $A := A_{11} \oplus \cdots \oplus A_{dd} \in \operatorname{Mat}(n, n, \mathbb{C})$.
If a conformally partitioned $B = [B_{ij}] \in \operatorname{Mat}(n, n, \mathbb{C})$ satisfies $AB = BA$, then $B_{ij} = 0$ for all distinct $i, j \in \{1, \ldots, d\}$.

Proof. By $AB = BA$ and Proposition 3.7.3(ii), $(\forall i, j \in \{1, \ldots, d\})\, A_{ii}B_{ij} - B_{ij}A_{jj} = 0$.
Fix $i, j \in \{1, \ldots, d\}$ with $i \neq j$. The spectra of A_{ii} and A_{jj} are disjoint.
Hence $B_{ij} = 0$ by the uniqueness assertion in Theorem 3.5.2 with zero right-hand side.
Structural Commentary: Block commutation reduces every off-diagonal entry to a homogeneous Sylvester equation.
Key Insight: Homogeneous spectral separation forces each off-diagonal block to vanish. □

4 Generalized Eigenspaces

4.1 Generalized Eigenspaces and Nilpotent Structure

Throughout this subsection, $\mathcal{V}$ denotes a vector space over $\mathbb{F}$. Generalized eigenvectors enlarge ordinary eigendirections by allowing vectors annihilated by powers of shifted operators.

Definition 4.1.1. *Generalized Eigenvectors and Generalized Eigenspaces*
Let $T \in \mathcal{L}(\mathcal{V})$ and $\lambda \in \mathbb{F}$. Then:

(i) A nonzero $\mathbf{v} \in \mathcal{V}$ is a *generalized eigenvector* of T corresponding to λ iff $(\exists j \in \mathbb{Z}_{>0})\,(T - \lambda I_{\mathcal{V}})^j \mathbf{v} = \mathbf{0}$.
(ii) The *generalized eigenspace* corresponding to λ is $\mathcal{G}_\lambda(T) := \{\mathbf{v} \in \mathcal{V} : (\exists j \in \mathbb{Z}_{>0})\,(T - \lambda I_{\mathcal{V}})^j \mathbf{v} = \mathbf{0}\}$.

Every eigenvector is generalized by taking $j = 1$. For a nonzero generalized eigenvector, successive applications of $T - \lambda I_{\mathcal{V}}$ eventually reach the ordinary eigenspace.

Proposition 4.1.2. *Kernels of Powers Increase*
Let $T \in \mathcal{L}(\mathcal{V})$, with $T^0 := I_{\mathcal{V}}$. Then:

(i) $\ker(T^0) = \{\mathbf{0}\}$;
(ii) $(\forall k \in \mathbb{Z}_{\geq 0})\ \ker(T^k) \subseteq \ker(T^{k+1})$.

Proof.

(i) By $T^0 = I_{\mathcal{V}}$, $\ker(T^0) = \{\mathbf{0}\}$.
(ii) Fix $k \in \mathbb{Z}_{\geq 0}$ and $\mathbf{v} \in \ker(T^k)$. Then $T^k \mathbf{v} = \mathbf{0}$, so $T^{k+1}\mathbf{v} = T(T^k \mathbf{v}) = \mathbf{0}$. Hence $\mathbf{v} \in \ker(T^{k+1})$.

Structural Commentary: The identity power starts the filtration; one additional application preserves annihilation.
Key Insight: An operator cannot revive a vector already sent to zero. □

Proposition 4.1.3. *Equality Forces Stabilization*
Let $T \in \mathcal{L}(\mathcal{V})$ and $m \in \mathbb{Z}_{\geq 0}$. If $\ker(T^m) = \ker(T^{m+1})$, then $(\forall k \in \mathbb{Z}_{\geq 0})\ \ker(T^{m+k}) = \ker(T^m)$.

Proof. By Proposition 4.1.2(ii), it suffices to prove $(\forall k \in \mathbb{Z}_{\geq 0})\ \ker(T^{m+k+1}) \subseteq \ker(T^{m+k})$.
Fix $k \in \mathbb{Z}_{\geq 0}$ and $\mathbf{v} \in \ker(T^{m+k+1})$. Then $T^{m+1}(T^k \mathbf{v}) = T^{m+k+1}\mathbf{v} = \mathbf{0}$, so $T^k \mathbf{v} \in \ker(T^{m+1}) = \ker(T^m)$.
Thus $T^{m+k}\mathbf{v} = T^m(T^k \mathbf{v}) = \mathbf{0}$, so $\mathbf{v} \in \ker(T^{m+k})$. Hence every adjacent inclusion in the kernel tail is an equality.
Structural Commentary: The initial equality converts every later kernel inclusion into equality.
Key Insight: Shift a later kernel vector into the already-stable pair. □

Theorem 4.1.4. *Kernels Stop Growing by $\dim(\mathcal{V})$*
Let $\mathcal{V}$ be finite-dimensional, let $T \in \mathcal{L}(\mathcal{V})$, and set $n := \dim(\mathcal{V})$. Then $(\forall k \in \mathbb{Z}_{\geq 0})\ \ker(T^{n+k}) = \ker(T^n)$.

Proof. Suppose $\ker(T^n) \neq \ker(T^{n+1})$. By Proposition 4.1.3, every inclusion in $\{\mathbf{0}\} = \ker(T^0) \subsetneq \ker(T) \subsetneq \cdots \subsetneq \ker(T^{n+1})$ is strict.
Thus $n + 1 \leq \dim \ker(T^{n+1}) \leq n$ by Proposition 1.6.3(i) and Proposition 1.4.3(i)–(ii), a contradiction.
Hence $\ker(T^n) = \ker(T^{n+1})$, and the claim follows by Proposition 4.1.3.
Structural Commentary: A hypothetical late growth step forces too many strict subspace inclusions.
Key Insight: An n-dimensional space permits at most n strict kernel increases. □

Figure 59 records the dimension-limited growth and eventual stabilization of the kernel filtration.

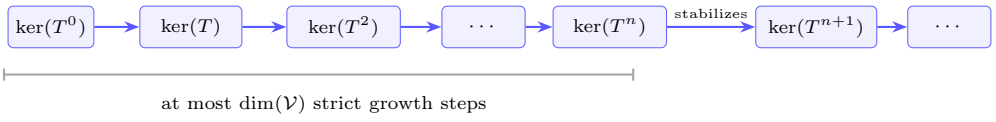

Figure 59: The kernel filtration grows until it stabilizes; after equality appears once, the tail is constant.

Theorem 4.1.5. *Stable Kernel-Range Decomposition*
Let $\mathcal{V}$ be finite-dimensional, let $T \in \mathcal{L}(\mathcal{V})$, and set $n := \dim(\mathcal{V})$. Then $\mathcal{V} = \ker(T^n) \oplus \operatorname{range}(T^n)$.

Proof. Let $\mathbf{v} \in \ker(T^n) \cap \operatorname{range}(T^n)$. Choose $\mathbf{u} \in \mathcal{V}$ with $\mathbf{v} = T^n \mathbf{u}$ by range membership.
Then $T^{2n}\mathbf{u} = T^n \mathbf{v} = \mathbf{0}$ by kernel membership. Thus $\mathbf{u} \in \ker(T^{2n}) = \ker(T^n)$ by Theorem 4.1.4, and $\mathbf{v} = T^n \mathbf{u} = \mathbf{0}$.
Hence $\ker(T^n) \cap \operatorname{range}(T^n) = \{\mathbf{0}\}$. By Theorem 1.7.3(ii), $\dim \ker(T^n) + \dim \operatorname{range}(T^n) = n$. The sum is direct by Proposition 2.1.8.
By Corollary 2.3.2, $\dim(\ker(T^n) \oplus \operatorname{range}(T^n)) = n$. Hence the direct sum equals $\mathcal{V}$ by Proposition 1.4.3(ii).
Structural Commentary: Kernel stabilization first kills the intersection; rank–nullity then fills the ambient dimension.
Key Insight: Stable image vectors cannot also lie in the stable kernel. □

Theorem 4.1.6. *Description of Generalized Eigenspaces*
Let $\mathcal{V}$ be finite-dimensional, let $T \in \mathcal{L}(\mathcal{V})$, let $\lambda \in \mathbb{F}$, and set $n := \dim(\mathcal{V})$. Then:

(i) $\mathcal{G}_\lambda(T) = \ker((T - \lambda I_{\mathcal{V}})^n)$;
(ii) $\mathcal{G}_\lambda(T)$ *is a subspace of* $\mathcal{V}$.

Proof. Set $S := T - \lambda I_{\mathcal{V}}$.

(i) Let $\mathbf{v} \in \mathcal{G}_\lambda(T)$. By Definition 4.1.1(ii), choose $j \in \mathbb{Z}_{>0}$ such that $S^j \mathbf{v} = \mathbf{0}$.
If $j \leq n$, then $\mathbf{v} \in \ker(S^n)$ by Proposition 4.1.2(ii); if $j > n$, then $\mathbf{v} \in \ker(S^j) = \ker(S^n)$ by Theorem 4.1.4. Thus $\mathcal{G}_\lambda(T) \subseteq \ker(S^n)$.
Conversely, $S^{n+1}\mathbf{v} = \mathbf{0}$ for every $\mathbf{v} \in \ker(S^n)$, so $\ker(S^n) \subseteq \mathcal{G}_\lambda(T)$ by Definition 4.1.1(ii).
(ii) By (i) and Proposition 1.6.3(i), $\mathcal{G}_\lambda(T) = \ker(S^n)$ is a subspace of $\mathcal{V}$.

Structural Commentary: Kernel-chain stabilization replaces all admissible exponents by the single exponent n.
Key Insight: Every generalized eigenvector is detected by the stabilized shifted kernel. □

Proposition 4.1.7. *Generalized Eigenspaces Are Invariant*
Let $\mathcal{V}$ be finite-dimensional and let $T \in \mathcal{L}(\mathcal{V})$. Then $(\forall \lambda \in \mathbb{F})\ T(\mathcal{G}_\lambda(T)) \subseteq \mathcal{G}_\lambda(T)$.

Proof. Fix $\lambda \in \mathbb{F}$, set $n := \dim(\mathcal{V})$, and let $p(z) := (z - \lambda)^n$. By Theorem 4.1.6(i) and Proposition 1.1.6(i), $\mathcal{G}_\lambda(T) = \ker(p(T))$.
Hence $\mathcal{G}_\lambda(T)$ is invariant under T by Proposition 3.5.1(i).
Structural Commentary: The stabilized shifted kernel is rewritten as a polynomial kernel in T.
Key Insight: Polynomial kernels remain invariant under their defining operator. □

Definition 4.1.8. *Nilpotent Operator*
An operator $N \in \mathcal{L}(\mathcal{V})$ is *nilpotent* iff $(\exists m \in \mathbb{Z}_{>0})\, N^m = 0$.

Corollary 4.1.9. *Nilpotent Power Bound*
Let $\mathcal{V}$ be finite-dimensional, let $N \in \mathcal{L}(\mathcal{V})$ be nilpotent, and set $n := \dim(\mathcal{V})$. Then $N^n = 0$.

Proof. By nilpotence, choose $m \in \mathbb{Z}_{>0}$ such that $N^m = 0$, so $\ker(N^m) = \mathcal{V}$. If $m \leq n$, then $\ker(N^m) \subseteq \ker(N^n)$ by Proposition 4.1.2(ii).
If $m > n$, then $\ker(N^m) = \ker(N^n)$ by Theorem 4.1.4. Thus $\ker(N^n) = \mathcal{V}$ in both cases, and therefore $N^n = 0$.
Structural Commentary: Kernel growth or stabilization transfers a full nilpotent kernel to exponent n.
Key Insight: The dimension bound never requires a larger nilpotence exponent. □

Lemma 4.1.10. *Nonzero Scalar Plus Nilpotent Is Invertible*
Let $N \in \mathcal{L}(\mathcal{V})$ be nilpotent and let $a \in \mathbb{F}$ with $a \neq 0$. Then $aI_{\mathcal{V}} + N$ is invertible.

Proof. Choose $m \in \mathbb{Z}_{>0}$ such that $N^m = 0$ by nilpotence, and set $X := -a^{-1}N$ and $B := a^{-1}\sum_{r=0}^{m-1} X^r$.
By Proposition 1.1.6(i)–(ii) and the finite geometric-series identity, $(aI_{\mathcal{V}}+N)B = B(aI_{\mathcal{V}}+N) = I_{\mathcal{V}} - X^m = I_{\mathcal{V}}$. Hence $B = (aI_{\mathcal{V}}+N)^{-1}$.
Structural Commentary: The finite geometric series verifies both inverse identities for the nilpotent perturbation.
Key Insight: Nilpotence makes the geometric-series remainder vanish exactly. □

Theorem 4.1.11. *Generalized Eigenvectors for Distinct Eigenvalues Are Independent*
Let $\mathcal{V}$ be finite-dimensional, let $T \in \mathcal{L}(\mathcal{V})$, and let $m \in \mathbb{Z}_{>0}$. Suppose $\lambda_1, \ldots, \lambda_m$ are distinct eigenvalues of T, and let $\mathbf{v}_1, \ldots, \mathbf{v}_m$ be corresponding generalized eigenvectors.
Then $(\mathbf{v}_1, \ldots, \mathbf{v}_m)$ is linearly independent.

Proof.
(i) *Candidate Relation*: Set $n := \dim(\mathcal{V})$ and suppose $a_1\mathbf{v}_1 + \cdots + a_m\mathbf{v}_m = \mathbf{0}$.
(ii) *Polynomial Filter*: Fix $r \in \{1, \ldots, m\}$ and set $Q_r(T) := \prod_{i \in \{1,\ldots,m\}\setminus\{r\}} (T - \lambda_i I_{\mathcal{V}})^n$, with the empty product equal to $I_{\mathcal{V}}$.
(iii) *Non-Target Annihilation*: By Theorem 4.1.6(i) and commutativity in Proposition 1.1.6(ii), $Q_r(T)\mathbf{v}_i = \mathbf{0}$ for $i \neq r$.
Hence applying $Q_r(T)$ to the candidate relation leaves $a_r Q_r(T)\mathbf{v}_r = \mathbf{0}$.
(iv) *Target Invertibility*: Set $\mathcal{G}_r := \mathcal{G}_{\lambda_r}(T)$ and $N_r := (T - \lambda_r I_{\mathcal{V}})|_{\mathcal{G}_r}$.
By Proposition 4.1.7 and Theorem 4.1.6(i)–(ii), $N_r \in \mathcal{L}(\mathcal{G}_r)$ and $N_r^n = 0$.
For $i \neq r$, $(T - \lambda_i I_{\mathcal{V}})|_{\mathcal{G}_r} = N_r + (\lambda_r - \lambda_i) I_{\mathcal{G}_r}$ with $\lambda_r - \lambda_i \neq 0$, so this restriction is invertible by Lemma 4.1.10.
Thus $Q_r(T)|_{\mathcal{G}_r}$, a product of nth powers of these restrictions or the identity if $m = 1$, is invertible by Proposition 1.6.6(i).
(v) *Coefficient Vanishing*: Since $\mathbf{v}_r \in \mathcal{G}_r \setminus \{\mathbf{0}\}$, $Q_r(T)\mathbf{v}_r \neq \mathbf{0}$ by item (iv), and hence $a_r = 0$ by item (iii).
Since r was arbitrary, $a_1 = \cdots = a_m = 0$, so $(\mathbf{v}_1, \ldots, \mathbf{v}_m)$ is linearly independent.

Structural Commentary: Polynomial filters annihilate non-target vectors while nilpotent-plus-scalar factors preserve the target.
Key Insight: Distinct spectral shifts are invertible on the remaining generalized eigenspace. □

Theorem 4.1.12. *Nilpotent Operators and Strictly Upper-Triangular Matrices*
Let $\mathcal{V}$ be nonzero and finite-dimensional, let $N \in \mathcal{L}(\mathcal{V})$, and set $n := \dim(\mathcal{V})$.
Then N is nilpotent iff some ordered basis β satisfies $[N]_\beta = [a_{ij}]$ and $(\forall i, j \in \{1, \ldots, n\})\, (i \geq j \implies a_{ij} = 0)$.

Proof.
(⇒) Suppose N is nilpotent. By Corollary 4.1.9 and Proposition 4.1.2(i)–(ii), $\{\mathbf{0}\} = \ker(N^0) \subseteq \ker(N) \subseteq \cdots \subseteq \ker(N^n) = \mathcal{V}$.
By Corollary 1.3.14(i)–(ii) and Theorem 1.3.13, choose an ordered basis β whose initial segments span the kernels in this chain.
If $\mathbf{v}$ first enters at level k, then $N\mathbf{v} \in \ker(N^{k-1})$, which is spanned by earlier vectors of β; hence $[N]_\beta$ is strictly upper triangular.
(⇐) Suppose $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$ and $[N]_\beta$ is strictly upper triangular.
Set $F_0 := \{\mathbf{0}\}$ and $F_j := \operatorname{span}(\mathbf{v}_1, \ldots, \mathbf{v}_j)$ for $j \in \{1, \ldots, n\}$. Then $(\forall j \in \{1, \ldots, n\})\, N(F_j) \subseteq F_{j-1}$.
By iteration, $N^n(\mathcal{V}) = N^n(F_n) \subseteq F_0 = \{\mathbf{0}\}$, so $N^n = 0$ and N is nilpotent by Definition 4.1.8.

Structural Commentary: The forward direction adapts a basis to kernels; the reverse direction descends basis indices.
Key Insight: Strict index descent forces every basis vector to reach zero. □

Figure 60 illustrates how a basis adapted to the kernel filtration makes nilpotent action move toward earlier layers.

Figure 60: Extending bases through the kernel filtration makes N move vectors to earlier layers.

Perspective 4.1.13. *Eigenvalue Plus Nilpotent Part*
Let $\mathcal{V}$ be finite-dimensional, let $T \in \mathcal{L}(\mathcal{V})$, let $\lambda \in \mathbb{F}$, and set $n := \dim(\mathcal{V})$. Define $\mathcal{G}_\lambda := \mathcal{G}_\lambda(T)$ and $N_\lambda := (T - \lambda I_{\mathcal{V}})|_{\mathcal{G}_\lambda}$.
By Proposition 4.1.7, $N_\lambda \in \mathcal{L}(\mathcal{G}_\lambda)$. By Theorem 4.1.6(i), $N_\lambda^n = 0$, and hence $N_\lambda^{n+1} = 0$. Thus N_λ is nilpotent and $T|_{\mathcal{G}_\lambda} = \lambda I_{\mathcal{G}_\lambda} + N_\lambda$.
Generalized eigenvectors therefore record the nilpotent component of T within the stabilized shifted kernel.

5 Primary Decomposition

5.1 Primary Decomposition and Spectral Splitting

Theorem 5.1.1. *Primary Decomposition over $\mathbb{C}$*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{C}$, $T \in \mathcal{L}(\mathcal{V})$, $m \in \mathbb{Z}_{>0}$. Suppose $\lambda_1, \dots, \lambda_m$ are the distinct eigenvalues of T. Then:
(i) $\mathcal{V} = \mathcal{G}_{\lambda_1}(T) \oplus \cdots \oplus \mathcal{G}_{\lambda_m}(T)$;
(ii) $(\forall j \in \{1, \dots, m\})\, (T - \lambda_j I_{\mathcal{V}})|_{\mathcal{G}_{\lambda_j}(T)}$ *is nilpotent.*

Proof. Set $n := \dim(\mathcal{V})$. For $j \in \{1, \dots, m\}$, set $S_j := T - \lambda_j I_{\mathcal{V}}$ and $\mathcal{G}_j := \mathcal{G}_{\lambda_j}(T)$.

(*i*) We prove $\mathcal{V} = \mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_m$ by induction on n.
(a) *Base Case*: Suppose $n = 1$. Choose $\mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\}$ by $\mathcal{V} \neq \{\mathbf{0}\}$. Then $(\mathbf{v})$ is a basis by $n = 1$.
Choose $\lambda \in \mathbb{C}$ with $T\mathbf{v} = \lambda \mathbf{v}$ by spanning. Then $T = \lambda I_{\mathcal{V}}$ by linearity, so $m = 1$, $\lambda = \lambda_1$, and $\mathcal{V} = \mathcal{G}_1$.
Assume henceforth that $n > 1$ and that (i) holds in every smaller positive dimension.
(b) *Stable Split*: Set $\mathcal{U} := \operatorname{range}(S_1^n)$. By Theorem 4.1.5 and Theorem 4.1.6(i), $\mathcal{V} = \mathcal{G}_1 \oplus \mathcal{U}$.
The subspace $\mathcal{U}$ is T-invariant by Proposition 3.5.1(ii).
Since λ_1 is an eigenvalue, $\mathcal{G}_1 \neq \{\mathbf{0}\}$ by Definition 4.1.1(i); hence $\dim(\mathcal{U}) < n$ by Theorem 2.3.4(i).
(c) *Zero Range*: Suppose $\mathcal{U} = \{\mathbf{0}\}$. Then $\mathcal{V} = \mathcal{G}_1$ by item (b). Fix $\lambda \in \operatorname{spec}(T)$ and $\mathbf{v} \in E_\lambda(T) \setminus \{\mathbf{0}\}$.
Then $0 = S_1^n \mathbf{v} = (\lambda - \lambda_1)^n \mathbf{v}$, so $\lambda = \lambda_1$. Thus $\operatorname{spec}(T) = \{\lambda_1\}$, $m = 1$, and (i) holds.
(d) *Restricted Spectrum*: Suppose $\mathcal{U} \neq \{\mathbf{0}\}$. Then $T|_{\mathcal{U}} \in \mathcal{L}(\mathcal{U})$ by item (b), and $\operatorname{spec}(T|_{\mathcal{U}}) \neq \emptyset$ by Theorem 5.3.2.
$\operatorname{spec}(T|_{\mathcal{U}}) \subseteq \operatorname{spec}(T) \setminus \{\lambda_1\}$ by restriction and $\mathcal{U} \cap \ker(S_1) \subseteq \mathcal{U} \cap \mathcal{G}_1 = \{\mathbf{0}\}$. Hence $m \geq 2$.
Fix $j \in \{2, \dots, m\}$ and choose an eigenvector $\mathbf{v}_j$ for λ_j by $\lambda_j \in \operatorname{spec}(T)$.
Then $\mathbf{v}_j = (\lambda_j - \lambda_1)^{-n} S_1^n \mathbf{v}_j \in \mathcal{U}$, so $\operatorname{spec}(T|_{\mathcal{U}}) = \{\lambda_2, \dots, \lambda_m\}$.
(e) *Inductive Decomposition*: By items (b) and (d) and the induction hypothesis, $\mathcal{U} = \mathcal{G}_{\lambda_2}(T|_{\mathcal{U}}) \oplus \cdots \oplus \mathcal{G}_{\lambda_m}(T|_{\mathcal{U}})$.
(f) *Eigenspace Identification*: Fix $j \in \{2, \dots, m\}$. By equality of restriction powers, $\mathcal{G}_{\lambda_j}(T|_{\mathcal{U}}) \subseteq \mathcal{G}_j$.
Conversely, let $\mathbf{v} \in \mathcal{G}_j$ and write $\mathbf{v} = \mathbf{g} + \mathbf{u}$ with $\mathbf{g} \in \mathcal{G}_1$ and $\mathbf{u} \in \mathcal{U}$ by item (b).
Choose $r \in \mathbb{Z}_{>0}$ with $S_j^r \mathbf{v} = \mathbf{0}$ by Definition 4.1.1(ii). Then $S_j^r \mathbf{g} \in \mathcal{G}_1$ and $S_j^r \mathbf{u} \in \mathcal{U}$ by Proposition 4.1.7 and item (b).
Both terms vanish by $S_j^r \mathbf{g} + S_j^r \mathbf{u} = \mathbf{0}$ and the directness in item (b). Thus $\mathbf{g} \in \mathcal{G}_1 \cap \mathcal{G}_j = \{\mathbf{0}\}$ by Theorem 4.1.11.
Hence $\mathbf{v} = \mathbf{u} \in \mathcal{G}_{\lambda_j}(T|_{\mathcal{U}})$. Therefore the generalized eigenspaces are equal, and items (b) and (e) prove (i).

(*ii*) Fix $j \in \{1, \dots, m\}$ and set $N_j := S_j|_{\mathcal{G}_j}$. By Theorem 4.1.6(ii) and Proposition 4.1.7, $N_j \in \mathcal{L}(\mathcal{G}_j)$.
By Theorem 4.1.6(i), $N_j^n = 0$, so N_j is nilpotent by Definition 4.1.8.

Structural Commentary: Stable kernel-range splitting isolates one primary summand; induction decomposes the invariant range.
Key Insight: Stable kernel-range splitting isolates one eigenvalue at a time. □

Figure 61 summarizes the primary summands and the nilpotent part of T on each one.

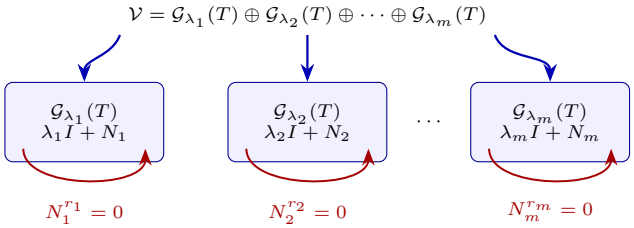

Figure 61: Primary decomposition: on $\mathcal{G}_{\lambda_j}(T)$, $T = \lambda_j I$ plus nilpotent.

Corollary 5.1.2. *Basis of Generalized Eigenvectors*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{C}$ and $T \in \mathcal{L}(\mathcal{V})$. Then $\mathcal{V}$ has a generalized-eigenvector basis for T.

Proof. Enumerate the distinct eigenvalues as $\lambda_1, \dots, \lambda_m$ by Theorem 5.3.2 and Proposition 2.1.16(i)–(ii).
By Theorem 5.1.1(i), $\mathcal{V} = \mathcal{G}_{\lambda_1}(T) \oplus \cdots \oplus \mathcal{G}_{\lambda_m}(T)$.
For $j \in \{1, \dots, m\}$, the space $\mathcal{G}_{\lambda_j}(T)$ has an ordered basis β_j by Theorem 4.1.6(ii) and Corollary 1.3.14(i)–(ii).
The concatenation $\beta := (\beta_1, \dots, \beta_m)$ is an ordered basis of $\mathcal{V}$ by Theorem 2.3.4(ii).
Every vector in β_j is nonzero and belongs to $\mathcal{G}_{\lambda_j}(T)$, so it is a generalized eigenvector corresponding to λ_j by Definition 4.1.1(i).
Structural Commentary: Primary decomposition supplies finite-dimensional summands whose ordered bases concatenate by directness.
Key Insight: Every primary-summand basis vector is generalized for its eigenvalue. □

Theorem 5.1.3. *Block Diagonal Form with Upper-Triangular Primary Blocks*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{C}$ and let $T \in \mathcal{L}(\mathcal{V})$.
Let $m \in \mathbb{Z}_{>0}$, let $(\lambda_j)_{j=1}^m$ list its distinct eigenvalues, and set $d_j := \dim \mathcal{G}_{\lambda_j}(T)$ for $j \in \{1, \dots, m\}$.
Then there are an ordered basis β of $\mathcal{V}$ and matrices $A_j \in \operatorname{Mat}(d_j, d_j, \mathbb{C})$, $j \in \{1, \dots, m\}$, such that $[T]_{\beta \leftarrow \beta} = A_1 \oplus \cdots \oplus A_m$.
Each A_j is upper triangular with diagonal $(\lambda_j, \dots, \lambda_j)$.

Proof.
(i) *Primary Summands*: Set $\mathcal{U}_j := \mathcal{G}_{\lambda_j}(T)$ and $N_j := (T - \lambda_j I_{\mathcal{V}})|_{\mathcal{U}_j}$ for $j \in \{1, \dots, m\}$.
By Theorem 5.1.1(i)–(ii), $\mathcal{V} = \mathcal{U}_1 \oplus \cdots \oplus \mathcal{U}_m$ and each $N_j \in \mathcal{L}(\mathcal{U}_j)$ is nilpotent.
(ii) *Nilpotent Bases*: Fix $j \in \{1, \dots, m\}$. Choose ordered basis β_j; $[N_j]_{\beta_j}$ strictly upper triangular by item (i), Theorem 4.1.12.
Set $A_j := [T|_{\mathcal{U}_j}]_{\beta_j \leftarrow \beta_j}$. By Proposition 3.2.4, $A_j = \lambda_j I_{d_j} + [N_j]_{\beta_j}$, so A_j is upper triangular with diagonal $(\lambda_j, \dots, \lambda_j)$.
(iii) *Adapted Basis*: The concatenation $\beta := (\beta_1, \dots, \beta_m)$ is an ordered basis of $\mathcal{V}$ by Theorem 2.3.4(ii).
(iv) *Block Verification*: By items (i)–(iii) and Definition 3.2.3, $[T]_{\beta \leftarrow \beta} = A_1 \oplus \cdots \oplus A_m$.

Structural Commentary: Primary summands determine the blocks; nilpotent-adapted bases determine their triangular shape.
Key Insight: On each generalized eigenspace, T is eigenvalue plus nilpotent. □

Figure 62 illustrates the block form obtained from bases adapted to the primary summands.

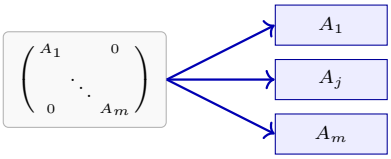

Figure 62: Primary blocks: $A_j = \lambda_j I + N_j$, with N_j strictly upper triangular.

Proposition 5.1.4. *Algebraic Multiplicity from the Generalized Eigenspace*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{C}$ and let $T \in \mathcal{L}(\mathcal{V})$.
Then $(\forall \lambda \in \operatorname{spec}(T))$, the multiplicity of λ as a root of q_T is $\dim \mathcal{G}_\lambda(T) = \dim \ker((T - \lambda I_\mathcal{V})^{\dim(\mathcal{V})})$.

Proof. Fix $\lambda \in \operatorname{spec}(T)$. By Theorem 5.1.3, $\exists$ ordered basis β, $A := [T]_{\beta \leftarrow \beta}$ upper triangular, diagonal has λ exactly $\dim \mathcal{G}_\lambda(T)$ times.
By Definition 2.1.15 and Proposition 2.1.6(iii), the multiplicity of λ as a root of q_T is $\dim \mathcal{G}_\lambda(T)$.
The identity $\mathcal{G}_\lambda(T) = \ker((T - \lambda I_\mathcal{V})^{\dim(\mathcal{V})})$ holds by Theorem 4.1.6(i).
Structural Commentary: Primary-block diagonal entries convert root multiplicity into generalized-eigenspace dimension.
Key Insight: Algebraic multiplicity is the dimension of the generalized eigenspace. □

Figure 63 records how the primary-summand dimensions determine the characteristic-polynomial exponents.

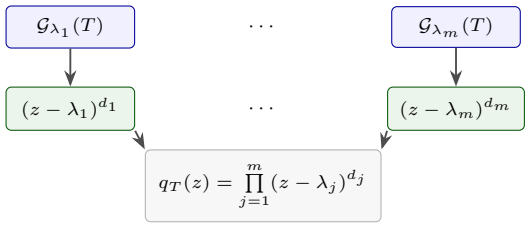

Figure 63: Each primary summand contributes $(z - \lambda_j)^{d_j}$, where $d_j = \dim \mathcal{G}_{\lambda_j}(T)$.

Proposition 5.1.5. *Sum of Multiplicities*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be a finite-dimensional complex vector space and let $T \in \mathcal{L}(\mathcal{V})$.
For $\lambda \in \operatorname{spec}(T)$, let $a(\lambda)$ be its multiplicity as a root of q_T. Then $\sum_{\lambda \in \operatorname{spec}(T)} a(\lambda) = \dim(\mathcal{V})$.

Proof. By Theorems 5.1.1(i) and 2.3.4(i), $\dim(\mathcal{V}) = \sum_{\lambda \in \operatorname{spec}(T)} \dim \mathcal{G}_\lambda(T)$.
By Proposition 5.1.4, $\dim \mathcal{G}_\lambda(T) = a(\lambda)$ for every $\lambda \in \operatorname{spec}(T)$, so the assertion follows.
Structural Commentary: Primary decomposition identifies algebraic multiplicities with summand dimensions.
Key Insight: Direct-sum dimensions add to $\dim(\mathcal{V})$. □

5.2 Real Spectral Data via Complexification

Lemma 5.2.1. *Conjugation Transfers Generalized Eigenspaces*
Let $\mathcal{V}$ be a real vector space and let $T \in \mathcal{L}(\mathcal{V})$. For $\mu \in \mathbb{C}$, set $S_\mu := T_\mathbb{C} - \mu I_{\mathcal{V}_\mathbb{C}}$.
Then $(\forall \lambda \in \mathbb{C})(\forall k \in \mathbb{Z}_{\geq 0})(\forall \mathbf{u}, \mathbf{v} \in \mathcal{V})\ \big(S_\lambda^k(\mathbf{u} + i\mathbf{v}) = \mathbf{0} \iff S_{\overline{\lambda}}^k(\mathbf{u} - i\mathbf{v}) = \mathbf{0}\big)$.

Proof. Define $\Gamma : \mathcal{V}_\mathbb{C} \to \mathcal{V}_\mathbb{C}$ by $\Gamma(\mathbf{a} + i\mathbf{b}) := \mathbf{a} - i\mathbf{b}$. By Definition 5.3.6, $(\forall \mathbf{x}, \mathbf{y} \in \mathcal{V}_\mathbb{C})\, \Gamma(\mathbf{x} + \mathbf{y}) = \Gamma\mathbf{x} + \Gamma\mathbf{y}$.
The same definition implies $(\forall \alpha \in \mathbb{C})(\forall \mathbf{x} \in \mathcal{V}_\mathbb{C})\, \Gamma(\alpha\mathbf{x}) = \overline{\alpha}\Gamma\mathbf{x}$ and $\Gamma^2 = I_{\mathcal{V}_\mathbb{C}}$, so Γ is a conjugate-linear bijection.
By Definition 5.3.10, $\Gamma T_\mathbb{C} = T_\mathbb{C}\Gamma$. Thus $(\forall \mu \in \mathbb{C})\, \Gamma S_\mu = S_{\overline{\mu}}\Gamma$. The corresponding power identity holds at exponent 0.
If it holds at $r \in \mathbb{Z}_{\geq 0}$, then it holds at $r + 1$ by composition with $\Gamma S_\lambda = S_{\overline{\lambda}}\Gamma$; $(\forall r \in \mathbb{Z}_{\geq 0})(\forall \mathbf{x} \in \mathcal{V}_\mathbb{C})\, \Gamma(S_\lambda^r \mathbf{x}) = S_{\overline{\lambda}}^r \Gamma\mathbf{x}$ by induction.

($\Rightarrow$) If $S_\lambda^k(\mathbf{u} + i\mathbf{v}) = \mathbf{0}$, then $S_{\overline{\lambda}}^k(\mathbf{u} - i\mathbf{v}) = \Gamma\mathbf{0} = \mathbf{0}$ by the power identity.
($\Leftarrow$) If $S_{\overline{\lambda}}^k(\mathbf{u} - i\mathbf{v}) = \mathbf{0}$, then $S_\lambda^k(\mathbf{u} + i\mathbf{v}) = \Gamma\mathbf{0} = \mathbf{0}$ by the power identity with $\overline{\lambda}$ in place of λ.
Structural Commentary: Conjugate-linearity intertwines every shifted power with its conjugate shift.
Key Insight: The involution Γ transports each shifted kernel to its conjugate kernel. □

Corollary 5.2.2. *Conjugate Eigenvalues Have Equal Multiplicity*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{R}$ and let $T \in \mathcal{L}(\mathcal{V})$. For $\lambda \in \operatorname{spec}(T_\mathbb{C})$:
(i) $\overline{\lambda} \in \operatorname{spec}(T_\mathbb{C})$;
(ii) $\dim_\mathbb{C} \mathcal{G}_\lambda(T_\mathbb{C}) = \dim_\mathbb{C} \mathcal{G}_{\overline{\lambda}}(T_\mathbb{C})$;
(iii) λ and $\overline{\lambda}$ have the same algebraic multiplicity.

Proof. For $\mu \in \mathbb{C}$, set $S_\mu := T_\mathbb{C} - \mu I_{\mathcal{V}_\mathbb{C}}$. Define $\Gamma : \mathcal{V}_\mathbb{C} \to \mathcal{V}_\mathbb{C}$ by $\Gamma(\mathbf{u} + i\mathbf{v}) := \mathbf{u} - i\mathbf{v}$. By Definition 5.3.6, $(\forall \mathbf{x}, \mathbf{y} \in \mathcal{V}_\mathbb{C})\, \Gamma(\mathbf{x} + \mathbf{y}) = \Gamma\mathbf{x} + \Gamma\mathbf{y}$.
The same definition implies $(\forall \alpha \in \mathbb{C})(\forall \mathbf{x} \in \mathcal{V}_\mathbb{C})\, \Gamma(\alpha\mathbf{x}) = \overline{\alpha}\Gamma\mathbf{x}$ and $\Gamma^2 = I_{\mathcal{V}_\mathbb{C}}$, so Γ is a conjugate-linear bijection.

(i) Choose a nonzero eigenvector $\mathbf{z} = \mathbf{u} + i\mathbf{v}$ for λ. By Lemma 5.2.1 with $k = 1$, $S_{\overline{\lambda}}\Gamma\mathbf{z} = \mathbf{0}$.
The vector $\Gamma\mathbf{z}$ is nonzero by $\Gamma^2 = I_{\mathcal{V}_\mathbb{C}}$, so $\overline{\lambda} \in \operatorname{spec}(T_\mathbb{C})$ by Definition 5.1.1.

(ii) Set $n := \dim_{\mathbb{C}} \mathcal{V}_{\mathbb{C}}$. By Theorem 4.1.6(i), the generalized eigenspaces are $\ker(S_\lambda^n)$ and $\ker(S_{\overline{\lambda}}^n)$.
By Lemma 5.2.1 with $k = n$ and $\Gamma^2 = I_{\mathcal{V}_{\mathbb{C}}}$, Γ restricts to a conjugate-linear bijection $\mathcal{G}_\lambda(T_{\mathbb{C}}) \to \mathcal{G}_{\overline{\lambda}}(T_{\mathbb{C}})$.
The space $\mathcal{G}_\lambda(T_{\mathbb{C}})$ is finite-dimensional by Theorem 4.1.6(ii) and Corollary 1.3.14(ii).
Set $d := \dim_{\mathbb{C}} \mathcal{G}_\lambda(T_{\mathbb{C}})$ and choose a basis $(\mathbf{z}_1, \dots, \mathbf{z}_d)$ by Corollary 1.3.14(i).
If $\sum_{j=1}^{d} a_j \Gamma \mathbf{z}_j = \mathbf{0}$, then $\sum_{j=1}^{d} \overline{a_j} \mathbf{z}_j = \mathbf{0}$ by conjugate-linearity and $\Gamma^2 = I_{\mathcal{V}_{\mathbb{C}}}$. Hence $(\forall j \in \{1, \dots, d\})\, a_j = 0$ by independence.
Fix $\mathbf{y} \in \mathcal{G}_{\overline{\lambda}}(T_{\mathbb{C}})$ and choose $b_1, \dots, b_d \in \mathbb{C}$ satisfying $\Gamma \mathbf{y} = \sum_{j=1}^{d} b_j \mathbf{z}_j$ by spanning.
Then $\mathbf{y} = \sum_{j=1}^{d} \overline{b_j} \Gamma \mathbf{z}_j$ by conjugate-linearity, $\Gamma^2 = I_{\mathcal{V}_{\mathbb{C}}}$. Thus $(\Gamma \mathbf{z}_1, \dots, \Gamma \mathbf{z}_d)$ is basis of $\mathcal{G}_{\overline{\lambda}}(T_{\mathbb{C}})$, its dimension is $d = \dim_{\mathbb{C}} \mathcal{G}_\lambda(T_{\mathbb{C}})$.

(iii) The algebraic multiplicities are the dimensions in (ii) by Proposition 5.1.4.

Structural Commentary: Kernel transport constructs an image basis; the multiplicity formula transfers its dimension equality.
Key Insight: Conjugation preserves generalized-eigenspace dimension. □

Corollary 5.2.3. *Odd-Dimensional Real Operators Have Eigenvalues*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be a finite-dimensional real vector space with $\dim_{\mathbb{R}} \mathcal{V}$ odd. Then $(\forall T \in \mathcal{L}(\mathcal{V}))$ $\operatorname{spec}(T) \neq \varnothing$.

Proof. Fix $T \in \mathcal{L}(\mathcal{V})$ and set $n := \dim_{\mathbb{R}} \mathcal{V}$. Then $\dim_{\mathbb{C}} \mathcal{V}_{\mathbb{C}} = n$ by Proposition 5.3.7(iii).
The algebraic multiplicities of the eigenvalues of $T_{\mathbb{C}}$ sum to n by Proposition 5.1.5.
If $\operatorname{spec}(T_{\mathbb{C}}) \cap \mathbb{R} = \varnothing$, then the spectrum partitions into pairs $\{\lambda, \overline{\lambda}\}$.
Each pair has total equal to twice its common algebraic multiplicity by Corollary 5.2.2(i),(iii). Thus n would be even, a contradiction.
Thus $T_{\mathbb{C}}$ has a real eigenvalue, which is an eigenvalue of T by Proposition 5.3.12.
Structural Commentary: Parity compares the total complex multiplicity with the even totals of nonreal conjugate pairs.
Key Insight: An odd multiplicity sum cannot consist only of conjugate pairs. □

Theorem 5.2.4. *Characteristic Polynomial over $\mathbb{R}$*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be a finite-dimensional real vector space and let $T \in \mathcal{L}(\mathcal{V})$. Let q_T be the characteristic polynomial of T.

(i) $q_T \in \mathbb{R}[z]$.
(ii) $\deg q_T = \dim_{\mathbb{R}} \mathcal{V}$.
(iii) The real zeros of q_T are precisely the eigenvalues of T.
(iv) $q_T(T) = 0$.

Proof.

(i) The relation $q_T \in \mathbb{R}[z]$ holds by Definition 2.1.15.
(ii) By Proposition 2.1.16(i), $\deg q_T = \dim_{\mathbb{R}} \mathcal{V}$.
(iii) By Proposition 2.1.16(ii), the zeros of q_T in $\mathbb{R}$ are precisely the eigenvalues of T.
(iv) Choose a basis β of $\mathcal{V}$ by Corollary 1.3.14(i), and set $\beta_{\mathbb{C}} := \operatorname{cpx}(\beta)$. The list $\beta_{\mathbb{C}}$ is a complex basis by Proposition 5.3.7(ii).
The identity $[T_{\mathbb{C}}]_{\beta_{\mathbb{C}} \leftarrow \beta_{\mathbb{C}}} = [T]_{\beta \leftarrow \beta}$ holds by Proposition 5.3.11(iii). Hence $q_{T_{\mathbb{C}}} = q_T$ by Definition 2.1.15.
By Theorem 3.1.2, $q_T(T_{\mathbb{C}}) = q_{T_{\mathbb{C}}}(T_{\mathbb{C}}) = 0$. Fix $\mathbf{u} \in \mathcal{V}$.
By (i), Proposition 5.3.11(ii), and linearity of polynomial evaluation, $\mathbf{0} = q_T(T_{\mathbb{C}})(\mathbf{u} + i\mathbf{0}) = q_T(T)\mathbf{u} + i\mathbf{0}$.
Thus $q_T(T)\mathbf{u} = \mathbf{0}$ by Definition 5.3.6(iv), so $q_T(T) = 0$ by the arbitrariness of $\mathbf{u}$.

Structural Commentary: Definition and root-degree properties settle (i)–(iii); unchanged coordinates transfer Cayley–Hamilton for (iv).
Key Insight: Complexification preserves the real coordinate matrix of T. □

The identity $q_{T_{\mathbb{C}}} = q_T$ holds by Proposition 5.3.11(iii) and Definition 2.1.15. If $\lambda \in \operatorname{spec}(T_{\mathbb{C}}) \setminus \mathbb{R}$ has algebraic multiplicity m, then $\overline{\lambda}$ has multiplicity m by Corollary 5.2.2(iii). Thus the paired factor is $(z - \lambda)^m (z - \overline{\lambda})^m = \left(z^2 - 2\operatorname{Re}(\lambda) z + |\lambda|^2\right)^m$.
Figure 64 records this real quadratic contribution.

Figure 64: Conjugate factors pair into real quadratics.

Corollary 5.2.5. *q_T Is a Multiple of μ_T over $\mathbb{R}$*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be a finite-dimensional real vector space and let $T \in \mathcal{L}(\mathcal{V})$. Then:

(i) μ_T divides q_T in $\mathbb{R}[z]$;
(ii) $\deg \mu_T \leq \dim_{\mathbb{R}} \mathcal{V}$.

Proof. By Theorem 5.2.4(iv), $q_T(T) = 0$.

(i) The divisibility $\mu_T \mid q_T$ in $\mathbb{R}[z]$ holds by Theorem 2.2.4.
(ii) By (i) and Theorem 5.2.4(ii), $\deg \mu_T \leq \deg q_T = \dim_{\mathbb{R}} \mathcal{V}$.

Structural Commentary: Real Cayley–Hamilton supplies an annihilator; minimal-polynomial divisibility then controls its degree.
Key Insight: The least monic annihilator divides q_T. □

Proposition 5.2.6. *Minimal Polynomial Survives Complexification*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{R}$ and let $T \in \mathcal{L}(\mathcal{V})$. Under $\mathbb{R}[z] \subseteq \mathbb{C}[z]$, $\mu_{T_{\mathbb{C}}} = \mu_T$.

Proof.

(i) *Extended Annihilation*: Fix $\mathbf{u}, \mathbf{v} \in \mathcal{V}$.
Then $\mu_T(T_{\mathbb{C}})(\mathbf{u} + i\mathbf{v}) = \mathbf{0}$ by $\mu_T(T) = 0$, Proposition 5.3.11(ii), and linearity of polynomial evaluation.
Thus $\mu_T(T_{\mathbb{C}}) = 0$ by the arbitrariness of $\mathbf{u}, \mathbf{v}$, and $\mu_{T_{\mathbb{C}}}$ divides μ_T in $\mathbb{C}[z]$ by Theorem 2.2.4.

(ii) *Real-Part Descent*: Set $q := \mu_{T_{\mathbb{C}}} = r + is$, where $r, s \in \mathbb{R}[z]$. Since q is monic, r is monic and $\deg r = \deg q$.
Fix $\mathbf{u} \in \mathcal{V}$. By Definition 2.2.2, Proposition 5.3.11(ii), and linearity of polynomial evaluation, $\mathbf{0} = q(T_{\mathbb{C}})(\mathbf{u}+i\mathbf{0}) = r(T)\mathbf{u}+is(T)\mathbf{u}$.
Hence $r(T)\mathbf{u} = s(T)\mathbf{u} = \mathbf{0}$ by Definition 5.3.6(iv), so $r(T) = s(T) = 0$ by the arbitrariness of $\mathbf{u}$.
Therefore μ_T divides r in $\mathbb{R}[z]$ by Theorem 2.2.4.
(iii) *Degree Comparison*: By the first two stages and $\deg r = \deg q$, $\deg q \leq \deg \mu_T \leq \deg r = \deg q$; hence $\deg q = \deg \mu_T$.
(iv) *Monic Identification*: Choose $c \in \mathbb{C}^\times$ satisfying $\mu_T = cq$ by divisibility and degree equality.
Both polynomials are monic, so $c = 1$ and $\mu_{T_{\mathbb{C}}} = q = \mu_T$.

Structural Commentary: Extended annihilation and real-part descent force equal degrees before monicity identifies the divisors.
Key Insight: The real part of the complex minimal polynomial remains monic and annihilates T. □

5.3 Normal Primary Structure

Corollary 5.3.1. *Normal Operators Have No Nilpotent Primary Part*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be a finite-dimensional complex inner-product space and let $T \in \mathcal{L}(\mathcal{V})$ be normal.
(i) $(\forall\, p \in \mathbb{C}[z])(\forall\, k \in \mathbb{Z}_{>0})\ \ker\big(p(T)^k\big) = \ker\big(p(T)\big)$.
(ii) $\mu_T(z) = \prod_{\lambda \in \operatorname{spec}(T)} (z - \lambda)$, *so μ_T is square-free.*

Proof. Set $n := \dim(\mathcal{V})$ and $J := \{1, \ldots, n\}$. By Theorem 6.1.11(i),(ii), choose an orthonormal eigenbasis $\beta = (\mathbf{e}_1, \ldots, \mathbf{e}_n)$.
Fix $(\lambda_1, \ldots, \lambda_n) \in \mathbb{C}^n$ satisfying $(\forall\, j \in J)\, T\mathbf{e}_j = \lambda_j \mathbf{e}_j$.
(i) Fix $p \in \mathbb{C}[z]$ and $k \in \mathbb{Z}_{>0}$, and set $S := p(T)$. By Proposition 1.1.8, $(\forall\, j \in J)\, S\mathbf{e}_j = p(\lambda_j)\mathbf{e}_j$.
The identity $(\forall\, j \in J)\, S^k\mathbf{e}_j = p(\lambda_j)^k\mathbf{e}_j$ holds by induction on k.
Hence $\ker(S^k) = \operatorname{span}\{\mathbf{e}_j : j \in J,\ p(\lambda_j)^k = 0\} = \operatorname{span}\{\mathbf{e}_j : j \in J,\ p(\lambda_j) = 0\} = \ker(S)$ by uniqueness of β-coordinates and $k > 0$.
(ii) Set $A := [T]_{\beta \leftarrow \beta} = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$.
Its distinct eigenvalues are precisely the elements of $\operatorname{spec}(T)$ by Proposition 3.2.5 and Proposition 3.2.2(ii),(iii).
The identity $\mu_A(z) = \prod_{\lambda \in \operatorname{spec}(T)} (z - \lambda)$ holds by Theorem 3.2.1(i),(ii).
The identity $(\forall\, f \in \mathbb{C}[z])\, [f(T)]_{\beta \leftarrow \beta} = f(A)$ holds by Proposition 3.2.4 and Proposition 3.4.4.
Thus $(\forall\, f \in \mathbb{C}[z])\, [f(T) = 0 \iff f(A) = 0]$ by Theorem 3.4.5. Hence $\mu_T = \mu_A$ by Definitions 2.2.2 and 2.2.3.
Therefore $\mu_T(z) = \prod_{\lambda \in \operatorname{spec}(T)} (z - \lambda)$. Its linear factors are pairwise distinct, so μ_T is square-free.

Structural Commentary: The spectral basis controls polynomial kernels by scalar evaluation and identifies μ_T by diagonalizability.
Key Insight: Positive powers preserve the zero set of each scalar $p(\lambda)$. □

Proposition 5.3.2. *Coprime Normal Primary Pieces Are Orthogonal*
Let $\mathcal{V}$ be a finite-dimensional complex inner-product space, let $T \in \mathcal{L}(\mathcal{V})$ be normal, and let $\mathcal{S}, \mathcal{R} \leq \mathcal{V}$ be T-invariant.
Let $(p, q, a, b) \in \mathbb{C}[z]^4$ satisfy $ap + bq = 1$, $p(T)|_{\mathcal{S}} = 0$, and $q(T)|_{\mathcal{R}} = 0$. Then $\mathcal{S} \perp \mathcal{R}$.

Proof. Fix $\mathbf{s} \in \mathcal{S}$ and $\mathbf{r} \in \mathcal{R}$.
(i) *Bézout Reduction*: By Proposition 1.1.6(i) and $ap + bq = 1$, $I_{\mathcal{V}} = a(T)p(T) + b(T)q(T)$. Hence $\mathbf{s} = b(T)q(T)\mathbf{s}$ by $p(T)|_{\mathcal{S}} = 0$.
(ii) *Adjoint Annihilation*: By Corollary 6.2.10(ii) and Proposition 2.3.9(ii), $b(T)^*\mathcal{R}, q(T)^*\mathcal{R} \subseteq \mathcal{R}$.
For $\mathbf{u}, \mathbf{v} \in \mathcal{R}$, $\langle q(T)^*\mathbf{u}, \mathbf{v}\rangle = \langle \mathbf{u}, q(T)\mathbf{v}\rangle = 0$ by $q(T)|_{\mathcal{R}} = 0$. Hence $q(T)^*\mathcal{R} \subseteq \mathcal{R} \cap \mathcal{R}^\perp = \{\mathbf{0}\}$, so $q(T)^*|_{\mathcal{R}} = 0$.
(iii) *Orthogonality*: Since $b(T)^*\mathbf{r} \in \mathcal{R}$, $\langle \mathbf{s}, \mathbf{r}\rangle = \langle b(T)q(T)\mathbf{s}, \mathbf{r}\rangle = \langle \mathbf{s}, q(T)^*b(T)^*\mathbf{r}\rangle = 0$. Since $\mathbf{s}$ and $\mathbf{r}$ were arbitrary, $\mathcal{S} \perp \mathcal{R}$.

Structural Commentary: The Bézout identity transfers $\mathbf{s}$ to $q(T)$, while normality transfers $q(T)$-annihilation to $q(T)^*$.
Key Insight: Adjoint invariance and $q(T)|_{\mathcal{R}} = 0$ place $q(T)^*\mathcal{R}$ in $\mathcal{R} \cap \mathcal{R}^\perp$. □

6 Jordan and Canonical Forms

6.1 Jordan Chains and Nilpotent Blocks

Jordan chains convert nilpotent primary components into explicit blocks; each block records an eigenvalue and a chain length.

Definition 6.1.1. *Jordan Chains, Blocks, and Matrices*
(i) Let $n, k \in \mathbb{Z}_{>0}$, $A \in \operatorname{Mat}(n, n, \mathbb{C})$, and $\lambda \in \mathbb{C}$. A *Jordan chain* for A at λ is $(\mathbf{x}_1, \ldots, \mathbf{x}_k) \in (\mathbb{C}^n)^k$ with $\mathbf{x}_1 \neq \mathbf{0}$.
For $\mathbf{x}_0 := \mathbf{0}$, its defining relations are $(\forall j \in \{1, \ldots, k\})\, (A - \lambda I_n)\mathbf{x}_j = \mathbf{x}_{j-1}$.
(ii) For $k \in \mathbb{Z}_{>0}$, the *nilpotent Jordan block* $J_k(0) \in \operatorname{Mat}(k, k, \mathbb{C})$ satisfies $(\forall i, j \in \{1, \ldots, k\})\, [J_k(0)]_{ij} = \delta_{j,i+1}$.
For $\lambda \in \mathbb{C}$, the *Jordan block* at λ is $J_k(\lambda) := \lambda I_k + J_k(0)$.
(iii) A *Jordan matrix* is a finite direct sum of Jordan blocks.
(iv) Let $\mathcal{V}$ be a finite-dimensional complex vector space and let $T \in \mathcal{L}(\mathcal{V})$.
An ordered basis β of $\mathcal{V}$ is a *Jordan basis* for T iff $[T]_{\beta \leftarrow \beta}$ is a Jordan matrix.

Proposition 6.1.2. *Jordan Chains as Matrix Columns*
Let $n \in \mathbb{Z}_{>0}$ and let $A \in \operatorname{Mat}(n, n, \mathbb{C})$. Then:
(i) Let $k \in \mathbb{Z}_{>0}$ and $\lambda \in \mathbb{C}$, and let $(\mathbf{x}_1, \ldots, \mathbf{x}_k)$ be a Jordan chain for A at λ. Set $X := [\mathbf{x}_1\ \cdots\ \mathbf{x}_k]$; then $AX = XJ_k(\lambda)$.
(ii) Let $M \in \operatorname{Mat}(n, n, \mathbb{C})^\times$ be formed by concatenating Jordan chains for A, and let J be the matching ordered direct sum of blocks. Then $AM = MJ$ and $M^{-1}AM = J$.

Proof.
(i) Fix $j \in \{1, \ldots, k\}$. Then $(AX)_{\cdot,j} = \mathbf{x}_{j-1} + \lambda\mathbf{x}_j$ by the chain relation.
The identity $(XJ_k(\lambda))_{\cdot,j} = \mathbf{x}_{j-1} + \lambda\mathbf{x}_j$ holds by the entries of $J_k(\lambda)$. Hence $AX = XJ_k(\lambda)$ by equality of corresponding columns.
(ii) Write $M = [X_1\ \cdots\ X_s]$, where X_i is the column matrix of a chain of length k_i at λ_i.
The identities $(\forall i \in \{1, \ldots, s\})\, AX_i = X_iJ_{k_i}(\lambda_i)$ hold by part (i).
Thus $AM = MJ$ by block multiplication, and $M^{-1}AM = J$ by left multiplication with M^{-1}.

Structural Commentary: Column identities pass from individual chains to their ordered block concatenation.
Key Insight: Superdiagonal ones encode predecessor vectors in successive columns. □

Figure 65 depicts $N\mathbf{x}_1 = \mathbf{0}$ and $N\mathbf{x}_j = \mathbf{x}_{j-1}$ along a Jordan chain.

Figure 65: A Jordan chain for $N = A - \lambda I$; each arrow records the image under N.

Theorem 6.1.3. *Nilpotent Jordan Chain Basis*
Let $\mathcal{V}$ be a finite-dimensional vector space over $\mathbb{F}$, $N \in \mathcal{L}(\mathcal{V})$ be nilpotent. For $\mathbf{v} \in \mathcal{V}$ and $m \in \mathbb{Z}_{\geq 0}$, set $\mathcal{C}_N(\mathbf{v}, m) := (N^{m-q}\mathbf{v})_{q=0}^{m}$.
For $r \in \mathbb{Z}_{\geq 0}$ and $(\mathbf{v}, \mathbf{m}) \in \mathcal{V}^r \times \mathbb{Z}_{\geq 0}^r$, let $\mathcal{B}_N(\mathbf{v}, \mathbf{m})$ denote the concatenation $(\mathcal{C}_N(\mathbf{v}_j, m_j))_{j=1}^{r}$.
Write $\mathsf{CB}_N(r, \mathbf{v}, \mathbf{m})$ when $\mathcal{B}_N(\mathbf{v}, \mathbf{m})$ is a basis of $\mathcal{V}$ and $(\forall j \in \{1, \dots, r\})\, N^{m_j+1}\mathbf{v}_j = \mathbf{0}$.
Then $(\exists r \in \mathbb{Z}_{\geq 0})(\exists \mathbf{v} \in \mathcal{V}^r)(\exists \mathbf{m} \in \mathbb{Z}_{\geq 0}^r)\, \mathsf{CB}_N(r, \mathbf{v}, \mathbf{m})$.

Proof. Set $n := \dim(\mathcal{V})$ and argue by strong induction on n, assuming the claim in every smaller dimension.

(i) *Zero Operator*: If $N = 0$, choose an ordered basis $(\mathbf{v}_1, \dots, \mathbf{v}_r)$ by Corollary 1.3.14(i).
Set $\mathbf{m} := (0, \dots, 0) \in \mathbb{Z}_{\geq 0}^r$; then $\mathcal{B}_N(\mathbf{v}, \mathbf{m}) = (\mathbf{v}_1, \dots, \mathbf{v}_r)$. The terminal relations $(\forall j \in \{1, \dots, r\})\, N\mathbf{v}_j = \mathbf{0}$ hold by $N = 0$.
Thus $\mathsf{CB}_N(r, \mathbf{v}, \mathbf{m})$ by its defining conditions; when $\mathcal{V} = \{\mathbf{0}\}$, $r = 0$ by linear independence of the chosen basis.

(ii) *Range Reduction*: Assume $N \neq 0$. Then $n > 0$ and $N^n = 0$ by Corollary 4.1.9.
If N were injective, then N^n would be injective by induction on n, contrary to $N^n = 0$ on the nonzero space $\mathcal{V}$.
Thus $\ker(N) \neq \{\mathbf{0}\}$ by noninjectivity, and $\dim \operatorname{range}(N) < n$ by Theorem 1.7.3(ii).
Set $\mathcal{W} := \operatorname{range}(N)$. The restriction $N|_{\mathcal{W}}$ is nilpotent by $N(\mathcal{W}) \subseteq \mathcal{W}$ and $(N|_{\mathcal{W}})^n = 0$.
Choose $t \in \mathbb{Z}_{\geq 0}$, $\mathbf{u} = (\mathbf{u}_j)_{j=1}^{t} \in \mathcal{W}^t$, and $\boldsymbol{\ell} = (\ell_j)_{j=1}^{t} \in \mathbb{Z}_{\geq 0}^t$ by the induction hypothesis for $N|_{\mathcal{W}}$.
Set $\mathcal{B}_{\mathcal{W}} := (\mathcal{C}_N(\mathbf{u}_j, \ell_j))_{j=1}^{t}$. This is a basis of $\mathcal{W}$ by equality of restriction powers and the induction hypothesis.
The identities $(\forall j \in \{1, \dots, t\})\, N^{\ell_j+1}\mathbf{u}_j = \mathbf{0}$ hold by the same facts.
For $j \in \{1, \dots, t\}$, choose $\mathbf{v}_j \in \mathcal{V}$ satisfying $N\mathbf{v}_j = \mathbf{u}_j$ by $\mathbf{u}_j \in \operatorname{range}(N)$. Set $\mathcal{L} := (\mathcal{C}_N(\mathbf{v}_j, \ell_j + 1))_{j=1}^{t}$.

(iii) *Lifted Independence*: Let $c_{j,q} \in \mathbb{F}$, where $1 \leq j \leq t$ and $0 \leq q \leq \ell_j + 1$.
Suppose $\sum_{j=1}^{t} \sum_{q=0}^{\ell_j+1} c_{j,q} N^q \mathbf{v}_j = \mathbf{0}$. The identities $(\forall j \in \{1, \dots, t\})\, N^{\ell_j+2}\mathbf{v}_j = N^{\ell_j+1}\mathbf{u}_j = \mathbf{0}$ hold by item (ii).
The image of the relation under N is $\sum_{j=1}^{t} \sum_{q=0}^{\ell_j} c_{j,q} N^q \mathbf{u}_j = \mathbf{0}$ by linearity and the terminal identities.
Thus $(\forall j \in \{1, \dots, t\})(\forall q \in \{0, \dots, \ell_j\})\, c_{j,q} = 0$ by linear independence of $\mathcal{B}_{\mathcal{W}}$.
The original relation reduces to $\sum_{j=1}^{t} c_{j,\ell_j+1} N^{\ell_j} \mathbf{u}_j = \mathbf{0}$ by these coefficient equalities.
Every remaining coefficient is zero by linear independence of $\mathcal{B}_{\mathcal{W}}$. Thus $\mathcal{L}$ is linearly independent by the vanishing of all coefficients.

(iv) *Kernel Completion*: The identities $(\forall j \in \{1, \dots, t\})(\forall q \in \{0, \dots, \ell_j\})\, N(N^q\mathbf{v}_j) = N^q\mathbf{u}_j$ hold by $N\mathbf{v}_j = \mathbf{u}_j$.
The inclusion $\mathcal{W} \subseteq N(\operatorname{span}(\mathcal{L}))$ holds by spanning of $\mathcal{B}_{\mathcal{W}}$. The reverse inclusion holds by $\mathcal{W} = \operatorname{range}(N)$, so $\mathcal{W} = N(\operatorname{span}(\mathcal{L}))$.
Choose $\mathbf{w}_1, \dots, \mathbf{w}_s$ such that $(\mathcal{L}, \mathbf{w}_1, \dots, \mathbf{w}_s)$ is a basis by Theorem 1.3.13.
Choose $(\mathbf{x}_i)_{i=1}^{s} \in \operatorname{span}(\mathcal{L})^s$ satisfying $(\forall i \in \{1, \dots, s\})\, N\mathbf{x}_i = N\mathbf{w}_i$ by $\mathcal{W} = N(\operatorname{span}(\mathcal{L}))$.
Set $\mathbf{z}_i := \mathbf{w}_i - \mathbf{x}_i$ for $i \in \{1, \dots, s\}$. Then $(\forall i \in \{1, \dots, s\})\, N\mathbf{z}_i = \mathbf{0}$ by construction.
The list $(\mathcal{L}, \mathbf{z}_1, \dots, \mathbf{z}_s)$ spans $\mathcal{V}$ by $\mathbf{w}_i = \mathbf{z}_i + \mathbf{x}_i$ and $\mathbf{x}_i \in \operatorname{span}(\mathcal{L})$. Suppose a linear combination of $(\mathcal{L}, \mathbf{z}_1, \dots, \mathbf{z}_s)$ is zero.
Substitute $\mathbf{z}_i = \mathbf{w}_i - \mathbf{x}_i$ in this relation. Every $\mathbf{w}_i$-coefficient is zero by linear independence of $(\mathcal{L}, \mathbf{w}_1, \dots, \mathbf{w}_s)$.
The remaining $\mathcal{L}$-coefficients are zero by linear independence of $\mathcal{L}$.
Thus $(\mathcal{L}, \mathbf{z}_1, \dots, \mathbf{z}_s)$ is linearly independent, hence a basis by the preceding spanning property.

(v) *Chain Verification*: Set $r := t + s$ and $\mathbf{v}' := (\mathbf{v}_1, \dots, \mathbf{v}_t, \mathbf{z}_1, \dots, \mathbf{z}_s)$. Set $\mathbf{m}' := (\ell_1 + 1, \dots, \ell_t + 1, \underbrace{0, \dots, 0}_{s \text{ entries}})$.
Then $\mathcal{B}_N(\mathbf{v}', \mathbf{m}') = (\mathcal{L}, \mathbf{z}_1, \dots, \mathbf{z}_s)$ is a basis by item (iv). The identities $(\forall j \in \{1, \dots, t\})\, N^{\ell_j+2}\mathbf{v}_j = \mathbf{0}$ hold by item (iii).
The identities $(\forall i \in \{1, \dots, s\})\, N\mathbf{z}_i = \mathbf{0}$ hold by item (iv). Thus $\mathsf{CB}_N(r, \mathbf{v}', \mathbf{m}')$ by its defining conditions.

Structural Commentary: Strong induction lifts a range-chain basis; kernel correction completes the lifted list.
Key Insight: The N-image of a lifted dependence lies in the known range basis. □

Figure 66 illustrates the nilpotent shift along one chain in the adapted basis order.

Figure 66: An ordered nilpotent chain shifts left under N and represents one Jordan block.

Computation Method 6.1.4. *Recursive Range-Lifting Jordan Construction*
Given $n \in \mathbb{Z}_{>0}$ and $A \in \operatorname{Mat}(n, n, \mathbb{C})$, construct basis matrix $M \in \operatorname{Mat}(n, n, \mathbb{C})^{\times}$. Construct Jordan matrix J with postcondition $AM = MJ$.
Fix $\lambda \in \operatorname{spec}(A)$ and set $\mathcal{G}_\lambda := \ker((A - \lambda I_n)^n)$. Set $N_\lambda := (A - \lambda I_n)|_{\mathcal{G}_\lambda}$.
The inclusion $(A - \lambda I_n)\mathcal{G}_\lambda \subseteq \mathcal{G}_\lambda$ holds by commutativity of powers of $A - \lambda I_n$. Thus $N_\lambda \in \mathcal{L}(\mathcal{G}_\lambda)$ and $N_\lambda^n = 0$ by the definition of $\mathcal{G}_\lambda$.

(i) If $N_\lambda = 0$, choose an ordered basis of $\mathcal{G}_\lambda$ and regard its vectors as singleton chains.
(ii) If $N_\lambda \neq 0$, recursively construct a chain basis for $N_\lambda|_{\operatorname{range}(N_\lambda)}$.
(iii) Given a returned chain $\mathcal{C}_{N_\lambda}(\mathbf{u}, \ell)$, choose $\mathbf{v} \in \mathcal{G}_\lambda$ with $N_\lambda\mathbf{v} = \mathbf{u}$. Replace the returned chain by $\mathcal{C}_{N_\lambda}(\mathbf{v}, \ell + 1)$.
(iv) Perform the kernel-completion correction from the proof of Theorem 6.1.3 on the lifted list.
Append the resulting kernel vectors as singleton chains.
(v) Repeat (i)–(iv) over $\lambda \in \operatorname{spec}(A)$, concatenate the resulting bases, and order the matching Jordan blocks identically.

If $N_\lambda \neq 0$, then N_λ is not injective because injectivity would make $N_\lambda^n = 0$ injective.
Thus its range dimension is strictly smaller by Theorem 1.7.3(ii), so the recursion terminates.
Steps (i)–(iv) produce a basis of $\mathcal{G}_\lambda$ by Theorem 6.1.3.
The concatenation in (v) is a basis by Theorem **??**(i).

Each returned $\mathcal{C}_{N_\lambda}(\mathbf{v}, m)$ satisfies $N_\lambda^{m+1}\mathbf{v} = \mathbf{0}$ by construction. It is a Jordan chain for A at λ by $N_\lambda = A - \lambda I_n$ on $\mathcal{G}_\lambda$. The postcondition $AM = MJ$ holds by Proposition 6.1.2(ii).

Proposition 6.1.5. *Powers of a Jordan Block*
Let $k \in \mathbb{Z}_{>0}$ and $\lambda \in \mathbb{C}$, using $0^0 := 1$ in (i). Then:

(i) $(\forall\, p \in \mathbb{Z}_{\geq 0})\; J_k(\lambda)^p = \sum_{r=0}^{\min(p,k-1)} \binom{p}{r} \lambda^{p-r} J_k(0)^r$.

(ii) $J_k(\lambda)^p \to 0$ *entrywise as* $p \to \infty$ *iff* $|\lambda| < 1$.

Proof.

(i) Fix $p \in \mathbb{Z}_{\geq 0}$, $R := J_k(0)$. For $0 \leq r < k$, matrix R^r has ones on rth superdiagonal, zeros elsewhere by induction on r.
The identity $(\forall r \in \mathbb{Z}_{\geq k})\; R^r = 0$ holds by the same induction.
By distributivity, each subset of the p factors in $(\lambda I_k + R)^p$ selects the factors contributing R.
For $r \in \{0, \ldots, p\}$, exactly $\binom{p}{r}$ subsets select r factors by Proposition 4.3.4.
The identity $(\lambda I_k + R)^p = \sum_{r=0}^{p} \binom{p}{r} \lambda^{p-r} R^r$ holds by commutativity and regrouping by subset size.
The identity in (i) holds by deleting the zero terms with $r \geq k$.

(ii) ($\Rightarrow$) The diagonal sequence satisfies $\lambda^p \to 0$ by entrywise convergence of $J_k(\lambda)^p$.
If $|\lambda| \geq 1$, then $(\forall p \in \mathbb{Z}_{\geq 0})\; |\lambda^p| \geq 1$, contrary to $\lambda^p \to 0$. Thus $|\lambda| < 1$ by contradiction.

(ii) ($\Leftarrow$) If $\lambda = 0$, then $(\forall p \in \mathbb{Z}_{\geq k})\; J_k(0)^p = 0$ by the power description in (i).
Assume $\rho := |\lambda| \in (0, 1)$ and fix $r \in \{0, \ldots, k-1\}$. Set $a_{p,r} := \binom{p}{r}\rho^{p-r}$ for $p \geq r$.
Set $\theta := \frac{1+\rho}{2} \in (\rho, 1)$. Choose $P \in \mathbb{Z}_{\geq r}$ satisfying $(\theta - \rho)(P+1) \geq \theta r$ by unboundedness of $\mathbb{Z}_{>0}$.
$(\forall p \in \mathbb{Z}_{\geq P})\; \frac{a_{p+1,r}}{a_{p,r}} = \frac{\rho(p+1)}{p+1-r} \leq \theta$ by factorial cancellation and the choice of P.
Hence $(\forall m \in \mathbb{Z}_{\geq 0})\; a_{P+m,r} \leq a_{P,r}\theta^m$ by induction on m. Fix $\varepsilon > 0$ and set $\delta := \theta^{-1} - 1 > 0$.
Choose $M \in \mathbb{Z}_{>0}$ satisfying $1 + M\delta > \frac{a_{P,r}}{\varepsilon}$ by unbounded $\mathbb{Z}_{>0}$. For $m \in \mathbb{Z}_{\geq M}$, $\theta^{-m} = (1+\delta)^m \geq 1 + m\delta$ by Proposition 4.3.7(i).
Thus $0 \leq a_{P+m,r} \leq \frac{a_{P,r}}{1+m\delta} < \varepsilon$, so $a_{p,r} \to 0$. Thus $(\forall r \in \{0, \ldots, k-1\})\; \binom{p}{r}\lambda^{p-r} \to 0$ as $p \to \infty$.
Each entry in the expansion from (i) is zero or $\binom{p}{r}\lambda^{p-r}$ for one $r \in \{0, \ldots, k-1\}$.
Its absolute value is therefore either 0 or $a_{p,r}$, and hence tends to 0. Thus $J_k(\lambda)^p \to 0$ by convergence of each entry.

Structural Commentary: Nilpotence truncates the expansion; diagonal entries and a geometric majorant resolve the limit criterion.
Key Insight: Each fixed superdiagonal has polynomial coefficients multiplied by geometric decay. □

6.2 Complex and Real Jordan Forms and Block Sizes

Jordan bases establish existence; shifted-power ranks recover block multiplicities and uniqueness.

Theorem 6.2.1. *Jordan Form over $\mathbb{C}$*
Let $\mathcal{V}$ be a complex vector space with $\dim_{\mathbb{C}} \mathcal{V} = n \in \mathbb{Z}_{>0}$, and let $T \in \mathcal{L}(\mathcal{V})$.
Then $\exists$ an ordered basis $\mathcal{B}$ of $\mathcal{V}$ and a Jordan matrix J such that $[T]_{\mathcal{B}\leftarrow\mathcal{B}} = J$.

Proof.

(i) *Primary Splitting*: Let $\operatorname{spec}(T) = \{\lambda_1, \ldots, \lambda_m\}$ and set $G_j := \mathcal{G}_{\lambda_j}(T)$ for $j \in \{1, \ldots, m\}$. Set $N_j := (T - \lambda_j I_{\mathcal{V}})|_{G_j}$.
The identity $\mathcal{V} = \bigoplus_{j=1}^{m} G_j$ holds, and every N_j is nilpotent, by Theorem 5.1.1(i)–(ii).

(ii) *Chain Bases*: For $j \in \{1, \ldots, m\}$, choose an N_j-chain basis $\mathcal{B}_j$ of G_j by Theorem 6.1.3.

(iii) *Block Identification*: On a chain of length r in $\mathcal{B}_j$, the matrix of N_j is $J_r(0)$ by the chain recurrence.
The matrix of $T|_{G_j} = \lambda_j I_{G_j} + N_j$ on the same chain is $J_r(\lambda_j)$ by Definition 6.1.1(ii).

(iv) *Basis Assembly*: The concatenation $\mathcal{B} := (\mathcal{B}_1, \ldots, \mathcal{B}_m)$ is an ordered basis of $\mathcal{V}$ by the primary direct sum.
Matrix $[T]_{\mathcal{B}\leftarrow\mathcal{B}}$ is matching direct sum of Jordan blocks by item (iii). Hence it is Jordan matrix by Definition 6.1.1(iii).

Structural Commentary: Primary splitting isolates nilpotent shifts; chain bases concatenate into a Jordan basis.
Key Insight: Each primary restriction is $\lambda_j I_{G_j}$ plus its nilpotent shift. □

Figure 67 tracks primary summands through nilpotent chains to Jordan blocks.

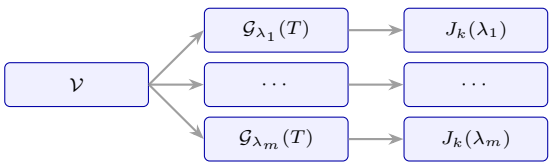

Figure 67: Primary pieces $\mathcal{G}_{\lambda_j}(T)$ decompose into nilpotent chains, which determine Jordan blocks.

Theorem 6.2.2. *Real Jordan Block Form*
Let $n \in \mathbb{Z}_{>0}$, $A \in \operatorname{Mat}(n, n, \mathbb{R})$. For $a \in \mathbb{R}$, $b > 0$, set $R(a,b) := \left(\begin{smallmatrix} a & b \\ -b & a \end{smallmatrix}\right)$. For $k \in \mathbb{Z}_{>0}$, define $\mathcal{J}_k(a,b) := [C_{rs}]_{r,s=1}^{k} \in \operatorname{Mat}(2k, 2k, \mathbb{R})$.
Its blocks satisfy $C_{rr} = R(a,b)$, $C_{r,r+1} = I_2$ for $r < k$, and $C_{rs} = 0_2$ otherwise. Then:

(i) *$\exists S \in \mathrm{GL}_n(\mathbb{R})$ such that $S^{-1}AS$ is a direct sum. Its scalar summands are $J_k(\lambda)$ with $(k, \lambda) \in \mathbb{Z}_{>0} \times \mathbb{R}$.*
Its remaining summands are $\mathcal{J}_k(a,b)$ with $(k, a, b) \in \mathbb{Z}_{>0} \times \mathbb{R} \times \mathbb{R}_{>0}$.

(ii) *For $k \in \mathbb{Z}_{>0}$, $a \in \mathbb{R}$, and $b > 0$, $\exists Q \in \mathrm{GL}_{2k}(\mathbb{C})$ such that $Q^{-1}\mathcal{J}_k(a,b)Q = J_k(a+ib) \oplus J_k(a-ib)$.*

Proof.

(*i*)

(a) *Primary Partition*: Regard A as an operator on $\mathbb{R}^n$ and let $A_{\mathbb{C}}$ be its complexification.
Set $\Lambda_{\mathbb{R}} := \operatorname{spec}(A_{\mathbb{C}}) \cap \mathbb{R}$, $\Lambda_+ := \{\lambda \in \operatorname{spec}(A_{\mathbb{C}}) : \operatorname{Im}(\lambda) > 0\}$. For $\mu \in \operatorname{spec}(A_{\mathbb{C}})$, set $G_\mu := \mathcal{G}_\mu(A_{\mathbb{C}})$. Set $\overline{\Lambda_+} := \{\overline{\lambda} : \lambda \in \Lambda_+\}$.
The spectrum is the disjoint union of $\Lambda_{\mathbb{R}}$, Λ_+, and $\overline{\Lambda_+}$ by Corollary 5.2.2(i).
Hence $\mathbb{C}^n = \bigoplus_{\lambda\in\Lambda_{\mathbb{R}}} G_\lambda \oplus \bigoplus_{\lambda\in\Lambda_+} (G_\lambda \oplus G_{\overline{\lambda}})$ by Theorem 5.1.1(i).

(b) *Real Primary Chains*: Fix $\lambda \in \Lambda_{\mathbb{R}}$ and set $G_\lambda^{\mathbb{R}} := \ker((A - \lambda I_n)^n)$.
The equality $(G_\lambda^{\mathbb{R}})_{\mathbb{C}} = \ker((A_{\mathbb{C}} - \lambda I_n)^n)$ holds by Proposition 5.3.11(ii) and equality of real and imaginary parts.
Thus $(G_\lambda^{\mathbb{R}})_{\mathbb{C}} = G_\lambda$ by Theorem 4.1.6(i). Subspace $G_\lambda^{\mathbb{R}}$ is invariant under $A - \lambda I_n$ by commutation with its nth power.
Set $N_\lambda := (A - \lambda I_n)|_{G_\lambda^{\mathbb{R}}}$; equality $N_\lambda^n = 0$ holds by definition of $G_\lambda^{\mathbb{R}}$. Choose an N_λ-chain basis $\mathcal{B}_\lambda$ by Theorem 6.1.3.
The corresponding matrix blocks of $A|_{G_\lambda^{\mathbb{R}}} = \lambda I_{G_\lambda^{\mathbb{R}}} + N_\lambda$ are $J_k(\lambda)$ by the chain recurrence and Definition 6.1.1.

(c) *Conjugate-Pair Chains*: Fix $\lambda = a + ib \in \Lambda_+$ and set $N_\lambda^{\mathbb{C}} := (A_{\mathbb{C}} - \lambda I_n)|_{G_\lambda}$.
This operator is nilpotent by Theorem 5.1.1(ii). Choose an $N_\lambda^{\mathbb{C}}$-chain basis by Theorem 6.1.3.
Each conjugate chain is a $\overline{\lambda}$-chain by conjugating its recurrence and using the real entries of A.
Conjugation is a conjugate-linear bijection $G_\lambda \to G_{\overline{\lambda}}$ by Lemma 5.2.1 and its involutivity.
Hence the conjugate chains form a basis of $G_{\overline{\lambda}}$ by coefficient conjugation.
Fix a chain $\mathcal{C} = (\mathbf{v}_1, \dots, \mathbf{v}_k)$, set $\mathbf{v}_0 := \mathbf{0}$, and write $\mathbf{v}_j = \mathbf{u}_j + i\mathbf{w}_j$ for $j \in \{0, \dots, k\}$.
Set $U_j := [\mathbf{u}_j\ \mathbf{w}_j]$ and $\mathcal{U}_{\mathcal{C}} := (\mathbf{u}_1, \mathbf{w}_1, \dots, \mathbf{u}_k, \mathbf{w}_k)$.
The lists $(\mathcal{C}, \overline{\mathcal{C}})$ and $\mathcal{U}_{\mathcal{C}}$ differ by an invertible change of coordinates by $\mathbf{u}_j = \frac{1}{2}(\mathbf{v}_j + \overline{\mathbf{v}}_j)$ and $\mathbf{w}_j = \frac{1}{2i}(\mathbf{v}_j - \overline{\mathbf{v}}_j)$.
Its inverse is $\mathbf{v}_j = \mathbf{u}_j + i\mathbf{w}_j$ and $\overline{\mathbf{v}}_j = \mathbf{u}_j - i\mathbf{w}_j$.
The identity $AU_j = U_j R(a, b) + U_{j-1}$ holds by separating the real and imaginary parts of the chain recurrence.
Thus the matrix of A on $\mathcal{U}_{\mathcal{C}}$ is $\mathcal{J}_k(a, b)$ by the block definition.

(d) *Real Basis Assembly*: Let $\mathcal{B}$ concatenate the bases $\mathcal{B}_\lambda$ for $\lambda \in \Lambda_{\mathbb{R}}$ and the lists $\mathcal{U}_{\mathcal{C}}$ over all chosen chains for $\lambda \in \Lambda_+$.
The complexified lists $\mathcal{B}_\lambda$ are bases of G_λ by (b) and Proposition 5.3.7(ii).
Hence $\mathcal{B}$ is a basis of $\mathbb{C}^n$ by the primary direct sum and the invertible replacements in (c).
The list $\mathcal{B}$ is a real basis of $\mathbb{R}^n$ by its complex linear independence and $\#\mathcal{B} = n$.
If S is its basis-column matrix, then $S \in \mathrm{GL}_n(\mathbb{R})$ and $S^{-1}AS$ has the asserted form by the block calculations in (b)–(c).

(*ii*) Fix $(k, a, b) \in \mathbb{Z}_{>0} \times \mathbb{R} \times \mathbb{R}_{>0}$ and let $(\mathbf{e}_j, \mathbf{f}_j)_{j=1}^k$ be the standard coordinate pairs of $\mathbb{C}^{2k}$, with $\mathbf{e}_0 = \mathbf{f}_0 := \mathbf{0}$.
Set $\lambda := a + ib$ and, for $j \in \{1, \dots, k\}$, set $\mathbf{v}_j := \mathbf{e}_j + i\mathbf{f}_j$.
The identity $(\forall j \in \{1, \dots, k\})\, (\mathcal{J}_k(a, b) - \lambda I_{2k})\mathbf{v}_j = \mathbf{v}_{j-1}$ holds by the block definition.
The conjugate identity $(\forall j \in \{1, \dots, k\})\, (\mathcal{J}_k(a, b) - \overline{\lambda} I_{2k})\overline{\mathbf{v}}_j = \overline{\mathbf{v}}_{j-1}$ holds by entrywise conjugation.
The list $(\mathbf{v}_1, \dots, \mathbf{v}_k, \overline{\mathbf{v}}_1, \dots, \overline{\mathbf{v}}_k)$ is a basis by the invertible pairwise relations $\mathbf{e}_j = \frac{1}{2}(\mathbf{v}_j + \overline{\mathbf{v}}_j)$ and $\mathbf{f}_j = \frac{1}{2i}(\mathbf{v}_j - \overline{\mathbf{v}}_j)$.
If Q is its basis-column matrix, then $Q^{-1}\mathcal{J}_k(a, b)Q = J_k(a + ib) \oplus J_k(a - ib)$ by the two chain recurrences.

Structural Commentary: Real and conjugate primary chains assemble the real blocks and their complex forms.
Key Insight: Pairing conjugate chains converts multiplication by $a + ib$ into $R(a, b)$. □

Corollary 6.2.3. *Diagonalizability in Jordan Form*
Let $n \in \mathbb{Z}_{>0}$, let $A \in \mathrm{Mat}(n, n, \mathbb{C})$, and let $J = \bigoplus_{\alpha=1}^s J_{k_\alpha}(\mu_\alpha)$ be a Jordan form of A.

For $(\lambda, \alpha) \in \operatorname{spec}(A) \times \{1, \dots, s\}$, set $\delta_{\lambda\alpha} := \delta_{\lambda,\mu_\alpha}$, and set $b_J(\lambda) := \sum_{\alpha=1}^s \delta_{\lambda\alpha}$. Then:

(i) $(\forall \lambda \in \operatorname{spec}(A))\ \dim E_\lambda(A) = b_J(\lambda)$;
(ii) *A is diagonalizable if and only if* $(\forall \alpha \in \{1, \dots, s\})\, k_\alpha = 1$.

Proof. Choose $S \in \mathrm{GL}_n(\mathbb{C})$ such that $A = SJS^{-1}$. For $\lambda \in \operatorname{spec}(A)$, set $a_J(\lambda) := \sum_{\alpha=1}^s k_\alpha \delta_{\lambda\alpha}$.
The algebraic multiplicity of λ in A equals that in J by Theorem 2.1.7(ii). The latter multiplicity is $a_J(\lambda)$ by Proposition 2.1.6(iii).

(*i*) Fix $\lambda \in \operatorname{spec}(A)$. The map S restricts to an isomorphism $E_\lambda(J) \to E_\lambda(A)$ by $A = SJS^{-1}$.
If $\mu_\alpha = \lambda$, then $E_\lambda(J_{k_\alpha}(\mu_\alpha)) = \operatorname{span}(\mathbf{e}_1)$ by Definition 6.1.1(ii). If $\mu_\alpha \neq \lambda$, then $J_{k_\alpha}(\mu_\alpha) - \lambda I_{k_\alpha}$ is invertible by Lemma 4.1.10.
Thus $\dim E_\lambda(J_{k_\alpha}(\mu_\alpha)) = \delta_{\lambda\alpha}$ and $\dim E_\lambda(A) = \sum_{\alpha=1}^s \delta_{\lambda\alpha} = b_J(\lambda)$ by the direct-sum block structure.

(*ii*) ($\Rightarrow$) If A is diagonalizable, then $(\forall \lambda \in \operatorname{spec}(A))\, a_J(\lambda) = b_J(\lambda)$ by Theorem 2.1.12 and part (i).
Fix $\alpha \in \{1, \dots, s\}$ and set $\lambda := \mu_\alpha$. Then $k_\alpha = 1$ by $0 = a_J(\lambda) - b_J(\lambda) = \sum_{\beta=1}^s (k_\beta - 1)\delta_{\lambda\beta}$ and nonnegativity of its summands.

(*ii*) ($\Leftarrow$) Suppose $(\forall \alpha \in \{1, \dots, s\})\, k_\alpha = 1$. The matrix $A = SJS^{-1}$ is diagonalizable by diagonality of J.

Structural Commentary: Blockwise kernels count eigendirections; multiplicity equality then excludes every longer block.
Key Insight: A Jordan block is diagonal exactly when its length is one. □

Lemma 6.2.4. *Powers of a Nilpotent Jordan Block*
Let $k \in \mathbb{Z}_{>0}$, let $p \in \mathbb{Z}_{\geq 0}$, and set $N := J_k(0) \in \mathrm{Mat}(k, k, \mathbb{C})$. Then:

(i) $\operatorname{rank}(N^p) = \max(k - p, 0)$;
(ii) $\dim \ker(N^p) = \min(p, k)$.

Proof. Let $(\mathbf{e}_j)_{j=1}^k$ be the standard basis. Set $(q)_+ := \max(q, 0)$ and $\mathcal{E}_m := \operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_m)$ for $m \in \{1, \dots, k\}$, with $\mathcal{E}_0 := \{\mathbf{0}\}$.
Set $\mathbf{e}_j := \mathbf{0}$ for $j \in \mathbb{Z}_{\leq 0}$. Then $(\forall j \in \{1, \dots, k\})\, N^p\mathbf{e}_j = \mathbf{e}_{j-p}$ by Definition 6.1.1(ii) and induction on p.

(i) If $p \geq k$, then $\operatorname{im}(N^p) = \mathcal{E}_0$ by the preceding power identity.
If $p < k$, then the nonzero images are exactly $\mathbf{e}_1, \dots, \mathbf{e}_{k-p}$, so $\operatorname{im}(N^p) = \mathcal{E}_{k-p}$.
Thus $\operatorname{im}(N^p) = \mathcal{E}_{(k-p)_+}$ and $\operatorname{rank}(N^p) = (k - p)_+ = \max(k - p, 0)$ in both cases.

(ii) The equality $\dim \ker(N^p) = k - (k - p)_+ = \min(p, k)$ holds by Corollary 3.3.1(i) and part (i).

Structural Commentary: The block shift identifies the surviving image basis; rank–nullity computes its complement.
Key Insight: The pth power deletes the first p chain positions. □

Definition 6.2.5. *Weyr Characteristic*
Let $n \in \mathbb{Z}_{>0}$, let $A \in \mathrm{Mat}(n,n,\mathbb{C})$, and let $\lambda \in \mathrm{spec}(A)$.

(i) For $p \in \mathbb{Z}_{\geq 0}$, the *shifted-power rank* is $r_p(\lambda, A) := \mathrm{rank}((A-\lambda I_n)^p)$.
(ii) For $p \in \mathbb{Z}_{>0}$, the pth *Weyr number* is $w_p(\lambda, A) := r_{p-1}(\lambda, A) - r_p(\lambda, A)$.

Identity $(\forall p \in \mathbb{Z}_{>0})\, w_p(\lambda, A) = \dim\ker((A-\lambda I_n)^p) - \dim\ker((A-\lambda I_n)^{p-1}) \geq 0$ holds by Proposition 4.1.2(ii) and Corollary 3.3.1(i).
The inequality $w_1(\lambda, A) > 0$ holds by $\lambda \in \mathrm{spec}(A)$ and Corollary 3.3.1(i).
The equality $(\forall p \in \mathbb{Z}_{\geq n+1})\, w_p(\lambda, A) = 0$ holds by Theorem 4.1.4 and Corollary 3.3.1(i).
Thus $s_\lambda(A) := \max\{p \in \{1,\dots,n\} : w_p(\lambda, A) > 0\}$ is well-defined.
The *Weyr characteristic* of A at λ is $\big(w_p(\lambda, A)\big)_{p=1}^{s_\lambda(A)}$.

Theorem 6.2.6. *Jordan Block Sizes from Rank Drops*
Let $n \in \mathbb{Z}_{>0}$, let $A \in \mathrm{Mat}(n,n,\mathbb{C})$, let $\lambda \in \mathrm{spec}(A)$, and let $J = \bigoplus_{\alpha=1}^{s} J_{k_\alpha}(\mu_\alpha)$ be a Jordan form of A.
For $q \in \mathbb{Z}_{\geq 0}$, set $r_q := \mathrm{rank}\big((A-\lambda I_n)^q\big)$; for $q \in \mathbb{Z}_{>0}$, set $w_q := r_{q-1} - r_q$.
For $p \in \mathbb{Z}_{>0}$, set $I_p := \{\alpha \in \{1,\dots,s\} : \mu_\alpha = \lambda,\ k_\alpha \geq p\}$. Then:

(i) $w_p = \#I_p$;
(ii) $w_p - w_{p+1} = \#(I_p \setminus I_{p+1}) = \#\{\alpha : \mu_\alpha = \lambda,\ k_\alpha = p\}$.

Proof. Choose $S \in \mathrm{GL}_n(\mathbb{C})$ such that $A = SJS^{-1}$. The identity $(\forall q \in \mathbb{Z}_{\geq 0})\,(A-\lambda I_n)^q = S(J-\lambda I_n)^q S^{-1}$ holds by induction on q.
Hence $(\forall q \in \mathbb{Z}_{\geq 0})\, r_q = \mathrm{rank}((J-\lambda I_n)^q)$ by Theorem 3.6.6(ii). Set $B_\alpha := J_{k_\alpha}(\mu_\alpha)$ and $\rho_q(B) := \mathrm{rank}((B-\lambda I)^q)$.

Image of $(J-\lambda I_n)^q$ is direct sum of images of $(B_\alpha - \lambda I_{k_\alpha})^q$ by block-diagonal form. Hence $r_q = \sum_{\alpha=1}^{s} \rho_q(B_\alpha)$ by Theorem 2.3.4(i).

Set $\Delta_{p,\alpha} := \rho_{p-1}(B_\alpha) - \rho_p(B_\alpha)$. Then $w_p = \sum_{\alpha=1}^{s} \Delta_{p,\alpha}$ by subtracting the two block-rank sums.

(i) Fix $\alpha \in \{1,\dots,s\}$. If $\mu_\alpha \neq \lambda$, then $B_\alpha - \lambda I_{k_\alpha} = (\mu_\alpha - \lambda) I_{k_\alpha} + J_{k_\alpha}(0)$ is invertible by Lemma 4.1.10.
Thus $\Delta_{p,\alpha} = 0$ by full rank of every power. If $\mu_\alpha = \lambda$, then $\Delta_{p,\alpha} = 1$ exactly when $k_\alpha \geq p$ by Lemma 6.2.4(i).
Thus $\Delta_{p,\alpha} = \mathbf{1}_{I_p}(\alpha)$, where $\mathbf{1}_{I_p}$ is the indicator of I_p, and $w_p = \sum_{\alpha=1}^{s} \mathbf{1}_{I_p}(\alpha) = \#I_p$.
(ii) The equality $w_p - w_{p+1} = \#I_p - \#I_{p+1} = \#(I_p \setminus I_{p+1})$ holds by $I_{p+1} \subseteq I_p$ and part (i).
By the definitions of I_p and I_{p+1}, $I_p \setminus I_{p+1} = \{\alpha : \mu_\alpha = \lambda,\ k_\alpha = p\}$.

Structural Commentary: Similarity reduces shifted ranks to block sums; each block contributes a surviving-level indicator.
Key Insight: A λ-block contributes one rank drop through its final level. □

Figure 68 tracks shifted-rank drops to Jordan-block counts.

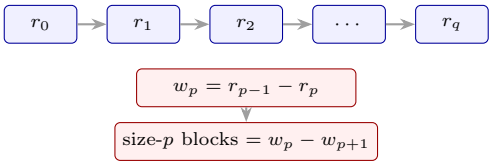

Figure 68: The pth shifted-rank drop counts chains of length at least p; consecutive differences count size-p blocks.

Corollary 6.2.7. *Uniqueness of Jordan Form*
Let $n \in \mathbb{Z}_{>0}$, let $A \in \mathrm{Mat}(n,n,\mathbb{C})$, and let J, J' be Jordan matrices similar to A.
For $M \in \{J, J'\}$, let $\mathfrak{B}(M)$ be its multiset of Jordan blocks and set $m_M(\lambda, k) := \#\{B \in \mathfrak{B}(M) : B = J_k(\lambda)\}$. Then:

(i) $(\forall\, (\lambda, k) \in \mathrm{spec}(A) \times \mathbb{Z}_{>0})\, m_J(\lambda, k) = m_{J'}(\lambda, k)$;
(ii) $\exists$ *a permutation matrix P that permutes whole Jordan-block coordinate groups and satisfies $J' = P^{-1}JP$.*

Proof.

(i) Fix $(\lambda, k) \in \mathrm{spec}(A) \times \mathbb{Z}_{>0}$.
The equality $m_J(\lambda, k) = w_k(\lambda, A) - w_{k+1}(\lambda, A) = m_{J'}(\lambda, k)$ holds by Theorem 6.2.6(ii) with J and J' in turn.
(ii) The ordered block lists of J and J' admit a bijection matching equal blocks by part (i).
Let P be the coordinate permutation matrix that carries each block group of J to its matched group in J'.
Then $P^{-1}JP = J'$ by equality of the matched blocks.

Structural Commentary: Rank-drop multiplicities match equal blocks; a coordinate permutation aligns their ordered groups.
Key Insight: Every block multiplicity is intrinsic to the shifted-rank sequence. □

Computation Method 6.2.8. *Jordan Form from Shifted-Rank Drops*
Given $n \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(n,n,\mathbb{C})$, the output is a Jordan matrix J similar to A. For $\lambda \in \mathrm{spec}(A)$, perform (i)–(iii).

(i) Compute $r_p(\lambda, A) := \mathrm{rank}((A-\lambda I_n)^p)$ through the first index $t_\lambda \in \mathbb{Z}_{>0}$ satisfying $r_{t_\lambda - 1}(\lambda, A) = r_{t_\lambda}(\lambda, A)$.
(ii) Set $w_p(\lambda, A) := r_{p-1}(\lambda, A) - r_p(\lambda, A)$ for $p \in \{1,\dots,t_\lambda\}$.
(iii) For $p \in \{1,\dots,t_\lambda - 1\}$, include $w_p(\lambda, A) - w_{p+1}(\lambda, A)$ copies of $J_p(\lambda)$.
(iv) Let J be the direct sum of the blocks obtained over $\lambda \in \mathrm{spec}(A)$.

The stopping index satisfies $t_\lambda \leq n+1$ by Theorem 4.1.4 and rank–nullity.
The stopping equality implies equality of adjacent shifted kernels by kernel inclusion and rank–nullity.
All later shifted-power ranks equal $r_{t_\lambda}(\lambda, A)$ by Proposition 4.1.3 and rank–nullity.
The matrix in (iv) is a Jordan form of A by the exact block counts in (iii) and Theorem 6.2.6(ii).

6.3 Products AB and BA and Jordan Structure

Proposition 6.3.1. *AB and BA Have the Same Characteristic Polynomial*
Let $\mathbb{F}$ be a field, let $n \in \mathbb{Z}_{>0}$, and let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) $p_{AB} = p_{BA}$.
(ii) If A or B is invertible, then AB and BA are similar.
(iii) There exist singular $A_0, B_0 \in \mathrm{Mat}(2, 2, \mathbb{F})$ such that A_0B_0 and B_0A_0 are not similar.

Proof.

(i) Regard z as an indeterminate over $\mathbb{F}$ and set $M := \left(\begin{smallmatrix} I_n & -z^{-1}A \\ -B & I_n \end{smallmatrix}\right) \in \mathrm{Mat}(2n, 2n, \mathbb{F}(z))$.
By block multiplication, $\left(\begin{smallmatrix} I_n & 0 \\ B & I_n \end{smallmatrix}\right) M = \left(\begin{smallmatrix} I_n & -z^{-1}A \\ 0 & I_n - z^{-1}BA \end{smallmatrix}\right)$. Similarly, $\left(\begin{smallmatrix} I_n & z^{-1}A \\ 0 & I_n \end{smallmatrix}\right) M = \left(\begin{smallmatrix} I_n - z^{-1}AB & 0 \\ -B & I_n \end{smallmatrix}\right)$.
The two left factors have determinant 1 by Theorem 3.8.4 and Theorem 3.8.2(i),(ix).
The right sides have determinants $\det(I_n - z^{-1}BA)$ and $\det(I_n - z^{-1}AB)$, respectively, by Theorem 3.8.4 and Theorem 3.8.2(ix).
Thus $\det(I_n - z^{-1}AB) = \det M = \det(I_n - z^{-1}BA)$ by Theorem 3.8.2(vi).
For $T \in \{AB, BA\}$, $p_T(z) = \det(zI_n - T)$ by Definition 2.1.2.
The identity $\det(zI_n - T) = z^n \det(I_n - z^{-1}T)$ holds by repeated column linearity in Theorem 3.8.2(ii).
Hence $p_{AB} = p_{BA}$ by the preceding determinant equality.

(ii) If A is invertible, then $BA = A^{-1}(AB)A$. If B is invertible, then $AB = B^{-1}(BA)B$.
In either case, AB and BA are similar by Definition 6.2.1.

(iii) Set $A_0 := \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ and $B_0 := \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$. Column spaces are one-dimensional, so both matrices have rank 1 by Definition 3.1.12.
Hence both are singular by Corollary 3.6.2. The identities $A_0B_0 = B_0$ and $B_0A_0 = 0$ hold by direct multiplication.
The products are not similar by their unequal ranks and Theorem 3.6.6(ii).

Structural Commentary: Elimination compares determinants; conjugation treats units; rank separates singular products.
Key Insight: The determinant identity survives singular factors, but conjugation need not. □

Theorem 6.3.2. *Nonzero Jordan Blocks of AB and BA*
Let $n \in \mathbb{Z}_{>0}$ and let $A, B \in \mathrm{Mat}(n, n, \mathbb{C})$. For $\lambda \in \mathbb{C} \setminus \{0\}$, the Jordan blocks of AB and BA at λ coincide.

Proof. Fix $\lambda \in \mathbb{C} \setminus \{0\}$.

(i) *Auxiliary Similarity*: Set $X := \left(\begin{smallmatrix} AB & A \\ 0 & 0 \end{smallmatrix}\right)$ and $Y := \left(\begin{smallmatrix} 0 & A \\ 0 & BA \end{smallmatrix}\right)$. Set $P := \left(\begin{smallmatrix} I_n & 0 \\ B & I_n \end{smallmatrix}\right)$.
The identities $P^{-1} = \left(\begin{smallmatrix} I_n & 0 \\ -B & I_n \end{smallmatrix}\right)$ and $PXP^{-1} = Y$ hold by block multiplication. Hence X and Y are similar by Definition 6.2.1.

(ii) *Shifted Powers*: Set $C := AB - \lambda I_n$, $D := -\lambda I_n$, $G := BA - \lambda I_n$, and $E_1 = F_1 := A$.
For $p \in \mathbb{Z}_{>0}$, define $E_{p+1} := C^pA + E_pD$ and $F_{p+1} := D^pA + F_pG$.
For $p \in \mathbb{Z}_{>0}$, let $\mathcal{P}_p^X$ denote $(X - \lambda I_{2n})^p = \left(\begin{smallmatrix} C^p & E_p \\ 0 & D^p \end{smallmatrix}\right)$. Let $\mathcal{P}_p^Y$ denote $(Y - \lambda I_{2n})^p = \left(\begin{smallmatrix} D^p & F_p \\ 0 & G^p \end{smallmatrix}\right)$, and set $\mathcal{P}_p := (\mathcal{P}_p^X \wedge \mathcal{P}_p^Y)$.
The relations $\mathcal{P}_1$ and $(\forall\, p \in \mathbb{Z}_{>0})\,(\mathcal{P}_p \Longrightarrow \mathcal{P}_{p+1})$ hold by the definitions and block multiplication with the recurrences.
Hence $(\forall\, p \in \mathbb{Z}_{>0})\,\mathcal{P}_p$ by Theorem 2.6.2.

(iii) *Rank Splitting*: The matrix D is invertible by $\lambda \neq 0$. For $p \in \mathbb{Z}_{>0}$, set $U_p := \left(\begin{smallmatrix} I_n & -E_pD^{-p} \\ 0 & I_n \end{smallmatrix}\right)$. Set $V_p := \left(\begin{smallmatrix} I_n & -D^{-p}F_p \\ 0 & I_n \end{smallmatrix}\right)$.
Both matrices are invertible by Proposition 3.8.8.
Identity $U_p \left(\begin{smallmatrix} C^p & E_p \\ 0 & D^p \end{smallmatrix}\right) = C^p \oplus D^p$ holds by block multiplication. Identity $\left(\begin{smallmatrix} D^p & F_p \\ 0 & G^p \end{smallmatrix}\right) V_p = D^p \oplus G^p$ holds by block multiplication.
For $H, K \in \mathrm{Mat}(n, n, \mathbb{C})$, $\mathrm{im}(H \oplus K) = \mathrm{im}(H) \oplus \mathrm{im}(K)$ by the coordinate-block action.
The matrix D^p has inverse D^{-p} by induction on p, so $\mathrm{rank}(D^p) = n$ by Corollary 3.6.2.
The equality $\mathrm{rank}((X - \lambda I_{2n})^p) = \mathrm{rank}(C^p \oplus D^p)$ holds by item (ii), invertibility of U_p, and Theorem 3.6.6(ii).
Thus $\mathrm{rank}((X - \lambda I_{2n})^p) = n + \mathrm{rank}(C^p)$ by the image identity and Theorem 2.3.4(i).
The equality $\mathrm{rank}((Y - \lambda I_{2n})^p) = \mathrm{rank}(D^p \oplus G^p)$ holds by item (ii), invertibility of V_p, and Theorem 3.6.6(ii).
Thus $\mathrm{rank}((Y - \lambda I_{2n})^p) = n + \mathrm{rank}(G^p)$ by the image identity and Theorem 2.3.4(i).

(iv) *Jordan Recovery*: For $p \in \mathbb{Z}_{>0}$, $(Y - \lambda I_{2n})^p = P(X - \lambda I_{2n})^p P^{-1}$ by the identity in (i) and induction on p.
Thus $\mathrm{rank}(C^p) = \mathrm{rank}(G^p)$ by item (iii) and Theorem 3.6.6(ii). The equality also holds for $p = 0$ by $C^0 = G^0 = I_n$.
Polynomials p_{AB} and p_{BA} are equal by Proposition 6.3.1(i). Hence λ belongs to both spectra or to neither by Theorem 2.1.3(ii).
If λ is outside spectra, neither product has λ-block. If λ belongs to spectra, shifted-rank differences agree by rank equalities.
Hence each λ-block size has equal multiplicity by Theorem 6.2.6(ii).

Structural Commentary: Auxiliary similarity transfers rank data; Weyr differences recover each nonzero block.
Key Insight: The added diagonal block is invertible exactly when $\lambda \neq 0$. □

Figure 69 tracks the auxiliary similarity to the two shifted-rank sequences.

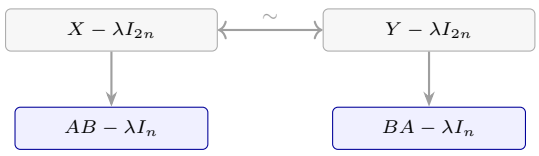

Figure 69: For $\lambda \neq 0$, the auxiliary similarity reduces the comparison to shifted ranks of AB and BA.

Corollary 6.3.3. *Similarity Criterion for AB and BA*
Let $n \in \mathbb{Z}_{>0}$ and let $A, B \in \mathrm{Mat}(n, n, \mathbb{C})$. Then AB is similar to BA if and only if $(\forall\, p \in \{1, \ldots, n\})$ $\mathrm{rank}((AB)^p) = \mathrm{rank}((BA)^p)$.

Proof.

($\Rightarrow$) Suppose AB and BA are similar. Choose $S \in \mathrm{GL}_n(\mathbb{C})$ satisfying $BA = S(AB)S^{-1}$ by Definition 6.2.1.
For $p \in \mathbb{Z}_{>0}$, $(BA)^p = S(AB)^pS^{-1}$ by induction on p. Hence $\mathrm{rank}((AB)^p) = \mathrm{rank}((BA)^p)$ by Theorem 3.6.6(ii).

($\Leftarrow$) Assume the stated rank equalities. At exponent 0, both powers equal I_n and have rank n.
For $T \in \{AB, BA\}$, $(\operatorname{rank}(T^q))_{q=n}^{\infty}$ is constant by Theorem 4.1.4 and Corollary 3.3.1(i).
The two power-rank sequences agree by the assumed equalities, the exponent-zero identity, and stabilization.
The nonzero Jordan blocks coincide by Theorem 6.3.2. The characteristic polynomials agree by Proposition 6.3.1(i).
Hence $0 \in \operatorname{spec}(AB) \iff 0 \in \operatorname{spec}(BA)$ by Theorem 2.1.3(ii). Regard AB and BA as matrix-induced operators on $\mathbb{C}^n$. Choose Jordan matrices J_{AB} and J_{BA} similar to them by Theorem 6.2.1.
If 0 belongs to these spectra, the power-rank differences agree by the equal sequences.
In this case, the zero-block multiplicities agree by Theorem 6.2.6(ii) with J_{AB} and J_{BA} in turn.
If 0 lies outside spectra, neither product has zero-Jordan block. Block multisets agree by nonzero- and zero-block comparisons.
Choose a common block ordering and let J be its direct sum.
Coordinate permutation matrices $Q_{AB}, Q_{BA} \in \mathrm{GL}_n(\mathbb{C})$ exist by the matching block multisets.
They satisfy $Q_{AB}^{-1} J_{AB} Q_{AB} = J = Q_{BA}^{-1} J_{BA} Q_{BA}$ by block multiplication. Hence AB and BA are similar by Proposition 6.2.2.

Structural Commentary: Power-rank invariance handles one direction; zero-block recovery handles the converse.
Key Insight: Nonzero blocks already match, so ordinary power ranks detect the remainder. □

Computation Method 6.3.4. *Checking Whether AB and BA Are Similar*
Given $n \in \mathbb{Z}_{>0}$ and $A, B \in \mathrm{Mat}(n, n, \mathbb{C})$, the output is a decision whether AB and BA are similar.

(i) Form $C := AB$ and $D := BA$.
(ii) Compute $\operatorname{rank}(C^p)$ and $\operatorname{rank}(D^p)$ for $p \in \{1, \ldots, n\}$.
(iii) Return "similar" if every computed rank pair agrees; otherwise return "not similar."
The first unequal pair certifies different zero-Jordan structures.

The nonzero Jordan blocks agree by Theorem 6.3.2. The output is correct by Corollary 6.3.3.

6.4 Nonderogatory Matrices and Commutants

Definition 6.4.1. *Nonderogatory Matrix*
Let $n \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(n, n, \mathbb{C})$. Matrix A *nonderogatory* if $(\forall \lambda \in \operatorname{spec}(A))$ its Jordan form contains exactly 1 block with eigenvalue λ. Equivalently, $(\forall \lambda \in \operatorname{spec}(A))\ \dim_{\mathbb{C}} E_\lambda(A) = 1$ by Corollary 6.2.3(i).

Lemma 6.4.2. *Commutant of One Jordan Block*
Let $m \in \mathbb{Z}_{>0}$, $\lambda \in \mathbb{C}$, $J := J_m(\lambda)$, and $X \in \mathrm{Mat}(m, m, \mathbb{C})$. If $XJ = JX$, then $(\exists a_0, \ldots, a_{m-1} \in \mathbb{C})\ X = \sum_{r=0}^{m-1} a_r J^r$.

Proof. Set $N := J_m(0)$; $J = \lambda I_m + N$, $XN = NX$ by $XJ = JX$. List $(\mathbf{e}_m, N\mathbf{e}_m, \ldots, N^{m-1}\mathbf{e}_m)$ is standard basis in reverse order.
Choose $b_0, \ldots, b_{m-1} \in \mathbb{C}$ satisfying $X\mathbf{e}_m = \sum_{r=0}^{m-1} b_r N^r \mathbf{e}_m$ by uniqueness of basis coordinates.
Set $p(z) := \sum_{r=0}^{m-1} b_r z^r$. For $s \in \{0, \ldots, m-1\}$, $p(N)N^s = N^s p(N)$ by Proposition 1.1.6(ii).
The equality $N^s X = X N^s$ holds by induction on s from $NX = XN$, and $(p(N) - X)N^s \mathbf{e}_m = 0$ by this equality and the choice of p.
Thus $p(N) = X$ by equality on a basis. Set $q(z) := p(z - \lambda)$.
By binomial expansion, $(\exists a_0, \ldots, a_{m-1} \in \mathbb{C})\ q(z) = \sum_{r=0}^{m-1} a_r z^r$. The equality $X = p(N) = q(J) = \sum_{r=0}^{m-1} a_r J^r$ holds by $J - \lambda I_m = N$.
Structural Commentary: Cyclic-basis equality propagates the image of $\mathbf{e}_m$ through every power of N.
Key Insight: Commutation determines the map from one cyclic vector. □

Theorem 6.4.3. *Nonderogatory Commutants Are Polynomials*
Let $n \in \mathbb{Z}_{>0}$ and let $A \in \mathrm{Mat}(n, n, \mathbb{C})$ be nonderogatory. Then $\operatorname{Comm}(A) = \{p(A) : p \in \mathbb{C}[z]\}$.

Proof.

(i) *Polynomial Inclusion*: Fix $h \in \mathbb{C}[z]$ and regard A as an operator on $\mathbb{C}^n$.
The equality $h(A)A = Ah(A)$ holds by Proposition 1.1.6(ii) with the polynomials h and z. Hence $\{p(A) : p \in \mathbb{C}[z]\} \subseteq \operatorname{Comm}(A)$.

(ii) *Jordan Reduction*: By Theorem 6.2.1, choose $S \in \mathrm{GL}_n(\mathbb{C})$ and a Jordan matrix J such that $A = SJS^{-1}$.
By nonderogatoriness, choose $d, m_1, \ldots, m_d \in \mathbb{Z}_{>0}$ and pairwise distinct $\lambda_1, \ldots, \lambda_d \in \mathbb{C}$.
For $i \in \{1, \ldots, d\}$, set $J_i := J_{m_i}(\lambda_i)$. Then $J = \bigoplus_{i=1}^{d} J_i$ and $\sum_{i=1}^{d} m_i = n$.
Fix $B \in \operatorname{Comm}(A)$, set $X := S^{-1}BS$, and partition $X = [X_{ij}]$ conformally with J.
Then $XJ = JX$ by multiplying $BA = AB$ on the left by S^{-1} and on the right by S.
The equality $(\forall i \in \{1, \ldots, d\})\ \operatorname{spec}(J_i) = \{\lambda_i\}$ holds by Proposition 2.1.6(ii). Thus the spectra of $J_1, \ldots, J_d$ are pairwise disjoint.
Hence $(\forall i, j \in \{1, \ldots, d\})\ [i \neq j \Rightarrow X_{ij} = 0]$ by Corollary 3.5.5.
Thus $X = \bigoplus_{i=1}^{d} X_{ii}$. For $i \in \{1, \ldots, d\}$, choose $p_i \in \mathbb{C}[z]$ such that $X_{ii} = p_i(J_i)$ by Lemma 6.4.2.

(iii) *Congruence Projectors*: For $v, w, f \in \mathbb{C}[z]$ with $f \neq 0$, write $v \equiv w \pmod f$ if $f \mid (v - w)$.
For $i \in \{1, \ldots, d\}$, set $f_i(z) := (z - \lambda_i)^{m_i}$ and $F_i(z) := \prod_{j \neq i} f_j(z)$, where an empty product equals 1.
Set $c_i := F_i(\lambda_i) = \prod_{j \neq i} (\lambda_i - \lambda_j)^{m_j} \neq 0$ and $u_i(z) := c_i^{-1} F_i(z) - 1$.
The divisibility $z - \lambda_i \mid u_i(z)$ holds by $u_i(\lambda_i) = 0$ and expansion in powers of $z - \lambda_i$. Set $e_i(z) := c_i^{-1} F_i(z) \sum_{r=0}^{m_i - 1} (-u_i(z))^r$.
The identity $e_i = 1 - (-u_i)^{m_i}$ holds by $c_i^{-1} F_i = 1 + u_i$ and the finite geometric-sum identity. Hence $e_i \equiv 1 \pmod{f_i}$ by $z - \lambda_i \mid u_i$.
The relation $(\forall k \in \{1, \ldots, d\} \setminus \{i\})\ e_i \equiv 0 \pmod{f_k}$ holds by $f_k \mid F_i$.

(iv) *Block Interpolation*: Set $p := \sum_{i=1}^{d} p_i e_i$. Then $(\forall i \in \{1, \ldots, d\})\ p \equiv p_i \pmod{f_i}$ by item (iii).
For $i \in \{1, \ldots, d\}$, choose $q_i \in \mathbb{C}[z]$ satisfying $p - p_i = f_i q_i$. The identity $J_i - \lambda_i I_{m_i} = J_{m_i}(0)$ holds by Definition 6.1.1(ii).
Hence $f_i(J_i) = J_{m_i}(0)^{m_i} = 0$ by Lemma 6.2.4(i) and Definition 3.1.12.

The equality $(p-p_i)(J_i) = f_i(J_i)q_i(J_i) = 0$ holds by Proposition 1.1.6(i). Thus $p(J_i) = p_i(J_i) = X_{ii}$.

The identity $p(J) = \bigoplus_{i=1}^{d} p(J_i)$ holds by Proposition 3.8.6(iv) and induction on d. Hence $p(J) = \bigoplus_{i=1}^{d} X_{ii} = X$ by item (ii).

(v) *Conjugation Back*: The identity $(\forall r \in \mathbb{Z}_{\geq 0})\, A^r = SJ^rS^{-1}$ holds by induction on r from $A = SJS^{-1}$.
Thus $p(A) = Sp(J)S^{-1} = SXS^{-1} = B$ by polynomial evaluation.
The claimed equality follows by the resulting reverse inclusion and item (i).

Structural Commentary: Block separation isolates local polynomials; congruence projectors merge them before conjugation.
Key Insight: Truncated geometric sums realize every block congruence in one polynomial. □

Figure 70 tracks local commutant blocks into one polynomial satisfying every Jordan congruence.

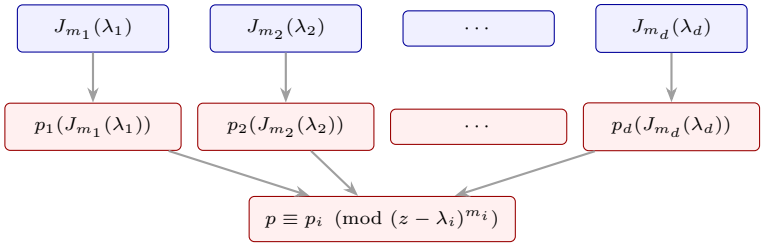

Figure 70: Blockwise polynomial data merge into one polynomial modulo the Jordan-block powers.

Corollary 6.4.4. *Simple Spectrum Commutants Are Polynomials*
Let $n \in \mathbb{Z}_{>0}$ and let $A \in \mathrm{Mat}(n,n,\mathbb{C})$ have n distinct eigenvalues. Then:
(i) $\mathrm{Comm}(A) = \{p(A) : p \in \mathbb{C}[z]\}$;
(ii) $\dim_{\mathbb{C}} \mathrm{Comm}(A) = n$.

Proof. List the eigenvalues as $\lambda_1, \ldots, \lambda_n$ and choose corresponding eigenvectors $\mathbf{v}_1, \ldots, \mathbf{v}_n$.
The list $(\mathbf{v}_1, \ldots, \mathbf{v}_n)$ is linearly independent by Theorem 5.1.5. It is a basis of $\mathbb{C}^n$ by Proposition 1.4.4(ii). Set $S := [\mathbf{v}_1 \ \cdots \ \mathbf{v}_n]$.
Then $S \in \mathrm{Mat}(n,n,\mathbb{C})^{\times}$ by Corollary 3.6.1. The identity $A = S\,\mathrm{diag}(\lambda_1, \ldots, \lambda_n)S^{-1}$ holds by the eigenvector relations.
This Jordan form has one block per eigenvalue, so A is nonderogatory by Definition 6.4.1.
The equality $(\forall i \in \{1, \ldots, n\})\ \dim_{\mathbb{C}} E_{\lambda_i}(A) = 1$ holds by Corollary 6.2.3(i).

(i) The equality $\mathrm{Comm}(A) = \{p(A) : p \in \mathbb{C}[z]\}$ holds by Theorem 6.4.3.

(ii) The equality $\dim_{\mathbb{C}} \mathrm{Comm}(A) = \sum_{i=1}^{n} 1^2 = n$ holds by Theorem 5.4.12(ii).

Structural Commentary: A full eigenbasis supplies nonderogatoriness; its eigenline dimensions feed the commutant formula.
Key Insight: A simple spectrum contributes one commutant parameter per eigenline. □

6.5 Jordan Operator Functions and Square Roots

For $z \in \mathbb{C}$, set $e^z := \sum_{m=0}^{\infty} \frac{z^m}{m!}$.

Definition 6.5.1. *Matrix Exponential*
Let $n \in \mathbb{Z}_{>0}$ and $C \in \mathrm{Mat}(n,n,\mathbb{C})$. The *matrix exponential* of C is $e^C = \exp(C) := \sum_{m=0}^{\infty} \frac{C^m}{m!}$.

Proposition 6.5.2. *Entrywise Absolute Convergence of the Matrix Exponential*
Let $n \in \mathbb{Z}_{>0}$ and $C \in \mathrm{Mat}(n,n,\mathbb{C})$. Then $(\forall i,j \in \{1, \ldots, n\})\ \sum_{m=0}^{\infty} \frac{|(C^m)_{ij}|}{m!} < \infty$.

Proof. Set $M := \max_{1 \leq i,j \leq n} |C_{ij}|$. By induction, $(\forall m \in \mathbb{Z}_{>0})(\forall i,j \in \{1, \ldots, n\})\ |(C^m)_{ij}| \leq n^{m-1}M^m$.
For $(i,j) \in \{1, \ldots, n\}^2$, $|(C^0)_{ij}| \leq 1$ and $\sum_{m=0}^{\infty} \frac{|(C^m)_{ij}|}{m!} \leq 1 + \frac{e^{nM}-1}{n} < \infty$ by the scalar exponential series.
Structural Commentary: The entrywise power bound reduces matrix convergence to one scalar exponential majorant.
Key Insight: Each matrix multiplication contributes at most one factor of nM. □

The real scalar facts used below are $(\forall x \in \mathbb{R})\, e^x > 0$ and $(\forall x \in \mathbb{R}_{>0})(\exists \ell \in \mathbb{R})\, e^{\ell} = x$.
For complex scalars, $(\forall \lambda \in \mathbb{C} \setminus \{0\})(\exists \ell \in \mathbb{C})\, e^{\ell} = \lambda$ and $(\forall \lambda \in \mathbb{C})(\exists \alpha \in \mathbb{C})\, \alpha^2 = \lambda$.

Proposition 6.5.3. *Exponential of a Jordan Block*
Let $k \in \mathbb{Z}_{>0}$ and $\lambda, t \in \mathbb{C}$. Then $e^{tJ_k(\lambda)} = e^{\lambda t} \sum_{r=0}^{k-1} \frac{t^r}{r!} J_k(0)^r$.

Proof. Set $N := J_k(0)$, so $J_k(\lambda) = \lambda I_k + N$ and $N^k = 0$. Adopt $\binom{m}{r} = 0$ for $r > m$.
For $m \in \mathbb{Z}_{\geq 0}$, $(tJ_k(\lambda))^m = \sum_{r=0}^{k-1} \binom{m}{r} (\lambda t)^{m-r} t^r N^r$ by induction and commutation of λI_k with N.
For $M \in \mathbb{Z}_{\geq 0}$ and $r \in \{0, \ldots, k-1\}$, the coefficient of N^r in the Mth exponential partial sum is $a_{M,r} := \sum_{m=r}^{M} \frac{1}{m!} \binom{m}{r} (\lambda t)^{m-r} t^r$.
The limit $\lim_{M \to \infty} a_{M,r} = \frac{t^r}{r!} \sum_{s=0}^{\infty} \frac{(\lambda t)^s}{s!} = \frac{t^r}{r!} e^{\lambda t}$ follows by setting $s = m - r$.
The asserted formula holds by taking the entrywise limit over the finite family $(N^r)_{r=0}^{k-1}$.
Structural Commentary: Jordan binomial expansion separates scalar powers from finitely many nilpotent powers before taking limits.
Key Insight: Nilpotence leaves finitely many scalar exponential coefficients. □

Proposition 6.5.4. *Commuting and Similarity Laws for the Exponential*
Let $n \in \mathbb{Z}_{>0}$, let $A, B \in \mathrm{Mat}(n,n,\mathbb{C})$, and let $S \in \mathrm{Mat}(n,n,\mathbb{C})^\times$. Then:
(i) $AB = BA \implies e^{A+B} = e^A e^B$.
(ii) $e^{SAS^{-1}} = Se^A S^{-1}$.

Proof.
(i) Since A and B commute, $(A+B)^m = \sum_{r=0}^{m} \binom{m}{r} A^r B^{m-r}$ by induction on $m \in \mathbb{Z}_{\geq 0}$.
The Cauchy product is valid by entrywise absolute convergence. Hence $e^A e^B = \sum_{m=0}^{\infty} \frac{1}{m!} \sum_{r=0}^{m} \binom{m}{r} A^r B^{m-r} = e^{A+B}$ by the binomial identity.
(ii) Set $X := SAS^{-1}$. Then $(\forall m \in \mathbb{Z}_{\geq 0})\ X^m = SA^m S^{-1}$ by induction from $S^{-1}S = I_n$.
Thus $(\forall M \in \mathbb{Z}_{\geq 0})\ \sum_{m=0}^{M} \frac{X^m}{m!} = S\left(\sum_{m=0}^{M} \frac{A^m}{m!}\right) S^{-1}$. The equality $e^X = Se^A S^{-1}$ holds by entrywise limits.

Structural Commentary: Binomial powers control products; conjugated powers control similarity before entrywise limits.
Key Insight: Absolute convergence permits the required finite-degree regrouping. □

Theorem 6.5.5. *Analytic Power Series on Jordan Blocks*
Let $n \in \mathbb{Z}_{>0}$, let $A \in \mathrm{Mat}(n,n,\mathbb{C})$, and let $f(z) = \sum_{m=0}^{\infty} c_m z^m$ have radius of convergence $R \in (0,\infty]$.
Set $\rho(A) := \max_{\lambda \in \mathrm{spec}(A)} |\lambda|$ and $D_R := \{z \in \mathbb{C} : |z| < R\}$, and suppose $\rho(A) < R$.
For $r \in \mathbb{Z}_{\geq 0}$ and $\lambda \in D_R$, set $f^{(r)}(\lambda) := \sum_{m=r}^{\infty} \frac{m!}{(m-r)!} c_m \lambda^{m-r}$. For $k \in \mathbb{Z}_{>0}$, set $N_k := J_k(0)$ and $F_k(\lambda) := \sum_{r=0}^{k-1} \frac{f^{(r)}(\lambda)}{r!} N_k^r$.
For $s, k_1, \ldots, k_s \in \mathbb{Z}_{>0}$ and $J = \bigoplus_{\alpha=1}^{s} J_{k_\alpha}(\lambda_\alpha)$ with $\lambda_\alpha \in D_R$, set $f(J) := \bigoplus_{\alpha=1}^{s} F_{k_\alpha}(\lambda_\alpha)$.
Then:
(i) $(\forall (k,\lambda) \in \mathbb{Z}_{>0} \times D_R)\ \sum_{m=0}^{\infty} c_m J_k(\lambda)^m = F_k(\lambda)$.
(ii) The series $f(A) := \sum_{m=0}^{\infty} c_m A^m$ converges.
(iii) If $A = SJS^{-1}$ is a Jordan decomposition, then $f(A) = Sf(J)S^{-1}$.

Proof. For $M \in \mathbb{Z}_{\geq 0}$, set $P_M(X) := \sum_{m=0}^{M} c_m X^m$, and adopt $\binom{m}{r} = 0$ for $r > m$.
(i) Fix $(k,\lambda) \in \mathbb{Z}_{>0} \times D_R$ and set $N := N_k$.
Then $(\forall m \in \mathbb{Z}_{\geq 0})\ J_k(\lambda)^m = \sum_{r=0}^{k-1} \binom{m}{r} \lambda^{m-r} N^r$ by $N^k = 0$ and the binomial identity.
If $\lambda = 0$, only the term $m = r$ is nonzero in $f^{(r)}(0)$, and $f^{(r)}(0) = r! c_r$. Suppose $\lambda \neq 0$, and choose η with $|\lambda| < \eta < R$.
For fixed r, the sequence $m^r (|\lambda|/\eta)^m$ is bounded, and $\sum_{m=0}^{\infty} |c_m| \eta^m < \infty$.
For $m \geq r$, $\frac{m!}{(m-r)!} |c_m| |\lambda|^{m-r} \leq |\lambda|^{-r} m^r (|\lambda|/\eta)^m |c_m| \eta^m$.
Hence each differentiated series defining $F_k(\lambda)$ converges absolutely.
For $M \in \mathbb{Z}_{\geq 0}$, $P_M(J_k(\lambda)) = \sum_{r=0}^{k-1} \left(\sum_{m=r}^{M} c_m \binom{m}{r} \lambda^{m-r} \right) N^r$, with an empty inner sum interpreted as 0.
For $r \in \{0, \ldots, k-1\}$, the coefficient tends to $\frac{f^{(r)}(\lambda)}{r!}$. The outer sum is finite, so $P_M(J_k(\lambda)) \to F_k(\lambda)$.
(ii) By Theorem 6.2.1, choose $S \in \mathrm{Mat}(n,n,\mathbb{C})^\times$ and $J = \bigoplus_{\alpha=1}^{s} J_{k_\alpha}(\lambda_\alpha)$ such that $A = SJS^{-1}$.
Each $\lambda_\alpha \in D_R$ by $|\lambda_\alpha| \leq \rho(A) < R$. Thus $P_M(J) \to f(J)$ by part (i) and Proposition 3.8.6(iv).
By induction, $(\forall m \in \mathbb{Z}_{\geq 0})\ A^m = SJ^m S^{-1}$. Hence $P_M(A) = SP_M(J)S^{-1} \to Sf(J)S^{-1}$, so $f(A)$ converges.
(iii) By part (ii), $f(A) = \lim_{M\to\infty} P_M(A) = S\left(\lim_{M\to\infty} P_M(J)\right) S^{-1} = Sf(J)S^{-1}$.

Structural Commentary: Blockwise binomial limits establish convergence before similarity transfers the resulting function.
Key Insight: Derivatives are precisely the nilpotent-power coefficients. □

Proposition 6.5.6. *Closed Form for a 2×2 Exponential*
Let $a, b, c, d \in \mathbb{C}$ and set $A := \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$. Set $\delta := \frac{a+d}{2}$ and $B := A - \delta I_2$. Choose $\Delta \in \mathbb{C}$ with $\Delta^2 = \left(\frac{a-d}{2}\right)^2 + bc$.
Define $\cosh w := \sum_{m=0}^{\infty} \frac{w^{2m}}{(2m)!}$ and $\psi(w) := \sum_{m=0}^{\infty} \frac{w^{2m}}{(2m+1)!}$. Then $e^A = e^\delta \big(\cosh(\Delta) I_2 + \psi(\Delta) B\big)$.

Proof. The relations $\mathrm{tr}(B) = 0$ and $\det(B) = -\Delta^2$ hold by direct calculation. Hence $B^2 = \Delta^2 I_2$ by Theorem 3.1.1.
Thus $(\forall m \in \mathbb{Z}_{\geq 0})\ B^{2m} = \Delta^{2m} I_2$ and $B^{2m+1} = \Delta^{2m} B$.
Hence $e^B = \cosh(\Delta) I_2 + \psi(\Delta) B$ by separating the even and odd exponential terms.
The matrices δI_2 and B commute, so $e^A = e^{\delta I_2} e^B = e^\delta \big(\cosh(\Delta) I_2 + \psi(\Delta) B\big)$ by Proposition 6.5.4(i).
Structural Commentary: Cayley–Hamilton reduces all powers to even scalar terms and odd multiples of B.
Key Insight: The series ψ remains defined when $\Delta = 0$. □

Theorem 6.5.7. *Spectral Mapping and Jordan Structure of the Exponential*
Let $n \in \mathbb{Z}_{>0}$, let $A \in \mathrm{Mat}(n,n,\mathbb{C})$, and let $A = SJS^{-1}$ be a Jordan decomposition with $S \in \mathrm{Mat}(n,n,\mathbb{C})^\times$.
Set $E := e^A$ and write $J = \bigoplus_{\alpha=1}^{s} B_\alpha$, where $s, k_1, \ldots, k_s \in \mathbb{Z}_{>0}$ and $B_\alpha := J_{k_\alpha}(\lambda_\alpha)$.

For $\rho \in \mathbb{C}$, set $I_\rho := \{\alpha \in \{1,\dots,s\} : e^{\lambda_\alpha} = \rho\}$ and $\Lambda_\rho(A) := \{\lambda \in \operatorname{spec}(A) : e^\lambda = \rho\}$.
Let $\mathcal{S}_\rho(M)$ denote the multiset of ρ-Jordan block sizes of M. Then:

(i) $\operatorname{spec}(E) = \{e^\lambda : \lambda \in \operatorname{spec}(A)\}$.
(ii) $(\forall\, \rho \in \operatorname{spec}(E))\ \mathcal{G}_\rho(E) = \bigoplus_{\lambda \in \Lambda_\rho(A)} \mathcal{G}_\lambda(A)$.
(iii) $(\forall\, \rho \in \operatorname{spec}(E))\ \mathcal{S}_\rho(E) = \{k_\alpha : \alpha \in I_\rho\}$ *as multisets.*
(iv) $\det(E) = e^{\operatorname{tr}(A)}$.

Proof. Set $\sigma(M) := \operatorname{spec}(M)$, $E_J := e^J$, and $E_\alpha := e^{B_\alpha}$. Then $E = SE_JS^{-1}$ by Proposition 6.5.4(ii).
The identity $E_J = \bigoplus_{\alpha=1}^{s} E_\alpha$ holds by Proposition 3.8.6(iv) for exponential partial sums and entrywise limits.
Let V_α be the coordinate space of B_α and set $K_\rho := \bigoplus_{\alpha \in I_\rho} V_\alpha$.
Write $B_\alpha = \lambda_\alpha I_{k_\alpha} + N_\alpha$, set $q_\alpha(z) := \sum_{r=0}^{k_\alpha - 1} \frac{z^r}{(r+1)!}$, and set $Q_\alpha := q_\alpha(N_\alpha)$. Then $E_\alpha - e^{\lambda_\alpha} I_{k_\alpha} = e^{\lambda_\alpha} N_\alpha Q_\alpha$ by Proposition 6.5.3.
Set $h_\alpha(z) := \sum_{r=1}^{k_\alpha - 1} \frac{z^{r-1}}{(r+1)!}$ and $M_\alpha := Q_\alpha - I_{k_\alpha} = N_\alpha h_\alpha(N_\alpha)$. Then $M_\alpha^{k_\alpha} = 0$.
Thus $Q_\alpha^{-1} = \sum_{j=0}^{k_\alpha - 1} (-M_\alpha)^j$ by direct multiplication. Therefore Q_α is invertible and commutes with N_α.
The identity $e^{\lambda_\alpha} e^{-\lambda_\alpha} = 1$ holds by Proposition 6.5.4(i) for 1×1 matrices, so $e^{\lambda_\alpha} \neq 0$.

(i) Each E_α is upper triangular with constant diagonal e^{λ_α} by Proposition 6.5.3.
Hence $\sigma(E_J) = \{e^{\lambda_\alpha} : \alpha \in \{1,\dots,s\}\}$ by Proposition 2.1.6(ii). The equality $\sigma(E) = \sigma(E_J)$ holds by Theorem 2.1.7(i).
Similarly, $\sigma(A) = \sigma(J) = \{\lambda_\alpha : \alpha \in \{1,\dots,s\}\}$ by Proposition 2.1.6(ii) and Theorem 2.1.7(i). Thus $\sigma(E) = \{e^\lambda : \lambda \in \sigma(A)\}$.

(ii) Fix $\rho \in \sigma(E)$. If $\alpha \in I_\rho$, then $(\forall r \in \mathbb{Z}_{\geq 0})\,(E_\alpha - \rho I_{k_\alpha})^r = \rho^r N_\alpha^r Q_\alpha^r$, so the k_αth shifted power is zero.
If $\alpha \notin I_\rho$, then $E_\alpha - \rho I_{k_\alpha}$ is upper triangular with nonzero diagonal and is invertible by Theorem 3.8.2(v),(vii).
Hence $\mathcal{G}_\rho(E_J) = K_\rho$. For $\lambda \in \mathbb{C}$ and $r \in \mathbb{Z}_{\geq 0}$, $(A - \lambda I_n)^r S = S(J - \lambda I_n)^r$ by induction from $A = SJS^{-1}$.
Similarly, $(\forall r \in \mathbb{Z}_{\geq 0})\,(E - \rho I_n)^r S = S(E_J - \rho I_n)^r$. Thus $S\mathcal{G}_\lambda(J) = \mathcal{G}_\lambda(A)$ and $S\mathcal{G}_\rho(E_J) = \mathcal{G}_\rho(E)$.
Consequently, $\mathcal{G}_\rho(E) = SK_\rho = \bigoplus_{\lambda \in \Lambda_\rho(A)} \mathcal{G}_\lambda(A)$.

(iii) Fix $\rho \in \sigma(E)$. For $\alpha \in I_\rho$ and $r \in \mathbb{Z}_{\geq 0}$, $\operatorname{rank}((E_\alpha - \rho I_{k_\alpha})^r) = \operatorname{rank}(N_\alpha^r)$ by Theorem 3.6.6(ii).
Thus the shifted rank drops of E_α equal those of $J_{k_\alpha}(\rho)$, and $\mathcal{S}_\rho(E_\alpha) = \{k_\alpha\}$ by Theorem 6.2.6.
If $\alpha \notin I_\rho$, then $\mathcal{S}_\rho(E_\alpha) = \varnothing$ by part (ii); $\mathcal{S}_\rho(E) = \{k_\alpha : \alpha \in I_\rho\}$ by direct-sum block decomposition, similarity of E_J and E.

(iv) For $X, Y \in \operatorname{Mat}(n,n,\mathbb{C})$, $\operatorname{tr}(XY) = \sum_{i=1}^{n}\sum_{j=1}^{n} X_{ij}Y_{ji} = \operatorname{tr}(YX)$ by Definition 3.8.1(i). Hence $\operatorname{tr}(A) = \operatorname{tr}(SJS^{-1}) = \operatorname{tr}(J) = \sum_{\alpha=1}^{s} k_\alpha \lambda_\alpha$.
The equality $\det(E) = \det(E_J) = \prod_{\alpha=1}^{s} e^{k_\alpha \lambda_\alpha}$ holds by Theorem 3.8.2(v),(vi),(viii), similarity, and triangularity of E_J.
This product equals $e^{\sum_{\alpha=1}^{s} k_\alpha \lambda_\alpha} = e^{\operatorname{tr}(A)}$ by repeated scalar instances of Proposition 6.5.4(i).

Structural Commentary: Similarity transfers block exponentials; invertible Q_α preserves their nilpotent rank profiles.
Key Insight: Exponentiation changes block labels but not block lengths. □

Definition 6.5.8. *Matrix Logarithm*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \operatorname{Mat}(n,n,\mathbb{C})$. A matrix $B \in \operatorname{Mat}(n,n,\mathbb{C})$ is a *matrix logarithm* of A if $e^B = A$.

Theorem 6.5.9. *Complex Matrix Logarithms*
Let $k, n \in \mathbb{Z}_{>0}$, let $\lambda \in \mathbb{C} \setminus \{0\}$, and choose $\ell \in \mathbb{C}$ satisfying $e^\ell = \lambda$.
Set $N := J_k(0)$, $X := \lambda^{-1}N$, and $L_k(\lambda,\ell) := \ell I_k + \sum_{r=1}^{k-1} \frac{(-1)^{r+1}}{r} X^r$, with an empty sum interpreted as 0. Let $A \in \operatorname{Mat}(n,n,\mathbb{C})$. Then:

(i) $e^{L_k(\lambda,\ell)} = J_k(\lambda)$.
(ii) $(\exists B \in \operatorname{Mat}(n,n,\mathbb{C}))\, e^B = A$ *if and only if* $A \in \operatorname{Mat}(n,n,\mathbb{C})^\times$.

Proof.

(i) Set $Y := \sum_{r=1}^{k-1} \frac{(-1)^{r+1}}{r} X^r$. If $k = 1$, then $X = Y = 0$ and $e^Y = I_k + X$. Suppose $k \geq 2$.
In $\mathbb{C}[[x]]$, set $y(x) := \sum_{r=1}^{k-1} \frac{(-1)^{r+1}}{r} x^r$ and write $e^{y(x)} = \sum_{q=0}^{\infty} b_q x^q$.
The coefficients through degree $k-2$ of $(1+x)(e^y)'$ and e^y agree by $(1+x)y'(x) = 1 + (-1)^k x^{k-1}$.
The relations $b_1 = 1$ and $(q+1)b_{q+1} = (1-q)b_q$ for $q \in \{1,\dots,k-2\}$ hold by $b_0 = 1$ and coefficient comparison.
Hence $b_q = 0$ for $q \in \{2,\dots,k-1\}$ by this recurrence. Set $h(z) := \sum_{r=1}^{k-1} \frac{(-1)^{r+1}}{r} z^{r-1}$. Then $Y = Xh(X)$, so $Y^k = 0$.
The equality $e^Y = \sum_{q=0}^{k-1} b_q X^q = I_k + X$ holds by regrouping its finite exponential by powers of X.
The summands ℓI_k and Y commute. Therefore $e^{L_k(\lambda,\ell)} = e^\ell(I_k + X) = \lambda I_k + N = J_k(\lambda)$ by Proposition 6.5.4(i).

(ii) ($\Rightarrow$) Suppose $A = e^B$. Then $Ae^{-B} = e^B e^{-B} = I_n = e^{-B}e^B = e^{-B}A$ by Proposition 6.5.4(i). Thus $A \in \operatorname{Mat}(n,n,\mathbb{C})^\times$.

(ii) ($\Leftarrow$) Suppose $A \in \operatorname{Mat}(n,n,\mathbb{C})^\times$. By Theorem 6.2.1, choose $S \in \operatorname{Mat}(n,n,\mathbb{C})^\times$ and $J = \bigoplus_{\alpha=1}^{s} J_{k_\alpha}(\lambda_\alpha)$ such that $A = SJS^{-1}$.
For $\alpha \in \{1,\dots,s\}$, $\lambda_\alpha \neq 0$ by Corollary 5.1.8. Choose $\ell_\alpha \in \mathbb{C}$ satisfying $e^{\ell_\alpha} = \lambda_\alpha$, and set $L_\alpha := L_{k_\alpha}(\lambda_\alpha, \ell_\alpha)$.
Set $L_J := \bigoplus_{\alpha=1}^{s} L_\alpha$, $B := SL_JS^{-1}$. Then $e^{L_J} = \bigoplus_{\alpha=1}^{s} e^{L_\alpha} = J$ by part (i), Proposition 3.8.6(iv) for partial sums, entrywise limits.
Hence $e^B = Se^{L_J}S^{-1} = A$ by Proposition 6.5.4(ii).

Structural Commentary: A formal truncated logarithm handles each nilpotent block before direct-sum and similarity assembly.
Key Insight: Modulo X^k, the truncated logarithm exponentiates exactly to $I_k + X$. □

Proposition 6.5.10. *Real Matrix Logarithm Conditions*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(n,n,\mathbb{R})^\times$. Then:

(i) If $(\exists B \in \mathrm{Mat}(n,n,\mathbb{R}))\, e^B = A$, then $\det(A) > 0$.
(ii) If $\mathrm{spec}(A) \cap \mathbb{R} \subset (0,\infty)$, then $(\exists B \in \mathrm{Mat}(n,n,\mathbb{R}))\, e^B = A$.
(iii) $(\exists C \in \mathrm{Mat}(n,n,\mathbb{R}))\, e^C = A^2$.

Proof. For $x, y \in \mathbb{R}$, set $R(x,y) := \left(\begin{smallmatrix} x & y \\ -y & x \end{smallmatrix}\right)$. For $m \in \mathbb{Z}_{>0}$ and $D = [d_{rs}] \in \mathrm{Mat}(m,m,\mathbb{C})$, set $\mathfrak{R}(D) := [R(\mathrm{Re}\, d_{rs}, \mathrm{Im}\, d_{rs})]_{r,s=1}^m$.
For $D, E \in \mathrm{Mat}(m,m,\mathbb{C})$, $\mathfrak{R}(D+E) = \mathfrak{R}(D) + \mathfrak{R}(E)$ and $\mathfrak{R}(DE) = \mathfrak{R}(D)\mathfrak{R}(E)$ by direct block multiplication.
Hence $e^{\mathfrak{R}(D)} = \mathfrak{R}(e^D)$ by exponential partial sums and entrywise limits.
For $\lambda = a + ib$ with $a \in \mathbb{R}$ and $b > 0$, $\mathfrak{R}(J_k(\lambda)) = \mathcal{J}_k(a,b)$ by the block definitions.

(i) If $A = e^B$ with $B \in \mathrm{Mat}(n,n,\mathbb{R})$, then $\det(A) = e^{\mathrm{tr}(B)} > 0$ by Theorem 6.5.7(iv) and positivity of the real scalar exponential.
(ii) By Theorem 6.2.2(i), choose $S \in \mathrm{GL}_n(\mathbb{R})$ such that $J_\mathbb{R} := S^{-1}AS$ is a direct sum of real Jordan blocks.
For a scalar summand $J_k(\lambda)$, $\lambda > 0$ by the hypothesis. Choose $\ell \in \mathbb{R}$ with $e^\ell = \lambda$.
Then $L_k(\lambda, \ell)$ is real, and $e^{L_k(\lambda,\ell)} = J_k(\lambda)$ by Theorem 6.5.9(i).
For a summand $\mathcal{J}_k(a,b)$, set $\lambda := a + ib$, choose $\ell \in \mathbb{C}$ with $e^\ell = \lambda$, and set $D := L_k(\lambda, \ell)$.
Then $e^{\mathfrak{R}(D)} = \mathfrak{R}(J_k(\lambda)) = \mathcal{J}_k(a,b)$ by the realification identities and Theorem 6.5.9(i).
Let $L_\mathbb{R}$ be the direct sum of these real block logarithms and set $B := SL_\mathbb{R}S^{-1}$.
Then $e^B = Se^{L_\mathbb{R}}S^{-1} = SJ_\mathbb{R}S^{-1} = A$ by Proposition 6.5.4(ii), exponential partial sums, and entrywise limits.
(iii) *Squared Block Sizes*: Fix $(k,\lambda) \in \mathbb{Z}_{>0} \times (\mathbb{C} \setminus \{0\})$, set $N := J_k(0)$, and set $X_\lambda := J_k(\lambda)^2$. Then $X_\lambda - \lambda^2 I_k = N(2\lambda I_k + N)$.
The matrix $2\lambda I_k + N$ is invertible by a finite geometric inverse and commutes with N.
Thus $(\forall r \in \mathbb{Z}_{\geq 0})$ $\mathrm{rank}((J_k(\lambda)^2 - \lambda^2 I_k)^r) = \mathrm{rank}(N^r)$ by Theorem 3.6.6(ii).
The matrix X_λ is upper triangular with constant diagonal λ^2, so its only eigenvalue is λ^2.
A Jordan form of X_λ exists by Theorem 6.2.1, and it consists of one block $J_k(\lambda^2)$ by Theorem 6.2.6 and the shifted-rank equality.
Real Assembly: Choose $S \in \mathrm{GL}_n(\mathbb{R})$ and a real Jordan block matrix $J_\mathbb{R} := S^{-1}AS$ by Theorem 6.2.2(i).
For scalar summand $J_k(\lambda)$, $\lambda \in \mathbb{R}\setminus\{0\}$. By squared-block step, Theorem 6.2.2(i), choose $Q \in \mathrm{GL}_k(\mathbb{R})$ s.t. $J_k(\lambda)^2 = QJ_k(\lambda^2)Q^{-1}$.
Choose $\ell \in \mathbb{R}$ with $e^\ell = \lambda^2$, $D := QL_k(\lambda^2, \ell)Q^{-1}$. Then D is real and $e^D = J_k(\lambda)^2$ by Theorem 6.5.9(i) and Proposition 6.5.4(ii).
For a summand $\mathcal{J}_k(a,b)$, set $\lambda := a + ib$. By the squared-block step, choose $Q_\lambda \in \mathrm{GL}_k(\mathbb{C})$ such that $X_\lambda = Q_\lambda J_k(\lambda^2)Q_\lambda^{-1}$.
Choose $\ell_\lambda \in \mathbb{C}$ with $e^{\ell_\lambda} = \lambda^2$, and set $D_\lambda := Q_\lambda L_k(\lambda^2, \ell_\lambda)Q_\lambda^{-1}$. Then $e^{D_\lambda} = X_\lambda$ by Theorem 6.5.9(i) and Proposition 6.5.4(ii).
Thus $e^{\mathfrak{R}(D_\lambda)} = \mathfrak{R}(X_\lambda) = \mathcal{J}_k(a,b)^2$ (realification identities). Let $C_\mathbb{R}$ be direct sum of resulting real log of all squared summands.
Set $C := SC_\mathbb{R}S^{-1}$. Then $e^C = Se^{C_\mathbb{R}}S^{-1} = SJ_\mathbb{R}^2S^{-1} = A^2$ by Proposition 6.5.4(ii), exponential partial sums, entrywise limits.

Structural Commentary: Realification handles nonreal blocks; shifted-rank profiles preserve block lengths after squaring.
Key Insight: The block realification map commutes with powers and exponentials. □

Proposition 6.5.11. *Jordan Resolvent and Primary Spectral Projectors*
Let $n \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(n,n,\mathbb{C})$; $\Sigma := \mathrm{spec}(A)$, $G_\nu := \mathcal{G}_\nu(A)$. For $m \in \mathbb{Z}_{>0}$, $M \in \mathrm{Mat}(m,m,\mathbb{C})$, $z \notin \mathrm{spec}(M)$, $R_M(z) := (zI_m - M)^{-1}$. The identity $\mathbb{C}^n = \bigoplus_{\nu\in\Sigma} G_\nu$ holds by Theorem 5.1.1. For $\mu \in \Sigma$, define $P_\mu \in \mathrm{Mat}(n,n,\mathbb{C})$ by $P_\mu|_{G_\nu} = \delta_{\mu\nu} I_{G_\nu}$.
When entries of matrix-valued function F admit Laurent expansions at μ, let $[F]_{\mu,-1}$ denote matrix of $(z-\mu)^{-1}$ coefficients. Then:

(i) For $k \in \mathbb{Z}_{>0}$, $\lambda \in \mathbb{C}$, $B := J_k(\lambda) = \lambda I_k + N$ with $N := J_k(0)$, and $z \neq \lambda$, $R_B(z) = \sum_{r=0}^{k-1} \frac{N^r}{(z-\lambda)^{r+1}}$.
(ii) $(\forall \mu \in \Sigma)\, [R_A]_{\mu,-1} = P_\mu$.
(iii) $(\forall \lambda, \mu \in \Sigma)\, P_\lambda P_\mu = \delta_{\lambda\mu} P_\mu$.
(iv) $(\forall \mu \in \Sigma)\, AP_\mu = P_\mu A$.
(v) $\sum_{\mu\in\Sigma} P_\mu = I_n$.

Proof.

(i) Set $a := (z-\lambda)^{-1}$. Since $N^k = 0$, $(I_k - aN)\sum_{r=0}^{k-1} a^r N^r = I_k - a^k N^k = I_k$ by direct multiplication.
Thus $(I_k - aN)^{-1} = \sum_{r=0}^{k-1} a^r N^r$. The equality $R_B(z) = a\sum_{r=0}^{k-1} a^r N^r = \sum_{r=0}^{k-1} \frac{N^r}{(z-\lambda)^{r+1}}$ holds by $zI_k - B = (z-\lambda)(I_k - aN)$.
(ii) By Theorem 6.2.1, choose $S \in \mathrm{Mat}(n,n,\mathbb{C})^\times$ and $J = \bigoplus_{\alpha=1}^{s} J_{k_\alpha}(\lambda_\alpha)$ such that $A = SJS^{-1}$.
The identity $R_A(z) = SR_J(z)S^{-1}$ holds by direct multiplication. Set $H_\nu := \mathcal{G}_\nu(J)$ and $C_\mu := [R_J]_{\mu,-1}$.
By part (i), C_μ is the identity on a block with eigenvalue μ and zero on the Laurent coefficient of every block regular at μ.
Hence $C_\mu|_{H_\nu} = \delta_{\mu\nu} I_{H_\nu}$. For $r \in \mathbb{Z}_{\geq 0}$, $(A - \nu I_n)^r S = S(J - \nu I_n)^r$ by induction, so $SH_\nu = G_\nu$. Thus $[R_A]_{\mu,-1} = SC_\mu S^{-1} = P_\mu$.
(iii) Let $\mathbf{v} = \sum_{\nu\in\Sigma} \mathbf{v}_\nu$ with $\mathbf{v}_\nu \in G_\nu$. Then $P_\lambda P_\mu \mathbf{v} = \delta_{\lambda\mu}\mathbf{v}_\mu = \delta_{\lambda\mu} P_\mu \mathbf{v}$.
(iv) Let $\mathbf{v}$ be as in part (iii). Since $AG_\nu \subseteq G_\nu$ by Proposition 4.1.7, $AP_\mu \mathbf{v} = A\mathbf{v}_\mu = P_\mu A\mathbf{v}$.
(v) For $\mathbf{v} = \sum_{\nu\in\Sigma} \mathbf{v}_\nu$ as in part (iii), $\left(\sum_{\mu\in\Sigma} P_\mu\right)\mathbf{v} = \sum_{\mu\in\Sigma} \mathbf{v}_\mu = \mathbf{v}$. Hence the operator sum equals I_n.

Structural Commentary: Jordan resolvents identify residues blockwise; primary decomposition then verifies projector algebra.
Key Insight: Only the matching Jordan blocks contribute a simple-pole coefficient. □

Definition 6.5.12. *Contracting, Neutral, and Expanding Primary Subspaces*
Let $n \in \mathbb{Z}_{>0}$, let $A \in \mathrm{Mat}(n,n,\mathbb{C})$, and let P_λ be the primary projection onto $\mathcal{G}_\lambda(A)$ from Proposition 6.5.11.
Set $\Sigma_- := \{\lambda \in \mathrm{spec}(A) : |\lambda| < 1\}$, $\Sigma_0 := \{\lambda \in \mathrm{spec}(A) : |\lambda| = 1\}$, and $\Sigma_+ := \{\lambda \in \mathrm{spec}(A) : |\lambda| > 1\}$. Define:

(i) $\mathcal{G}^-(A) := \bigoplus_{\lambda\in\Sigma_-} \mathcal{G}_\lambda(A)$ and $P_A^- := \sum_{\lambda\in\Sigma_-} P_\lambda$, the *contracting* part.
(ii) $\mathcal{G}^0(A) := \bigoplus_{\lambda\in\Sigma_0} \mathcal{G}_\lambda(A)$ and $P_A^0 := \sum_{\lambda\in\Sigma_0} P_\lambda$, the *neutral* part.

(iii) $\mathcal{G}^+(A) := \bigoplus_{\lambda\in\Sigma_+} \mathcal{G}_\lambda(A)$ and $P_A^+ := \sum_{\lambda\in\Sigma_+} P_\lambda$, the *expanding* part.

Empty direct sum is understood as $\{\mathbf{0}\}$, empty projector sum as 0. Identity $\mathbb{C}^n = \mathcal{G}^-(A) \oplus \mathcal{G}^0(A) \oplus \mathcal{G}^+(A)$ holds by Theorem 5.1.1. Proposition 6.5.11(iii),(v) identifies P_A^-, P_A^0, and P_A^+ as the corresponding projections.

Lemma 6.5.13. *Identity Plus Nilpotent Has a Square Root*
Let $\mathcal{V}$ be a complex vector space and let $N \in \mathcal{L}(\mathcal{V})$ be nilpotent. Then $\exists\, R \in \mathcal{L}(\mathcal{V})$ such that $R^2 = I_\mathcal{V} + N$.

Proof. Choose $m \in \mathbb{Z}_{>0}$ with $N^m = 0$ and set $a_0 := 1$. For $k \in \{1, \dots, m-1\}$, set $s_k := \sum_{r=1}^{k-1} a_r a_{k-r}$ and $a_k := \frac{1}{2}(\delta_{k1} - s_k)$.
Set $R := \sum_{k=0}^{m-1} a_k N^k$. For $k \in \{0, \dots, m-1\}$, the coefficient of N^k in the formal square is $c_k := \sum_{r=0}^{k} a_r a_{k-r}$.
The relations $c_0 = 1$ and $(\forall k \in \{1, \dots, m-1\})\, c_k = 2a_k + s_k = \delta_{k1}$ hold by the recursion.
Every term of degree at least m vanishes at N, so $R^2 = \sum_{k=0}^{m-1} c_k N^k = I_\mathcal{V} + N$.
Structural Commentary: Recursive coefficient matching constructs the square root before nilpotence truncates higher terms.
Key Insight: The recursion forces the formal square to equal $1 + x$. □

Figure 71: Recursive coefficients and nilpotence reduce the polynomial square to $R^2 = I + N$.

Figure 71 depicts the finite polynomial square-root construction.

Theorem 6.5.14. *Invertible Complex Operators Have Square Roots*
Let $\mathcal{V}$ be finite-dimensional over $\mathbb{C}$ and let $T \in \mathcal{L}(\mathcal{V})$ be invertible. Then $\exists\, R \in \mathcal{L}(\mathcal{V})$ such that $R^2 = T$.

Proof.
(i) *Primary Reduction*: If $\mathcal{V} = \{\mathbf{0}\}$, take $R = I_\mathcal{V}$. Assume $\mathcal{V} \neq \{\mathbf{0}\}$.
List the distinct eigenvalues as $\lambda_1, \dots, \lambda_m$, where $m \in \mathbb{Z}_{>0}$, and set $\mathcal{U}_j := \mathcal{G}_{\lambda_j}(T)$.
Identity $\mathcal{V} = \bigoplus_{j=1}^{m} \mathcal{U}_j$ holds, $N_j := (T - \lambda_j I_\mathcal{V})|_{\mathcal{U}_j}$ is nilpotent, by Theorem 5.1.1. For $j \in \{1, \dots, m\}$, $\lambda_j \neq 0$ by Corollary 5.1.7.
(ii) *Local Roots*: Set $M_j := \lambda_j^{-1} N_j$, so $T|_{\mathcal{U}_j} = \lambda_j(I_{\mathcal{U}_j} + M_j)$. By Lemma 6.5.13, choose $B_j \in \mathcal{L}(\mathcal{U}_j)$ with $B_j^2 = I_{\mathcal{U}_j} + M_j$.
Choose $\alpha_j \in \mathbb{C}$ with $\alpha_j^2 = \lambda_j$ and set $R_j := \alpha_j B_j$. Then $R_j^2 = \lambda_j B_j^2 = T|_{\mathcal{U}_j}$.
(iii) *Assembly*: Define $R \in \mathcal{L}(\mathcal{V})$ by $R(\sum_{j=1}^{m} \mathbf{v}_j) := \sum_{j=1}^{m} R_j \mathbf{v}_j$ for $\mathbf{v}_j \in \mathcal{U}_j$. For $j \in \{1, \dots, m\}$, $(R^2)|_{\mathcal{U}_j} = R_j^2 = T|_{\mathcal{U}_j}$. Hence $R^2 = T$.

Structural Commentary: Primary decomposition reduces T to scalar multiples of identity-plus-nilpotent restrictions before assembly.
Key Insight: Each nonzero eigenvalue separates into scalar and nilpotent square roots. □

7 Transpose and Conjugate Similarity

7.1 Transpose Similarity and Conjugate Similarity

Theorem 7.1.1. *Conjugate Similarity Criterion*
Let $n \in \mathbb{Z}_{>0}$ and let $A \in \mathrm{Mat}(n, n, \mathbb{C})$. Write $\sim$ for similarity on $\mathrm{Mat}(n, n, \mathbb{C})$.
For $(\lambda, k) \in \mathbb{C} \times \mathbb{Z}_{>0}$, let $m_A(\lambda, k)$ count the $J_k(\lambda)$ blocks in any Jordan form of A.
Then $A \sim \overline{A} \iff (\forall\, (\lambda, k) \in \mathbb{C} \times \mathbb{Z}_{>0})\, m_A(\lambda, k) = m_A(\overline{\lambda}, k)$.

Proof. The function m_A is well-defined by Corollary 6.2.7(i), with $m_A(\lambda, k) = 0$ for $\lambda \notin \mathrm{spec}(A)$.
By Theorem 6.2.1, choose $S \in \mathrm{Mat}(n, n, \mathbb{C})^\times$ and a Jordan matrix J satisfying $A = SJS^{-1}$.
Then $\overline{A} = \overline{S}\,\overline{J}\,\overline{S}^{-1}$, and the $J_k(\lambda)$-multiplicity in $\overline{J}$ is $m_A(\overline{\lambda}, k)$ by blockwise conjugation.
($\Rightarrow$) Assume $A \sim \overline{A}$. The chain $J \sim A \sim \overline{A} \sim \overline{J}$ holds by Proposition 6.2.2.
By Corollary 6.2.7(ii), choose a block-permutation matrix P satisfying $\overline{J} = P^{-1}JP$.
The equality $(\forall\, (\lambda, k) \in \mathbb{C} \times \mathbb{Z}_{>0})\, m_A(\lambda, k) = m_A(\overline{\lambda}, k)$ holds by $\overline{J} = P^{-1}JP$ and the conjugate-block identity.
($\Leftarrow$) Assume $(\forall\, (\lambda, k) \in \mathbb{C} \times \mathbb{Z}_{>0})\, m_A(\lambda, k) = m_A(\overline{\lambda}, k)$.
By the hypothesis and conjugate-block identity, choose a block-permutation matrix P satisfying $\overline{J} = P^{-1}JP$.
Set $Q := \overline{S}P^{-1}S^{-1} \in \mathrm{Mat}(n, n, \mathbb{C})^\times$. Then $\overline{A} = \overline{S}P^{-1}JP\overline{S}^{-1} = QAQ^{-1}$, so $A \sim \overline{A}$.
Structural Commentary: Conjugation relabels Jordan blocks; block-permutation uniqueness converts their counts into similarity.
Key Insight: $J_k(\lambda)$ becomes $J_k(\overline{\lambda})$ without changing k. □

Definition 7.1.2. *Reversal Matrix*
For $k \in \mathbb{Z}_{>0}$, the *reversal matrix* $R_k \in \mathrm{Mat}(k, k, \mathbb{C})$ is defined by $(\forall\, i, j \in \{1, \dots, k\})\, (R_k)_{ij} := \delta_{i+j,k+1}$.
The identities $R_k^t = R_k$ and $(R_k^2)_{ij} = \sum_{r=1}^{k} \delta_{i+r,k+1}\delta_{r+j,k+1} = \delta_{ij}$ hold by the entry rule. Hence $R_k^2 = I_k$.

Lemma 7.1.3. *Reversal Conjugates a Jordan Block to Its Transpose*
Let $k \in \mathbb{Z}_{>0}$ and $\lambda \in \mathbb{C}$. Then:
(i) $J_k(\lambda)^t = R_k J_k(\lambda) R_k$;
(ii) $R_k J_k(\lambda)$ and $J_k(\lambda) R_k$ are symmetric.

Proof. Set $N := J_k(0)$.
(i) For $i, j \in \{1, \dots, k\}$, $(R_k N R_k)_{ij} = N_{k+1-i,k+1-j} = \delta_{i,j+1} = (N^t)_{ij}$ by the entry rules for R_k and N.
Thus $R_k J_k(\lambda) R_k = \lambda R_k^2 + R_k N R_k = \lambda I_k + N^t = J_k(\lambda)^t$.

(ii) The identities $\big(R_k J_k(\lambda)\big)^t = J_k(\lambda)^t R_k = R_k J_k(\lambda)$ and $\big(J_k(\lambda) R_k\big)^t = R_k J_k(\lambda)^t = J_k(\lambda) R_k$ hold by part (i) and $R_k^2 = I_k$.

Structural Commentary: The reversal entry rule turns the superdiagonal shift into its transposed subdiagonal shift.
Key Insight: Reversal reads each Jordan chain in the opposite order. □

Theorem 7.1.4. *Transpose Similarity and Symmetric Factorisations*
Let $n \in \mathbb{Z}_{>0}$ and let $A \in \mathrm{Mat}(n,n,\mathbb{C})$. Then:
(i) $(\exists P \in \mathrm{Mat}(n,n,\mathbb{C})^\times)\ P^t = P \ \wedge\ PAP^{-1} = A^t$.
(ii) $(\exists B,C,D,E \in \mathrm{Mat}(n,n,\mathbb{C}))\ A = BC = DE$.
The witnesses satisfy $B, E \in \mathrm{Mat}(n,n,\mathbb{C})^\times$ and $B^t = B$, $C^t = C$, $D^t = D$, and $E^t = E$.

Proof. By Theorem 6.2.1, choose $S \in \mathrm{Mat}(n,n,\mathbb{C})^\times$ and a Jordan matrix J satisfying $A = SJS^{-1}$.
Let R be the direct sum of the reversal matrices matching the blocks of J.
The identities $J^t = RJR$, $R^t = R$, and $R^2 = I_n$ hold blockwise by Lemma 7.1.3(i), while RJ and JR are symmetric by Lemma 7.1.3(ii).
(i) Set $P := (S^{-1})^t R S^{-1}$. Then $P^t = P$ and $P^{-1} = SRS^t$ by $R^t = R = R^{-1}$.
The identity $PAP^{-1} = (S^{-1})^t RJRS^t = (S^{-1})^t J^t S^t = A^t$ holds by $A = SJS^{-1}$ and $J^t = RJR$.
(ii) Set $B := SRS^t$ and $C := (S^{-1})^t RJS^{-1}$. Set $D := SJRS^t$ and $E := (S^{-1})^t R S^{-1}$.
The matrices B, C, D, E are symmetric by congruence of R, RJ, JR, R, respectively, and B, E are invertible.
The identities $BC = SJS^{-1} = A$ and $DE = SJS^{-1} = A$ hold by $R^2 = I_n$.

Structural Commentary: Jordan reversal transfers through congruence to a symmetric similarity and two symmetric factor pairs.
Key Insight: The reversal involution both transposes blocks and cancels between factors. □

Figure 72 illustrates how reversing a Jordan chain converts the superdiagonal shift into its transpose.

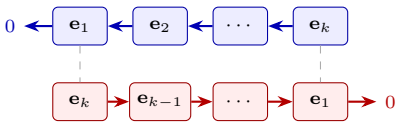

Figure 72: The identity $R_k J_k(0) R_k = J_k(0)^t$ records the same chain read backwards.

Corollary 7.1.5. *Hermitian Products and Conjugate Products*
Let $n \in \mathbb{Z}_{>0}$ and let $A, H, K \in \mathrm{Mat}(n,n,\mathbb{C})$, where H and K are Hermitian. Then:
(i) HK is similar to KH.
(ii) $A\overline{A}$ is similar to $\overline{A}A$.

Proof. For $M \in \mathrm{Mat}(n,n,\mathbb{C})$, $\ker(\overline{M}) = \{\overline{\mathbf{v}} : \mathbf{v} \in \ker(M)\}$ by $\overline{M}\,\overline{\mathbf{v}} = \overline{M\mathbf{v}}$ and involutivity of conjugation.
The identity $\mathrm{rank}(M^*) = \mathrm{rank}(\overline{M}^{\,t}) = \mathrm{rank}(\overline{M}) = \mathrm{rank}(M)$ holds by Theorem 3.3.2, Corollary 3.3.1(i), and the kernel identity.
(i) The equality $(\forall p \in \{1,\dots,n\})\ \big((HK)^p\big)^* = \big((HK)^*\big)^p = (KH)^p$ holds by $H^* = H$ and $K^* = K$.
Thus $(\forall p \in \{1,\dots,n\})\ \mathrm{rank}((HK)^p) = \mathrm{rank}((KH)^p)$, so HK is similar to KH by Corollary 6.3.3.
(ii) The equality $(\forall p \in \{1,\dots,n\})\ \overline{(A\overline{A})^p} = (\overline{A}A)^p$ holds by entrywise conjugation of products.
Thus $(\forall p \in \{1,\dots,n\})\ \mathrm{rank}((A\overline{A})^p) = \mathrm{rank}((\overline{A}A)^p)$, so $A\overline{A}$ is similar to $\overline{A}A$ by Corollary 6.3.3.

Structural Commentary: Adjoint and conjugation preserve every required power rank before the AB–BA criterion.
Key Insight: Equal power ranks convert reordered products into similar matrices. □

Theorem 7.1.6. *Conjugate Similarity and Hermitian Products*
Let $n \in \mathbb{Z}_{>0}$ and let $A \in \mathrm{Mat}(n,n,\mathbb{C})$. The following are equivalent:
(i) A is similar to $\overline{A}$.
(ii) A is similar to A^*.
(iii) $(\exists R \in \mathrm{Mat}(n,n,\mathbb{C})^\times)\ R^* = R \ \wedge\ A = RA^*R^{-1}$.
(iv) $(\exists H,K,L,M \in \mathrm{Mat}(n,n,\mathbb{C}))\ A = HK = LM$.
The witnesses satisfy $H, M \in \mathrm{Mat}(n,n,\mathbb{C})^\times$ and $H^* = H$, $K^* = K$, $L^* = L$, and $M^* = M$.
(v) $(\exists H,K \in \mathrm{Mat}(n,n,\mathbb{C}))\ H^* = H \ \wedge\ K^* = K \ \wedge\ A = HK$.

Proof. Write $\sim$ for similarity on $\mathrm{Mat}(n,n,\mathbb{C})$, which is transitive by Proposition 6.2.2.
(i) $\Rightarrow$ *(ii)* $A \sim \overline{A} \sim \overline{A}^{\,t} = A^*$ by part (i) and Theorem 7.1.4(i).
(ii) $\Rightarrow$ *(iii)* Choose $S \in \mathrm{Mat}(n,n,\mathbb{C})^\times$ satisfying $A = SA^*S^{-1}$, equivalently $AS = SA^*$, and set $Q := S^{-1}S^*$.
For $\theta \in \mathbb{R}$, set $S_\theta := e^{i\theta}S$ and $H_\theta := S_\theta + S_\theta^*$.
The identities $AH_\theta = H_\theta A^*$, $H_\theta^* = H_\theta$, and $S_\theta^{-1}H_\theta = I_n + e^{-2i\theta}Q$ hold by $AS = SA^*$, its adjoint, and the definitions.
For $\theta \in \mathbb{R}$, $H_\theta \notin \mathrm{Mat}(n,n,\mathbb{C})^\times \iff -e^{2i\theta} \in \mathrm{spec}(Q)$ by the last identity and invertibility of S_θ.
The existence $(\exists \theta \in \mathbb{R})\ -e^{2i\theta} \notin \mathrm{spec}(Q)$ holds by Corollary 5.1.6 and infinitude of $\{-e^{2i\phi} : \phi \in \mathbb{R}\}$.
For such θ, $H_\theta \in \mathrm{Mat}(n,n,\mathbb{C})^\times$, $H_\theta^* = H_\theta$, and $A = H_\theta A^* H_\theta^{-1}$ by the preceding identities.
(iii) $\Rightarrow$ *(iv)* Choose $R \in \mathrm{Mat}(n,n,\mathbb{C})^\times$ satisfying $R^* = R$ and $A = RA^*R^{-1}$, and set $(H,K,L,M) := (R, A^*R^{-1}, RA^*, R^{-1})$.
$A = HK = LM$ and $H, M \in \mathrm{Mat}(n,n,\mathbb{C})^\times$ by the definitions and part (iii).
$(H^*, K^*, L^*, M^*) = (H,K,L,M)$ by $R^* = R$, $AR = RA^*$, and $R^{-1}A = A^*R^{-1}$.
(iv) $\Rightarrow$ *(v)* The witnesses (H,K) from part (iv) satisfy $H^* = H \ \wedge\ K^* = K \ \wedge\ A = HK$.
(v) $\Rightarrow$ *(i)* Choose $H, K \in \mathrm{Mat}(n,n,\mathbb{C})$ satisfying $H^* = H$, $K^* = K$, and $A = HK$ by part (v).
$A = HK \sim KH \sim (KH)^t = H^tK^t = \overline{H}\,\overline{K} = \overline{A}$ by Corollary 7.1.5(i), Theorem 7.1.4(i), and Hermitianity of H, K.

Structural Commentary: Transpose similarity starts the cycle; phase averaging Hermitianizes the adjoint-similarity witness.
Key Insight: A phase avoids the finitely many singular Hermitian averages. □

Figure 73 summarizes the implication cycle connecting conjugate similarity, adjoint similarity, and Hermitian factorization.

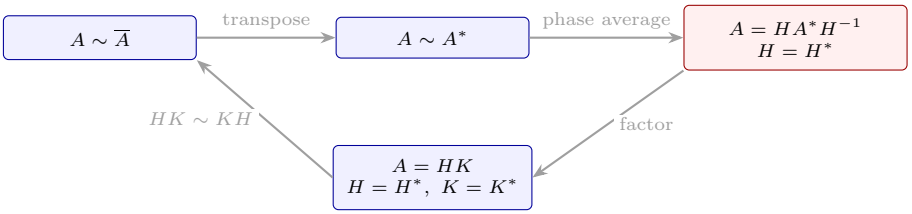

Figure 73: Conjugate similarity, adjoint similarity, and Hermitian product factorisations are equivalent.

Part VI
Matrix Analysis and Numerical Linear Algebra

Matrix classes package operator structure in coordinates. Trace, determinant, rank, positivity, idempotents, nilpotents, spectral radius, and structured products give computable invariants.

1 Trace, Determinant, Rank, and Matrix Invariants

1.1 Trace and Determinant

Proposition 1.1.1. *Trace Arithmetic*
Let $n \in \mathbb{Z}_{>0}$, $A = [a_{jk}], B = [b_{jk}] \in \mathrm{Mat}(n, n, \mathbb{F})$, and $r \in \mathbb{F}$. Then
(i) $\mathrm{tr}(rA) = r\,\mathrm{tr}(A)$;
(ii) $\mathrm{tr}(A + B) = \mathrm{tr}(A) + \mathrm{tr}(B)$.

Proof.
(i) $\mathrm{tr}(rA) = \sum_{j=1}^{n} ra_{jj} = r \sum_{j=1}^{n} a_{jj} = r\,\mathrm{tr}(A)$ by Definition 3.8.1.
(ii) $\mathrm{tr}(A + B) = \sum_{j=1}^{n} (a_{jj} + b_{jj}) = \sum_{j=1}^{n} a_{jj} + \sum_{j=1}^{n} b_{jj} = \mathrm{tr}(A) + \mathrm{tr}(B)$ by Definition 3.8.1.
Structural Commentary: Each identity reduces trace to a finite diagonal sum.
Key Insight: Finite summation commutes with scalar multiplication and addition. □

Example 1.1.2. *Trace Functional and the Frobenius Inner Product*
Let $n \in \mathbb{Z}_{>0}$ and $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and equip $\mathrm{Mat}(n, n, \mathbb{F})$ with the Frobenius inner product from Example 1.1.7.
Map $A \mapsto \mathrm{tr}(A)$ is a linear functional by Proposition 1.1.1. Riesz vector is I_n as $(\forall\, A = [a_{jk}] \in \mathrm{Mat}(n, n, \mathbb{F}))\ \langle A, I_n \rangle_F = \sum_{j=1}^{n} a_{jj} = \mathrm{tr}(A)$.

Proposition 1.1.3. *Trace Is Cyclic for Two Factors*
Let $m, n \in \mathbb{Z}_{>0}$, $A = [a_{jk}] \in \mathrm{Mat}(m, n, \mathbb{F})$, and $B = [b_{kj}] \in \mathrm{Mat}(n, m, \mathbb{F})$. Then $\mathrm{tr}(AB) = \mathrm{tr}(BA)$.

Proof. $\mathrm{tr}(AB) = \sum_{j=1}^{m} \sum_{k=1}^{n} a_{jk} b_{kj} = \sum_{k=1}^{n} \sum_{j=1}^{m} b_{kj} a_{jk} = \mathrm{tr}(BA)$ by commutativity of $\mathbb{F}$ and interchange of finite sums.
Structural Commentary: Entry expansion identifies both traces after interchanging the finite indices.
Key Insight: Both traces sum the scalars $a_{jk} b_{kj}$. □

Proposition 1.1.4. *Cyclic Products*
Let $m \in \mathbb{Z}_{\geq 2}$ and $n_1, \ldots, n_m \in \mathbb{Z}_{>0}$, and set $n_{m+1} := n_1$. Suppose $(\forall\, j \in \{1, \ldots, m\})\ A_j \in \mathrm{Mat}(n_j, n_{j+1}, \mathbb{F})$. Then:
(i) $\mathrm{tr}(A_1 \cdots A_m) = \mathrm{tr}(A_m A_1 \cdots A_{m-1})$;
(ii) $(\forall\, n \in \mathbb{Z}_{>0})(\forall\, A, B, C \in \mathrm{Mat}(n, n, \mathbb{F}))\ \mathrm{tr}(ABC) = \mathrm{tr}(BCA) = \mathrm{tr}(CAB)$.

Proof.
(i) Set $X := A_1 \cdots A_{m-1} \in \mathrm{Mat}(n_1, n_m, \mathbb{F})$. Then $\mathrm{tr}(A_1 \cdots A_m) = \mathrm{tr}(X A_m) = \mathrm{tr}(A_m X)$ by Proposition 1.1.3.
(ii) Fix $n \in \mathbb{Z}_{>0}$ and $A, B, C \in \mathrm{Mat}(n, n, \mathbb{F})$. Then $\mathrm{tr}(ABC) = \mathrm{tr}(CAB) = \mathrm{tr}(BCA)$ by two applications of part (i).
Structural Commentary: Two-factor cyclicity proves one general rotation, whose repeated use proves the specialization.
Key Insight: Grouping $A_1 \cdots A_{m-1}$ reduces rotation to two factors. □

Example 1.1.5. *Cyclicity Is Not Arbitrary Commutativity*
Let $A = E_{1,2}$, $B = E_{2,1}$, and $C = E_{1,1}$ in $\mathrm{Mat}(2, 2, \mathbb{F})$. Then $\mathrm{tr}(ABC) = 1$, while $\mathrm{tr}(ACB) = 0$.
Thus trace permits cyclic rotations of factors, but not arbitrary rearrangements.

For real 2×2 matrices, Figure 74 illustrates the column geometry behind Theorem 3.8.2.

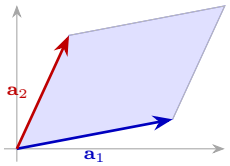

Figure 74: The columns $\mathbf{a}_1, \mathbf{a}_2 \in \mathbb{R}^2$ span a parallelogram whose signed area is their determinant.

Computation Method 1.1.6. *Determinant by Structure*
Given $n \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$, the output is $\det A$, computed by the first reduction that lowers the calculation:
(i) if A is triangular, multiply its diagonal entries;
(ii) if the columns are linearly dependent, including when two coincide, return 0;
(iii) if a column decomposition exposes triangular or dependent summands, expand that column by linearity;
(iv) if a column permutation exposes useful pivots, track the sign of the permutation;
(v) if $A = BC$ and the factors have simpler determinants, compute $\det B \det C$.
Each reduction and its output are valid by Theorem 3.8.2; verify that every column swap has been counted exactly once.

For real linear maps, Figure 75 summarizes the geometric scaling interpretation behind the determinant-by-structure method.

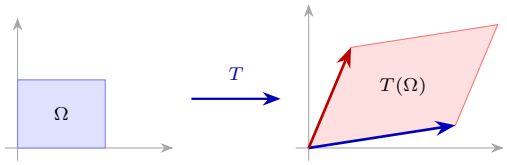

Figure 75: A real linear map scales oriented volume by its determinant; singular maps collapse volume to zero.

Definition 1.1.7. *Schur Complements*
Let $r, s \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(r, r, \mathbb{F})$, $B \in \mathrm{Mat}(r, s, \mathbb{F})$, $C \in \mathrm{Mat}(s, r, \mathbb{F})$, and $D \in \mathrm{Mat}(s, s, \mathbb{F})$. Set $M := \left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$.
(i) If A is invertible, the *Schur complement of A in M* is $M/A := D - CA^{-1}B$.
(ii) If D is invertible, the *Schur complement of D in M* is $M/D := A - BD^{-1}C$.

Proposition 1.1.8. *Schur Complement Determinant Formula*
Let $r, s \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(r, r, \mathbb{F})$, $B \in \mathrm{Mat}(r, s, \mathbb{F})$, $C \in \mathrm{Mat}(s, r, \mathbb{F})$, $D \in \mathrm{Mat}(s, s, \mathbb{F})$, and $M := \left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$.
If A is invertible, then $\det M = \det(A) \det(M/A)$.

Proof. Set $E := \left(\begin{smallmatrix} I_r & 0 \\ -CA^{-1} & I_s \end{smallmatrix}\right)$. Then $EM = \left(\begin{smallmatrix} A & B \\ 0 & M/A \end{smallmatrix}\right)$; $\det E = 1$ by Theorem 3.8.2(v).
Thus $\det M = \det(EM) = \det(A) \det(M/A)$ by Theorems 3.8.2(vi) and 3.8.4.
Structural Commentary: Unit block elimination replaces C by zero and exposes M/A.
Key Insight: The elimination factor has determinant one. □

Proposition 1.1.9. *Schur Complement of the Lower-Right Block*
Let $r, s \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(r, r, \mathbb{F})$, $B \in \mathrm{Mat}(r, s, \mathbb{F})$, $C \in \mathrm{Mat}(s, r, \mathbb{F})$, $D \in \mathrm{Mat}(s, s, \mathbb{F})$, and $M := \left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$.
If D is invertible, then $\det M = \det(D) \det(M/D)$.

Proof. Set $E := \left(\begin{smallmatrix} I_r & -BD^{-1} \\ 0 & I_s \end{smallmatrix}\right)$. Then $EM = \left(\begin{smallmatrix} M/D & 0 \\ C & D \end{smallmatrix}\right)$; $\det E = 1$ by Theorem 3.8.2(v). The transpose of EM is block upper triangular.
Thus $\det M = \det(EM) = \det(M/D) \det D$ by Theorems 3.8.2(vi),(ix) and 3.8.4.
Structural Commentary: Unit block elimination replaces B by zero before transposing the triangular form.
Key Insight: Transposition converts the lower block-triangular product to the proved upper case. □

Proposition 1.1.10. *Bordered Determinant Formulas*
Let $n \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$, $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$, and $c \in \mathbb{F}$.
(i) If $c \neq 0$, then $\det \left(\begin{smallmatrix} c & \mathbf{x}^t \\ \mathbf{y} & A \end{smallmatrix}\right) = c \det\left(A - c^{-1}\mathbf{y}\mathbf{x}^t\right)$.
(ii) If A is invertible, then $\det \left(\begin{smallmatrix} A & \mathbf{x} \\ \mathbf{y}^t & c \end{smallmatrix}\right) = \left(c - \mathbf{y}^t A^{-1}\mathbf{x}\right) \det A$.

Proof.
(i) Claim (i) holds by Proposition 1.1.8 with upper-left block $[c]$ and $M/[c] = A - c^{-1}\mathbf{y}\mathbf{x}^t$.
(ii) Claim (ii) holds by Proposition 1.1.8 with upper-left block A, $M/A = c - \mathbf{y}^t A^{-1}\mathbf{x}$, and commutativity of $\mathbb{F}$.
Structural Commentary: Each border orientation specializes the upper-left Schur determinant formula.
Key Insight: A scalar block turns its Schur complement into a rank-one correction. □

Theorem 1.1.11. *Sylvester Determinant Identity*
Let $m, n \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(n, m, \mathbb{F})$, and $B \in \mathrm{Mat}(m, n, \mathbb{F})$. Then $\det(I_n + AB) = \det(I_m + BA)$.

Proof. Set $M := \left(\begin{smallmatrix} I_n & -A \\ B & I_m \end{smallmatrix}\right)$. Then $\det M = \det(I_n + AB)$ by Proposition 1.1.9, while $\det M = \det(I_m + BA)$ by Proposition 1.1.8.
Structural Commentary: The two Schur determinant formulas evaluate one block matrix from opposite corners.
Key Insight: Both identity blocks have determinant one. □

Theorem 1.1.12. *Nonzero Eigenvalues of AB and BA*
Let $m, n \in \mathbb{Z}_{>0}$ with $n \geq m$, let $A \in \mathrm{Mat}(m, n, \mathbb{C})$, and let $B \in \mathrm{Mat}(n, m, \mathbb{C})$.
(i) $(\forall z \in \mathbb{C})\, p_{BA}(z) = z^{n-m} p_{AB}(z)$;
(ii) $(\forall \lambda \in \mathbb{C} \setminus \{0\})\, m_{BA}(\lambda) = m_{AB}(\lambda)$;
(iii) $m_{BA}(0) = m_{AB}(0) + n - m$.

Proof.
(i) For $z \neq 0$, $p_{BA}(z) = z^n \det(I_n - z^{-1}BA) = z^n \det(I_m - z^{-1}AB) = z^{n-m} p_{AB}(z)$ by Theorem 1.1.11 with $-z^{-1}B$ and A.
If $n = m$, then $p_{BA}(0) = (-1)^n \det(BA) = (-1)^n \det(AB) = p_{AB}(0)$ by Theorem 3.8.2(vi) and commutativity of $\mathbb{C}$.
If $n > m$, then $\mathrm{col}(BA) \subseteq \mathrm{col}(B)$ because $(\forall \mathbf{x} \in \mathbb{C}^n)\, BA\mathbf{x} = B(A\mathbf{x})$.
Thus $\mathrm{rank}(BA) \leq \mathrm{rank}(B) \leq m < n$ by Definition 3.1.12, Proposition 1.4.3(i), and Corollary 3.3.1(i).
BA singular by Corollary 3.6.2. Then $p_{BA}(0) = (-1)^n \det(BA) = 0 = 0^{n-m} p_{AB}(0)$ by Definition 2.1.2, Theorem 3.8.2(vii).
(ii) $m_{BA}(\lambda) = m_{AB}(\lambda)$ for $\lambda \neq 0$ by part (i), because z^{n-m} has multiplicity zero at λ.
(iii) $m_{BA}(0) = m_{AB}(0) + n - m$ by part (i), because z^{n-m} has multiplicity $n - m$ at 0.
Structural Commentary: Sylvester transfer proves the polynomial identity before root orders split into zero and nonzero cases.
Key Insight: The size difference appears only as the factor z^{n-m}. □

Theorem 1.1.13. *Trace and Determinant Are Similarity Invariants*
Let $n \in \mathbb{Z}_{>0}$ and let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$ be similar.
(i) $\mathrm{tr}\, A = \mathrm{tr}\, B$;

(ii) $\det A = \det B$.

Proof. Choose an invertible P with $B = PAP^{-1}$ by Definition 6.2.1.

(i) $\operatorname{tr} B = \operatorname{tr}\big(P(AP^{-1})\big) = \operatorname{tr}\big((AP^{-1})P\big) = \operatorname{tr} A$ by Proposition 1.1.3.
(ii) $\det B = \det(P)\det(A)\det(P^{-1}) = \det A$ by Theorem 3.8.2(vi),(viii).

Structural Commentary: Cyclicity and multiplicativity remove the conjugating factors from the two invariants.
Key Insight: In both calculations, $P^{-1}P = I_n$. □

Proposition 1.1.14. *Trace and Determinant from Eigenvalues*
Let $n \in \mathbb{Z}_{>0}$, let $A \in \operatorname{Mat}(n,n,\mathbb{C})$, and let $\lambda_1, \dots, \lambda_n$ list its eigenvalues with algebraic multiplicity.

(i) $\operatorname{tr} A = \sum_{j=1}^{n} \lambda_j$;
(ii) $\det A = \prod_{j=1}^{n} \lambda_j$.

Proof. $p_A(z) = \prod_{j=1}^{n} (z - \lambda_j)$ by the algebraic-multiplicity list and monicity.
The identity $p_A(z) = z^n - (\operatorname{tr} A)z^{n-1} + \cdots + (-1)^n \det A$ holds by Theorem 2.1.3.

(i) $\operatorname{tr} A = \sum_{j=1}^{n} \lambda_j$ by comparison of the z^{n-1} coefficients.
(ii) $\det A = \prod_{j=1}^{n} \lambda_j$ by comparison of the constant coefficients.

Structural Commentary: Two coefficient comparisons transfer the root factorization to trace and determinant.
Key Insight: The next-to-leading and constant coefficients encode the root sum and product. □

Proposition 1.1.15. *Transpose, Conjugate, and Adjoint Spectra*
Let $n \in \mathbb{Z}_{>0}$, $A \in \operatorname{Mat}(n,n,\mathbb{C})$, and $\lambda \in \operatorname{spec}(A)$.

(i) $p_{A^t} = p_A$;
(ii) $(\forall z \in \mathbb{C})\, p_{\overline{A}}(z) = \overline{p_A(\overline{z})}$;
(iii) $(\forall z \in \mathbb{C})\, p_{A^*}(z) = \overline{p_A(\overline{z})}$;
(iv) $m_{A^t}(\lambda) = m_A(\lambda)$;
(v) $m_{\overline{A}}(\overline{\lambda}) = m_A(\lambda)$;
(vi) $m_{A^*}(\overline{\lambda}) = m_A(\lambda)$.

Proof.

(i) $(\forall z \in \mathbb{C})\, p_{A^t}(z) = \det((zI_n - A)^t) = p_A(z)$ by Theorem 3.8.2(ix).
(ii) $(\forall X \in \operatorname{Mat}(n,n,\mathbb{C}))\ \det(\overline{X}) = \overline{\det X}$ by conjugation of each term in the permutation formula.
Hence $(\forall z \in \mathbb{C})\, p_{\overline{A}}(z) = \det(\overline{z}I_n - \overline{A}) = \overline{p_A(\overline{z})}$.
(iii) $(\forall z \in \mathbb{C})\, p_{A^*}(z) = p_{\overline{A}}(z) = \overline{p_A(\overline{z})}$ by $A^* = \overline{A}^{\,t}$ and parts (i)–(ii).
(iv) $m_{A^t}(\lambda) = m_A(\lambda)$ by part (i).
(v) Set $k := m_A(\lambda)$. Choose $q \in \mathbb{C}[z]$ satisfying $p_A(z) = (z-\lambda)^k q(z)$ and $q(\lambda) \neq 0$ by Definition 2.1.4.
Identity $p_{\overline{A}}(z) = (z - \overline{\lambda})^k \overline{q(\overline{z})}$ holds by part (ii), while $\overline{q(\lambda)} \neq 0$ by choice of q. Thus $m_{\overline{A}}(\overline{\lambda}) = k = m_A(\lambda)$ by Definition 2.1.4.
(vi) $m_{A^*}(\overline{\lambda}) = m_A(\lambda)$ by parts (iii) and (v).

Structural Commentary: Determinant transposition preserves factors, while entrywise conjugation transports each root.
Key Insight: The adjoint adds no spectral change beyond complex conjugation. □

Perspective 1.1.16. *Similarity Invariants and Canonical Forms*
For square complex matrices, trace and determinant are similarity invariants by Theorem 1.1.13.
The characteristic and minimal polynomials are similarity invariants by Theorems 2.1.7 and 2.2.5.
Set $J := J_3(0) \oplus J_3(0)$ and $K := J_3(0) \oplus J_2(0) \oplus J_1(0)$.
Both have characteristic polynomial z^6 by Proposition 2.1.6(i).
Both are nilpotent of index 3 by Lemma 6.2.4 and Proposition 3.8.6(iii).
Hence $\mu_J = \mu_K = z^3$ by Theorem 2.2.4 and Definition 2.2.3.
They are not similar by Corollary 6.2.7(i), because their Jordan block multisets differ.
Thus Theorem 6.2.1 and that corollary make the Jordan block multiset a complete similarity invariant.

Theorem 1.1.17. *Trace and Determinant of an Operator Are Basis-Independent*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional, let $T \in \mathcal{L}(\mathcal{V})$, and let β, γ be bases of $\mathcal{V}$.

(i) $\operatorname{tr}\big([T]_{\beta\leftarrow\beta}\big) = \operatorname{tr}\big([T]_{\gamma\leftarrow\gamma}\big)$;
(ii) $\det\big([T]_{\beta\leftarrow\beta}\big) = \det\big([T]_{\gamma\leftarrow\gamma}\big)$.

Proof. $[T]_{\gamma\leftarrow\gamma} = C_{\gamma\leftarrow\beta}[T]_{\beta\leftarrow\beta}C_{\beta\leftarrow\gamma}$ by Theorem 5.1.1(i). Thus the representing matrices are similar by Definition 6.2.1.

(i) The traces are equal by Theorem 1.1.13(i).
(ii) The determinants are equal by Theorem 1.1.13(ii).

Structural Commentary: Change of basis reduces both claims to the corresponding similarity invariants.
Key Insight: Every representing matrix lies in one conjugacy class. □

Figure 76 summarizes the conjugation relation that makes operator trace and determinant basis-independent.

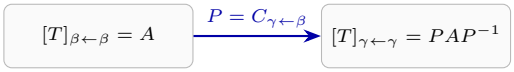

Figure 76: Basis changes conjugate matrices; trace and determinant are unchanged.

Definition 1.1.18. *Trace and Determinant of an Operator*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional, let $T \in \mathcal{L}(\mathcal{V})$, and choose a basis β of $\mathcal{V}$.

(i) The *trace* of T is $\operatorname{tr} T := \operatorname{tr}\big([T]_{\beta\leftarrow\beta}\big)$.
(ii) The *determinant* of T is $\det T := \det\big([T]_{\beta\leftarrow\beta}\big)$.

Both quantities are independent of β by Theorem 1.1.17.

Proposition 1.1.19. *Unitary Matrices and Isometries Have Determinant of Modulus One*
Let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.

(i) If $n \in \mathbb{Z}_{>0}$ and $U \in \operatorname{Mat}(n, n, \mathbb{F})$ is unitary, then $|\det U| = 1$.
(ii) If $\mathcal{V} \neq \{\mathbf{0}\}$ is a finite-dimensional inner-product space over $\mathbb{F}$ and $S \in \mathcal{L}(\mathcal{V})$ is an isometry, then $|\det S| = 1$.

Proof.

(i) $\det(U^*) = \overline{\det U}$ by the permutation formula and Theorem 3.8.2(ix).
Taking determinants in $U^*U = I_n$, $1 = \overline{\det U}\det U = |\det U|^2$ by Theorem 3.8.2(i),(vi), so $|\det U| = 1$.
(ii) Set $n := \dim \mathcal{V}$. Choose an orthonormal basis β by Corollary 1.3.11 and set $U := [S]_{\beta\leftarrow\beta}$.
Then $U^*U = I_n$ by Theorems 2.6.6 and 2.3.7 and Proposition 3.4.4. Thus $|\det S| = |\det U| = 1$ by part (i) and Definition 1.1.18.

Structural Commentary: The matrix identity is proved first, then orthonormal coordinates transfer it to operators.
Key Insight: Determinants convert $U^*U = I_n$ into $|\det U|^2 = 1$. □

Proposition 1.1.20. *Trace and Determinant from q_T*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ be finite-dimensional over $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, let $n := \dim \mathcal{V}$, let $T \in \mathcal{L}(\mathcal{V})$, and write $q_T(z) = z^n + c_{n-1}z^{n-1} + \cdots + c_1 z + c_0$.

(i) $\operatorname{tr} T = -c_{n-1}$;
(ii) $\det T = (-1)^n c_0$;
(iii) if $\mathbb{F} = \mathbb{C}$ and $\lambda_1, \ldots, \lambda_n$ list the eigenvalues of T with algebraic multiplicity, then $\operatorname{tr} T = \sum_{j=1}^{n} \lambda_j$;
(iv) under the hypotheses of (iii), $\det T = \prod_{j=1}^{n} \lambda_j$.

Proof. Choose a basis β and set $A := [T]_{\beta\leftarrow\beta}$.
Then $q_T = p_A$ by Definition 2.1.15, while $\operatorname{tr} T = \operatorname{tr} A$ and $\det T = \det A$ by Definition 1.1.18.

(i) $\operatorname{tr} T = -c_{n-1}$ by Theorem 2.1.3.
(ii) $\det T = (-1)^n c_0$ by Theorem 2.1.3.
(iii) Under the hypotheses of (iii), $\lambda_1, \ldots, \lambda_n$ also list the eigenvalues of A with algebraic multiplicity by $q_T = p_A$.
Hence $\operatorname{tr} T = \sum_{j=1}^{n} \lambda_j$ by Proposition 1.1.14(i).
(iv) Under the same hypotheses, $\det T = \prod_{j=1}^{n} \lambda_j$ by Proposition 1.1.14(ii) with the list from part (iii).

Structural Commentary: A basis identifies q_T with p_A, after which matrix coefficient formulas transfer claimwise.
Key Insight: Operator trace and determinant are the corresponding matrix invariants in any basis. □

1.2 Minors, Cofactors, and Rank

Definition 1.2.1. *Minors, Cofactors, and Adjugate*
Let $n \geq 1$ and $A \in \operatorname{Mat}(n, n, \mathbb{F})$. Set $\det(\emptyset_{0\times 0}) := 1$.

(i) For $i, j \in \{1, \ldots, n\}$, the *minor matrix* $M_{ij}(A)$ is obtained by deleting row i and column j from A.
The corresponding *minor* is $\det(M_{ij}(A))$.
(ii) The (i,j)-*cofactor* is $C_{ij}(A) := (-1)^{i+j}\det(M_{ij}(A))$.
(iii) The *cofactor matrix* is $C(A) := [C_{ij}(A)]$, and the *adjugate* is $\operatorname{adj}(A) := C(A)^t$.

When A is fixed, write M_{ij} and C_{ij}.

Lemma 1.2.2. *Cofactor Expansion*
Let $n \geq 1$ and $A = [a_{ij}] \in \operatorname{Mat}(n, n, \mathbb{F})$.

(i) $(\forall i \in J_n)\ \det A = \sum_{k=1}^{n} a_{ik}C_{ik}$.
(ii) $(\forall j \in J_n)\ \det A = \sum_{k=1}^{n} a_{kj}C_{kj}$.

Proof.

(i) Fix $i \in J_n$. For $k \in J_n$, set $\mathfrak{S}_{i,k} := \{\sigma \in \mathfrak{S}_n : \sigma(i) = k\}$ and $T_{i,k} := \sum_{\sigma\in\mathfrak{S}_{i,k}} \operatorname{sign}(\sigma) \prod_{r=1}^{n} a_{r,\sigma(r)}$.

$(\forall k \in J_n)\, T_{i,k} = a_{ik}(-1)^{i+k}\det(M_{ik}) = a_{ik}C_{ik}$ by the order-preserving deletion bijection $\mathfrak{S}_{i,k} \xrightarrow{\sim} \mathfrak{S}_{n-1}$, $i + k - 2$ adjacent transpositions, the determinant and cofactor definitions, and Theorem 3.8.2(ix).

$\det A = \sum_{k\in J_n} T_{i,k} = \sum_{k=1}^{n} a_{ik}C_{ik}$ by $\mathfrak{S}_n = \bigsqcup_{k\in J_n} \mathfrak{S}_{i,k}$, Definition 3.8.1(ii), Theorem 3.8.2(ix), and the preceding identity.

(ii) Fix $j \in J_n$. $(\forall k \in J_n)\,[M_{jk}(A^t) = M_{kj}(A)^t \wedge C_{jk}(A^t) = C_{kj}(A)]$ by Definition 1.2.1 and Theorem 3.8.2(ix).
$\det A = \det(A^t) = \sum_{k=1}^{n} a_{kj} C_{jk}(A^t) = \sum_{k=1}^{n} a_{kj} C_{kj}(A)$ by Theorem 3.8.2(ix), part (i) for row j of A^t, and the preceding identities.

Structural Commentary: Permutation fibers prove the row formula; transposition transfers it to columns.
Key Insight: Deleting a fixed row and column leaves the corresponding minor sum. □

Theorem 1.2.3. *Adjugate Identity and Cramer's Rule*
Let $n \geq 1$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$, and $\mathbf{b} \in \mathbb{F}^n$. For $j \in \{1, \ldots, n\}$, let $A_j(\mathbf{b})$ be obtained from A by replacing column j by $\mathbf{b}$.
(i) $A\,\mathrm{adj}(A) = \mathrm{adj}(A)A = (\det A) I_n$.
(ii) $(\forall j \in \{1, \ldots, n\}) \quad (\mathrm{adj}(A)\mathbf{b})_j = \det(A_j(\mathbf{b}))$.
(iii) If $\det A \neq 0$, then $A^{-1} = (\det A)^{-1}\,\mathrm{adj}(A)$.
(iv) If $\det A \neq 0$, then the unique solution of $A\mathbf{x} = \mathbf{b}$ satisfies $(\forall j \in \{1, \ldots, n\}) \quad x_j = \frac{\det(A_j(\mathbf{b}))}{\det A}$.

Proof.

(i) For $i, j \in J_n$, $(A\,\mathrm{adj}(A))_{ij} = \sum_{k=1}^{n} a_{ik} C_{jk}$ by Definition 1.2.1.
The identity $\sum_{k=1}^{n} a_{ik} C_{jk} = \delta_{ij} \det A$ holds by Lemma 1.2.2(i) and Theorem 3.8.2(iv),(ix) with $A_{j,\cdot} \leftarrow A_{i,\cdot}$ when $i \neq j$.
Likewise, $(\mathrm{adj}(A)A)_{ij} = \sum_{k=1}^{n} C_{ki} a_{kj}$ by Definition 1.2.1.
The identity $\sum_{k=1}^{n} C_{ki} a_{kj} = \delta_{ij} \det A$ holds by Lemma 1.2.2(ii) and Theorem 3.8.2(iv) with $A_{\cdot,i} \leftarrow A_{\cdot,j}$ when $i \neq j$.
Hence $A\,\mathrm{adj}(A) = \mathrm{adj}(A)A = (\det A) I_n$.

(ii) Fix $j \in J_n$; $(\forall i \in J_n)\, C_{ij}(A_j(\mathbf{b})) = C_{ij}(A)$ by Definition 1.2.1. Identity $(\mathrm{adj}(A)\mathbf{b})_j = \sum_{i=1}^{n} C_{ij}(A) b_i$ holds by Definition 1.2.1.
$\sum_{i=1}^{n} C_{ij}(A) b_i = \sum_{i=1}^{n} C_{ij}(A_j(\mathbf{b})) b_i = \det(A_j(\mathbf{b}))$ by the preceding cofactor identity and Lemma 1.2.2(ii).

(iii) If $\det A \neq 0$, then $A((\det A)^{-1}\,\mathrm{adj}(A)) = I_n = ((\det A)^{-1}\,\mathrm{adj}(A))A$ by part (i).
Hence $A^{-1} = (\det A)^{-1}\,\mathrm{adj}(A)$ by the definition of a matrix inverse.

(iv) If $\det A \neq 0$, then $\{\mathbf{x} \in \mathbb{F}^n : A\mathbf{x} = \mathbf{b}\} = \{A^{-1}\mathbf{b}\}$ by part (iii).
For $\mathbf{x} = A^{-1}\mathbf{b}$, $(\forall j \in J_n)\, x_j = (\det A)^{-1}(\mathrm{adj}(A)\mathbf{b})_j = \frac{\det(A_j(\mathbf{b}))}{\det A}$ by parts (ii)–(iii).

Structural Commentary: Row and column replacements establish the adjugate identity before its inverse and solution consequences.
Key Insight: Off-diagonal cofactor sums create a repeated row or column. □

Proposition 1.2.4. *Adjugate Form of the Bordered Formula*
Let $n \geq 1$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$, $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$, and $c \in \mathbb{F}$.
Then $\det \left[\begin{smallmatrix} A & \mathbf{x} \\ \mathbf{y}^t & c \end{smallmatrix}\right] = c \det(A) - \mathbf{y}^t\,\mathrm{adj}(A)\mathbf{x}$, *without any invertibility assumption on A.*

Proof. Set $D := \left[\begin{smallmatrix} A & \mathbf{x} \\ \mathbf{y}^t & c \end{smallmatrix}\right]$. $(\forall j \in J_n)$, $M_{n+1,j}(D) = [A_{\cdot,1} \;\cdots\; A_{\cdot,j-1}\; A_{\cdot,j+1} \;\cdots\; A_{\cdot,n}\; \mathbf{x}]$.
$(\forall j \in J_n)$, $\det(M_{n+1,j}(D)) = (-1)^{n-j} \det(A_j(\mathbf{x}))$ by $n - j$ column swaps and Theorem 3.8.2(iii).
$(\forall j \in J_n)$, $C_{n+1,j}(D) = (-1)^{n+1+j+n-j} \det(A_j(\mathbf{x})) = -\det(A_j(\mathbf{x}))$ by Definition 1.2.1.
$\det D = c \det A - \sum_{j=1}^{n} y_j \det(A_j(\mathbf{x}))$ by Lemma 1.2.2(i) for row $n+1$ and the preceding cofactor identity.
$\det D = c \det A - \mathbf{y}^t\,\mathrm{adj}(A)\mathbf{x}$ by Theorem 1.2.3(ii) and the preceding identity.
Structural Commentary: Last-row expansion converts each border entry into a one-column replacement determinant.
Key Insight: The cofactor and column-move signs combine to one minus sign. □

Theorem 1.2.5. *Cauchy–Binet Formula*
Let $1 \leq k \leq n$, $A \in \mathrm{Mat}(k, n, \mathbb{F})$, and $B \in \mathrm{Mat}(n, k, \mathbb{F})$. Let $\mathcal{J}_{k,n}$ be the set of k-element subsets of $\{1, \ldots, n\}$.
For $J = \{q_1 < \cdots < q_k\} \in \mathcal{J}_{k,n}$, let A^J consist of the columns of A indexed by J, and let B_J consist of the rows of B indexed by J.
Then $\det(AB) = \sum_{J \in \mathcal{J}_{k,n}} \det(A^J) \det(B_J)$.

Proof. For $\mathbf{j} = (j_1, \ldots, j_k) \in J_n^k$, set $B_{\mathbf{j}} := [b_{j_r,s}]_{r,s=1}^{k}$. Then $(\forall r \in J_k)\,(AB)_{r,\cdot} = \sum_{j \in J_n} a_{rj} B_{j,\cdot}$.
Hence $\det(AB) = \sum_{\mathbf{j} \in J_n^k} \left(\prod_{r=1}^{k} a_{rj_r} \right) \det(B_{\mathbf{j}})$ by Theorem 3.8.2(ii),(ix) and finite distributivity.
$[(\exists r, s \in J_k)\,(r \neq s \wedge j_r = j_s)] \Rightarrow \det(B_{\mathbf{j}}) = 0$ by Theorem 3.8.2(iv),(ix).
Fix $J = \{q_1 < \cdots < q_k\} \in \mathcal{J}_{k,n}$ and set $\mathbf{q}^\tau := (q_{\tau^{-1}(r)})_{r \in J_k}$ for $\tau \in \mathfrak{S}_k$.
Then $\{\mathbf{j} \in J_n^k : \{j_r : r \in J_k\} = J\} = \{\mathbf{q}^\tau : \tau \in \mathfrak{S}_k\}$, and $(\forall \tau \in \mathfrak{S}_k)\ \det(B_{\mathbf{q}^\tau}) = \mathrm{sign}(\tau) \det(B_J)$ by Theorem 3.8.2(iii),(ix).
$\sum_{\tau \in \mathfrak{S}_k} \mathrm{sign}(\tau) \left(\prod_{r=1}^{k} a_{\tau(r),q_r} \right) \det(B_J) = \det(A^J) \det(B_J)$ by Definition 3.8.1(ii).
Therefore $\det(AB) = \sum_{J \in \mathcal{J}_{k,n}} \det(A^J) \det(B_J)$ by the preceding expansion, vanishing implication, and identities.
Structural Commentary: Row multilinearity expands over J_n^k; alternation restricts the sum to $\mathcal{J}_{k,n}$.
Key Insight: Each surviving subset contributes one column minor times one row minor. □

Proposition 1.2.6. *Transpose Preserves Spectrum and Geometric Multiplicity*
Let $n \geq 1$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$, and $\lambda \in \mathbb{F}$.
(i) $\dim(E_\lambda(A)) = \dim(E_\lambda(A^t))$.
(ii) $\lambda \in \mathrm{spec}(A)$ *iff* $\lambda \in \mathrm{spec}(A^t)$.

Proof.

(*i*) Since $(A-\lambda I_n)^t = A^t - \lambda I_n$, $\operatorname{rank}(A-\lambda I_n) = \operatorname{rank}(A^t-\lambda I_n)$ by Theorem 3.3.2.
Hence $\dim(E_\lambda(A)) = n - \operatorname{rank}(A-\lambda I_n) = n - \operatorname{rank}(A^t-\lambda I_n) = \dim(E_\lambda(A^t))$ by Corollary 3.3.1(i).
(*ii*) ($\Rightarrow$) If $\lambda \in \operatorname{spec}(A)$, then $\dim(E_\lambda(A)) > 0$ by the matrix-spectrum definition.
Hence $\dim(E_\lambda(A^t)) > 0$ by part (i), so $\lambda \in \operatorname{spec}(A^t)$ by the matrix-spectrum definition.
(*ii*) ($\Leftarrow$) If $\lambda \in \operatorname{spec}(A^t)$, then $\dim(E_\lambda(A^t)) > 0$ by the matrix-spectrum definition.
Hence $\dim(E_\lambda(A)) > 0$ by part (i), so $\lambda \in \operatorname{spec}(A)$ by the matrix-spectrum definition.

Structural Commentary: Transpose-invariant rank fixes shifted-kernel dimensions before the two spectral directions.
Key Insight: Spectrum and geometric multiplicity are nontriviality and dimension of shifted kernels. □

Corollary 1.2.7. *Nonsingularity by Rank, Determinant, and Spectrum*
Let $n \geq 1$ and $A \in \operatorname{Mat}(n,n,\mathbb{F})$. The following are equivalent:

(*i*) *A is invertible;*
(*ii*) $\operatorname{rank}(A) = n$;
(*iii*) $\det A \neq 0$;
(*iv*) $0 \notin \operatorname{spec}(A)$.

Proof.

(*i*) $\Rightarrow$ (*ii*) If A is invertible, then $\operatorname{rank}(A) = n$ by Corollary 3.6.2.
(*ii*) $\Rightarrow$ (*iii*) If $\operatorname{rank}(A) = n$, then A is invertible by Corollary 3.6.2. Hence $\det A \neq 0$ by Theorem 3.8.2(vii).
(*iii*) $\Rightarrow$ (*iv*) If $\det A \neq 0$, then A is invertible by Theorem 3.8.2(vii). Hence $0 \notin \operatorname{spec}(A)$ by Corollary 5.1.8.
(*iv*) $\Rightarrow$ (*i*) If $0 \notin \operatorname{spec}(A)$, then A is invertible by Corollary 5.1.8.

Structural Commentary: The cycle passes through full rank and determinant before returning through zero-spectrum exclusion.
Key Insight: Invertibility has equivalent range, determinant, and shifted-kernel tests. □

Theorem 1.2.8. *Rank Bounds for Products and Concatenations*
Let $A \in \operatorname{Mat}(m,k,\mathbb{F})$, $B \in \operatorname{Mat}(k,n,\mathbb{F})$, and $C \in \operatorname{Mat}(m,p,\mathbb{F})$. Set $D := [\,A\ C\,]$.

(*i*) $\operatorname{rank}(AB) \leq \min(\operatorname{rank}(A), \operatorname{rank}(B))$.
(*ii*) $\operatorname{rank}(AB) = \operatorname{rank}(A) \iff \operatorname{col}(AB) = \operatorname{col}(A)$.
(*iii*) $\max(\operatorname{rank}(A), \operatorname{rank}(C)) \leq \operatorname{rank}(D)$.
(*iv*) $\operatorname{rank}(D) = \operatorname{rank}(A) \iff \operatorname{col}(C) \subseteq \operatorname{col}(A)$.

Proof. Column-space inclusion is rank-monotone, with equality iff the spaces coincide, by the rank definition and Proposition 1.4.3.
For matrices X, Y of compatible dimensions, $\operatorname{col}(XY) \subseteq \operatorname{col}(X)$ by Propositions 3.1.10 and 3.1.9.
The identities $(XY)^t = Y^tX^t$ and $\operatorname{rank}(X^t) = \operatorname{rank}(X)$ hold by Proposition 3.1.16 and Theorem 3.3.2, respectively.
The identity $\operatorname{col}(D) = \operatorname{col}(A) + \operatorname{col}(C)$ holds by the definition of D and the column-space definition.

(*i*) $\operatorname{rank}(AB) \leq \operatorname{rank}(A)$ by the product-column inclusion and the rank criterion.
$\operatorname{rank}(AB) \leq \operatorname{rank}(B)$ by the transpose identities, the product-column inclusion for B^tA^t, and the rank criterion.
(*ii*) ($\Rightarrow$) $\operatorname{col}(AB) = \operatorname{col}(A)$ by $\operatorname{rank}(AB) = \operatorname{rank}(A)$, the product-column inclusion, and the rank criterion.
(*ii*) ($\Leftarrow$) $\operatorname{rank}(AB) = \operatorname{rank}(A)$ by $\operatorname{col}(AB) = \operatorname{col}(A)$ and the rank definition.
(*iii*) $\max(\operatorname{rank}(A), \operatorname{rank}(C)) \leq \operatorname{rank}(D)$ by $\operatorname{col}(A) \cup \operatorname{col}(C) \subseteq \operatorname{col}(D)$, the concatenation identity, and the rank criterion.
(*iv*) ($\Rightarrow$) $\operatorname{col}(C) \subseteq \operatorname{col}(D) = \operatorname{col}(A)$ by the concatenation identity, $\operatorname{rank}(D) = \operatorname{rank}(A)$, and the rank criterion.
(*iv*) ($\Leftarrow$) $\operatorname{col}(C) \subseteq \operatorname{col}(A) \Rightarrow \operatorname{col}(D) = \operatorname{col}(A)$ by the concatenation identity.
Hence $\operatorname{rank}(D) = \operatorname{rank}(A)$ by the rank definition.

Structural Commentary: Product and concatenation identities reduce every claim to nested column spaces.
Key Insight: Equal dimensions force equality after column-space inclusion is established. □

Theorem 1.2.9. *Sylvester Rank Inequality*
Let $A \in \operatorname{Mat}(m,k,\mathbb{F})$ and $B \in \operatorname{Mat}(k,n,\mathbb{F})$. Then $\operatorname{rank}(A) + \operatorname{rank}(B) - k \leq \operatorname{rank}(AB)$.

Proof. Set $R := \operatorname{col}(B)$ and define $S : R \to \mathbb{F}^m$ by $S(\mathbf{x}) := A\mathbf{x}$.
The identities $\operatorname{range}(S) = \operatorname{col}(AB)$ and $\ker(S) = R \cap \ker(A)$ hold by Proposition 3.1.10 and the definitions of R and S.
$\operatorname{rank}(AB) = \dim(R) - \dim(R \cap \ker(A)) \geq \operatorname{rank}(B) - \dim(\ker(A))$ by Theorem 1.7.3(ii), the rank definition, and Proposition 1.4.3(i).
$\operatorname{rank}(AB) \geq \operatorname{rank}(B) - (k - \operatorname{rank}(A)) = \operatorname{rank}(A) + \operatorname{rank}(B) - k$ by the preceding bound and Corollary 3.3.1(i).
Structural Commentary: Rank–nullity restricts A to $\operatorname{col}(B)$ and isolates the lost middle-space directions.
Key Insight: Only $\operatorname{col}(B) \cap \ker(A)$ can disappear under multiplication. □

Proposition 1.2.10. *Sylvester's Law of Nullity*
For a matrix X, write $\operatorname{nullity}(X) := \dim(\ker(X))$.

(*i*) *If $A \in \operatorname{Mat}(m,k,\mathbb{F})$ and $B \in \operatorname{Mat}(k,n,\mathbb{F})$, then $\operatorname{nullity}(AB) \leq \operatorname{nullity}(A) + \operatorname{nullity}(B)$.*
(*ii*) *If $A, B \in \operatorname{Mat}(n,n,\mathbb{F})$, then $\max(\operatorname{nullity}(A), \operatorname{nullity}(B)) \leq \operatorname{nullity}(AB)$.*

Proof.

(i) $\operatorname{nullity}(AB) \leq n - \operatorname{rank}(A) - \operatorname{rank}(B) + k = \operatorname{nullity}(A) + \operatorname{nullity}(B)$ by Theorem 1.2.9 and Corollary 3.3.1(i) for AB, A, and B.
(ii) $\operatorname{nullity}(AB) \geq \max(n - \operatorname{rank}(A), n - \operatorname{rank}(B)) = \max(\operatorname{nullity}(A), \operatorname{nullity}(B))$ by Theorem 1.2.8(i) and Corollary 3.3.1(i).

Structural Commentary: Rank–nullity reverses the lower and upper product-rank bounds into nullity bounds.
Key Insight: Subtracting rank from a fixed domain dimension reverses inequalities. □

Theorem 1.2.11. *Frobenius Rank Inequality*
Let $A \in \operatorname{Mat}(m,k,\mathbb{F})$, $B \in \operatorname{Mat}(k,p,\mathbb{F})$, and $C \in \operatorname{Mat}(p,n,\mathbb{F})$. Then $\operatorname{rank}(AB) + \operatorname{rank}(BC) \leq \operatorname{rank}(B) + \operatorname{rank}(ABC)$.

Proof. Set $R := \mathrm{col}(B)$ and $S := \mathrm{col}(BC)$, and define $T_A : \mathbb{F}^k \to \mathbb{F}^m$ by $T_A(\mathbf{x}) := A\mathbf{x}$.
The identities $S \subseteq R$, $T_A(R) = \mathrm{col}(AB)$, and $T_A(S) = \mathrm{col}(ABC)$ hold by Proposition 3.1.10.
$(\forall U \in \{R, S\})\ \dim(T_A(U)) = \dim(U) - \dim(U \cap \ker(A))$ by Theorem 1.7.3(ii) for $T_A|_U$ and the definition of restriction.
The Frobenius inequality holds by $S \cap \ker(A) \subseteq R \cap \ker(A)$, Proposition 1.4.3(i), the preceding identities, and the rank definition.
Structural Commentary: Rank–nullity compares A on the nested column spaces of BC and B.
Key Insight: The smaller space cannot meet $\ker(A)$ in more dimensions. □

Theorem 1.2.11 contains both two-factor bounds as degenerations: a zero outer factor recovers Theorem 1.2.8(i), while an identity middle factor recovers Theorem 1.2.9.

Theorem 1.2.12. *Rank Triangle Inequality*
Let $A, B \in \mathrm{Mat}(m, n, \mathbb{F})$.
(i) $\mathrm{rank}(A + B) \leq \mathrm{rank}(A) + \mathrm{rank}(B)$.
(ii) $|\mathrm{rank}(A) - \mathrm{rank}(B)| \leq \mathrm{rank}(A + B)$.

Proof.
(i) $\mathrm{col}(A + B) \subseteq \mathrm{col}(A) + \mathrm{col}(B)$ by adding corresponding columns.
$\mathrm{rank}(A + B) \leq \mathrm{rank}(A) + \mathrm{rank}(B)$ by Proposition 1.4.3(i), Theorem 2.3.1, and the rank definition.
(ii) $|\mathrm{rank}(A) - \mathrm{rank}(B)| \leq \mathrm{rank}(A + B)$ by part (i) with $A = (A + B) + (-B)$,
and $B = (A + B) + (-A)$, $(\forall X \in \{A, B\})\ \mathrm{col}(-X) = \mathrm{col}(X)$, and the rank and absolute-value definitions.
Structural Commentary: The column-space sum proves the upper bound; rearranging each summand proves both reverse bounds.
Key Insight: Rewriting either summand converts the upper bound into a lower bound. □

1.3 Commutators and Special Matrix Classes

Definition 1.3.1. *Commutator*
(i) For $S, T \in \mathcal{L}(\mathcal{V})$, their *commutator* is $[S, T] := ST - TS$.
(ii) For $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$, their *matrix commutator* is $[A, B] := AB - BA$.

Proposition 1.3.2. *Trace Obstruction for Commutators*
Let $A, B, C \in \mathrm{Mat}(n, n, \mathbb{F})$.
(i) $\mathrm{tr}([A, B]) = 0$.
(ii) If C is similar to $[A, B]$, then $\mathrm{tr}(C) = 0$.

Proof.
(i) $\mathrm{tr}([A, B]) = \mathrm{tr}(AB) - \mathrm{tr}(BA) = 0$ by Proposition 1.1.1(i),(ii) and Proposition 1.1.3.
(ii) If C is similar to $[A, B]$, then $\mathrm{tr}(C) = \mathrm{tr}([A, B]) = 0$ by Theorem 1.1.13(i) and part (i).
Structural Commentary: Trace cyclicity annihilates a commutator; similarity invariance transfers the obstruction.
Key Insight: The two product traces cancel exactly. □

Corollary 1.3.3. *The Identity Is Not a Commutator*
Let $\mathcal{V}$ be finite-dimensional over $\mathbb{F}$ and $(\dim \mathcal{V}) \cdot 1_{\mathbb{F}} \neq 0$. Then $(\nexists S, T \in \mathcal{L}(\mathcal{V}))\ [S, T] = I_{\mathcal{V}}$.

Proof. Set $n := \dim \mathcal{V}$, and suppose $[S, T] = I_{\mathcal{V}}$. Choose a basis β of $\mathcal{V}$ and set $A := [S]_{\beta \leftarrow \beta}$ and $B := [T]_{\beta \leftarrow \beta}$.
Then $[A, B] = [ST - TS]_{\beta \leftarrow \beta} = I_n$ by Propositions 3.4.4 and 3.2.4.
By Proposition 1.3.2(i), $0 = \mathrm{tr}([A, B]) = \mathrm{tr}(I_n) = n \cdot 1_{\mathbb{F}}$, contrary to the hypothesis.
Structural Commentary: Coordinate matrices transfer the operator equation to the matrix trace obstruction.
Key Insight: The identity has trace $(\dim \mathcal{V}) \cdot 1_{\mathbb{F}}$. □

Lemma 1.3.4. *Scalar Matrices and One-Step Orbits*
Let $n \geq 2$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$. Then $(\forall \mathbf{x} \in \mathbb{F}^n)$ $(\mathbf{x}, A\mathbf{x})$ is linearly dependent iff A is a scalar matrix.

Proof.
($\Rightarrow$) Suppose $(\forall \mathbf{x} \in \mathbb{F}^n)$ $(\mathbf{x}, A\mathbf{x})$ is linearly dependent. Since $\mathbf{e}_i \neq \mathbf{0}$, $(\exists\, a_i \in \mathbb{F})$ $A\mathbf{e}_i = a_i\mathbf{e}_i$ for $i \in \{1, \ldots, n\}$.
For $i \in \{2, \ldots, n\}$, the dependence of $\mathbf{e}_1 + \mathbf{e}_i$ and $A(\mathbf{e}_1 + \mathbf{e}_i) = a_1\mathbf{e}_1 + a_i\mathbf{e}_i$ implies $(\exists\, b_i \in \mathbb{F})$ $a_1\mathbf{e}_1 + a_i\mathbf{e}_i = b_i(\mathbf{e}_1 + \mathbf{e}_i)$.
Thus $a_1 = b_i = a_i$ by independence of $(\mathbf{e}_1, \mathbf{e}_i)$. Hence $(\forall\, i \in \{1, \ldots, n\})$ $A\mathbf{e}_i = a_1\mathbf{e}_i$, so $A = a_1 I_n$ by equality on standard basis.
($\Leftarrow$) If $A = cI_n$, then $(\forall \mathbf{x} \in \mathbb{F}^n)$ $A\mathbf{x} = c\mathbf{x}$, so each pair $(\mathbf{x}, A\mathbf{x})$ is linearly dependent.
Structural Commentary: Coordinate lines produce individual scalars; diagonal lines force those scalars to coincide.
Key Insight: Dependence along $\mathbf{e}_1 + \mathbf{e}_i$ equates the coordinate eigenvalues. □

Lemma 1.3.5. *Nonscalar Matrices Have a Zero Diagonal Entry After Similarity*
Let $n \geq 2$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$. If A is not scalar, then A is similar over $\mathbb{F}$ to a matrix whose $(1, 1)$ entry is 0.

Proof. Choose $\mathbf{x} \in \mathbb{F}^n$ such that $(\mathbf{x}, A\mathbf{x})$ linearly independent by Lemma 1.3.4. Extend this pair to basis β of $\mathbb{F}^n$ by Theorem 1.3.13.
Let $T_A : \mathbb{F}^n \to \mathbb{F}^n$ be defined by $T_A(\mathbf{y}) := A\mathbf{y}$, and set $C := [T_A]_{\beta \leftarrow \beta}$. The first column of C is $[A\mathbf{x}]_\beta = (0, 1, 0, \ldots, 0)^t$.
Hence the $(1, 1)$ entry of C is zero, and C is similar to A by Theorem 5.1.1(i), with the standard basis as the original basis.
Structural Commentary: A noninvariant line begins a basis whose second vector is $A\mathbf{x}$.
Key Insight: The coordinate vector of $A\mathbf{x}$ begins with zero. □

Theorem 1.3.6. *Similarity to a Constant-Diagonal Matrix*
Let $n \geq 1$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$, and $(\forall\, k \in \{1, \ldots, n\})$ $k \cdot 1_{\mathbb{F}} \neq 0$. Then A is similar to a matrix with constant diagonal $\frac{1}{n}\mathrm{tr}(A)$.

Proof.
(i) *Trace Shift*: Set $\tau := \frac{1}{n}\mathrm{tr}(A)$ and $B := A - \tau I_n$. Then $\mathrm{tr}(B) = \mathrm{tr}(A) - (n \cdot 1_{\mathbb{F}})\tau = 0$ by Proposition 1.1.1(i),(ii).
It suffices to show that every trace-zero matrix of size at most n is similar to a zero-diagonal matrix.
Indeed, adding τI_n preserves similarity by Theorem 6.2.8(i), with shift $-\tau$.

(ii) *Induction*: For $m \in \{1, \dots, n\}$, let $\mathcal{P}_m$ assert that every trace-zero matrix in $\mathrm{Mat}(m, m, \mathbb{F})$ is similar to a zero-diagonal matrix.
Property $\mathcal{P}_1$ holds because a trace-zero 1×1 matrix is $[0]$.
Fix $m \in \{2, \dots, n\}$, assume $\mathcal{P}_{m-1}$, and let $C \in \mathrm{Mat}(m, m, \mathbb{F})$ satisfy $\mathrm{tr}(C) = 0$.
(iii) *Scalar Case*: If $C = cI_m$, then $0 = \mathrm{tr}(C) = (m \cdot 1_{\mathbb{F}})c$. Thus $c = 0$ by $m \cdot 1_{\mathbb{F}} \neq 0$, so C already has zero diagonal.
(iv) *Nonscalar Case*: If C is not scalar, then C is similar to $D := \left[\begin{smallmatrix} 0 & \mathbf{u}^t \\ \mathbf{v} & C_1 \end{smallmatrix}\right]$ by Lemma 1.3.5.
The equality $\mathrm{tr}(C_1) = \mathrm{tr}(D) = \mathrm{tr}(C) = 0$ holds by Theorem 1.1.13(i) and the block diagonal entries.
Choose $S_1 \in \mathrm{Mat}(m-1, m-1, \mathbb{F})^{\times}$ such that $S_1^{-1} C_1 S_1$ has zero diagonal by $\mathcal{P}_{m-1}$. Set $R := I_1 \oplus S_1$.
Then $R^{-1} D R$ has zero diagonal because its lower-right block is $S_1^{-1} C_1 S_1$.
Thus C is similar to a zero-diagonal matrix by Proposition 6.2.2, so $\mathcal{P}_m$ holds.
Therefore $\mathcal{P}_n$ holds by induction, and the original assertion follows by the trace shift in part (i).

Structural Commentary: A trace shift reduces to zero diagonal; induction isolates one diagonal entry at a time.
Key Insight: The remaining block retains trace zero after the first entry vanishes. □

Theorem 1.3.7. *Shoda's Theorem in the Distinct-Diagonal Case*
Let $n \geq 1$, $(\forall\, k \in \{1, \dots, n\})\ k \cdot 1_{\mathbb{F}} \neq 0$, *and* $A \in \mathrm{Mat}(n, n, \mathbb{F})$.
(i) A *is a commutator in* $\mathrm{Mat}(n, n, \mathbb{F})$ *iff* $\mathrm{tr}(A) = 0$.
(ii) No nonzero scalar matrix in $\mathrm{Mat}(n, n, \mathbb{F})$ *is a commutator.*

Proof.
(i) ($\Rightarrow$) If $A = [U, V]$ for $U, V \in \mathrm{Mat}(n, n, \mathbb{F})$, then $\mathrm{tr}(A) = 0$ by Proposition 1.3.2(i).
(i) ($\Leftarrow$) Suppose $\mathrm{tr}(A) = 0$. Choose $S \in \mathrm{Mat}(n, n, \mathbb{F})^{\times}$ such that $B := S^{-1} A S = [b_{ij}]$ has zero diagonal by Theorem 1.3.6.
For $i \in \{1, \dots, n\}$, set $d_i := i \cdot 1_{\mathbb{F}}$, and let $X := \mathrm{diag}(d_1, \dots, d_n)$. Define $Y = [y_{ij}]$ by $y_{ii} := 0$ and $y_{ij} := (d_i - d_j)^{-1} b_{ij}$ for $i \neq j$.
For $i \neq j$, set $k := |i - j|$. Then $1 \leq k \leq n - 1$ and $d_i - d_j \in \{k \cdot 1_{\mathbb{F}}, -k \cdot 1_{\mathbb{F}}\} \subseteq \mathbb{F}^{\times}$ by the hypothesis.
Hence $[X, Y]_{ii} = 0 = b_{ii}$ and $[X, Y]_{ij} = (d_i - d_j) y_{ij} = b_{ij}$, so $B = [X, Y]$.
Therefore $A = [SXS^{-1}, SYS^{-1}]$ by direct multiplication, and A is a commutator.
(ii) If $c \in \mathbb{F} \setminus \{0\}$, then $\mathrm{tr}(cI_n) = (n \cdot 1_{\mathbb{F}})c \neq 0$. Thus cI_n is not a commutator by part (i).

Structural Commentary: Trace supplies necessity; constant-diagonal similarity and distinct scalars construct the converse.
Key Insight: Dividing each off-diagonal entry by $d_i - d_j$ realizes the commutator. □

Remark 1.3.8. *Field Hypothesis in the Diagonal Proof*
Theorem 1.3.7 uses the field hypothesis twice: the scalars $d_1, \dots, d_n$ must be distinct, and every block size in the induction must remain nonzero. In small characteristic this diagonal construction requires replacement.

Computation Method 1.3.9. *Trace–Determinant Invariant Computation*
Let $n \geq 1$, $A, C \in \mathrm{Mat}(n, n, \mathbb{F})$, and suppose $p_A(z) = \prod_{j=1}^{n} (z - \lambda_j)$ over a field containing $\mathbb{F}$. The following procedure extracts aggregate eigenvalue data and screens a commutator equation:
(i) If A represents an operator, choose a basis in which its representing matrix is easiest to compute.
(ii) Compute $\mathrm{tr}(A)$ from the diagonal entries and $\det(A)$ by a convenient determinant formula.
(iii) Record $\sum_{j=1}^{n} \lambda_j = \mathrm{tr}(A)$ and $\prod_{j=1}^{n} \lambda_j = \det(A)$ by Theorem 2.1.3(i).
(iv) For $[X, Y] = C$, first compute $\mathrm{tr}(C)$. If it is nonzero, no solution exists by Proposition 1.3.2(i).

Definition 1.3.10. *Idempotent and Nilpotent Matrices*
Let $A \in \mathrm{Mat}(n, n, \mathbb{F})$.
(i) A is *idempotent* iff $A^2 = A$.
(ii) A is *nilpotent* iff $(\exists\, k \in \mathbb{Z}_{>0})\ A^k = 0$.

Proposition 1.3.11. *Basic Invariants of Idempotents*
Let $P \in \mathrm{Mat}(n, n, \mathbb{F})$ *satisfy* $P^2 = P$, *and set* $r := \mathrm{rank}(P)$.
(i) $\mathbb{F}^n = \mathrm{range}(P) \oplus \ker(P)$.
(ii) $(\forall\, \mathbf{y} \in \mathrm{range}(P))\ P\mathbf{y} = \mathbf{y}$ *and* $(\forall\, \mathbf{z} \in \ker(P))\ P\mathbf{z} = \mathbf{0}$.
(iii) P *is similar to* $I_r \oplus 0_{n-r}$.
(iv) P *is diagonalizable over* $\mathbb{F}$.
(v) $\mathrm{spec}(P) \subseteq \{0, 1\}$.
(vi) $\mathrm{tr}(P) = \mathrm{rank}(P)$.
(vii) If $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, *then* P *is the orthogonal projection onto* $\mathrm{range}(P)$ *iff* $P = P^*$.

Proof.
(i) For $\mathbf{x} \in \mathbb{F}^n$, write $\mathbf{x} = P\mathbf{x} + (\mathbf{x} - P\mathbf{x})$, where $P\mathbf{x} \in \mathrm{range}(P)$.
Since $P(\mathbf{x} - P\mathbf{x}) = P\mathbf{x} - P^2\mathbf{x} = \mathbf{0}$, the second term lies in $\ker(P)$.
If $\mathbf{x} \in \mathrm{range}(P) \cap \ker(P)$, write $\mathbf{x} = P\mathbf{u}$. Then $\mathbf{x} = P^2\mathbf{u} = P\mathbf{x} = \mathbf{0}$, so the sum is direct.
(ii) If $\mathbf{y} = P\mathbf{u} \in \mathrm{range}(P)$, then $P\mathbf{y} = P^2\mathbf{u} = P\mathbf{u} = \mathbf{y}$. The assertion on $\ker(P)$ follows from its definition.
(iii) Choose a basis $(\mathbf{u}_1, \dots, \mathbf{u}_r)$ of $\mathrm{range}(P)$ and a basis $(\mathbf{v}_1, \dots, \mathbf{v}_{n-r})$ of $\ker(P)$ by Corollary 3.3.1(i).
Their concatenation is a basis by part (i).
By part (ii), the representing matrix in this basis is $I_r \oplus 0_{n-r}$. Thus P is similar to this matrix by Theorem 5.1.1(i).
(iv) The matrix $I_r \oplus 0_{n-r}$ is diagonal, and the similarity in part (iii) is a diagonalization of P.
(v) If $P\mathbf{x} = \lambda\mathbf{x}$ for $\mathbf{x} \neq \mathbf{0}$, then $\lambda^2\mathbf{x} = P^2\mathbf{x} = P\mathbf{x} = \lambda\mathbf{x}$. Hence $\lambda(\lambda - 1) = 0$, so $\lambda \in \{0, 1\}$.
(vi) By Theorem 1.1.13(i) and part (iii), $\mathrm{tr}(P) = \mathrm{tr}(I_r \oplus 0_{n-r}) = r = \mathrm{rank}(P)$.
(vii) ($\Rightarrow$) Regarding P as an operator on the standard inner-product space, $P = P^*$ by Theorem 2.5.6.
(vii) ($\Leftarrow$) Regarding P as an operator on the standard inner-product space, it is the orthogonal projection onto $\mathrm{range}(P)$ by the idempotence hypothesis, $P = P^*$, and Theorem 2.5.6.

Structural Commentary: Range–kernel coordinates determine invariants; self-adjointness characterizes orthogonal projection.
Key Insight: In an adapted basis, every idempotent is $I_r \oplus 0_{n-r}$. □

2 Positive Definite and Structured Matrices

2.1 Positive Semidefinite and Positive Definite Matrices

Definition 2.1.1. *Positive Semidefinite and Positive Definite Matrices*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and $A \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) The matrix A is *positive semidefinite*, written $A \succeq 0$, iff $A = A^*$ and $(\forall\, \mathbf{x} \in \mathbb{F}^n)\, \mathbf{x}^* A \mathbf{x} \geq 0$.
(ii) The matrix A is *positive definite*, written $A \succ 0$, iff $A = A^*$ and $(\forall\, \mathbf{x} \in \mathbb{F}^n \setminus \{\mathbf{0}\})\, \mathbf{x}^* A \mathbf{x} > 0$.
(iii) The matrix A is *negative semidefinite* iff $-A \succeq 0$.
(iv) The matrix A is *negative definite* iff $-A \succ 0$.

Proposition 2.1.2. *Rectangular Gram Products Are Positive Semidefinite*
Let $m, n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and $R \in \mathrm{Mat}(m, n, \mathbb{F})$.

(i) $R^* R \succeq 0$.
(ii) $RR^* \succeq 0$.
(iii) $(\forall\, j \in \{1, \ldots, n\})\, (R^* R)_{j,j} = \|R_{\cdot,j}\|_2^2$.
(iv) $(\forall\, i \in \{1, \ldots, m\})\, (RR^*)_{i,i} = \|R_{i,\cdot}\|_2^2$.
(v) If $\mathrm{rank}(R) = n$, *then* $R^* R \succ 0$.
(vi) If $\mathrm{rank}(R) = m$, *then* $RR^* \succ 0$.

Proof. For $(A, d) \in \{(R, n), (R^*, m)\}$, $(A^* A)^* = A^* A$ by Proposition 2.3.8(ii),(iii).
For the same pairs, $(\forall\, \mathbf{z} \in \mathbb{F}^d)\, \mathbf{z}^* A^* A \mathbf{z} = \|A\mathbf{z}\|_2^2 \geq 0$.

(i) $R^* R \succeq 0$ by the preceding identities with $(A, d) = (R, n)$.
(ii) $RR^* \succeq 0$ by the preceding identities with $(A, d) = (R^*, m)$.
(iii) $(\forall\, j \in \{1, \ldots, n\})\, (R^* R)_{j,j} = \mathbf{e}_j^* R^* R \mathbf{e}_j = \|R\mathbf{e}_j\|_2^2 = \|R_{\cdot,j}\|_2^2$.
(iv) $(\forall\, i \in \{1, \ldots, m\})\, (RR^*)_{i,i} = \mathbf{e}_i^* R R^* \mathbf{e}_i = \|R^* \mathbf{e}_i\|_2^2 = \|R_{i,\cdot}\|_2^2$.
(v) If $\mathrm{rank}(R) = n$, then $\ker(R) = \{\mathbf{0}\}$ by Corollary 3.3.1(i). Thus $(\forall\, \mathbf{x} \in \mathbb{F}^n \setminus \{\mathbf{0}\})\, \mathbf{x}^* R^* R \mathbf{x} = \|R\mathbf{x}\|_2^2 > 0$, and $R^* R \succ 0$ by part (i).
(vi) If $\mathrm{rank}(R) = m$, then $\mathrm{col}(R) = \mathbb{F}^m$ by rank definition, Proposition 1.4.3(ii); $\ker(R^*) = \mathrm{col}(R)^\perp = \{\mathbf{0}\}$ by Proposition 2.3.10(i). Therefore $(\forall\, \mathbf{y} \in \mathbb{F}^m \setminus \{\mathbf{0}\})\, \mathbf{y}^* R R^* \mathbf{y} = \|R^* \mathbf{y}\|_2^2 > 0$, and $RR^* \succ 0$ by part (ii).

Structural Commentary: Adjoint identities establish self-adjointness; rank removes the kernels in the two squared-norm forms.
Key Insight: A Gram form is strictly positive exactly off its factor's kernel. □

Theorem 2.1.3. *Equivalent Forms of Positive Semidefiniteness*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and $A \in \mathrm{Mat}(n, n, \mathbb{F})$. The following are equivalent:

(i) $A \succeq 0$.
(ii) $A = A^*$ *and* $\mathrm{spec}(A) \subseteq [0, \infty)$.
(iii) $(\exists\, C \in \mathrm{Mat}(n, n, \mathbb{F}))\, [C \succeq 0 \wedge C^2 = A]$.
(iv) $(\exists\, m \in \mathbb{Z}_{>0})(\exists\, B \in \mathrm{Mat}(m, n, \mathbb{F}))\, A = B^* B$.

Proof. Identify each square matrix with its induced operator on $\mathbb{F}^n$.

(i) $\Rightarrow$ *(ii)* $A = A^*$ and $\mathrm{spec}(A) \subseteq [0, \infty)$ by Theorem 6.3.6(i)$\Rightarrow$(ii).
(ii) $\Rightarrow$ *(iii)* Choose $C \succeq 0$ with $C^2 = A$ by Theorem 6.3.6(ii)$\Rightarrow$(iii).
(iii) $\Rightarrow$ *(iv)* If $C \succeq 0$ and $C^2 = A$, then $A = C^2 = C^* C$; take $(m, B) = (n, C)$.
(iv) $\Rightarrow$ *(i)* $A \succeq 0$ by Proposition 2.1.2(i) for $A = B^* B$.

Structural Commentary: Operator positivity supplies the spectral root; self-adjointness converts that root into a Gram factor.
Key Insight: For $C \succeq 0$, the identities $C^2 = C^* C$ coincide. □

Corollary 2.1.4. *Unique Positive Semidefinite Square Root*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and $A \in \mathrm{Mat}(n, n, \mathbb{F})$ satisfy $A \succeq 0$.

(i) $(\exists!\, C \in \mathrm{Mat}(n, n, \mathbb{F}))\, [C \succeq 0 \wedge C^2 = A]$; *this matrix is denoted by* $A^{1/2}$.
(ii) If $A = U \,\mathrm{diag}(\lambda_1, \ldots, \lambda_n) U^*$, *where U is unitary and* $(\forall\, j \in \{1, \ldots, n\})\, \lambda_j \geq 0$, *then* $A^{1/2} = U \,\mathrm{diag}(\sqrt{\lambda_1}, \ldots, \sqrt{\lambda_n}) U^*$.

Proof.

(i) Existence and uniqueness hold by Proposition 6.3.7 for the operator induced by A.
(ii) Set $C := U \,\mathrm{diag}(\sqrt{\lambda_1}, \ldots, \sqrt{\lambda_n}) U^*$. Then $C = C^*$, $\mathrm{spec}(C) \subseteq [0, \infty)$, and $C^2 = A$. Thus $C \succeq 0$ by Theorem 2.1.3(ii)$\Rightarrow$(i), and $C = A^{1/2}$ by part (i).

Structural Commentary: Spectral coordinates construct the root; operator uniqueness identifies every positive semidefinite root.
Key Insight: Each nonnegative eigenvalue has one nonnegative square root. □

Theorem 2.1.5. *Kernel, Rank, and Columns of $B^* B$*
Let $m, n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, $B \in \mathrm{Mat}(m, n, \mathbb{F})$, and $A = B^* B$.

(i) $A \succeq 0$;
(ii) $\ker(A) = \ker(B)$;
(iii) $\mathrm{rank}(A) = \mathrm{rank}(B)$;
(iv) $\mathrm{col}(A) = \mathrm{col}(B^*)$;
(v) $A = 0$ *iff* $B = 0$.

Proof.

(i) $A \succeq 0$ by Proposition 2.1.2(i).
(ii) $\ker(B) \subseteq \ker(A)$ by $A = B^* B$. If $\mathbf{x} \in \ker(A)$, then $\|B\mathbf{x}\|_2^2 = \mathbf{x}^* A \mathbf{x} = 0$, so $\mathbf{x} \in \ker(B)$.
(iii) $\mathrm{rank}(A) = n - \dim \ker(A) = n - \dim \ker(B) = \mathrm{rank}(B)$ by part (ii) and Corollary 3.3.1(i).
(iv) $\mathrm{col}(A) = \ker(A)^\perp = \ker(B)^\perp = \mathrm{col}(B^*)$ by parts (i)–(ii) and Proposition 2.3.10(iii).
(v) ($\Rightarrow$) If $A = 0$, then $\mathrm{rank}(B) = \mathrm{rank}(A) = 0$ by part (iii), so $B = 0$.

(v) $(\Leftarrow)$ $B = 0 \Rightarrow A = B^*B = 0$.

Structural Commentary: Squared-norm identity fixes the kernel; rank–nullity and adjoint orthogonality determine rank and columns.
Key Insight: B^*B and B vanish on exactly the same vectors. □

Figure 77 summarizes the squared-norm argument that transfers kernel data from B^*B to B.

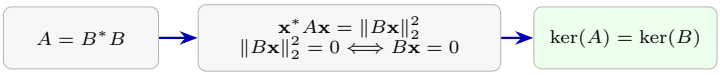

Figure 77: For $A = B^*B$, the squared-norm identity certifies $\ker(A) = \ker(B)$.

Corollary 2.1.6. *Zero Quadratic Form Detects the Kernel*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and $A \in \mathrm{Mat}(n, n, \mathbb{F})$ satisfy $A \succeq 0$. Then $(\forall\, \mathbf{x} \in \mathbb{F}^n)\, [\mathbf{x}^*A\mathbf{x} = 0 \iff A\mathbf{x} = \mathbf{0}]$.

Proof. Fix $\mathbf{x} \in \mathbb{F}^n$, and choose $m \in \mathbb{Z}_{>0}$ and $B \in \mathrm{Mat}(m, n, \mathbb{F})$ with $A = B^*B$ by Theorem 2.1.3(iv).
$(\Rightarrow)$ $\mathbf{x}^*A\mathbf{x} = 0 \Rightarrow \|B\mathbf{x}\|_2^2 = 0 \Rightarrow B\mathbf{x} = \mathbf{0} \Rightarrow A\mathbf{x} = \mathbf{0}$.
$(\Leftarrow)$ $A\mathbf{x} = \mathbf{0} \Rightarrow \mathbf{x}^*A\mathbf{x} = 0$.

Structural Commentary: Gram factorization converts the quadratic value into a norm whose zero set is $\ker(A)$.
Key Insight: $\|B\mathbf{x}\|_2^2 = 0$ forces $B\mathbf{x} = \mathbf{0}$. □

Computation Method 2.1.7. *PSD Spectral Factorization*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and let $A \in \mathrm{Mat}(n, n, \mathbb{F})$ satisfy $A = A^*$.
The procedure decides whether $A \succeq 0$, constructs $A^{1/2}$ when it exists, and transfers kernel and rank questions to that factor.
(i) Compute a unitary diagonalization $A = U \operatorname{diag}(\lambda_1, \ldots, \lambda_n) U^*$ by the appropriate spectral theorem.
(ii) If $(\exists\, j \in \{1, \ldots, n\})\, \lambda_j < 0$, conclude that $A \not\succeq 0$. If $(\forall\, j \in \{1, \ldots, n\})\, \lambda_j \geq 0$, conclude that $A \succeq 0$ by Theorem 2.1.3(ii).
(iii) In the positive semidefinite case, form $C = U \operatorname{diag}(\sqrt{\lambda_1}, \ldots, \sqrt{\lambda_n}) U^*$. Then $C = A^{1/2}$ and $A = C^*C$ by Corollary 2.1.4(i),(ii).
(iv) Read the kernel, rank, column-space, and zero-quadratic-form data from C by Theorem 2.1.5 and Corollary 2.1.6.

Theorem 2.1.8. *Equivalent Forms of Positive Definiteness*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and $A \in \mathrm{Mat}(n, n, \mathbb{F})$. The following are equivalent:
(i) $A \succ 0$.
(ii) $A = A^*$ *and* $\mathrm{spec}(A) \subseteq (0, \infty)$.
(iii) $A \succeq 0$ *and* A *is invertible.*
(iv) $(\exists\, B \in \mathrm{Mat}(n, n, \mathbb{F})^\times)\, A = B^*B$.
(v) A *is invertible and* $A^{-1} \succ 0$.

Proof.
(i) $\Rightarrow$ *(ii)* $A = A^*$ by positive definiteness. For $\lambda \in \mathrm{spec}(A)$ and $\mathbf{v} \in E_\lambda(A) \setminus \{\mathbf{0}\}$, $0 < \mathbf{v}^*A\mathbf{v} = \lambda \|\mathbf{v}\|_2^2$, so $\lambda > 0$.
(ii) $\Rightarrow$ *(iii)* $A \succeq 0$ by Theorem 2.1.3(ii)$\Rightarrow$(i), and A is invertible by Corollary 5.1.8.
(iii) $\Rightarrow$ *(iv)* Set $C := A^{1/2}$. Then $A = C^2 = C^*C$ by Corollary 2.1.4(i), while $\ker(C) \subseteq \ker(A) = \{\mathbf{0}\}$.
Thus C is invertible by Corollary 3.6.3(vi)$\Rightarrow$(i).
(iv) $\Rightarrow$ *(v)* $A = B^*B$ is invertible and $A^{-1} = B^{-1}(B^{-1})^*$ by Corollary 3.1.17(i) and Proposition 2.3.9(i).
The equality $\mathrm{rank}(B^{-1}) = n$ holds by Corollary 3.6.2, so $A^{-1} \succ 0$ by Proposition 2.1.2(vi) with $R = B^{-1}$.
(v) $\Rightarrow$ *(i)* $(A^{-1})^* = A^{-1}$ by positive definiteness, so $A^* = ((A^{-1})^*)^{-1} = A$ by Proposition 2.3.9(i).
For $\mathbf{x} \in \mathbb{F}^n \setminus \{\mathbf{0}\}$, set $\mathbf{y} := A\mathbf{x} \neq \mathbf{0}$. Then $0 < \mathbf{y}^*A^{-1}\mathbf{y} = \mathbf{x}^*A\mathbf{x}$, so $A \succ 0$.

Structural Commentary: Spectral positivity removes zero, the square root supplies a Gram factor, and substitution reverses inversion.
Key Insight: $\mathbf{y} = A\mathbf{x}$ transfers strict positivity from A^{-1} to A. □

Proposition 2.1.9. *Trace and Determinant of Positive Semidefinite Matrices*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and $A \in \mathrm{Mat}(n, n, \mathbb{F})$ satisfy $A \succeq 0$.
(i) $\mathrm{tr}(A) \geq 0$.
(ii) $\mathrm{tr}(A) = 0$ *iff* $A = 0$.
(iii) $\det(A) \geq 0$.
(iv) $\det(A) > 0$ *iff* $A \succ 0$.

Proof. Write $A = U \operatorname{diag}(\lambda_1, \ldots, \lambda_n) U^*$ by the appropriate one of Theorems 6.1.11 and 6.1.12.
The relation $(\forall\, j \in \{1, \ldots, n\})\, \lambda_j \geq 0$ holds by Theorem 2.1.3(ii). Then $\mathrm{tr}(A) = \sum_{j=1}^{n} \lambda_j$ and $\det(A) = \prod_{j=1}^{n} \lambda_j$ by Theorem 1.1.13(i),(ii).

(i) $\mathrm{tr}(A) = \sum_{j=1}^{n} \lambda_j \geq 0$.
(ii) $(\Rightarrow)$ $\mathrm{tr}(A) = 0 \Rightarrow (\forall\, j \in \{1, \ldots, n\})\, \lambda_j = 0 \Rightarrow A = 0$.
(ii) $(\Leftarrow)$ $A = 0 \Rightarrow \mathrm{tr}(A) = 0$.
(iii) $\det(A) = \prod_{j=1}^{n} \lambda_j \geq 0$.
(iv) $(\Rightarrow)$ $\det(A) > 0 \Rightarrow (\forall\, j \in \{1, \ldots, n\})\, \lambda_j > 0$, so $A \succ 0$ by Theorem 2.1.8(ii).
(iv) $(\Leftarrow)$ $A \succ 0 \Rightarrow (\forall\, j \in \{1, \ldots, n\})\, \lambda_j > 0$ by Theorem 2.1.8(ii), so $\det(A) > 0$.

Structural Commentary: Unitary diagonalization transfers trace and determinant to a nonnegative eigenvalue sum and product.
Key Insight: The sum detects universal vanishing; the product detects any vanishing. □

Theorem 2.1.10. *Stability Rules for Positive Semidefinite Matrices*
Let $m, n, p \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$. Let $A, C \in \mathrm{Mat}(n, n, \mathbb{F})$, $B \in \mathrm{Mat}(m, m, \mathbb{F})$, $S \in \mathrm{Mat}(n, p, \mathbb{F})$. Fix $a, b \in \mathbb{R}_{\geq 0}$, suppose $A, C, B \succeq 0$.
(i) $aA + bC \succeq 0$.
(ii) $S^*AS \succeq 0$.

(iii) $A \oplus B \succeq 0$.
(iv) *If* $a, b > 0$ *and either* $A \succ 0$ *or* $C \succ 0$, *then* $aA + bC \succ 0$.
(v) $S^*AS \succ 0$ *iff* $(\forall\, \mathbf{x} \in \mathbb{F}^p \setminus \{\mathbf{0}\})\, S\mathbf{x} \notin \ker(A)$.
(vi) $A \oplus B \succ 0$ *iff* $A \succ 0$ *and* $B \succ 0$.

Proof. For a square matrix M and compatible vector $\mathbf{z}$, set $q_M(\mathbf{z}) := \mathbf{z}^*M\mathbf{z}$.
(i) $(aA + bC)^* = aA + bC$ and $(\forall\, \mathbf{x} \in \mathbb{F}^n)\, q_{aA+bC}(\mathbf{x}) = aq_A(\mathbf{x}) + bq_C(\mathbf{x}) \geq 0$, so $aA + bC \succeq 0$.
(ii) $(S^*AS)^* = S^*AS$ by Proposition 2.3.8(ii),(iii). The identity $(\forall\, \mathbf{x} \in \mathbb{F}^p)\, q_{S^*AS}(\mathbf{x}) = q_A(S\mathbf{x}) \geq 0$ implies $S^*AS \succeq 0$.
(iii) $(A \oplus B)^* = A \oplus B$, and $(\forall\, (\mathbf{x}, \mathbf{y}) \in \mathbb{F}^n \times \mathbb{F}^m)\, q_{A\oplus B}(\mathbf{x} \oplus \mathbf{y}) = q_A(\mathbf{x}) + q_B(\mathbf{y})$. The right side is nonnegative, so $A \oplus B \succeq 0$.
(iv) If $a, b > 0$ and $A \succ 0$, then $(\forall\, \mathbf{x} \in \mathbb{F}^n \setminus \{\mathbf{0}\})\, aq_A(\mathbf{x}) > 0$ and $bq_C(\mathbf{x}) \geq 0$, so $aA + bC \succ 0$ by part (i).
If $a, b > 0$ and $C \succ 0$, then $(\forall\, \mathbf{x} \in \mathbb{F}^n \setminus \{\mathbf{0}\})\, aq_A(\mathbf{x}) \geq 0$ and $bq_C(\mathbf{x}) > 0$, so again $aA + bC \succ 0$.
(v) $(\Rightarrow)$ If $S^*AS \succ 0$ and $\mathbf{x} \in \mathbb{F}^p \setminus \{\mathbf{0}\}$, then $q_A(S\mathbf{x}) = q_{S^*AS}(\mathbf{x}) > 0$. Thus $S\mathbf{x} \notin \ker(A)$ by Corollary 2.1.6.
(v) $(\Leftarrow)$ If $\mathbf{x} \in \mathbb{F}^p \setminus \{\mathbf{0}\}$, then $S\mathbf{x} \notin \ker(A)$ by hypothesis.
Thus $q_{S^*AS}(\mathbf{x}) = q_A(S\mathbf{x}) > 0$ by $A \succeq 0$ and Corollary 2.1.6, and $S^*AS \succ 0$ by part (ii).
(vi) $(\Rightarrow)$ If $A \oplus B \succ 0$, then $(\forall\, \mathbf{x} \in \mathbb{F}^n \setminus \{\mathbf{0}\})\, q_A(\mathbf{x}) = q_{A\oplus B}(\mathbf{x} \oplus \mathbf{0}) > 0$.
Likewise, $(\forall\, \mathbf{y} \in \mathbb{F}^m \setminus \{\mathbf{0}\})\, q_B(\mathbf{y}) = q_{A\oplus B}(\mathbf{0} \oplus \mathbf{y}) > 0$, so $A \succ 0$ and $B \succ 0$.
(vi) $(\Leftarrow)$ If $A \succ 0$, $B \succ 0$, and $(\mathbf{x}, \mathbf{y}) \neq (\mathbf{0}, \mathbf{0})$, then $q_{A\oplus B}(\mathbf{x} \oplus \mathbf{y}) = q_A(\mathbf{x}) + q_B(\mathbf{y}) > 0$. Thus $A \oplus B \succ 0$ by part (iii).
Structural Commentary: The identities for q_M preserve nonnegativity and expose the zero sets of each construction.
Key Insight: Strict positivity is the absence of nonzero vectors in the transformed zero set. □

Proposition 2.1.11. *Explicit Square Root for a* 2×2 *Positive Semidefinite Matrix*
Let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$ *and* $A \in \mathrm{Mat}(2, 2, \mathbb{F})$ *satisfy* $A \succeq 0$ *and* $A \neq 0$. *Set* $\tau := \big(\mathrm{tr}(A) + 2\sqrt{\det(A)}\big)^{1/2}$.
(i) $\tau > 0$.
(ii) $A^{1/2} = \frac{1}{\tau}\big(A + \sqrt{\det(A)}\, I_2\big)$.

Proof.
(i) $\det(A) \geq 0$ and $\mathrm{tr}(A) > 0$ by Proposition 2.1.9(ii),(iii), so $\tau > 0$.
(ii) Set $C := \frac{1}{\tau}\big(A + \sqrt{\det(A)}\, I_2\big)$. Then $C \succeq 0$ by Theorem 2.1.10(i), since $I_2 \succeq 0$ and $\tau^{-1}, \tau^{-1}\sqrt{\det(A)} \geq 0$.
The identity $A^2 - \mathrm{tr}(A)A + \det(A)I_2 = 0$ holds by Theorems 2.1.3 and 3.1.1, regarding a real A as complex when necessary.
Thus $\tau^2 C^2 = A^2 + 2\sqrt{\det(A)}A + \det(A)I_2 = \tau^2 A$, so $C^2 = A$ and $C = A^{1/2}$ by Corollary 2.1.4(i).
Structural Commentary: Cayley–Hamilton reduces the squared linear candidate, and positive-root uniqueness identifies it.
Key Insight: $\tau^2 = \mathrm{tr}(A) + 2\sqrt{\det(A)}$ normalizes the square to A. □

Definition 2.1.12. *Directed Incidence Matrix*
Let $m, n \in \mathbb{Z}_{>0}$, and let $G = (V, E)$ be a directed graph with $V = \{1, \ldots, n\}$ and ordered edges $E = (e_k)_{k=1}^m$, where $e_k = u_k \to v_k$.
Its *directed incidence matrix* is the matrix $B \in \mathrm{Mat}(m, n, \mathbb{R})$ satisfying $(\forall\, k \in \{1, \ldots, m\})\, B_{k,\cdot} = -\mathbf{e}_{u_k}^t + \mathbf{e}_{v_k}^t$.

Figure 78 records the chosen edge orientations and their corresponding signed incidence rows.

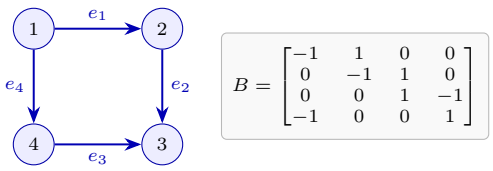

Figure 78: A directed incidence matrix records oriented edge differences from vertices to edges.

Example 2.1.13. *A Directed Incidence Matrix*
For Figure 78, the directed incidence matrix is

$$B = \begin{bmatrix} -1 & 1 & 0 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & 1 & -1 \\ -1 & 0 & 0 & 1 \end{bmatrix}.$$

For node potentials $\mathbf{x} = (x_1, x_2, x_3, x_4)^t$, the edge-difference vector is

$$B\mathbf{x} = \begin{bmatrix} x_2 - x_1 \\ x_3 - x_2 \\ x_3 - x_4 \\ x_4 - x_1 \end{bmatrix}.$$

The equivalence $B\mathbf{x} = \mathbf{0} \iff x_1 = x_2 = x_3 = x_4$ implies $\ker(B) = \mathrm{span}\{(1, 1, 1, 1)^t\}$.
Thus $\mathrm{rank}(B) = 3$ by Corollary 3.3.1(i). For $\mathbf{y} := (1, 1, -1, -1)^t$, $B^t\mathbf{y} = \mathbf{0}$ by direct multiplication.
The equality $\mathrm{rank}(B^t) = 3$ holds by Theorem 3.3.2, so $\ker(B^t) = \mathrm{span}\{\mathbf{y}\}$ by Corollary 3.3.1(i).
Thus $\mathbf{b} \in \mathrm{col}(B)$ iff $\mathbf{y}^t\mathbf{b} = b_1 + b_2 - b_3 - b_4 = 0$ by Proposition 2.3.10(iv). This is the Kirchhoff loop-compatibility condition.
Structural Commentary: The kernel records constant-potential freedom; the left kernel records edge-data compatibility.
Key Insight: The oriented rows encode both edge differences and the cycle relation that determines which edge data are realizable.

Perspective 2.1.14. *Incidence Data and Least Squares*
For an incidence matrix B as in Example 2.1.13, $B\mathbf{x} = \mathbf{b}$ seeks node potentials reproducing prescribed edge differences.
If loop compatibility fails, a least-squares solution projects $\mathbf{b}$ onto $\mathrm{col}(B)$ and satisfies $B^*(B\mathbf{x}_0 - \mathbf{b}) = \mathbf{0}$ by Theorem 2.4.4.
The constant-vector kernel makes the potentials unique only after fixing a reference node or selecting the minimum-norm solution.

Proposition 2.1.15. *Incidence Laplacians Are Positive Semidefinite*
Let $G = (V, E)$ be a directed graph, let $B \in \mathrm{Mat}(m, n, \mathbb{R})$ be its directed incidence matrix, and set $L := B^t B$. Let G_{u} be the underlying undirected graph obtained by forgetting edge orientations.

(i) $L \succeq 0$.
(ii) $(\forall\, \mathbf{x} \in \mathbb{R}^n)\, \mathbf{x}^t L \mathbf{x} = \sum_{e=(u\to v)\in E} (x_v - x_u)^2$.
(iii) $\ker(L)$ *is the subspace of vectors that are constant on each connected component of* G_{u}.

Proof.
(i) $L = B^* B \succeq 0$ by Proposition 2.1.2(i).
(ii) For $\mathbf{x} \in \mathbb{R}^n$, $(\forall\, e = (u \to v) \in E)\, (B\mathbf{x})_e = x_v - x_u$ by the incidence-row formula. Thus $\mathbf{x}^t L \mathbf{x} = \|B\mathbf{x}\|_2^2 = \sum_{e=(u\to v)\in E} (x_v - x_u)^2$.
(iii) $\ker(L) = \ker(B)$ by Theorem 2.1.5(ii). For $\mathbf{x} \in \mathbb{R}^n$, $B\mathbf{x} = \mathbf{0}$ iff $x_u = x_v$ on every edge.
These equalities propagate along paths and are equivalent to componentwise constancy on G_{u}.

Structural Commentary: The Gram identity converts the Laplacian form and kernel into edge-difference conditions.
Key Insight: Zero edge differences are exactly componentwise-constant vertex values. □

2.2 Principal Minors and Inertia

Definition 2.2.1. *Principal and Leading Principal Minors*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and $A = [a_{ij}] \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) If $\varnothing \neq I \subseteq \{1, \dots, n\}$, then $A[I] := [a_{ij}]_{i,j\in I}$ is the *principal submatrix indexed by* I.
Its determinant $\det A[I]$ is the corresponding *principal minor*.
(ii) If $k \in \{1, \dots, n\}$, then $\det A[\{1, \dots, k\}]$ is the kth *leading principal minor* of A.

Corollary 2.2.2. *Principal Blocks and Column Inclusion*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, $k \in \{1, \dots, n\}$, and $A \in \mathrm{Mat}(n, n, \mathbb{F})$ satisfy $A \succeq 0$. Partition $A = \left(\begin{smallmatrix} A_{11} & A_{12} \\ A_{12}^* & A_{22} \end{smallmatrix}\right)$ with $A_{11} \in \mathrm{Mat}(k, k, \mathbb{F})$.

(i) $A_{11} \succeq 0$.
(ii) $\mathrm{col}(A_{12}) \subseteq \mathrm{col}(A_{11})$.
(iii) $\mathrm{rank}(A_{12}) \leq \mathrm{rank}(A_{11})$.
(iv) If $A \succ 0$, then $A_{11} \succ 0$.

Proof. Choose $m \in \mathbb{Z}_{>0}$ and $B \in \mathrm{Mat}(m, n, \mathbb{F})$ with $A = B^* B$ by Theorem 2.1.3(iv).
Write $B = [B_1\ B_2]$ conformally; then $A_{11} = B_1^* B_1$ and $A_{12} = B_1^* B_2$.

(i) $A_{11} \succeq 0$ by Proposition 2.1.2(i).
(ii) $\mathrm{col}(A_{12}) \subseteq \mathrm{col}(B_1^*)$ by $A_{12} = B_1^* B_2$. The identity $\mathrm{col}(B_1^*) = \mathrm{col}(B_1^* B_1) = \mathrm{col}(A_{11})$ holds by Theorem 2.1.5(iv).
(iii) $\mathrm{rank}(A_{12}) = \dim \mathrm{col}(A_{12}) \leq \dim \mathrm{col}(A_{11}) = \mathrm{rank}(A_{11})$ by part (ii).
(iv) If $A \succ 0$ and $\mathbf{x} \in \mathbb{F}^k \setminus \{\mathbf{0}\}$, set $\mathbf{z} := \left(\begin{smallmatrix} \mathbf{x} \\ \mathbf{0} \end{smallmatrix}\right)$.
Then $\mathbf{z} \neq \mathbf{0}$ and $\mathbf{x}^* A_{11} \mathbf{x} = \mathbf{z}^* A \mathbf{z} > 0$, so $A_{11} \succ 0$ by part (i) and the definition of positive definiteness.

Structural Commentary: The Gram partition proves the block claims; zero padding transfers strict positivity.
Key Insight: $A_{11} = B_1^* B_1$ and $A_{12} = B_1^* B_2$ share the same left factor. □

Figure 79 highlights the principal and cross blocks involved in the positive-semidefinite column-inclusion result.

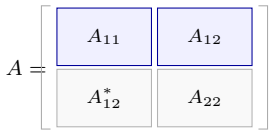

Figure 79: For $A \succeq 0$, factorisation forces $\mathrm{col}(A_{12}) \subseteq \mathrm{col}(A_{11})$.

Theorem 2.2.3. *Sylvester's Criterion*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and let $A \in \mathrm{Mat}(n, n, \mathbb{F})$ satisfy $A = A^*$. Then $A \succ 0$ iff $(\forall\, k \in \{1, \dots, n\})$ $\det A[\{1, \dots, k\}] > 0$.

Proof.
(⇒) The relation $A \succeq 0$ holds by positive definiteness. Fix $k \in \{1, \dots, n\}$ and set $A_k := A[\{1, \dots, k\}]$.
Then $A_k \succ 0$ by Corollary 2.2.2(iv), so $A_k \succeq 0$ by definition and $\det A_k > 0$ by Proposition 2.1.9(iv).
(⇐) Induct on n. If $n = 1$, then $A = [a]$ with $a > 0$, so $A \succ 0$ by definition. Assume $n \geq 2$ and the converse in dimension $n - 1$.
Write $A = \left(\begin{smallmatrix} B & \mathbf{y} \\ \mathbf{y}^* & a \end{smallmatrix}\right)$. Then $B = B^*$ and its leading principal minors are positive, so $B \succ 0$ by the induction hypothesis and B is invertible by Theorem 2.1.8(iii). Set $\delta := a - \mathbf{y}^* B^{-1} \mathbf{y}$. Then $\delta = \frac{\det A}{\det B} > 0$ by Proposition 1.1.8 and leading-minor hypothesis.
For $\mathbf{z} = \left(\begin{smallmatrix} \mathbf{u} \\ t \end{smallmatrix}\right)$, set $\mathbf{w} := \mathbf{u} + B^{-1} \mathbf{y} t$. Then $\mathbf{z}^* A \mathbf{z} = \mathbf{w}^* B \mathbf{w} + \delta\, |t|^2$ by direct expansion. Terms nonnegative by $B \succ 0$, $\delta > 0$.
For $\mathbf{z} \neq \mathbf{0}$, $t \neq 0 \Rightarrow \delta\, |t|^2 > 0$, while $t = 0 \Rightarrow \mathbf{w} = \mathbf{u} \neq \mathbf{0} \Rightarrow \mathbf{w}^* B \mathbf{w} > 0$. Thus $A \succ 0$ by definition.

Structural Commentary: Induction handles the leading block; the Schur complement supplies the final square coefficient.
Key Insight: Positive leading minors make every completed-square pivot positive. □

Computation Method 2.2.4. 2×2 *Quadratic Form Test*
Given a real symmetric matrix $A = \left(\begin{smallmatrix} a & b \\ b & c \end{smallmatrix}\right)$, set $q(x, y) := ax^2 + 2bxy + cy^2$.
The output is the sign classification of q. Set $\Delta := ac - b^2$ and proceed as follows:

(i) If $a \neq 0$, complete the square as $q(x, y) = a\left(x + \frac{b}{a} y\right)^2 + \frac{\Delta}{a} y^2$.
(ii) If $a = 0$ and $c \neq 0$, interchange x and y and repeat part (i); if $a = c = 0$, inspect $q(x, y) = 2bxy$ directly.
(iii) Conclude that $A \succ 0$ iff $a > 0$ and $\Delta > 0$, while $-A \succ 0$ iff $a < 0$ and $\Delta > 0$.

(iv) Conclude that q takes both positive and negative values iff $\Delta < 0$.
(v) If $\Delta = 0$, conclude that $A \succeq 0$ iff $a, c \geq 0$, while $-A \succeq 0$ iff $a, c \leq 0$.

The strict classifications in part (iii) agree with Theorem 2.2.3.
The completed-square and zero-diagonal branches determine parts (iv) and (v).

Theorem 2.2.5. *Principal Axes for Real Quadratic Forms*
Let $n \in \mathbb{Z}_{>0}$ and let $A \in \mathrm{Mat}(n,n,\mathbb{R})$ satisfy $A = A^t$. Set $q_A(\mathbf{x}) := \mathbf{x}^t A \mathbf{x}$.

(i) $(\exists\, Q \in \mathrm{Mat}(n,n,\mathbb{R}))(\exists\, \lambda_1, \ldots, \lambda_n \in \mathbb{R})[Q^t Q = I_n \wedge A = Q\,\mathrm{diag}(\lambda_1, \ldots, \lambda_n) Q^t]$. *Let $Q, \lambda_1, \ldots, \lambda_n$ be any choice satisfying these conditions.*
Then $(\forall\, \mathbf{x} \in \mathbb{R}^n)\, q_A(\mathbf{x}) = \sum_{j=1}^{n} \lambda_j (Q^t \mathbf{x})_j^2$. *Parts (ii)–(iv) are stated with respect to this choice.*
(ii) $A \succeq 0$ *iff* $(\forall\, j \in \{1, \ldots, n\})\, \lambda_j \geq 0$.
(iii) $A \succ 0$ *iff* $(\forall\, j \in \{1, \ldots, n\})\, \lambda_j > 0$.
(iv) q_A *takes both positive and negative values iff* $(\exists\, j, k \in \{1, \ldots, n\})[\lambda_j > 0 \wedge \lambda_k < 0]$.

Proof.
(i) Fix an orthogonal Q_0 and $\mu_1, \ldots, \mu_n \in \mathbb{R}$ with $A = Q_0\,\mathrm{diag}(\mu_1, \ldots, \mu_n) Q_0^t$ by Theorem 6.1.12(i)⇒(iii).
Then $(\forall\, \mathbf{x} \in \mathbb{R}^n)\, q_A(\mathbf{x}) = \sum_{j=1}^{n} \mu_j (Q_0^t \mathbf{x})_j^2$. For parts (ii)–(iv), fix any $Q, \lambda_1, \ldots, \lambda_n$ satisfying part (i).
(ii) (⇒) $(\forall\, j \in \{1, \ldots, n\})\, \lambda_j = q_A(Q\mathbf{e}_j) \geq 0$ by part (i) and $A \succeq 0$.
(ii) (⇐) $(\forall\, \mathbf{x} \in \mathbb{R}^n)\, q_A(\mathbf{x}) \geq 0$ by part (i) and $(\forall\, j \in \{1, \ldots, n\})\, \lambda_j \geq 0$. Thus $A \succeq 0$ by $A = A^t$ and definition.
(iii) (⇒) $(\forall\, j \in \{1, \ldots, n\})\, \lambda_j = q_A(Q\mathbf{e}_j) > 0$ by part (i) and $A \succ 0$.
(iii) (⇐) If $\mathbf{x} \neq \mathbf{0}$, then $Q^t \mathbf{x} \neq \mathbf{0}$ and $q_A(\mathbf{x}) > 0$ by part (i) and $(\forall\, j \in \{1, \ldots, n\})\, \lambda_j > 0$. Thus $A \succ 0$ by $A = A^t$ and definition.
(iv) (⇒) If $\mathbf{u}, \mathbf{v} \in \mathbb{R}^n$ satisfy $q_A(\mathbf{u}) > 0 > q_A(\mathbf{v})$, then $(\exists\, j, k \in \{1, \ldots, n\})[\lambda_j > 0 \wedge \lambda_k < 0]$ by part (i).
(iv) (⇐) If $j, k \in \{1, \ldots, n\}$ satisfy $\lambda_j > 0 > \lambda_k$, then $q_A(Q\mathbf{e}_j) = \lambda_j > 0 > \lambda_k = q_A(Q\mathbf{e}_k)$.
Structural Commentary: Spectral coordinates diagonalise the form; coordinate vectors and the square sum classify its signs.
Key Insight: Each eigenvalue is the form value on its eigenvector. □

Computation Method 2.2.6. *Quadratic Form Principal-Axes Method*
Given a real quadratic form q in n variables, the output is an orthogonal coordinate representation of q and its sign classification.

(i) Write $q(\mathbf{x}) = \mathbf{x}^t A \mathbf{x}$ with $A = A^t$, assigning half of each cross-term coefficient to each of the symmetric entries a_{ij} and a_{ji}.
(ii) Compute an orthogonal diagonalisation $A = Q \Lambda Q^t$.
(iii) Set $\mathbf{y} = Q^t \mathbf{x}$ and rewrite $q(\mathbf{x}) = \sum_{j=1}^{n} \lambda_j y_j^2$.
(iv) Classify the form from the signs of the diagonal entries of Λ by Theorem 2.2.5(ii)–(iv).

Figure 80 illustrates the orthogonal change of coordinates underlying the principal-axes method.

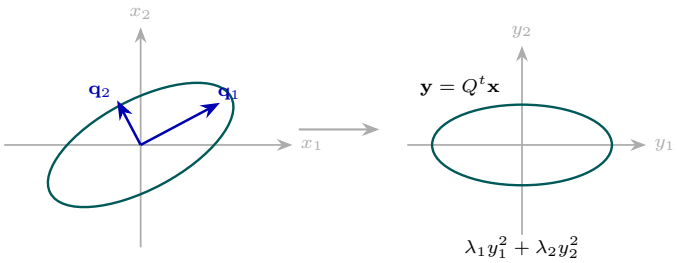

Figure 80: Orthogonal coordinates reveal the principal axes of a quadratic form.

Definition 2.2.7. *$*$-Congruence and Hermitian Inertia*
Let $n \in \mathbb{Z}_{>0}$ and $A, B \in \mathrm{Mat}(n,n,\mathbb{C})$.

(i) The matrices A and B are *$*$-congruent* iff $(\exists\, S \in \mathrm{Mat}(n,n,\mathbb{C})^{\times})\, A = SBS^*$.
(ii) If $A = A^*$, its *inertia* is $\mathrm{in}(A) := (n_+(A), n_-(A), n_0(A))$.
The entries count the positive, negative, and zero eigenvalues, respectively, with algebraic multiplicity.

Lemma 2.2.8. *Positive Subspaces and Inertia*
Let $n \in \mathbb{Z}_{>0}$ and let $A \in \mathrm{Mat}(n,n,\mathbb{C})$ satisfy $A = A^*$.

(i) $\max\{\dim \mathcal{U} : \mathcal{U} \leq \mathbb{C}^n \wedge (\forall\, \mathbf{x} \in \mathcal{U} \setminus \{\mathbf{0}\})\, \mathbf{x}^* A \mathbf{x} > 0\} = n_+(A)$.
(ii) $\max\{\dim \mathcal{U} : \mathcal{U} \leq \mathbb{C}^n \wedge (\forall\, \mathbf{x} \in \mathcal{U} \setminus \{\mathbf{0}\})\, \mathbf{x}^* A \mathbf{x} < 0\} = n_-(A)$.

Proof.
(i) The matrix A is normal by $A = A^*$, and its eigenvalues are real by Theorem 6.1.5.
Let $\mathcal{E}_+$ and $\mathcal{E}_{\leq 0}$ be the orthogonal sums of its positive and nonpositive eigenspaces by Theorem 6.1.11(i)⇒(ii).
Then $\dim \mathcal{E}_+ = n_+(A)$ and $\dim \mathcal{E}_{\leq 0} = n - n_+(A)$.
The inequalities $(\forall\, \mathbf{x} \in \mathcal{E}_+ \setminus \{\mathbf{0}\})\, \mathbf{x}^* A \mathbf{x} > 0$ and $(\forall\, \mathbf{x} \in \mathcal{E}_{\leq 0})\, \mathbf{x}^* A \mathbf{x} \leq 0$ hold by the spectral decomposition.
If $\dim \mathcal{U} > n_+(A)$, then $\mathcal{U} \cap \mathcal{E}_{\leq 0} \neq \{\mathbf{0}\}$ by Corollary 2.3.3(i), so $\mathcal{U}$ is not positive. Thus $\mathcal{E}_+$ attains the maximal dimension $n_+(A)$.
(ii) A subspace is negative for A iff it is positive for $-A$.
Its maximal dimension is $n_+(-A) = n_-(A)$ by part (i) and $(-A)\mathbf{x} = \lambda \mathbf{x} \iff A\mathbf{x} = -\lambda \mathbf{x}$.
Structural Commentary: A spectral sign subspace attains the bound; its complementary sign range obstructs enlargement.
Key Insight: Excess dimension forces intersection with the wrong-sign spectral subspace. □

Theorem 2.2.9. *Sylvester's Inertia Theorem*
Let $n \in \mathbb{Z}_{>0}$ and let $A, B \in \mathrm{Mat}(n, n, \mathbb{C})$ be Hermitian. Then A and B are $*$-congruent iff $n_+(A) = n_+(B)$ and $n_-(A) = n_-(B)$.

Proof.
($\Rightarrow$) Suppose $A = SBS^*$ with S invertible. The map S^* preserves subspace dimension and satisfies $(S^*\mathbf{x})^*B(S^*\mathbf{x}) = \mathbf{x}^*A\mathbf{x}$.
Thus $n_+(A) \le n_+(B)$ and $n_-(A) \le n_-(B)$ by Lemma 2.2.8.
The reverse inequalities hold by the same lemma and $B = S^{-1}A(S^{-1})^*$, so $n_+(A) = n_+(B)$ and $n_-(A) = n_-(B)$.
($\Leftarrow$) Set $p := n_+(A) = n_+(B)$, $q := n_-(A) = n_-(B)$, $r := n - p - q$, and $D := I_p \oplus (-I_q) \oplus 0_r$.
Fix $M \in \{A, B\}$. The matrix M is normal by $M = M^*$ and its eigenvalues are real by Theorem 6.1.5.
Order them as $\lambda_1^{(M)}, \dots, \lambda_n^{(M)}$ by positive, negative, and zero sign. Set $\Lambda_M := \mathrm{diag}(\lambda_1^{(M)}, \dots, \lambda_n^{(M)})$.
Fix a unitary U_M with $M = U_M \Lambda_M U_M^*$ by Theorem 6.1.11(i)$\Rightarrow$(iii). Set $d_j^{(M)} := \sqrt{\left|\lambda_j^{(M)}\right|}$ for $\lambda_j^{(M)} \neq 0$ and $d_j^{(M)} := 1$ otherwise.
Put $E_M := \mathrm{diag}(d_1^{(M)}, \dots, d_n^{(M)})$ and $R_M := U_M E_M$. Then R_M is invertible, $\Lambda_M = E_M D E_M$, and $M = R_M D R_M^*$.
The construction defines R_A, R_B. For $S := R_A R_B^{-1}$, $SBS^* = R_A D R_A^* = A$, so A and B are $*$-congruent.
Structural Commentary: Sign-subspace transport proves invariance; spectral rescaling constructs the shared signed diagonal form.
Key Insight: $I_p \oplus (-I_q) \oplus 0_r$ is the complete $*$-congruence invariant. □

Figure 81 summarizes the $*$-congruence reduction to positive, negative, and zero coordinate directions.

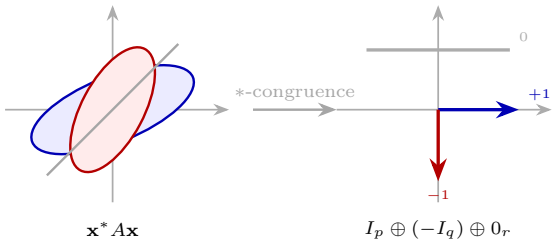

Figure 81: $*$-congruence reduces a Hermitian form to signed coordinate axes.

2.3 Hermitian and Normal Matrix Structure

Theorem 2.3.1. *Simultaneous Congruence with One Positive Definite Form*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$ satisfy $A = A^*$, $B = B^*$, and $A \succ 0$.
Then $(\exists\, S \in \mathrm{Mat}(n, n, \mathbb{F})^\times)(\exists\, \lambda_1, \dots, \lambda_n \in \mathbb{R})$ such that, for $\Lambda := \mathrm{diag}(\lambda_1, \dots, \lambda_n)$:
(i) $A = SS^*$ and $B = S\Lambda S^*$.
(ii) $p_{A^{-1}B}(z) = \prod_{j=1}^{n} (z - \lambda_j)$.

Proof. Choose an invertible T with $A = TT^*$ by Theorem 2.1.8(iv), and set $C := T^{-1}B(T^*)^{-1}$.
The identity $C^* = C$ holds by Propositions 2.3.8(ii),(iii) and 2.3.9(i). Thus C is self-adjoint and normal.
If $\mathbb{F} = \mathbb{R}$, choose a unitary U and diagonal Λ with $C = U\Lambda U^*$ by Theorem 6.1.12(i)$\Rightarrow$(iii).
If $\mathbb{F} = \mathbb{C}$, make the same choice by Theorem 6.1.11(i)$\Rightarrow$(iii).
Its diagonal entries are real automatically over $\mathbb{R}$ and by Theorem 6.1.5 over $\mathbb{C}$.
Write $\Lambda = \mathrm{diag}(\lambda_1, \dots, \lambda_n)$ with $\lambda_1, \dots, \lambda_n \in \mathbb{R}$, and set $S := TU$.
(i) The matrix S is invertible, and $SS^* = TUU^*T^* = A$ and $S\Lambda S^* = TCT^* = B$.
(ii) The identity $A^{-1}B = (S^*)^{-1}\Lambda S^*$ holds by part (i).
Hence $p_{A^{-1}B} = p_\Lambda$ by Theorem 2.1.7(i). The identity $p_\Lambda(z) = \prod_{j=1}^{n} (z - \lambda_j)$ holds by Proposition 2.1.6(i).
Structural Commentary: The Gram factor turns simultaneous congruence into one self-adjoint diagonalization.
Key Insight: Diagonalizing C once produces both S and the generalized eigenvalues. □

Corollary 2.3.2. *Products with One Positive Definite Factor*
Let $n \in \mathbb{Z}_{>0}$, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$ satisfy $A \succ 0$.
(i) If $B = B^*$, then AB is diagonalizable over $\mathbb{F}$ and $\mathrm{spec}(AB) \subseteq \mathbb{R}$.
(ii) If $B \succeq 0$, then AB is diagonalizable over $\mathbb{F}$ and $\mathrm{spec}(AB) \subseteq [0, \infty)$.
(iii) If $B \succeq 0$ and $B \neq 0$, then $(\exists\, \lambda \in \mathrm{spec}(AB))\, \lambda > 0$.
(iv) If $B \succ 0$, then AB is diagonalizable over $\mathbb{F}$ and $\mathrm{spec}(AB) \subseteq (0, \infty)$.

Proof. The matrix $A^{-1} \succ 0$ by Theorem 2.1.8(i)$\Rightarrow$(v). If $B = B^*$, choose S and Λ by Theorem 2.3.1 for (A^{-1}, B).
Write $\Lambda = \mathrm{diag}(\lambda_1, \dots, \lambda_n)$, where $\lambda_1, \dots, \lambda_n \in \mathbb{R}$, S invertible. Then $A^{-1} = SS^*$ and $B = S\Lambda S^*$, so $AB = (S^*)^{-1}\Lambda S^*$.
(i) The identity $AB = (S^*)^{-1}\Lambda S^*$ diagonalizes AB over $\mathbb{F}$ with real eigenvalues $\lambda_1, \dots, \lambda_n$.
(ii) The identity $B = B^*$ holds by positive semidefiniteness, so part (i) applies.
Set $\mathbf{x}_j := (S^*)^{-1}\mathbf{e}_j$ for $j \in \{1, \dots, n\}$. Then $(\forall\, j \in \{1, \dots, n\})\, \lambda_j = \mathbf{x}_j^* B \mathbf{x}_j \ge 0$.
(iii) By parts (i) and (ii), $\mathrm{spec}(AB) = \{\lambda_1, \dots, \lambda_n\} \subseteq [0, \infty)$. Since $B = S\Lambda S^* \neq 0$, one has $\Lambda \neq 0$, so $(\exists\, \lambda \in \mathrm{spec}(AB))\, \lambda > 0$.
(iv) The identity $B = B^*$ holds by positive definiteness, so part (i) applies. Set $\mathbf{x}_j := (S^*)^{-1}\mathbf{e}_j$ for $j \in \{1, \dots, n\}$.
Since S is invertible, $(\forall\, j \in \{1, \dots, n\})[\mathbf{x}_j \neq \mathbf{0} \wedge \lambda_j = \mathbf{x}_j^* B \mathbf{x}_j > 0]$.
Structural Commentary: The simultaneous form of (A^{-1}, B) makes AB similar to the same real diagonal matrix.
Key Insight: Its eigenvalue signs are the quadratic-form signs of B on transformed coordinate vectors. □

Definition 2.3.3. *Phase Inertia Matrix*
Let $n \in \mathbb{Z}_{>0}$ and $D = [d_{jk}] \in \mathrm{Mat}(n, n, \mathbb{C})$. The matrix D is a *phase inertia matrix* iff D is diagonal and $(\forall\, j \in \{1, \dots, n\})\ |d_{jj}| \in \{0, 1\}$.

Proposition 2.3.4. *Phase Inertia Form for Normal Matrices*
Let $n \in \mathbb{Z}_{>0}$ and let $A \in \mathrm{Mat}(n,n,\mathbb{C})$ be normal. Let $\lambda_1,\dots,\lambda_n$ list its eigenvalues with algebraic multiplicity. For $j \in \{1,\dots,n\}$, set $d_j := 0$ if $\lambda_j = 0$ and $d_j := \frac{\lambda_j}{|\lambda_j|}$ otherwise. Put $D := \mathrm{diag}(d_1,\dots,d_n)$.

(i) D is a phase inertia matrix.
(ii) $(\exists\, S \in \mathrm{Mat}(n,n,\mathbb{C})^\times)\ A = SDS^*$.

Proof.
(i) By the definition of d_j, $(\forall\, j \in \{1,\dots,n\})\ |d_j| \in \{0,1\}$. Hence D is a phase inertia matrix.
(ii) Set $L := \mathrm{diag}(\lambda_1,\dots,\lambda_n)$. After permuting its eigenbasis, choose a unitary U with $A = ULU^*$ by Theorem 6.1.11(i)⇒(iii).
For $j \in \{1,\dots,n\}$, set $r_j := 1$ if $\lambda_j = 0$ and $r_j := |\lambda_j|$ otherwise. Then $(\forall\, j \in \{1,\dots,n\})[r_j > 0 \wedge r_j d_j = \lambda_j]$.
Set $S := U\,\mathrm{diag}(\sqrt{r_1},\dots,\sqrt{r_n})$. Then S is invertible and $SDS^* = U\,\mathrm{diag}(r_1 d_1,\dots,r_n d_n)U^* = A$.
Structural Commentary: Spectral diagonalization separates phase from positive radius, which the congruence factor absorbs.
Key Insight: Radial square roots provide the diagonal scaling in S. □

Perspective 2.3.5. *Hermitian Inertia as Real Phase Inertia*
Proposition 2.3.4 reduces a normal matrix to its eigenvalue phases under $*$-congruence.
Hermitian eigenvalues are real by Theorem 6.1.5, so their nonzero phases are ± 1;
Theorem 2.2.9 strengthens this reduction to a complete classification by sign multiplicities.

3 Matrix Products, Vectorization, and Spectral Radius

3.1 Kronecker Products and Vectorization

Throughout, $\mathbb{F}$ denotes a field.

Definition 3.1.1. *Kronecker Product*
Let $m,n,p,q \in \mathbb{Z}_{>0}$, $A = [a_{ij}] \in \mathrm{Mat}(m,n,\mathbb{F})$, and $B \in \mathrm{Mat}(p,q,\mathbb{F})$.
The *Kronecker product*, or *matrix tensor product*, is the block matrix $A \otimes B := [a_{ij}B]_{i\in J_m, j\in J_n} \in \mathrm{Mat}(mp,nq,\mathbb{F})$.

Proposition 3.1.2. *Basic Kronecker Identities*
Let $m,n,p,q,r,s \in \mathbb{Z}_{>0}$, $c \in \mathbb{F}$, and $A, A' \in \mathrm{Mat}(m,n,\mathbb{F})$.
Let $B, B' \in \mathrm{Mat}(p,q,\mathbb{F})$ and $C \in \mathrm{Mat}(r,s,\mathbb{F})$.

(i) $c(A\otimes B) = (cA)\otimes B = A\otimes(cB)$;
(ii) $(A+A')\otimes B = A\otimes B + A'\otimes B$ and $A\otimes(B+B') = A\otimes B + A\otimes B'$;
(iii) $(A\otimes B)\otimes C = A\otimes(B\otimes C)$;
(iv) $(A\otimes B)^t = A^t \otimes B^t$;
(v) $I_m \otimes I_p = I_{mp}$;
(vi) If $\mathbb{F} = \mathbb{C}$, then $\overline{A\otimes B} = \overline{A}\otimes\overline{B}$ and $(A\otimes B)^* = A^*\otimes B^*$.

Proof. Write $A = [a_{ij}]$ and $B = [b_{uv}]$.
(i) The corresponding blocks in the three matrices are $c(a_{ij}B) = (ca_{ij})B = a_{ij}(cB)$.
(ii) For $A' = [a'_{ij}]$, $(a_{ij}+a'_{ij})B = a_{ij}B + a'_{ij}B$ and $a_{ij}(B+B') = a_{ij}B + a_{ij}B'$.
(iii) Write $C = [c_{\alpha\beta}]$. Under lexicographic indexing, the $((i,u,\alpha),(j,v,\beta))$ entry of each side is $a_{ij}b_{uv}c_{\alpha\beta}$.
(iv) The corresponding (j,i) blocks are $(a_{ij}B)^t = a_{ij}B^t$.
(v) The diagonal blocks of $I_m \otimes I_p$ are I_p, and its other blocks are zero; hence $I_m\otimes I_p = I_{mp}$.
(vi) Suppose $\mathbb{F} = \mathbb{C}$. The first identity holds by blockwise conjugation. By part (iv), $(A\otimes B)^* = (\overline{A}\otimes\overline{B})^t = \overline{A}^{\,t}\otimes\overline{B}^{\,t} = A^*\otimes B^*$.
Structural Commentary: Entry factorization handles linearity, reindexing, and adjoints uniformly.
Key Insight: Each Kronecker entry is a product $a_{ij}b_{uv}$. □

Theorem 3.1.3. *Mixed Product Property*
Let $m,n,p,q,r,s \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(m,n,\mathbb{F})$. Let $B \in \mathrm{Mat}(p,q,\mathbb{F})$ and $C \in \mathrm{Mat}(n,r,\mathbb{F})$.
Let $D \in \mathrm{Mat}(q,s,\mathbb{F})$. Then $(A\otimes B)(C\otimes D) = (AC)\otimes(BD)$.

Proof. Write $A = [a_{ik}]$ and $C = [c_{kj}]$, and fix $(i,j) \in J_m \times J_r$.
The (i,j) block of $(A\otimes B)(C\otimes D)$ is $\sum_{k=1}^{n}(a_{ik}B)(c_{kj}D) = \left(\sum_{k=1}^{n} a_{ik}c_{kj}\right)BD = (AC)_{ij}BD$.
This is the corresponding block of $(AC)\otimes(BD)$, so the matrices are equal.
Structural Commentary: Block multiplication separates the contracted index from the factor product BD.
Key Insight: The k-sum is the (i,j) entry of AC. □

Corollary 3.1.4. *Inverse of a Kronecker Product*
Let $m,n \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(m,m,\mathbb{F})^\times$, and $B \in \mathrm{Mat}(n,n,\mathbb{F})^\times$. Then $A\otimes B \in \mathrm{Mat}(mn,mn,\mathbb{F})^\times$ and $(A\otimes B)^{-1} = A^{-1}\otimes B^{-1}$.

Proof. Set $K := A^{-1}\otimes B^{-1}$. The identity $(A\otimes B)K = (AA^{-1})\otimes(BB^{-1}) = I_{mn}$ holds by Theorem 3.1.3 and Proposition 3.1.2(v).
The identity $K(A\otimes B) = (A^{-1}A)\otimes(B^{-1}B) = I_{mn}$ holds by the same theorem and proposition.
Structural Commentary: The mixed-product law verifies both inverse equations factorwise.
Key Insight: The two-sided inverse is $A^{-1}\otimes B^{-1}$. □

Proposition 3.1.5. *Kronecker Product and Sum Spectra in the Diagonalizable Case*
Let $n,q \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(n,n,\mathbb{F})$, and $B \in \mathrm{Mat}(q,q,\mathbb{F})$. Let $P \in \mathrm{Mat}(n,n,\mathbb{F})^\times$ and $Q \in \mathrm{Mat}(q,q,\mathbb{F})^\times$.
Let $\lambda_1,\dots,\lambda_n \in \mathbb{F}$ and $\mu_1,\dots,\mu_q \in \mathbb{F}$. Set $\Lambda := \mathrm{diag}(\lambda_1,\dots,\lambda_n)$ and $M := \mathrm{diag}(\mu_1,\dots,\mu_q)$. Suppose $A = P\Lambda P^{-1}$ and $B = QMQ^{-1}$.

(i) $A\otimes B \sim \Lambda\otimes M$.
(ii) $A\otimes I_q + I_n\otimes B \sim \Lambda\otimes I_q + I_n\otimes M$.
(iii) $\mathrm{spec}(A\otimes B) = \{\lambda_i\mu_j : (i,j) \in J_n\times J_q\}$.
(iv) $\mathrm{spec}(A\otimes I_q + I_n\otimes B) = \{\lambda_i+\mu_j : (i,j)\in J_n\times J_q\}$.

Proof. Set $R := P \otimes Q$. Then $R \in \mathrm{Mat}(nq, nq, \mathbb{F})^\times$ and $R^{-1} = P^{-1} \otimes Q^{-1}$ by Corollary 3.1.4.

(i) The identity $A \otimes B = R(\Lambda \otimes M)R^{-1}$ holds by Theorem 3.1.3. Hence $A \otimes B \sim \Lambda \otimes M$.
(ii) By distributivity and Theorem 3.1.3, $A \otimes I_q + I_n \otimes B = R(\Lambda \otimes I_q + I_n \otimes M)R^{-1}$. Hence $A \otimes I_q + I_n \otimes B \sim \Lambda \otimes I_q + I_n \otimes M$.
(iii) The matrix $\Lambda \otimes M$ is diagonal with entries $(\lambda_i \mu_j)_{(i,j)\in J_n \times J_q}$.
Thus $\mathrm{spec}(A \otimes B) = \{\lambda_i \mu_j : (i,j) \in J_n \times J_q\}$ by part (i) and Theorem 2.1.7(i).
(iv) The matrix $\Lambda \otimes I_q + I_n \otimes M$ is diagonal with entries $(\lambda_i + \mu_j)_{(i,j)\in J_n \times J_q}$.
Thus $\mathrm{spec}(A \otimes I_q + I_n \otimes B) = \{\lambda_i + \mu_j : (i,j) \in J_n \times J_q\}$ by part (ii) and Theorem 2.1.7(i).

Structural Commentary: The similarity $P \otimes Q$ transfers product and sum to diagonal coordinates.
Key Insight: Paired diagonal entries multiply for products and add for sums. □

For $r \in \mathbb{Z}_{>0}$, set $T_r := \mathrm{tridiag}(-1, 2, -1) \in \mathrm{Mat}(r, r, \mathbb{R})$.
For $(m, n) \in \mathbb{Z}^2_{>0}$, Figure 82 depicts the interior stencil of $T_m \otimes I_n + I_m \otimes T_n$.
The two summands act in the vertical and horizontal coordinate directions, respectively.

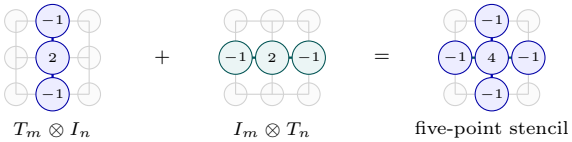

Figure 82: The two tridiagonal factors combine into center weight 4 and four neighboring weights −1.

Definition 3.1.6. *Vectorisation*
Let $m, n \in \mathbb{Z}_{>0}$ and $X = [\mathbf{x}_1 \ \mathbf{x}_2 \ \cdots \ \mathbf{x}_n] \in \mathrm{Mat}(m, n, \mathbb{F})$. The *vectorisation map* is $\mathrm{vec}\colon \mathrm{Mat}(m, n, \mathbb{F}) \to \mathbb{F}^{mn}$.
For X as above, $\mathrm{vec}(X) := (\mathbf{x}_1^t \ \cdots \ \mathbf{x}_n^t)^t$.

Theorem 3.1.7. *Vectorisation of a Triple Product*
Let $m, n, p, q \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(m, n, \mathbb{F})$. Let $X \in \mathrm{Mat}(n, p, \mathbb{F})$ and $B \in \mathrm{Mat}(p, q, \mathbb{F})$. Then $\mathrm{vec}(AXB) = (B^t \otimes A)\,\mathrm{vec}(X)$.

Proof. Write $B = [b_{ik}] = [\mathbf{b}_1 \ \cdots \ \mathbf{b}_q]$ and $X = [\mathbf{x}_1 \ \cdots \ \mathbf{x}_p]$.
For $k \in J_q$, the kth block on each side is $AX\mathbf{b}_k = \sum_{i=1}^{p} b_{ik} A\mathbf{x}_i$; hence the vectors are equal.

Structural Commentary: Column stacking matches the kth block with the kth column of AXB.
Key Insight: Both blocks equal $\sum_{i=1}^{p} b_{ik} A\mathbf{x}_i$. □

Perspective 3.1.8. *Vectorising a Minimal-Polynomial Test*
The candidate step in Method 3.2.3 admits a vectorised form. Fix $n \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$, and $m \in \{1, \ldots, n^2\}$.
For $(a_0, \ldots, a_{m-1}) \in \mathbb{F}^m$, set $p_m(z) := a_0 + a_1 z + \cdots + a_{m-1} z^{m-1} + z^m$. Set $V_m(A) := [\mathrm{vec}(I_n) \ \mathrm{vec}(A) \ \cdots \ \mathrm{vec}(A^{m-1})] \in \mathrm{Mat}(n^2, m, \mathbb{F})$.
Set $\mathbf{a} := (a_0, \ldots, a_{m-1})^t$. Then $p_m(A) = 0 \iff V_m(A)\mathbf{a} = -\mathrm{vec}(A^m)$.
Structural Commentary: Vectorisation turns the candidate equation into an $n^2 \times m$ scalar system.
Key Insight: Its columns are vectorised matrix powers.

3.2 Hadamard Products

Throughout this subsection, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.

Definition 3.2.1. *Hadamard Product*
Let $m, n \in \mathbb{Z}_{>0}$ and $A = [a_{ij}], B = [b_{ij}] \in \mathrm{Mat}(m, n, \mathbb{F})$.
The *Hadamard product*, or *entrywise product*, of A and B is $A \circ B := [a_{ij} b_{ij}] \in \mathrm{Mat}(m, n, \mathbb{F})$.

Proposition 3.2.2. *Basic Hadamard Identities*
Let $m, n \in \mathbb{Z}_{>0}$, $\gamma \in \mathbb{F}$, and $A = [a_{ij}], B = [b_{ij}], C = [c_{ij}] \in \mathrm{Mat}(m, n, \mathbb{F})$. Set $E := [1]_{i\in J_m, j\in J_n} \in \mathrm{Mat}(m, n, \mathbb{F})$.

(i) $A \circ B = B \circ A$;
(ii) $A \circ (\gamma B + C) = \gamma(A \circ B) + A \circ C$;
(iii) $(A \circ B)^* = A^* \circ B^*$;
(iv) $A \circ E = A$;
(v) if $m = n$, $d_1, \ldots, d_n \in \mathbb{F}$, and $D = \mathrm{diag}(d_1, \ldots, d_n)$, then $A \circ D = \mathrm{diag}(a_{11}d_1, \ldots, a_{nn}d_n)$.

Proof. Fix $(i, j) \in J_m \times J_n$.

(i) $(A \circ B)_{ij} = a_{ij} b_{ij} = b_{ij} a_{ij} = (B \circ A)_{ij}$.
(ii) $\big(A \circ (\gamma B + C)\big)_{ij} = a_{ij}(\gamma b_{ij} + c_{ij}) = \gamma(A \circ B)_{ij} + (A \circ C)_{ij}$.
(iii) $\big((A \circ B)^*\big)_{ji} = \overline{a_{ij} b_{ij}} = \overline{a_{ij}}\,\overline{b_{ij}} = (A^* \circ B^*)_{ji}$.
(iv) $(A \circ E)_{ij} = a_{ij} = A_{ij}$.
(v) If $m = n$, then $(A \circ D)_{ij} = a_{ij} D_{ij}$ equals $a_{ii} d_i$ if $i = j$ and 0 otherwise.

Structural Commentary: A fixed entry reduces (i)–(iv) to scalar arithmetic; (v) holds by the support of D.
Key Insight: No summation couples distinct coordinate pairs. □

Theorem 3.2.3. *Schur Product Theorem*
Let $n \in \mathbb{Z}_{>0}$ and $A = [a_{ij}], B = [b_{ij}] \in \mathrm{Mat}(n, n, \mathbb{F})$ satisfy $A \succeq 0$ and $B \succeq 0$. Then $A \circ B \succeq 0$.

Proof. Set $R := A^{1/2}$ and $S := B^{1/2}$; then $A = R^2 = R^*R$ and $B = S^2 = S^*S$ by Corollary 2.1.4(i).
Write $R = [\mathbf{u}_1 \ \cdots \ \mathbf{u}_n]$, $S = [\mathbf{v}_1 \ \cdots \ \mathbf{v}_n]$, and set $(\mathbf{w}_j)_{j=1}^n := (\mathbf{u}_j \otimes \mathbf{v}_j)_{j=1}^n$. $(\forall\, i \in J_n)\ \mathbf{w}_i^* = \mathbf{u}_i^* \otimes \mathbf{v}_i^*$ by Proposition 3.1.2(iv),(vi).
$(\forall\, (i,j) \in J_n^2)\ \mathbf{w}_i^*\mathbf{w}_j = (\mathbf{u}_i^*\mathbf{u}_j)(\mathbf{v}_i^*\mathbf{v}_j) = a_{ij}b_{ij} = (A \circ B)_{ij}$ by Theorem 3.1.3.
$A \circ B = \operatorname{Gram}(\mathbf{w}_1, \dots, \mathbf{w}_n) \succeq 0$ by the preceding identity and Proposition 1.5.3(i),(ii).
Structural Commentary: Gram factorizations and the mixed-product law identify $A \circ B$ as a Gram matrix.
Key Insight: The jth tensor column multiplies the two ij-Gram entries. □

Figure 83 records the Gram-to-Gram transfer from paired tensor vectors to the Hadamard product.

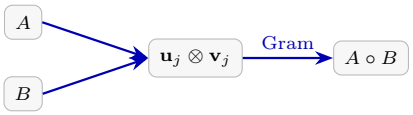

Figure 83: The paired vectors $\mathbf{u}_j \otimes \mathbf{v}_j$ form a Gram representation of $A \circ B$.

Corollary 3.2.4. *Positive Definite Hadamard Products*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \operatorname{Mat}(n,n,\mathbb{F})$, $B = [b_{ij}] \in \operatorname{Mat}(n,n,\mathbb{F})$ satisfy $A \succeq 0$ and $B \succeq 0$.
(i) If $A \succ 0$ and $(\forall\, j \in J_n)\ b_{jj} > 0$, then $A \circ B \succ 0$.
(ii) If $A \succ 0$ and $B \succ 0$, then $A \circ B \succ 0$.

Proof.
(i) By Theorem 2.1.8(ii), set $\lambda_{\min} := \min \operatorname{spec}(A) > 0$.
Then $A - \lambda_{\min} I_n \succeq 0$ by Theorem 2.1.3(ii) and $\operatorname{spec}(A - \lambda_{\min} I_n) = \{\lambda - \lambda_{\min} : \lambda \in \operatorname{spec}(A)\} \subseteq [0, \infty)$.
Set $C := (A - \lambda_{\min} I_n) \circ B$. Then $C \succeq 0$ by Theorem 3.2.3. Fix $\mathbf{x} = (x_1, \dots, x_n)^t \in \mathbb{F}^n \setminus \{\mathbf{0}\}$.
The identity $\mathbf{x}^*(A \circ B)\mathbf{x} = \mathbf{x}^* C \mathbf{x} + \lambda_{\min} \sum_{j=1}^n b_{jj} |x_j|^2$ holds by Proposition 3.2.2(i),(ii),(v).
Its right side is positive by $C \succeq 0$, $\lambda_{\min} > 0$, the diagonal hypothesis, and $\mathbf{x} \neq \mathbf{0}$.
$A \circ B \succ 0$ by Theorem 3.2.3, the preceding strict inequality, and arbitrariness of $\mathbf{x}$.
(ii) The hypothesis in (i), $(\forall\, j \in J_n)\ b_{jj} = \mathbf{e}_j^* B \mathbf{e}_j > 0$, holds by $B \succ 0$. $A \circ B \succ 0$ by (i).
Structural Commentary: A spectral-floor split separates a semidefinite Hadamard term from a positive diagonal term.
Key Insight: $I_n \circ B = \operatorname{diag}(b_{11}, \dots, b_{nn})$ transfers diagonal positivity. □

Proof Method 3.2.5. *Hadamard-Product Positivity Certificate*
Let $n \in \mathbb{Z}_{>0}$ and $X, Y \in \operatorname{Mat}(n,n,\mathbb{F})$ satisfy $X \succeq 0$ and $Y \succeq 0$. The following steps construct a Gram certificate for $X \circ Y \succeq 0$:
(i) set $R := X^{1/2}$ and $S := Y^{1/2}$; then $X = R^2 = R^*R$ and $Y = S^2 = S^*S$ by Corollary 2.1.4(i);
(ii) write $R = [\mathbf{u}_1 \ \cdots \ \mathbf{u}_n]$, $S = [\mathbf{v}_1 \ \cdots \ \mathbf{v}_n]$, and set $(\mathbf{w}_j)_{j=1}^n := (\mathbf{u}_j \otimes \mathbf{v}_j)_{j=1}^n$;
(iii) verify $(\forall\, (i,j) \in J_n^2)\ (X \circ Y)_{ij} = \mathbf{w}_i^*\mathbf{w}_j$ by Proposition 3.1.2(iv),(vi) and Theorem 3.1.3;
(iv) return $X \circ Y = \operatorname{Gram}(\mathbf{w}_1, \dots, \mathbf{w}_n) \succeq 0$ by Proposition 1.5.3(i),(ii).

3.3 Spectral Radius and Matrix Powers

Throughout this subsection, $\mathbb{F}$ is a field.

Theorem 3.3.1. *Ranks of Matrix Powers Stabilize*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \operatorname{Mat}(n,n,\mathbb{F})$. Then:
(i) $(\forall\, k \in \mathbb{Z}_{>0})\ \operatorname{rank}(A^k) \geq \operatorname{rank}(A^{k+1})$;
(ii) if $k \in \mathbb{Z}_{>0}$ and $\operatorname{rank}(A^k) = \operatorname{rank}(A^{k+1})$, then $(\forall\, p \in \mathbb{Z}_{>0})\ \big[\operatorname{col}(A^k) = \operatorname{col}(A^{k+p}) \ \wedge\ \operatorname{rank}(A^k) = \operatorname{rank}(A^{k+p})\big]$;
(iii) if A is not invertible, then $\min\{q \in \mathbb{Z}_{>0} : \operatorname{rank}(A^q) = \operatorname{rank}(A^{q+1})\} \in J_n$.

Proof.
(i) Fix $k \in \mathbb{Z}_{>0}$. Then $\operatorname{col}(A^{k+1}) \subseteq \operatorname{col}(A^k)$ by $A^{k+1} = A^k A$, and the rank inequality holds by taking dimensions.
(ii) Fix $k \in \mathbb{Z}_{>0}$ with $\operatorname{rank}(A^k) = \operatorname{rank}(A^{k+1})$, and set $U := \operatorname{col}(A^k)$.
The identities $U = \operatorname{col}(A^{k+1})$ and $A(U) = U$ hold by part (i), equality of dimensions, and $AA^k = A^{k+1}$.
$(\forall\, p \in \mathbb{Z}_{>0})\ \operatorname{col}(A^{k+p}) = U$ by induction; the rank identities hold by taking dimensions.
(iii) $\operatorname{rank}(A) \leq n - 1$ by Corollary 3.6.2 and noninvertibility.
If $(\forall\, q \in J_n)\ \operatorname{rank}(A^q) > \operatorname{rank}(A^{q+1})$, then $\operatorname{rank}(A^{n+1}) \leq \operatorname{rank}(A) - n \leq -1$, contradicting nonnegativity of rank.
The relation $(\exists\, q \in J_n)\ \operatorname{rank}(A^q) = \operatorname{rank}(A^{q+1})$ holds by this contradiction.
The minimum in (iii) belongs to J_n by this witness and well-ordering.
Structural Commentary: Nested column spaces and dimension equality create an invariant image; finite dimension forces stabilization.
Key Insight: Each strict rank drop consumes at least one dimension. □

Definition 3.3.2. *Index of a Matrix*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \operatorname{Mat}(n,n,\mathbb{F})$.
(i) If A is invertible, its *index* is 0.
(ii) If A is not invertible, its *index* is $\min\{q \in \mathbb{Z}_{>0} : \operatorname{rank}(A^q) = \operatorname{rank}(A^{q+1})\}$.

Definition 3.3.3. *Spectral Radius and Convergent Matrix*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \operatorname{Mat}(n,n,\mathbb{C})$.
(i) The *spectral radius* is $\rho(A) := \max_{\lambda \in \operatorname{spec}(A)} |\lambda|$.
(ii) The notation $A^p \to 0$ means $(\forall\, (i,j) \in J_n^2)\ \lim_{p \to \infty} (A^p)_{ij} = 0$.

Proposition 3.3.4. *Basic Invariants of Nilpotents*
Let $n \in \mathbb{Z}_{>0}$ and $N \in \mathrm{Mat}(n, n, \mathbb{F})$. The following are equivalent:

(i) *N is nilpotent;*
(ii) *the characteristic polynomial of N is z^n;*
(iii) *$N^n = 0$.*

Under these equivalent conditions, $\mathrm{tr}(N) = \det(N) = 0$ and, if $\mathbb{F} = \mathbb{C}$, $\rho(N) = 0$.

Proof.

(i) $\Rightarrow$ *(ii)* By nilpotency, choose $r \in \mathbb{Z}_{>0}$ satisfying $N^r = 0$.
Every eigenvalue λ over an algebraic closure equals 0 by $\lambda^r \mathbf{v} = N^r \mathbf{v} = \mathbf{0}$ for an associated $\mathbf{v} \neq \mathbf{0}$.
$p_N(z) = z^n$ by complete splitting and Theorem 2.1.3(i).
(ii) $\Rightarrow$ *(iii)* $p_N(N) = N^n = 0$ by Theorem 3.1.1.
(iii) $\Rightarrow$ *(i)* Matrix N is nilpotent by $N^n = 0$.

Assume the equivalent conditions. The identities $\mathrm{tr}(N) = \det(N) = 0$ hold by $p_N(z) = z^n$ and Theorem 2.1.3(i).
If $\mathbb{F} = \mathbb{C}$, then $\mathrm{spec}(N) = \{0\}$ by Theorem 2.1.3(ii), and $\rho(N) = 0$ by the spectral-radius formula.
Structural Commentary: Eigenvalue collapse identifies p_N; Cayley–Hamilton and its coefficients recover the remaining invariants.
Key Insight: Vanishing eigenvalues precede the uniform exponent $N^n = 0$. □

Theorem 3.3.5. *Matrix Powers Converge to Zero*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(n, n, \mathbb{C})$. Then $A^p \to 0$ if and only if $\rho(A) < 1$.

Proof. By Theorem 6.2.1, choose $S \in \mathrm{Mat}(n, n, \mathbb{C})^\times$ and a Jordan matrix J satisfying $A = SJS^{-1}$.
$A^p \to 0 \iff J^p \to 0$ by $A^p = SJ^pS^{-1}$, $J^p = S^{-1}A^pS$, and finite sums.
The convergence $J^p \to 0$ is equivalent to convergence of each Jordan block power by the block-diagonal structure of J.
$(\Rightarrow)$ $\rho(A) = \max_{\lambda \in \mathrm{spec}(A)} |\lambda| < 1$ by the block reduction and Proposition 6.1.5(ii).
$(\Leftarrow)$ Each Jordan block power tends to 0 by $\rho(A) < 1$ and Proposition 6.1.5(ii). $A^p \to 0$ by the two reductions above.
Structural Commentary: Similarity transfers entrywise convergence to block powers, which reduce it to eigenvalue moduli.
Key Insight: Geometric decay dominates each fixed polynomial superdiagonal factor. □

Figure 84 depicts the Jordan-block threshold at the unit circle.

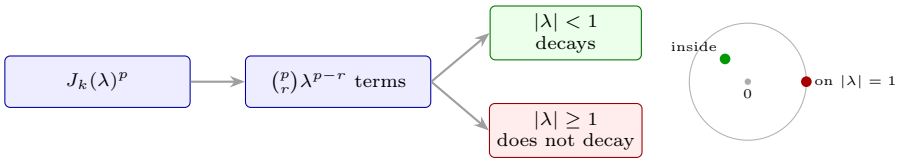

Figure 84: Jordan block powers decay for $|\lambda| < 1$, but not on or outside the gray unit circle.

Definition 3.3.6. *Power Bounded Matrix*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(n, n, \mathbb{C})$. The matrix A is *power bounded* if $(\forall\, (i, j) \in J_n^2) \sup_{p \in \mathbb{Z}_{>0}} |(A^p)_{ij}| < \infty$.

Theorem 3.3.7. *Power Bounded Jordan Criterion*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(n, n, \mathbb{C})$. The following are equivalent:

(i) *A is power bounded.*
(ii) *$\rho(A) \leq 1$, and Jordan blocks associated with eigenvalues of modulus 1 have size 1.*
(iii) *$\rho(A) \leq 1$, and $(\forall\, \lambda \in \mathrm{spec}(A))\ \big(|\lambda| = 1 \Longrightarrow \dim E_\lambda(A) = m_A(\lambda)\big)$.*

Proof. By Theorem 6.2.1, choose $S \in \mathrm{Mat}(n, n, \mathbb{C})^\times$ and a Jordan matrix J satisfying $A = SJS^{-1}$.
Power boundedness of A and J is equivalent by $A^p = SJ^pS^{-1}$, $J^p = S^{-1}A^pS$, and entrywise fixed finite linear combinations.

(i) $\Rightarrow$ *(ii)* The matrix J is power bounded by (i) and the fixed-similarity equivalence.
A block with $|\lambda| > 1$ is excluded by its unbounded diagonal sequence $(\lambda^p)_{p \geq 1}$.
If $|\lambda| = 1$ and $k \geq 2$, then $J_k(\lambda)^p$ is unbounded by Proposition 6.1.5(i) and $\left|p\lambda^{p-1}\right| = p$. Condition (ii) holds by these exclusions.
(ii) $\Rightarrow$ *(iii)* Fix $\lambda \in \mathrm{spec}(A)$ with $|\lambda| = 1$.
The dimension $\dim E_\lambda(A)$ is the number of Jordan blocks at λ by Corollary 6.2.3(i).
The multiplicity $m_A(\lambda)$ is the sum of their sizes by Theorem 2.1.7(ii) and Proposition 2.1.6(iii).
The desired equality holds by these two counting identities and the size-one condition in (ii).
(iii) $\Rightarrow$ *(i)* All unit-circle blocks have size 1 by (iii), the preceding counts, and positive integral block sizes.
Blocks with $|\lambda| < 1$ converge to 0 by Proposition 6.1.5(ii), while the size-one unit-circle blocks are bounded by $|\lambda^p| = 1$.
The matrix J is power bounded by $\rho(A) \leq 1$, these block bounds, and its block-diagonal structure.
The matrix A is power bounded by the fixed-similarity equivalence.

Structural Commentary: Jordan form separates exponential and boundary polynomial growth; block counts detect nilpotent parts.
Key Insight: A unit-circle block is bounded exactly when its size is one. □

4 Matrix Decompositions

Decompositions expose usable structure in a matrix. LU, QR, Cholesky, SVD, compact SVD, and polar decomposition separate elimination, geometry, positivity, rank, and stretching.

Perspective 4.0.1. *Matrix Factorisation Roadmap*
Factorisations expose structure by task: elimination gives LU and LDL^t (Theorem 4.1.4, Corollary 4.1.5); positivity gives Cholesky (Theorem 4.1.11); geometry gives QR (Theorem 4.1.7); singular directions give SVD, compact SVD, and the pseudoinverse (Theorems 4.2.9, 4.2.14, Definition 5.2.4); polar decomposition separates motion from stretch (Theorem 4.2.18). Spectral factorisations appeared earlier: diagonalisation, spectral theorems, Jordan form, and Schur form (Theorems 5.4.3, 6.1.11, 6.1.12, 6.2.1, 2.1.9).
Key Insight: Choose the factorisation that exposes the needed structure.

4.1 LU, QR, and Cholesky-Type Decompositions

Throughout this subsection, $\mathbb{F}$ is a field.

Definition 4.1.1. *Full-Rank Factorization*
Let $m, n, r \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(m, n, \mathbb{F})$.
A factorization $A = XY$, with $X \in \mathrm{Mat}(m, r, \mathbb{F})$ and $Y \in \mathrm{Mat}(r, n, \mathbb{F})$, is a *full-rank factorization* if $\mathrm{rank}(X) = \mathrm{rank}(Y) = r$.

Theorem 4.1.2. *Full-Rank Factorization*
Let $m, n \in \mathbb{Z}_{>0}$ and let $A \in \mathrm{Mat}(m, n, \mathbb{F})$ have rank $r \geq 1$. Let the columns of $X \in \mathrm{Mat}(m, r, \mathbb{F})$ form a basis of $\mathrm{col}(A)$. Then:
(i) $(\exists!\, Y \in \mathrm{Mat}(r, n, \mathbb{F}))\ A = XY$;
(ii) for this matrix Y, $\mathrm{rank}(X) = \mathrm{rank}(Y) = r$.

Proof.
(i) Write $A = [\mathbf{a}_1 \ \cdots \ \mathbf{a}_n]$. By the basis hypothesis, $(\forall\, j \in J_n)(\exists!\, \mathbf{y}_j \in \mathbb{F}^r)\, \mathbf{a}_j = X\mathbf{y}_j$.
For $Y := [\mathbf{y}_1 \ \cdots \ \mathbf{y}_n]$, one has $A = XY$. If $A = XZ$ with $Z = [\mathbf{z}_1 \ \cdots \ \mathbf{z}_n]$, then $Z = Y$ by coordinate uniqueness.
(ii) $\mathrm{rank}(X) = r$ by the basis hypothesis, and $r = \mathrm{rank}(XY) \leq \mathrm{rank}(Y) \leq r$ by Theorem 1.2.8(i) and the row count of Y.

Structural Commentary: Basis coordinates construct Y uniquely; the product-rank bound forces full row rank.
Key Insight: Column coordinates determine the right factor. □

Definition 4.1.3. *LU Factorisation*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$.
(i) An *LU factorisation* is a product $A = LU$ with L lower triangular and U upper triangular.
(ii) For $L = [l_{ij}]$, it is a *unit-lower-triangular LU factorisation* if $(\forall\, k \in J_n)\, l_{kk} = 1$.

Theorem 4.1.4. *LU Factorisation from Nonzero Leading Principal Minors*
Let $n \in \mathbb{Z}_{>0}$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$. Assume every leading principal minor of A is nonzero.
Then a unique pair $(L, U) \in \mathrm{Mat}(n, n, \mathbb{F})^2$ satisfies $A = LU$, with L unit lower triangular and U upper triangular.

Proof. Induct on n.
(i) *Base Case*: If $n = 1$, then $A = [a] = [1][a]$ uniquely, where $a \neq 0$ by hypothesis.
(ii) *Schur Reduction*: For $n \geq 2$, write $A = \left[\begin{smallmatrix} a & \mathbf{r} \\ \mathbf{c} & B \end{smallmatrix}\right]$ with $a \neq 0$, and set $\boldsymbol{\ell} := a^{-1}\mathbf{c}$ and $S := B - a^{-1}\mathbf{c}\mathbf{r}$.
For the leading blocks A_k and S_{k-1}, $\det(A_k) = a \det(S_{k-1})$ by Proposition 1.1.8.
Every leading principal minor of S is nonzero by this identity and the hypothesis. Hence $S = L_1U_1$ uniquely, with L_1 unit lower triangular and U_1 upper triangular, by the induction hypothesis.
(iii) *Construction*: Set $L := \left[\begin{smallmatrix} 1 & 0 \\ \boldsymbol{\ell} & L_1 \end{smallmatrix}\right]$ and $U := \left[\begin{smallmatrix} a & \mathbf{r} \\ 0 & U_1 \end{smallmatrix}\right]$. Then L and U have the required forms, and $LU = \left[\begin{smallmatrix} a & \mathbf{r} \\ \mathbf{c} & B \end{smallmatrix}\right] = A$.
(iv) *Uniqueness*: For another admissible pair, write $\widetilde{L} = \left[\begin{smallmatrix} 1 & 0 \\ \widetilde{\boldsymbol{\ell}} & \widetilde{L}_1 \end{smallmatrix}\right]$ and $\widetilde{U} = \left[\begin{smallmatrix} \widetilde{a} & \widetilde{\mathbf{r}} \\ 0 & \widetilde{U}_1 \end{smallmatrix}\right]$.
Then $(\widetilde{a}, \widetilde{\mathbf{r}}, \widetilde{\boldsymbol{\ell}}) = (a, \mathbf{r}, \boldsymbol{\ell})$ by the first row and column. Then $S = \widetilde{L}_1\widetilde{U}_1$, so $(\widetilde{L}_1, \widetilde{U}_1) = (L_1, U_1)$ by the induction hypothesis.

Structural Commentary: Schur reduction transfers the pivot hypothesis before block reconstruction and uniqueness.
Key Insight: The first pivot fixes the border blocks. □

Corollary 4.1.5. *Symmetric LU and an LDL^t Factorisation*
Let $n \in \mathbb{Z}_{>0}$ and let $A = A^t \in \mathrm{Mat}(n, n, \mathbb{R})$ have nonzero leading principal minors.
Then $(\exists\, L, D \in \mathrm{Mat}(n, n, \mathbb{R}))\ A = LDL^t$, where L is unit lower triangular and D is diagonal and invertible.

Proof. By Theorem 4.1.4, write $A = LU$ uniquely with L unit lower triangular and U upper triangular.
The relation $0 \neq \det(A) = \det(U) = \prod_{k=1}^{n} u_{kk}$ holds by Theorem 3.8.2(v)–(vi) and $\det(L) = 1$.
Thus $D := \mathrm{diag}(u_{11}, \ldots, u_{nn})$ is invertible. For $U_0 := D^{-1}U$, one has $A = LDU_0$, with U_0 unit upper triangular.
By symmetry, $A = U_0^t(DL^t)$ is another admissible LU factorisation; hence $U_0^t = L$ by Theorem 4.1.4. Thus $A = LDL^t$.
Structural Commentary: Pivot extraction normalises U; symmetry and LU uniqueness identify its unit factor.
Key Insight: Symmetry forces $U_0 = L^t$. □

Definition 4.1.6. *Wide and Narrow QR Factorisation*
Let $m, n \in \mathbb{Z}_{>0}$ satisfy $m \geq n$ and let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$. Let $A \in \mathrm{Mat}(m, n, \mathbb{F})$.
(i) A *wide QR factorisation* is $A = V \left[\begin{smallmatrix} R \\ 0 \end{smallmatrix}\right]$, where $V \in \mathrm{Mat}(m, m, \mathbb{F})$ is unitary and $R \in \mathrm{Mat}(n, n, \mathbb{F})$ is upper triangular.
(ii) For $V = [Q\ Q']$ with $Q \in \mathrm{Mat}(m, n, \mathbb{F})$, the corresponding *narrow QR factorisation* is $A = QR$, where $Q^*Q = I_n$.

Theorem 4.1.7. *QR Factorisation*
Let $m, n \in \mathbb{Z}_{>0}$ satisfy $m \geq n$ and let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$. Let $A \in \mathrm{Mat}(m, n, \mathbb{F})$.
(i) $(\exists\, V \in \mathrm{Mat}(m, m, \mathbb{F}))(\exists\, R \in \mathrm{Mat}(n, n, \mathbb{F}))\ A = V \left[\begin{smallmatrix} R \\ 0 \end{smallmatrix}\right]$. *Here V is unitary, $R = [r_{ij}]$ is upper triangular with $(\forall\, k \in J_n)\, r_{kk} \in \mathbb{R}_{\geq 0}$. For $V = [Q\ Q']$ with $Q \in \mathrm{Mat}(m, n, \mathbb{F})$, one has $A = QR$ and $Q^*Q = I_n$.*
(ii) If $\mathrm{rank}(A) = n$, then a unique pair (Q, R) satisfies $A = QR$ and $Q^*Q = I_n$.
Here $Q \in \mathrm{Mat}(m, n, \mathbb{F})$ and $R = [r_{ij}] \in \mathrm{Mat}(n, n, \mathbb{F})$ is upper triangular with $(\forall\, k \in J_n)\, r_{kk} > 0$.

Proof.

(i) Process $k \in J_n$ in increasing order, and let $\mathbf{x}_k \in \mathbb{F}^{m-k+1}$ be the active tail of column k.
For $\mathbf{x}_k = \mathbf{0}$, set $(H_k, r_{kk}) := (I_{m-k+1}, 0)$. Otherwise set $\mathbf{y}_k := \|\mathbf{x}_k\|_2 \mathbf{e}_1$ and choose $\sigma_k, \mathbf{w}_k$ by Theorem 2.7.3(i)–(iii).
Then $H_k := \sigma_k U_{\mathbf{w}_k}$ satisfies $H_k^* H_k = I_{m-k+1}$ by Theorem 2.7.3(i) and Theorem 2.7.2(iii).
It also satisfies $H_k \mathbf{x}_k = r_{kk}\mathbf{e}_1$ for $r_{kk} := \|\mathbf{x}_k\|_2$ by Theorem 2.7.3(iii).
In both cases, $\widehat{H}_k := I_{k-1} \oplus H_k$ preserves prior zeros by acting only on rows $k, \dots, m$.
Thus $WA = \left[\begin{smallmatrix} R \\ 0 \end{smallmatrix}\right]$ for $W := \widehat{H}_n \cdots \widehat{H}_1$, with R upper triangular and $(\forall\, k \in J_n)\, r_{kk} \geq 0$.
For $V := W^* = [Q\ Q']$, $A = V \left[\begin{smallmatrix} R \\ 0 \end{smallmatrix}\right] = QR$ and $Q^*Q = I_n$ by unitarity and block multiplication.

(ii) Assume $\operatorname{rank}(A) = n$. Then $\operatorname{rank}(R) = n$ by Theorem 3.6.6(ii), so R is invertible by Corollary 3.6.2.
Its nonnegative diagonal is positive by Theorem 3.8.2(v),(vii), proving existence.
If $A = Q_1R_1 = Q_2R_2$ are admissible, then each R_i is invertible by Theorem 3.8.2(v),(vii), and $R_1^*R_1 = A^*A = R_2^*R_2$.
For $D := R_1R_2^{-1}$, D is upper triangular by Theorem 3.8.9(ii) and the product-entry formula.
The identity $D^*D = (R_2^{-1})^*R_1^*R_1R_2^{-1} = I_n$ holds, and $DD^* = I_n$ by Theorem 2.6.8(i)⇒(iii).
Viewed over $\mathbb{C}$ when $\mathbb{F} = \mathbb{R}$, D is diagonal by Lemma 6.1.10.
Now $d_{kk} = (R_1)_{kk}(R_2)_{kk}^{-1} > 0$ and $|d_{kk}| = 1$, so $D = I_n$. Therefore $R_1 = R_2$ and $Q_1 = AR_1^{-1} = Q_2$.

Structural Commentary: Householder tail maps construct R; triangular normality reduces uniqueness to diagonal phases.
Key Insight: Positivity eliminates every unitary diagonal phase. □

Corollary 4.1.8. *Prefix Column Spaces in QR Factorisation*
Let $m, n \in \mathbb{Z}_{>0}$ satisfy $m \geq n$ and let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.
Let $A = QR \in \operatorname{Mat}(m, n, \mathbb{F})$ satisfy $\operatorname{rank}(A) = n$ and $Q^*Q = I_n$, where R is upper triangular with positive diagonal.
For $k \in J_n$, let A_k and Q_k be the first k columns of A and Q. Then:

(i) $(\forall\, k \in J_n)\ \operatorname{col}(A_k) = \operatorname{col}(Q_k)$;
(ii) $(\forall\, k \in J_n)$, *the columns of Q_k form an orthonormal basis of* $\operatorname{col}(A_k)$.

Proof.

(i) Fix $k \in J_n$, and let R_k be the leading $k \times k$ block of R. Then R_k is invertible by Theorem 3.8.2(v),(vii).
Since $A_k = Q_kR_k$ and $Q_k = A_kR_k^{-1}$, one has $\operatorname{col}(A_k) = \operatorname{col}(Q_k)$.

(ii) Fix $k \in J_n$. The columns of Q_k are orthonormal by $Q_k^*Q_k = I_k$, and they span $\operatorname{col}(A_k)$ by part (i).

Structural Commentary: Invertible triangular prefixes transfer column spaces; $Q_k^*Q_k = I_k$ supplies orthonormality.
Key Insight: Each prefix uses only the first k orthonormal columns. □

Figure 85 depicts orthonormal column replacement and upper-triangular coordinates.

Figure 85: QR records the original columns in an orthonormal basis while preserving every prefix column space.

Perspective 4.1.9. *Gram–Schmidt and Householder QR*
For a full-column-rank matrix, Gram–Schmidt preserves prefix spans by Theorem 1.3.6(i)–(ii).
Householder transformations instead triangularise entire column tails in Theorem 4.1.7(i).
Both constructions reach the unique positive-diagonal factorisation in Theorem 4.1.7(ii).
Gram–Schmidt orthogonalises columns; Householder transformations act unitarily on rows.

Perspective 4.1.10. *Rank-Deficient QR from Gram–Schmidt*
Zero Gram–Schmidt remainders detect dependent prefix columns by Corollary 1.3.8.
The QR factorisation still exists by Theorem 4.1.7(i).
Rank defect blocks the positive-diagonal uniqueness hypothesis in Theorem 4.1.7(ii).

Theorem 4.1.11. *Cholesky Factorisation*
Let $n \in \mathbb{Z}_{>0}$, let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and let $A \in \operatorname{Mat}(n, n, \mathbb{F})$.

(i) If $A \succeq 0$, then $(\exists\, L \in \operatorname{Mat}(n, n, \mathbb{F}))\ A = LL^*$, where L is lower triangular with nonnegative diagonal entries.
(ii) If $A \succ 0$, then $\exists!\, L \in \operatorname{Mat}(n, n, \mathbb{F})$ satisfying $A = LL^*$, where L is lower triangular with positive diagonal entries.

Proof.

(i) Set $B := A^{1/2}$ by Corollary 2.1.4(i), so $B = B^*$ and $B^2 = A$.
Choose $B = QR$ with $Q^*Q = I_n$ and R upper triangular with nonnegative diagonal by Theorem 4.1.7(i).
Then $A = B^*B = R^*R$, so $L := R^*$ has the required form.

(ii) Assume $A \succ 0$. Then A is invertible by Theorem 2.1.8(i)⇒(iii).
For the factor L in (i), $n = \operatorname{rank}(A) \leq \operatorname{rank}(L) \leq n$ by Theorem 1.2.8(i).
Thus L is invertible by Corollary 3.6.2, so its nonnegative diagonal is positive by Theorem 3.8.2(v),(vii).
For uniqueness, set $B := A^{1/2}$ and suppose $A = L_1L_1^* = L_2L_2^*$ for admissible L_1, L_2.
Since $B^2 = A$ and A is invertible, $\ker(B) \subseteq \ker(A) = \{\mathbf{0}\}$; hence B is invertible by Corollary 3.6.3(vi)⇒(i).
For $R_i := L_i^*$, each R_i is upper triangular with positive diagonal and is invertible by Theorem 3.8.2(v),(vii). Set $Q_i := BR_i^{-1}$.
Then $B = Q_iR_i$ and $Q_i^*Q_i = (R_i^{-1})^*B^2R_i^{-1} = I_n$. Hence $R_1 = R_2$ by Theorem 4.1.7(ii), and therefore $L_1 = L_2$.

Structural Commentary: QR of $A^{1/2}$ constructs R^*; positive-diagonal QR uniqueness identifies competitors.
Key Insight: Cholesky is the adjoint triangular factor of $A^{1/2}$. □

Figure 86 depicts the Cholesky factor obtained from QR of the positive square root.

Figure 86: For $B = A^{1/2} = QR$, the choice $L = R^*$ satisfies $A = LL^*$; positive definiteness makes L unique.

4.2 Polar and Singular Value Decompositions

Throughout this subsection, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and all matrix dimensions are positive integers.
Every inner-product space is finite-dimensional over $\mathbb{F}$.

Theorem 4.2.1. *Polar Decomposition*
Let $T \in \mathcal{L}(\mathcal{V})$. Then $(\exists S \in \mathcal{L}(\mathcal{V}))\,[S$ is an isometry $\wedge\, T = S\sqrt{T^*T}]$.

Proof.
(i) *Positive Factor*: Set $P := \sqrt{T^*T}$ by Theorem 6.3.6(v)⇒(i) and Proposition 6.3.7.
$(\forall \mathbf{v} \in \mathcal{V})\ \|T\mathbf{v}\|^2 = \langle P^2\mathbf{v}, \mathbf{v}\rangle = \|P\mathbf{v}\|^2$ by $P = P^*$. $\ker(P) = \ker(T)$ by this norm identity.
(ii) *Range Isometry*: The rule $S_1(P\mathbf{v}) := T\mathbf{v}$ defines a linear bijection $\operatorname{range}(P) \to \operatorname{range}(T)$ by (i).
S_1 is an isometry by $\|S_1(P\mathbf{v})\| = \|P\mathbf{v}\|$ from (i).
(iii) *Complement Extension*: $\dim \operatorname{range}(P)^\perp = \dim \operatorname{range}(T)^\perp$ by (i), Theorem 1.7.3, and Corollary 2.1.7.
Set $d := \dim \operatorname{range}(P)^\perp$. Choose orthonormal bases $(\mathbf{a}_j)_{j=1}^d$ and $(\mathbf{b}_j)_{j=1}^d$ of the two complements by Corollary 1.3.11.
Define $S_0\mathbf{a}_j := \mathbf{b}_j$. Then $(\forall i, j \in J_d)\ \langle S_0\mathbf{a}_i, S_0\mathbf{a}_j\rangle = \langle \mathbf{a}_i, \mathbf{a}_j\rangle = \delta_{ij}$. Thus S_0 is an isometry by sesquilinearity and Theorem 2.6.4.
(iv) *Global Isometry*: $\mathcal{V} = \operatorname{range}(P) \odot \operatorname{range}(P)^\perp$ by Theorem 2.1.5. Define $S(\mathbf{x} + \mathbf{y}) := S_1\mathbf{x} + S_0\mathbf{y}$.
S is an isometry by the orthogonal source and target decompositions. Finally, $(\forall \mathbf{v} \in \mathcal{V})\, SP\mathbf{v} = S_1(P\mathbf{v}) = T\mathbf{v}$.

Structural Commentary: The Gram norm identity builds a range isometry, extended across equidimensional complements.
Key Insight: $\ker\sqrt{T^*T} = \ker T$ synchronizes the two range dimensions. □

Corollary 4.2.2. *Uniqueness in Operator Polar Decomposition*
Let $T \in \mathcal{L}(\mathcal{V})$, and set $|T| := \sqrt{T^*T}$ and $|T^*| := \sqrt{TT^*}$.
(i) If $T = SP$, $S^*S = I_{\mathcal{V}}$, and $P \geq 0$, then $P = |T|$; hence the positive right polar factor is unique.
(ii) $(\exists R \in \mathcal{L}(\mathcal{V}))\,[R$ is an isometry $\wedge\, T = |T^*|\,R]$, and $|T^*|$ is the unique positive left polar factor.
(iii) If T is invertible, then both isometric factors are unique: $S = T\,|T|^{-1}$ and $R = |T^*|^{-1}\,T$.

Proof.
(i) If $T = SP$, then $T^*T = PS^*SP = P^2$, so $P = |T|$ by Proposition 6.3.7.
(ii) Fix $T^* = S_0\,|T^*|$ by Theorem 4.2.1.
Then $R := S_0^*$ is an isometry and $T = |T^*|\,R$ by Theorem 2.6.6 and Proposition 2.6.2(iii)–(iv).
If $T = Q\widetilde{R}$ with $Q \geq 0$ and $\widetilde{R}$ isometric, then $TT^* = Q^2$ by $\widetilde{R}\widetilde{R}^* = I_{\mathcal{V}}$; hence $Q = |T^*|$ by Proposition 6.3.7.
(iii) If T is invertible, then $\ker|T| = \ker|T^*| = \{\mathbf{0}\}$ by invertibility of their squares.
Thus both moduli are invertible by Theorem 1.7.7, and $S = T\,|T|^{-1}$, $R = |T^*|^{-1}\,T$.

Structural Commentary: Gram squaring fixes each modulus; invertibility then isolates its isometry.
Key Insight: Positivity selects one square root of each Gram operator. □

Figure 87 summarizes the range isometry used to separate the positive stretch from the isometric factor.

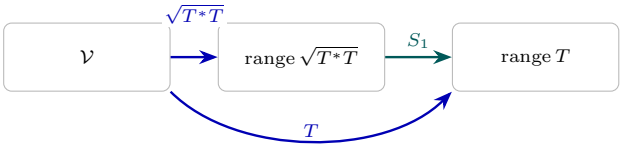

Figure 87: Polar decomposition builds S_1 using $\|T\mathbf{v}\| = \left\|\sqrt{T^*T}\mathbf{v}\right\|$.

Definition 4.2.3. *Singular Values*
For $T \in \mathcal{L}(\mathcal{U}, \mathcal{V})$, the *singular values* of T are the eigenvalues of $\sqrt{T^*T} \in \mathcal{L}(\mathcal{U})$, listed with their eigenspace multiplicities.

Theorem 4.2.4. *Singular Value Decomposition*
Let $T \in \mathcal{L}(\mathcal{V})$, set $n := \dim \mathcal{V}$, and list its singular values as $s_1, \ldots, s_n$.
Then $\exists$ orthonormal bases $(\mathbf{e}_1, \ldots, \mathbf{e}_n)$ and $(\mathbf{f}_1, \ldots, \mathbf{f}_n)$ of $\mathcal{V}$ such that $(\forall \mathbf{v} \in \mathcal{V})\, T\mathbf{v} = \sum_{j=1}^{n} s_j \langle \mathbf{v}, \mathbf{e}_j\rangle \mathbf{f}_j$.

Proof. Set $|T| := \sqrt{T^*T}$. Fix an orthonormal eigenbasis $(\mathbf{e}_1, \ldots, \mathbf{e}_n)$ of $|T|$ with $(\forall j \in J_n)\ |T|\,\mathbf{e}_j = s_j\mathbf{e}_j$ by Theorem 6.1.12 when $\mathbb{F} = \mathbb{R}$ and Theorem 6.1.11 when $\mathbb{F} = \mathbb{C}$. Fix $T = S\,|T|$ by Theorem 4.2.1, and set $(\forall j \in J_n)\, \mathbf{f}_j := S\mathbf{e}_j$.
The list $(\mathbf{f}_1, \ldots, \mathbf{f}_n)$ is an orthonormal basis by Theorem 2.6.4 and Proposition 2.6.2(iii). $(\forall \mathbf{v} \in \mathcal{V})\, T\mathbf{v} = \sum_{j=1}^{n} s_j \langle \mathbf{v}, \mathbf{e}_j\rangle \mathbf{f}_j$ by Theorem 1.4.1.
Structural Commentary: Spectral coordinates diagonalise $|T|$; the polar isometry transports its eigenbasis.
Key Insight: $T\mathbf{e}_j = s_j\mathbf{f}_j$ pairs stretch with direction. □

Figure 88 shows each right singular direction stretched and carried isometrically to its left singular direction.

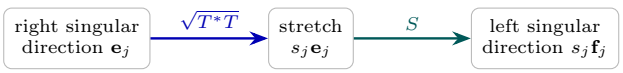

Figure 88: Since $T = S\sqrt{T^*T}$, each $\mathbf{e}_j$ maps to $s_j\mathbf{f}_j$.

Proposition 4.2.5. *Singular Values from T^*T*
The singular values of $T \in \mathcal{L}(\mathcal{U}, \mathcal{V})$ are the nonnegative square roots of the eigenvalues of T^*T, with the same eigenspace multiplicities.

Proof. Set $n := \dim \mathcal{U}$ and $G := T^*T$. Then $G \geq 0$ by Theorem 6.3.6(v)⇒(i).
Fix an orthonormal eigenbasis $(\mathbf{e}_j)_{j=1}^n$ with $G\mathbf{e}_j = \lambda_j \mathbf{e}_j$ by Theorem 6.1.12 when $\mathbb{F} = \mathbb{R}$ and Theorem 6.1.11 when $\mathbb{F} = \mathbb{C}$.
$(\forall j \in J_n)\, \lambda_j \geq 0$ by Theorem 6.3.6(i)⇒(ii). Define $(\forall j \in J_n)\, R\mathbf{e}_j := \sqrt{\lambda_j}\mathbf{e}_j$.
Then $R \geq 0$ by Theorem 6.3.6(ii)⇒(i), and $R^2 = G$; hence $R = \sqrt{G}$ by Proposition 6.3.7.
The eigenspace multiplicities are preserved by $(\forall \lambda \geq 0)\, E_\lambda(G) = E_{\sqrt{\lambda}}(R)$.
Structural Commentary: One Gram eigenbasis constructs the root and identifies every eigenspace.
Key Insight: $\lambda \mapsto \sqrt{\lambda}$ is injective on the nonnegative spectrum. □

Theorem 4.2.6. *Singular Vectors for a Linear Map*
Let $T \in \mathcal{L}(\mathcal{U}, \mathcal{V})$ have rank r. Set $n := \dim \mathcal{U}$, $m := \dim \mathcal{V}$, $\mathcal{U}_+ := \operatorname{range}(T^*)$, $\mathcal{U}_0 := \ker(T)$, $\mathcal{V}_+ := \operatorname{range}(T)$, and $\mathcal{V}_0 := \ker(T^*)$.
Then $\exists$ ordered orthonormal bases $\beta = (\mathbf{u}_1, \dots, \mathbf{u}_n)$ and $\gamma = (\mathbf{v}_1, \dots, \mathbf{v}_m)$
with $\operatorname{span}\{\mathbf{u}_j : j \in J_r\} = \mathcal{U}_+$, $\operatorname{span}\{\mathbf{u}_j : j \in J_n \setminus J_r\} = \mathcal{U}_0$, $\operatorname{span}\{\mathbf{v}_j : j \in J_r\} = \mathcal{V}_+$, and $\operatorname{span}\{\mathbf{v}_j : j \in J_m \setminus J_r\} = \mathcal{V}_0$,
and positive scalars $(s_k)_{k \in J_r}$ such that $(\forall k \in J_r)\, T\mathbf{u}_k = s_k \mathbf{v}_k$ and $T^*\mathbf{v}_k = s_k \mathbf{u}_k$.
The s_k are the positive singular values; $\mathbf{u}_k$ and $\mathbf{v}_k$ are right and left singular vectors.

Proof.

(i) *Gram Reduction*: For $G := T^*T$, $G \geq 0$, $\ker(G) = \ker(T)$ by Theorem 6.3.6, Proposition 2.3.11; $\operatorname{rank}(G) = r$ by Theorem 1.7.3.
(ii) *Right Singular Basis*: Choose orthonormal eigenbasis $(\mathbf{u}_1, \dots, \mathbf{u}_n)$ of G by Theorem 6.1.12 if $\mathbb{F} = \mathbb{R}$, Theorem 6.1.11 if $\mathbb{F} = \mathbb{C}$.
Order it so that $G\mathbf{u}_k = s_k^2 \mathbf{u}_k$ for $k \in J_r$ and $G\mathbf{u}_k = \mathbf{0}$ for $k \in J_n \setminus J_r$.
These groups span $\mathcal{U}_+$ and $\mathcal{U}_0$ by Proposition 2.3.10(iii), and the s_k are the positive singular values by Proposition 4.2.5.
(iii) *Left Singular Vectors*: Set $(\forall k \in J_r)\, \mathbf{v}_k := s_k^{-1} T\mathbf{u}_k$. Then $(\forall i, j \in J_r)\, \langle \mathbf{v}_i, \mathbf{v}_j \rangle = \frac{\langle \mathbf{u}_i, G\mathbf{u}_j \rangle}{s_i s_j} = \delta_{ij}$.
$(\forall k \in J_r)\, T\mathbf{u}_k = s_k \mathbf{v}_k$ and $T^*\mathbf{v}_k = s_k \mathbf{u}_k$ by the definitions of $\mathbf{v}_k$ and G.
(iv) *Codomain Completion*: The identity $\mathcal{V}_+ = T(\mathcal{U}_+) = \operatorname{span}\{\mathbf{v}_k : k \in J_r\}$ holds by $\mathcal{U} = \mathcal{U}_+ \odot \mathcal{U}_0$.
Complete $(\mathbf{v}_1, \dots, \mathbf{v}_r)$ orthonormally by Corollary 1.3.12. The remaining vectors lie in $\mathcal{V}_+^\perp = \mathcal{V}_0$ by Proposition 2.3.10(i).

Structural Commentary: The Gram spectrum splits the domain; normalized images build the active codomain basis.
Key Insight: $T^*T\mathbf{u}_k = s_k^2 \mathbf{u}_k$ forces both singular-vector relations. □

Figure 89 summarizes the paired active subspaces and kernels for T and T^*.

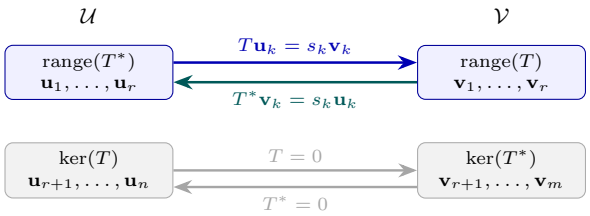

Figure 89: The singular-vector bases split the domain and codomain into active singular subspaces and kernels.

Definition 4.2.7. *Matrix Modulus*
Let $A \in \operatorname{Mat}(m, n, \mathbb{F})$. The matrices A^*A and AA^* are positive semidefinite by Proposition 2.1.2(i)–(ii).
Their unique positive semidefinite square roots exist by Corollary 2.1.4(i).
The *moduli* of A and A^* are $|A| := (A^*A)^{1/2} \in \operatorname{Mat}(n, n, \mathbb{F})$ and $|A^*| := (AA^*)^{1/2} \in \operatorname{Mat}(m, m, \mathbb{F})$.

Definition 4.2.8. *Matrix Singular Values*
Let $A \in \operatorname{Mat}(m, n, \mathbb{F})$, $q := \min(m, n)$, and $r := \operatorname{rank}(A)$.
The matrix $|A|$ has exactly r positive eigenvalues by Theorem 2.1.5(iii) and Corollary 2.1.4(ii).
These eigenvalues, counted with multiplicity, are the *positive singular values* of A.
For $r \geq 1$, list them as $\sigma_1 \geq \cdots \geq \sigma_r > 0$; for $r = 0$, this list is empty.
The full singular-value list has length q; if $r < q$, set $\sigma_{r+1} = \cdots = \sigma_q = 0$.

Theorem 4.2.9. *Matrix Singular Value Decomposition*
Let $A \in \operatorname{Mat}(m, n, \mathbb{F})$ have singular values $\sigma_1 \geq \cdots \geq \sigma_q \geq 0$, where $q := \min(m, n)$. Then $\exists$ unitary matrices $V \in \operatorname{Mat}(m, m, \mathbb{F})$ and $W \in \operatorname{Mat}(n, n, \mathbb{F})$ such that $A = V\Sigma W^*$, where the rectangular diagonal matrix $\Sigma \in \operatorname{Mat}(m, n, \mathbb{R})$ satisfies $(\forall j \in J_q)\, \Sigma_{jj} = \sigma_j$.

Proof.

(i) *Gram Spectrum*: Set $r := \operatorname{rank}(A)$. If $r = 0$, take $(V, W, \Sigma) = (I_m, I_n, 0)$; assume $r \geq 1$ below.
Choose a unitary eigenvector matrix $W = [\mathbf{w}_1 \ \cdots \ \mathbf{w}_n]$ for A^*A by Theorem 6.1.12 when $\mathbb{F} = \mathbb{R}$ and Theorem 6.1.11 when $\mathbb{F} = \mathbb{C}$.
Then $W^*A^*AW = \operatorname{diag}(\sigma_1^2, \dots, \sigma_r^2, 0, \dots, 0)$ by Corollary 2.1.4(ii).
(ii) *Left Singular Vectors*: Set $(\forall j \in J_r)\, \mathbf{v}_j := \sigma_j^{-1} A\mathbf{w}_j$. Then $(\forall i, j \in J_r)\, \mathbf{v}_i^* \mathbf{v}_j = \frac{\mathbf{w}_i^* A^* A \mathbf{w}_j}{\sigma_i \sigma_j} = \delta_{ij}$.
(iii) *Unitary Completion*: Complete $(\mathbf{v}_1, \dots, \mathbf{v}_r)$ to an orthonormal basis by Corollary 1.3.12.
The matrix V with these columns is unitary by Theorem 2.6.8(ii)⇒(i).
(iv) *Factorisation*: For $j \in J_n \setminus J_r$, $\|A\mathbf{w}_j\|_2^2 = \mathbf{w}_j^* A^* A \mathbf{w}_j = 0$. $AW = V\Sigma$ by (ii) and the preceding identity, so $A = V\Sigma W^*$.

Structural Commentary: The Gram eigenbasis fixes W, Σ; normalized images construct V.
Key Insight: $\mathbf{v}_j = \sigma_j^{-1} A\mathbf{w}_j$ orthonormalizes the nonzero images. □

Figure 90 traces the unit ball through the three SVD factors.

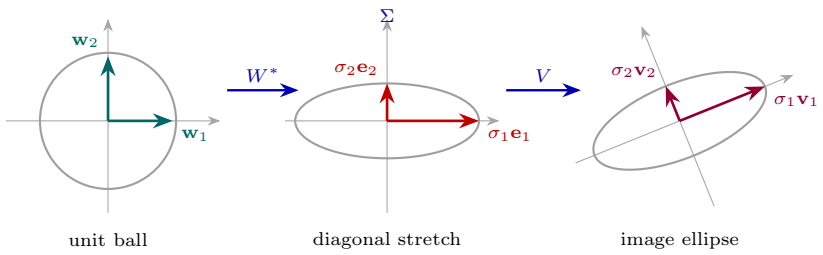

Figure 90: The factors W^*, Σ, and V rotate, stretch, and reorient the unit ball.

Perspective 4.2.10. *Operator-to-Matrix SVD Bridge*
In the bases from Theorem 4.2.6, the matrix of T is rectangular diagonal with positive entries $s_1, \dots, s_r$ and zeros elsewhere. Changing to standard orthonormal bases produces the matrix SVD in Theorem 4.2.9 without changing the singular data.

Proposition 4.2.11. *Basic Singular Value Identities*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ have singular values $\sigma_1 \geq \cdots \geq \sigma_q \geq 0$, where $q := \min(m,n)$ and $r := \mathrm{rank}(A)$. Let $c \in \mathbb{F}$.

(i) The positive eigenvalues of A^*A and AA^* are $\sigma_1^2, \dots, \sigma_r^2$.
(ii) $\sum_{j=1}^{q} \sigma_j^2 = \mathrm{tr}(A^*A) = \mathrm{tr}(AA^*) = \|A\|_F^2$, where $\|A\|_F^2 := \mathrm{tr}(A^*A)$.
(iii) A and A^* have the same singular values. Over $\mathbb{C}$, so do A^t and $\overline{A}$.
(iv) The singular values of cA are $|c|\,\sigma_1, \dots, |c|\,\sigma_q$.

Proof. Fix an SVD $A = V\Sigma W^*$ by Theorem 4.2.9. Then $A^*A = W(\Sigma^*\Sigma)W^*$ and $AA^* = V(\Sigma\Sigma^*)V^*$.

(i) The positive eigenvalues of both Gram matrices are $\sigma_1^2, \dots, \sigma_r^2$ by the two unitary similarities and Theorem 2.1.7(i)–(ii).

(ii) $\mathrm{tr}(A^*A) = \mathrm{tr}(AA^*) = \displaystyle\sum_{j=1}^{q} \sigma_j^2 = \|A\|_F^2$ by Theorem 1.1.13(i).

(iii) Claim for A^* holds by (i). Over $\mathbb{C}$, $(A^t)^*A^t = (AA^*)^t$, $(\overline{A})^*\overline{A} = (A^*A)^t$, with unchanged Gram spectra by Proposition 1.1.15.

(iv) The singular values of cA are $|c|\,\sigma_1, \dots, |c|\,\sigma_q$ by $(cA)^*(cA) = |c|^2\, A^*A$.

Structural Commentary: Unitary Gram reductions transfer spectra, traces, adjoints, and scalar scaling.
Key Insight: Both Gram spectra contain the squared entries of Σ. □

Corollary 4.2.12. *Square Invertibility and Singular Values*
Let $A \in \mathrm{Mat}(n,n,\mathbb{F})$, $\mathbb{F} \in \{\mathbb{R},\mathbb{C}\}$, have singular values $\sigma_1 \geq \cdots \geq \sigma_n \geq 0$. The following are equivalent:

(i) A is invertible;
(ii) $\mathrm{rank}(A) = n$;
(iii) $\sigma_n > 0$;
(iv) $A^*A \succ 0$.

Proof.

(i) $\Rightarrow$ (ii) $\mathrm{rank}(A) = n$ by Corollary 3.6.2.
(ii) $\Rightarrow$ (iii) $\sigma_n > 0$ by the definition of the full singular-value list.
(iii) $\Rightarrow$ (iv) Since all n singular values are positive, $\mathrm{rank}(A) = n$ and $A^*A \succ 0$ by Proposition 2.1.2(v).
(iv) $\Rightarrow$ (i) $\ker(A) = \{\mathbf{0}\}$ by $(\forall \mathbf{x} \in \mathbb{F}^n)\,[A\mathbf{x} = \mathbf{0} \Rightarrow \mathbf{x}^*A^*A\mathbf{x} = 0 \Rightarrow \mathbf{x} = \mathbf{0}]$.
Thus $\mathrm{rank}(A) = n$ by Theorem 1.7.3, and A is invertible by Corollary 3.6.2.

Structural Commentary: Rank links invertibility and σ_n; the Gram form detects injectivity.
Key Insight: $\sigma_n > 0$ is exactly full rank for a square matrix. □

Definition 4.2.13. *Compact Singular Value Decomposition*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ have rank $r \geq 1$. Factorisation $A = X\Sigma_r Y^*$ is a *compact singular value decomposition* if $X \in \mathrm{Mat}(m,r,\mathbb{F})$, $Y \in \mathrm{Mat}(n,r,\mathbb{F})$, $X^*X = Y^*Y = I_r$, and $\Sigma_r = \mathrm{diag}(\sigma_1, \dots, \sigma_r)$ with $\sigma_1 \geq \cdots \geq \sigma_r > 0$.

Theorem 4.2.14. *Compact Singular Value Decomposition*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ have rank $r \geq 1$.

(i) If $A = V\Sigma W^*$ is an SVD and X, Y are the first r columns of V, W, then $A = X\Sigma_r Y^*$.
(ii) Conversely, if $X \in \mathrm{Mat}(m,r,\mathbb{F})$ and $Y \in \mathrm{Mat}(n,r,\mathbb{F})$ have orthonormal columns and $\Sigma_r = \mathrm{diag}(\sigma_1, \dots, \sigma_r)$, with $\sigma_1 \geq \cdots \geq \sigma_r > 0$, then $X\Sigma_r Y^*$ has positive singular values $\sigma_1, \dots, \sigma_r$.

Proof.

(i) For $V = [X\ X_0]$ and $W = [Y\ Y_0]$, $A = V\Sigma W^* = X\Sigma_r Y^*$ by block multiplication.

(ii) Set $B := X\Sigma_r Y^*$. Then $B^*B = Y\Sigma_r^2 Y^*$ by $X^*X = I_r$. Complete Y to a unitary $\widetilde{Y} = [Y\ Y_0]$ by Theorem 2.6.13(ii). Then $\widetilde{Y}^*B^*B\widetilde{Y} = \mathrm{diag}(\Sigma_r^2, 0)$, so B has positive singular values $\sigma_1, \dots, \sigma_r$ by Corollary 2.1.4(ii).

Structural Commentary: Block truncation constructs the compact form; unitary completion recovers its Gram spectrum.
Key Insight: $B^*B = Y\Sigma_r^2 Y^*$ retains exactly the positive singular data. □

Theorem 4.2.15. *Column and Kernel Spaces from Compact SVD*
Let $A = X\Sigma_r Y^*$ be a compact SVD. Then:

(i) $\mathrm{col}(A) = \mathrm{col}(X) = (\ker A^*)^\perp$;
(ii) $\ker(A) = \mathrm{col}(Y)^\perp = (\mathrm{col}(A^*))^\perp$.

Proof.

(i) $\mathrm{col}(A) = \mathrm{col}(X)$ by $A = X\Sigma_r Y^*$ and $AY\Sigma_r^{-1} = X$, while $\mathrm{col}(A) = (\ker A^*)^\perp$ by Proposition 2.3.10(iv).

(ii) $(\forall \mathbf{z} \in \mathbb{F}^n)\, A\mathbf{z} = \mathbf{0} \iff Y^*\mathbf{z} = \mathbf{0} \iff \mathbf{z} \perp \mathrm{col}(Y)$ by $X^*X = I_r$ and invertibility of Σ_r. $\ker(A) = (\mathrm{col}(A^*))^\perp$ by Proposition 2.3.10(ii).

Structural Commentary: Invertible middle scaling transfers the image and isolates the right orthogonal kernel.
Key Insight: $X\Sigma_r$ is injective on the right singular coordinates. □

Figure 91 summarizes the active right singular subspace, its image, and the kernel annihilated by A.

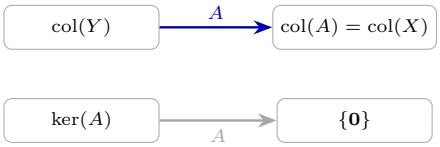

Figure 91: Compact SVD: A maps $\mathrm{col}(Y)$ onto $\mathrm{col}(X)$ and kills $\ker(A) = \mathrm{col}(Y)^\perp$.

Theorem 4.2.16. *Uniqueness of Compact SVD up to Singular Subspaces*
Let $A = X_1\Sigma_r Y_1^* = X_2\Sigma_r Y_2^*$ be compact SVDs with the same Σ_r.
Then $\exists$ unitary matrix $U \in \mathrm{Mat}(r, r, \mathbb{F})$, block diagonal on equal-value blocks of Σ_r, such that $X_1 = X_2U$, $Y_1 = Y_2U$, $U\Sigma_r = \Sigma_r U$.

Proof.
(i) *Coordinate Changes*: The equalities $\mathrm{col}(X_1) = \mathrm{col}(X_2)$ and $\mathrm{col}(Y_1) = \mathrm{col}(Y_2)$ hold by Theorem 4.2.15.
For $U := X_2^*X_1$ and $Z := Y_2^*Y_1$, $X_1 = X_2U$, $Y_1 = Y_2Z$, and U, Z are unitary by the common column spaces and orthonormality.
(ii) *Gram Coupling*: $\Sigma_r = U\Sigma_r Z^*$ by substitution, so $U\Sigma_r = \Sigma_r Z$. $U\Sigma_r^2U^* = \Sigma_r^2$ by this equality and its adjoint.
(iii) *Block Ambiguity*: The matrix U is block diagonal on the equal-value blocks of Σ_r by $U\Sigma_r^2 = \Sigma_r^2U$ and Lemma 5.4.10(ii).
$U\Sigma_r = \Sigma_r U$ by this block structure.
(iv) *Common Change*: $Z = U$ by $U\Sigma_r = \Sigma_r Z = \Sigma_r U$ and invertibility of Σ_r.

Structural Commentary: Common subspaces create two unitary changes; Gram coupling identifies them blockwise.
Key Insight: Commutation with Σ_r^2 confines motion to equal-value blocks. □

Proposition 4.2.17. *Modulus from SVD*
Let $A = V\Sigma W^*$ be an SVD. Then:
(i) $|A| = W(\Sigma^*\Sigma)^{1/2}W^*$;
(ii) $|A^*| = V(\Sigma\Sigma^*)^{1/2}V^*$.

Proof. Set $D_R := (\Sigma^*\Sigma)^{1/2}$ and $D_L := (\Sigma\Sigma^*)^{1/2}$.
(i) The matrix WD_RW^* is positive semidefinite by Theorem 2.1.10(ii) and squares to A^*A. Hence $|A| = WD_RW^*$ by Corollary 2.1.4(i).
(ii) The matrix VD_LV^* is positive semidefinite by Theorem 2.1.10(ii) and squares to AA^*. Hence $|A^*| = VD_LV^*$ by Corollary 2.1.4(i).

Structural Commentary: Unitary conjugation transports each diagonal root to its Gram matrix.
Key Insight: The two moduli express Σ in opposite singular bases. □

Theorem 4.2.18. *Rectangular Polar Decomposition*
Let $A = V\Sigma W^* \in \mathrm{Mat}(m, n, \mathbb{F})$ be an SVD.
(i) If $m \geq n$, let V_n be the first n columns of V and set $U = V_nW^*$. Then $U^*U = I_n$ and $A = U|A|$.
(ii) If $m \leq n$, let W_m be the first m columns of W and set $U = VW_m^*$. Then $UU^* = I_m$ and $A = |A^*|U$.
(iii) If $m = n$, then $U = VW^*$ is unitary and $A = U|A| = |A^*|U$.

Proof.
(i) For $D_R := (\Sigma^*\Sigma)^{1/2}$, $V_nD_R = V\Sigma$; hence $U|A| = A$ by Proposition 4.2.17(i), while $U^*U = WV_n^*V_nW^* = I_n$.
(ii) By (i) with $A^* = W\Sigma^*V^*$, $A^* = U_0|A^*|$ for $U_0 := W_mV^*$ and $U_0^*U_0 = I_m$.
For $U = U_0^* = VW_m^*$, $A = |A^*|U$ and $UU^* = I_m$ by taking adjoints.
(iii) If $m = n$, then $V_n = V$, $W_m = W$, and $U = VW^*$ is unitary; both identities hold by (i)–(ii).

Structural Commentary: Each dimensional regime absorbs the compatible singular bases into a one-sided isometry.
Key Insight: VW^* preserves the diagonal stretch encoded by the modulus. □

Computation Method 4.2.19. *SVD and Polar Factor Computation*
Given $A \in \mathrm{Mat}(m, n, \mathbb{F})$, method constructs full SVD, its compact form when $A \neq 0$, and the dimension-compatible polar factorisation:
(i) Set $r := \mathrm{rank}(A)$ and diagonalise A^*A with a unitary eigenvector matrix $W = [\mathbf{w}_1 \ \cdots \ \mathbf{w}_n]$.
For $r \geq 1$, order its positive eigenvalues as $\sigma_1^2 \geq \cdots \geq \sigma_r^2 > 0$; for $r = 0$, the positive list is empty.
(ii) Set $(\forall j \in J_r)\, \mathbf{v}_j := \sigma_j^{-1}A\mathbf{w}_j$, and complete $(\mathbf{v}_1, \ldots, \mathbf{v}_r)$ to an orthonormal basis of $\mathbb{F}^m$. Let V contain this basis.
(iii) Form the rectangular diagonal Σ with diagonal $\sigma_1, \ldots, \sigma_r, 0, \ldots, 0$. Verify $AW = V\Sigma$, and hence $A = V\Sigma W^*$.
(iv) If $r \geq 1$, set $X := [\mathbf{v}_1 \ \cdots \ \mathbf{v}_r]$, $Y := [\mathbf{w}_1 \ \cdots \ \mathbf{w}_r]$, and $\Sigma_r := \mathrm{diag}(\sigma_1, \ldots, \sigma_r)$. Then $A = X\Sigma_rY^*$ by Theorem 4.2.14(i).
(v) Compute the moduli by Proposition 4.2.17. For $m \geq n$, set $U := V_nW^*$ and obtain $A = U|A|$.
For $m \leq n$, set $U := VW_m^*$ and obtain $A = |A^*|U$ by Theorem 4.2.18.

Theorem 4.2.20. *Uniqueness of the Positive Polar Factor*
Let $A \in \mathrm{Mat}(m, n, \mathbb{F})$.
(i) If $m \geq n$ and $A = UB$ with $U^*U = I_n$ and $B \succeq 0$, then $B = |A|$. If $\mathrm{rank}(A) = n$, then $U = A|A|^{-1}$ is unique.
(ii) If $m \leq n$ and $A = CU$ with $UU^* = I_m$ and $C \succeq 0$, then $C = |A^*|$. If $\mathrm{rank}(A) = m$, then $U = |A^*|^{-1}A$ is unique.

Proof.

(i) From $A^*A = BU^*UB = B^2$, $B = |A|$ by Corollary 2.1.4(i). If $\operatorname{rank}(A) = n$, then $A^*A \succ 0$ by Proposition 2.1.2(v). Thus $\ker |A| = \{\mathbf{0}\}$ and $U = A\,|A|^{-1}$ by Corollary 3.6.2.

(ii) From $AA^* = CUU^*C = C^2$, $C = |A^*|$ by Corollary 2.1.4(i). If $\operatorname{rank}(A) = m$, then $AA^* \succ 0$ by Proposition 2.1.2(vi). Thus $\ker |A^*| = \{\mathbf{0}\}$ and $U = |A^*|^{-1} A$ by Corollary 3.6.2.

Structural Commentary: Gram squaring fixes each positive factor; full rank makes it invertible.
Key Insight: An invertible modulus uniquely isolates the one-sided isometry. □

Theorem 4.2.21. *Normality and Polar Commutation*
Let $A \in \operatorname{Mat}(n, n, \mathbb{F})$ and suppose $A = U\,|A|$ with U unitary. Then A is normal if and only if $U\,|A| = |A|\,U$.

Proof.

($\Rightarrow$) $|A|^2 = A^*A = AA^* = U\,|A|^2\,U^*$ by normality. $U\,|A|\,U^*$ is positive semidefinite by Theorem 2.1.10(ii), and $(U\,|A|\,U^*)^2 = |A|^2$. Thus $U\,|A|\,U^* = |A|$ by Corollary 2.1.4(i), and $U\,|A| = |A|\,U$.

($\Leftarrow$) $AA^* = U\,|A|^2\,U^* = |A|^2 = A^*A$ by $U\,|A| = |A|\,U$.

Structural Commentary: Normality identifies positive roots; commutation reverses the Gram identity.
Key Insight: Root uniqueness converts Gram equality into polar commutation. □

Perspective 4.2.22. *Polar Decomposition Separates Stretch and Direction*
In square factorisation $A = U\,|A|$, positive factor records metric stretch, unitary factor records direction, paralleling scalar modulus and phase. For normal A, these factors commute by Theorem 4.2.21.
In rectangular case, Theorem 4.2.18 supplies only dimension-compatible one-sided isometry.

Proposition 4.2.23. *Absolute Determinant Comes from the Positive Polar Factor*
Let $\mathcal{V} \neq \{\mathbf{0}\}$ and $T \in \mathcal{L}(\mathcal{V})$. Then $|\det T| = \det \sqrt{T^*T}$.

Proof. Set $P := \sqrt{T^*T}$ and fix an isometry S satisfying $T = SP$ by Theorem 4.2.1. Then $|\det S| = 1$ by Proposition 1.1.19(ii).
Fix an orthonormal eigenbasis of P by Theorem 6.1.12 when $\mathbb{F} = \mathbb{R}$ and Theorem 6.1.11 when $\mathbb{F} = \mathbb{C}$.
Its eigenvalues are nonnegative by Theorem 6.3.6(i)$\Rightarrow$(ii), so $\det P \geq 0$ by Theorem 3.8.2(v).
Thus $|\det T| = |\det S|\,|\det P| = \det P$ by Theorem 3.8.2(vi).
Structural Commentary: Polar multiplicativity separates unit-modulus motion from the nonnegative spectral product.
Key Insight: The positive factor alone carries the absolute determinant. □

5 Norms, Conditioning, Perturbation, and Stability

Matrix norms measure stretch, energy, approximation quality, and sensitivity. Singular values organize norms, low-rank approximation, pseudoinverses, conditioning, and error bounds.

Perturbation theory studies how matrix information changes under small errors. Bauer–Fike, Gersgorin, interlacing, Weyl inequalities, and pseudospectra measure robustness.

5.1 Matrix Norms

Throughout this subsection, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$ and $m, n, k \in \mathbb{Z}_{>0}$ whenever they occur as dimensions.

Definition 5.1.1. *Spectral Norm and Extreme Singular Values*
Let $A \in \operatorname{Mat}(m, n, \mathbb{F})$ and $q := \min(m, n)$.

(i) The *spectral norm* of A is $\|A\|_2 := \sup_{\|\mathbf{x}\|_2 = 1} \|A\mathbf{x}\|_2$.

(ii) If $\sigma_1 \geq \cdots \geq \sigma_q \geq 0$ are the singular values of A, set $(\forall j \in J_q)\,\sigma_j(A) := \sigma_j$ and $\sigma_{\max}(A) := \sigma_1$.

(iii) If $m = n$, set $\sigma_{\min}(A) := \sigma_n$.

Theorem 5.1.2. *Spectral Norm is the Largest Singular Value*
Let $A \in \operatorname{Mat}(m, n, \mathbb{F})$ have singular values $\sigma_1 \geq \cdots \geq \sigma_q \geq 0$.

(i) $\|A\|_2 = \sigma_{\max}(A)$.

(ii) If $A = V\Sigma W^*$ is an SVD and $\mathbf{w}_1$ is first column of W, then $\|A\mathbf{w}_1\|_2 = \sigma_1$. Hence supremum in Definition 5.1.1(i) is attained.

Proof. Fix an SVD $A = V\Sigma W^*$ by Theorem 4.2.9, and let $\mathbf{w}_1, \ldots, \mathbf{w}_n$ be the columns of W.

(i) For $\mathbf{x} = \sum_{j=1}^{n} c_j \mathbf{w}_j$ with $\|\mathbf{x}\|_2 = 1$, $\sum_{j=1}^{n} |c_j|^2 = 1$ by Theorem 2.6.8(vii). Thus $\|A\mathbf{x}\|_2^2 = \sum_{j=1}^{q} \sigma_j^2\,|c_j|^2 \leq \sigma_1^2$ by the SVD, so $\|A\|_2 \leq \sigma_1$.

(ii) The SVD has $A\mathbf{w}_1 = \sigma_1 \mathbf{v}_1$ with unit vectors $\mathbf{w}_1, \mathbf{v}_1$, so $\|A\mathbf{w}_1\|_2 = \sigma_1$. Hence $\|A\|_2 \geq \sigma_1$, attained at $\mathbf{w}_1$.

Structural Commentary: The SVD reduces unit-vector stretch to a weighted coefficient sum.
Key Insight: The coefficient bound is sharp at $\mathbf{w}_1$. □

Proposition 5.1.3. *Basic Properties of the Spectral Norm*
Let $A, B \in \operatorname{Mat}(m, n, \mathbb{F})$, $C \in \operatorname{Mat}(n, k, \mathbb{F})$, and $c \in \mathbb{F}$.

(i) $\|A\|_2 \geq 0$;
(ii) $\|A\|_2 = 0$ *if and only if* $A = 0$;
(iii) $\|cA\|_2 = |c|\,\|A\|_2$;
(iv) $\|A + B\|_2 \leq \|A\|_2 + \|B\|_2$;
(v) $\|AC\|_2 \leq \|A\|_2\,\|C\|_2$.

Proof. If $\mathbf{y} \neq \mathbf{0}$, then $\|A\mathbf{y}\|_2 \leq \|A\|_2\,\|\mathbf{y}\|_2$ by Definition 5.1.1(i), after normalization. For $\mathbf{y} = \mathbf{0}$, the same estimate is immediate.

(i) $\|A\|_2 \geq 0$ by Definition 5.1.1(i).
(ii) ($\Rightarrow$) If $\|A\|_2 = 0$, the estimate forces $(\forall \mathbf{y} \in \mathbb{F}^n)\,A\mathbf{y} = \mathbf{0}$, so $A = 0$.
(ii) ($\Leftarrow$) If $A = 0$, then $\|A\|_2 = 0$ by Definition 5.1.1(i).

(iii) $\|cA\|_2 = \sup_{\|\mathbf{x}\|_2=1} \|cA\mathbf{x}\|_2 = |c|\,\|A\|_2$ by Euclidean homogeneity.
(iv) For $\|\mathbf{x}\|_2 = 1$, $\|(A+B)\mathbf{x}\|_2 \le \|A\mathbf{x}\|_2 + \|B\mathbf{x}\|_2 \le \|A\|_2 + \|B\|_2$. Thus $\|A+B\|_2 \le \|A\|_2 + \|B\|_2$ by the unit-sphere supremum.
(v) For $\|\mathbf{x}\|_2 = 1$, $\|AC\mathbf{x}\|_2 \le \|A\|_2\,\|C\mathbf{x}\|_2 \le \|A\|_2\,\|C\|_2$. Thus $\|AC\|_2 \le \|A\|_2\,\|C\|_2$ by the unit-sphere supremum.

Structural Commentary: The scaled-vector estimate feeds definiteness, homogeneity, addition, and composition.
Key Insight: Euclidean control precedes the unit-sphere supremum. □

Definition 5.1.4. *Operator Norm and Induced Metric on $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$*
For $A, B \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$, define $\|A\|_{\mathrm{op}} := \sup_{\|\mathbf{h}\|_2 \le 1} \|A\mathbf{h}\|_2$ and $d(A,B) := \|A - B\|_{\mathrm{op}}$.
Under standard-basis identification, $\|A\|_{\mathrm{op}} = \|[A]\|_2$ by scaling; hence $(\forall \mathbf{h} \in \mathbb{R}^n)\ \|A\mathbf{h}\|_2 \le \|A\|_{\mathrm{op}}\,\|\mathbf{h}\|_2$.
The norm laws for sums and compatible compositions are Proposition 5.1.3.

Proposition 5.1.5. *Frobenius and Spectral Norm Comparison*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ have singular values $\sigma_1 \ge \cdots \ge \sigma_q \ge 0$.

(i) $\|A\|_F^2 = \sum_{j=1}^{q} \sigma_j^2$.
(ii) $\|A\|_2 \le \|A\|_F$.
(iii) If $A \neq 0$, then $\|A\|_2 = \|A\|_F$ if and only if $\mathrm{rank}(A) = 1$.

Proof.
(i) The identity holds by Proposition 4.2.11(ii).
(ii) $\|A\|_2^2 = \sigma_1^2 \le \sum_{j=1}^{q} \sigma_j^2 = \|A\|_F^2$ by Theorem 5.1.2(i) and part (i).
(iii) ($\Rightarrow$) If $A \neq 0$ and $\|A\|_2 = \|A\|_F$, then $\sum_{j=2}^{q} \sigma_j^2 = \|A\|_F^2 - \|A\|_2^2 = 0$ by parts (i)–(ii). Thus $\mathrm{rank}(A) = 1$ by Definition 4.2.8.
(iii) ($\Leftarrow$) If $\mathrm{rank}(A) = 1$, then $\sigma_2 = \cdots = \sigma_q = 0$ by Definition 4.2.8; hence $\|A\|_2 = \|A\|_F$ by parts (i)–(ii).

Structural Commentary: Frobenius aggregates all squared singular values; spectral isolates their maximum.
Key Insight: Equality excludes every singular direction except one. □

Theorem 5.1.6. *Submultiplicativity of Frobenius and Spectral Norms*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$ and $B \in \mathrm{Mat}(n,k,\mathbb{F})$.

(i) $\|AB\|_F \le \|A\|_2\,\|B\|_F \le \|A\|_F\,\|B\|_F$.
(ii) $\|AB\|_2 \le \|A\|_2\,\|B\|_2$.

Proof.
(i) Write $B = [\mathbf{b}_1\ \cdots\ \mathbf{b}_k]$. Then $(\forall j \in J_k)\ \|A\mathbf{b}_j\|_2 \le \|A\|_2\,\|\mathbf{b}_j\|_2$ by Definition 5.1.1(i) and scaling.
Hence $\|AB\|_F^2 = \sum_{j=1}^{k} \|A\mathbf{b}_j\|_2^2 \le \|A\|_2^2 \sum_{j=1}^{k} \|\mathbf{b}_j\|_2^2 = \|A\|_2^2\,\|B\|_F^2$; $\|AB\|_F \le \|A\|_2\,\|B\|_F \le \|A\|_F\,\|B\|_F$ by Proposition 5.1.5(ii).
(ii) The spectral-norm inequality holds by Proposition 5.1.3(v).

Structural Commentary: Columnwise spectral bounds sum to Frobenius control; norm comparison closes the chain.
Key Insight: Each column of AB inherits the same factor $\|A\|_2$. □

Proposition 5.1.7. *Unitary Invariance of Singular Values*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$, and let $U \in \mathrm{Mat}(m,m,\mathbb{F})$ and $V \in \mathrm{Mat}(n,n,\mathbb{F})$ be unitary.

(i) A and UAV have the same singular values.
(ii) $\|UAV\|_2 = \|A\|_2$.
(iii) $\|UAV\|_F = \|A\|_F$.

Proof.
(i) Fix an SVD $A = X\Sigma Y^*$ by Theorem 4.2.9.
Since UX and V^*Y are unitary, $UAV = (UX)\Sigma(V^*Y)^*$ is an SVD with the same diagonal Σ.
(ii) $\|UAV\|_2 = \|A\|_2$ by part (i) and Theorem 5.1.2(i).
(iii) $\|UAV\|_F = \|A\|_F$ by part (i) and Proposition 4.2.11(ii).

Structural Commentary: Multiplying the two SVD bases absorbs the exterior unitary factors.
Key Insight: The diagonal singular factor Σ remains unchanged. □

Counterexample 5.1.8. *Similarity Need Not Preserve Singular Values*
The claim that arbitrary similarity preserves singular values fails in $\mathrm{Mat}(2,2,\mathbb{R})$. Set $A = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 1 & 2 \\ 0 & 1 \end{smallmatrix}\right)$, and $D = \mathrm{diag}(2,1)$.
Then $B = DAD^{-1}$, so A and B are similar. Their Gram matrices are $A^*A = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ and $B^*B = \left(\begin{smallmatrix} 1 & 2 \\ 2 & 5 \end{smallmatrix}\right)$.
Both A and B are invertible, so all their Gram eigenvalues are positive. The Gram matrices have traces 3 and 6.
Hence their spectra, and therefore the singular values of A and B, differ by Proposition 4.2.11(i).
Thus Proposition 5.1.7 cannot be extended from unitary left-right equivalence to arbitrary similarity.

Theorem 5.1.9. *Schur's Inequality and Normality*
Let $A \in \mathrm{Mat}(n,n,\mathbb{C})$ have eigenvalues $\lambda_1, \ldots, \lambda_n$, counted with algebraic multiplicity.

(i) $\sum_{j=1}^{n} |\lambda_j|^2 \le \|A\|_F^2$.
(ii) Equality holds in (i) if and only if A is normal.

Proof. Fix a unitary U such that $T := U^*AU = [t_{ij}]$ is upper triangular by Theorem 5.4.14(i) with $\mathcal{F} = \{A\}$.
Relabel the eigenvalues so that $(\forall j \in J_n)\, t_{jj} = \lambda_j$ by Proposition 2.1.6(iii).

(*i*) $\|A\|_F^2 = \|T\|_F^2 = \sum_{i,j=1}^{n} |t_{ij}|^2$ by Propositions 5.1.7(iii) and 4.2.11(ii), with direct matrix multiplication.

Thus $\|A\|_F^2 = \sum_{j=1}^{n} |\lambda_j|^2 + \sum_{i<j} |t_{ij}|^2$ by triangularity, and (i) holds by nonnegativity of the final sum.

(*ii*) ($\Rightarrow$) Equality forces $\sum_{i<j} |t_{ij}|^2 = 0$ by part (i), so T is diagonal and $A = UTU^*$ is normal.

(*ii*) ($\Leftarrow$) If A is normal, then $T^*T = U^*A^*AU = U^*AA^*U = TT^*$, so T is diagonal by Lemma 6.1.10. Equality follows by part (i).

Structural Commentary: Unitary Schur form partitions Frobenius energy into diagonal spectral and strict-upper terms.
Key Insight: Equality is equivalent to vanishing strict-upper energy. □

Definition 5.1.10. *Defect from Normality*

Let $A \in \mathrm{Mat}(n, n, \mathbb{C})$ have eigenvalues $\lambda_1, \dots, \lambda_n$ with algebraic multiplicity. Its *defect from normality* is $\Delta(A) := \|A\|_F^2 - \sum_{j=1}^{n} |\lambda_j|^2$.

Then $\Delta(A) \geq 0$, and $\Delta(A) = 0$ if and only if A is normal, by Theorem 5.1.9(i)–(ii).

Theorem 5.1.11. *Normality Transfers from AB to BA*
Let $A, B \in \mathrm{Mat}(n, n, \mathbb{C})$. If A, B, and AB are normal, then BA is normal.

Proof. AB, BA have same eigenvalue multiset by Theorem 1.1.12(i) with equal sizes. Set $M := A^*A = AA^*$, $N := B^*B = BB^*$.
Then $\|BA\|_F^2 = \mathrm{tr}(A^*NA) = \mathrm{tr}(MN)$ and $\|AB\|_F^2 = \mathrm{tr}(B^*MB) = \mathrm{tr}(NM) = \mathrm{tr}(MN)$ by Propositions 4.2.11(ii) and 1.1.4(i).
Hence $\Delta(BA) = \Delta(AB)$ by Definition 5.1.10, $\Delta(AB) = 0$ by Theorem 5.1.9(ii); $\Delta(BA) = 0$, so BA is normal by Theorem 5.1.9(ii).
Structural Commentary: Common spectral data and a cyclic trace identity transfer the Schur defect from AB to BA.
Key Insight: Normal factors force $\|BA\|_F = \|AB\|_F$. □

Theorem 5.1.12. *Eigenvalues Versus Singular Values*
Let $A \in \mathrm{Mat}(n, n, \mathbb{C})$ have eigenvalues $\lambda_1, \dots, \lambda_n$ ordered so that $|\lambda_1| \geq \cdots \geq |\lambda_n|$.
Let $\sigma_1 \geq \cdots \geq \sigma_n \geq 0$ be its singular values.

(*i*) $|\det A| = \prod_{j=1}^{n} |\lambda_j| = \prod_{j=1}^{n} \sigma_j$;
(*ii*) $\rho(A) \leq \|A\|_2$;
(*iii*) $\sigma_n \leq |\lambda_n|$;
(*iv*) *A is normal if and only if* $(\forall j \in J_n)\ |\lambda_j| = \sigma_j$;
(*v*) *A is positive semidefinite if and only if* $(\forall j \in J_n)\ \lambda_j = \sigma_j$.

Proof.

(*i*) $|\det A| = \prod_{j=1}^{n} |\lambda_j|$ by Proposition 1.1.14(ii).

For an SVD $A = V\Sigma W^*$, $|\det A| = |\det \Sigma| = \prod_{j=1}^{n} \sigma_j$ by Proposition 1.1.19(i) and Theorem 3.8.2(v)–(vi).

(*ii*) If $A\mathbf{x} = \lambda\mathbf{x}$ and $\|\mathbf{x}\|_2 = 1$, then $|\lambda| = \|A\mathbf{x}\|_2 \leq \|A\|_2$ by Definition 5.1.1(i); hence (ii) by maximizing over λ.

(*iii*) If A is singular, $|\lambda_n| = \sigma_n = 0$ by Corollaries 5.1.8 and 4.2.12.
If A is invertible, then $\rho(A^{-1}) = |\lambda_n|^{-1}$ by Corollary 2.1.10. For an SVD $A = V\Sigma W^*$, $A^{-1} = W\Sigma^{-1}V^*$, so $\left\|A^{-1}\right\|_2 = \sigma_n^{-1}$ by Theorem 5.1.2(i), after reversing the diagonal order. Thus $\sigma_n \leq |\lambda_n|$ by part (ii) for A^{-1}.

(*iv*) ($\Rightarrow$) After reordering, fix $A = U\,\mathrm{diag}(\lambda_1, \dots, \lambda_n)U^*$ by Theorem 6.1.11(i)$\Rightarrow$(ii).
Then $(\forall j \in J_n)\, \sigma_j = |\lambda_j|$ by Proposition 5.1.7(i) and Definition 4.2.8.

(*iv*) ($\Leftarrow$) If $(\forall j \in J_n)\ |\lambda_j| = \sigma_j$, then $\sum_{j=1}^{n} |\lambda_j|^2 = \sum_{j=1}^{n} \sigma_j^2 = \|A\|_F^2$ by Proposition 4.2.11(ii). Thus A is normal by Theorem 5.1.9(ii).

(*v*) ($\Rightarrow$) If $A \succeq 0$, then A is Hermitian with nonnegative eigenvalues by Theorem 2.1.3(i)$\Rightarrow$(ii).
Hence A is normal and $(\forall j \in J_n)\, \lambda_j = \sigma_j$ by part (iv).

(*v*) ($\Leftarrow$) If $(\forall j \in J_n)\, \lambda_j = \sigma_j$, then A is normal by part (iv) and its eigenvalues are nonnegative.
By Theorem 6.1.11(i)$\Rightarrow$(ii), $A = U\,\mathrm{diag}(\lambda_1, \dots, \lambda_n)U^*$ for a unitary U, so $A = A^*$ and $A \succeq 0$ by Theorem 2.1.3(ii)$\Rightarrow$(i).

Structural Commentary: Determinants, extremal norms, and Schur energy compare eigenvalues with singular values.
Key Insight: Equality of squared spectral masses detects normality. □

Theorem 5.1.13. *Trace Bound by Singular Values*
Let $A = [a_{ij}] \in \mathrm{Mat}(n, n, \mathbb{C})$ have eigenvalues $\lambda_1, \dots, \lambda_n$, counted with algebraic multiplicity. Let $\sigma_1, \dots, \sigma_n$ be its singular values.

(*i*) $|\mathrm{tr}\, A| \leq \sum_{j=1}^{n} \sigma_j$;
(*ii*) $\sum_{j=1}^{n} |\lambda_j| \leq \sum_{j=1}^{n} \sigma_j$;
(*iii*) $\sum_{j=1}^{n} |a_{jj}| \leq \sum_{j=1}^{n} \sigma_j$.

Proof. Set $\omega : \mathbb{C} \to \mathbb{C}$ by $\omega(0) := 1$ and $\omega(z) := \overline{z}/\,|z|$ for $z \neq 0$; then $(\forall z \in \mathbb{C})\ |\omega(z)| = 1$ and $\omega(z)z = |z|$.

(i) Fix an SVD $A = V\Sigma W^*$ by Theorem 4.2.9, and write $\mathbf{v}_j, \mathbf{w}_j$ for the columns of V, W.
$\mathrm{tr}\, A = \sum_{j=1}^{n} \sigma_j \mathbf{w}_j^* \mathbf{v}_j$ by Proposition 1.1.3, while $(\forall j \in J_n)\ \left|\mathbf{w}_j^* \mathbf{v}_j\right| \leq 1$ by Theorem 1.1.13(i); $|\mathrm{tr}\, A| \leq \sum_{j=1}^{n} \sigma_j$ by triangle inequality.

(ii) Fix a Schur form $T := U^*AU = [t_{ij}]$ by Theorem 5.4.14(i) with $\mathcal{F} = \{A\}$.
Relabel so that $(\forall j \in J_n)\, t_{jj} = \lambda_j$ by Proposition 2.1.6(iii). For $D_\lambda := \mathrm{diag}(\omega(\lambda_1), \dots, \omega(\lambda_n))$, $\mathrm{tr}(D_\lambda T) = \sum_{j=1}^{n} |\lambda_j|$.
The matrices $D_\lambda T$ and A have the same singular values by Proposition 5.1.7(i), so (ii) holds by part (i) for $D_\lambda T$.

(iii) For $D_A := \operatorname{diag}(\omega(a_{11}), \dots, \omega(a_{nn}))$, $\operatorname{tr}(D_A A) = \sum_{j=1}^{n} |a_{jj}|$.

The matrices $D_A A$ and A have the same singular values by Proposition 5.1.7(i), so (iii) holds by part (i) for $D_A A$.

Structural Commentary: SVD controls trace; diagonal phase rotations transfer that bound to Schur and coordinate diagonals.
Key Insight: Choose phases so every selected diagonal contribution is nonnegative. □

5.2 Low-Rank Approximation and Pseudoinverses

Throughout this subsection, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$; every matrix dimension is positive.

Proposition 5.2.1. *Rank-One SVD Terms and Truncation Error*
Let $A = X\Sigma_r Y^* = \sum_{j=1}^{r} \sigma_j \mathbf{x}_j \mathbf{y}_j^*$ be a compact SVD, with $\sigma_1 \geq \cdots \geq \sigma_r > 0$. For $k \in \{0, \dots, r\}$, set $A_k := \sum_{j=1}^{k} \sigma_j \mathbf{x}_j \mathbf{y}_j^*$, where $A_0 := 0$.

(i) $(\forall i, j \in J_r)\ \left\langle \sigma_i \mathbf{x}_i \mathbf{y}_i^*, \sigma_j \mathbf{x}_j \mathbf{y}_j^* \right\rangle_F = \sigma_i^2 \delta_{ij}$.

(ii) $\|A\|_F^2 = \sum_{j=1}^{r} \sigma_j^2$ *and* $\|A - A_k\|_F^2 = \sum_{j=k+1}^{r} \sigma_j^2$.

(iii) $k < r \implies \|A - A_k\|_2 = \sigma_{k+1}$, *while* $k = r \implies \|A - A_k\|_2 = 0$.

Proof.

(i) $(\forall i, j \in J_r)\ \left\langle \sigma_i \mathbf{x}_i \mathbf{y}_i^*, \sigma_j \mathbf{x}_j \mathbf{y}_j^* \right\rangle_F = \sigma_i \sigma_j (\mathbf{y}_i^* \mathbf{y}_j)(\mathbf{x}_j^* \mathbf{x}_i) = \sigma_i^2 \delta_{ij}$ by orthonormality.

(ii) The first identity holds by Proposition 4.2.11(ii). For $k < r$, the residual is $A - A_k = \sum_{j=k+1}^{r} \sigma_j \mathbf{x}_j \mathbf{y}_j^*$.

Its positive singular values are $\sigma_{k+1}, \dots, \sigma_r$ by Theorem 4.2.14(ii).
The second identity now holds by Proposition 4.2.11(ii); for $k = r$, it is $0 = 0$.

(iii) If $k < r$, then $\|A - A_k\|_2 = \sigma_{k+1}$ by (ii) and Theorem 5.1.2(i); if $k = r$, then $A - A_k = 0$.

Structural Commentary: Frobenius orthogonality separates rank-one terms; compact SVD identifies the residual spectrum.
Key Insight: Truncation leaves exactly the singular-value tail. □

Figure 92 separates the retained and discarded singular-value terms.

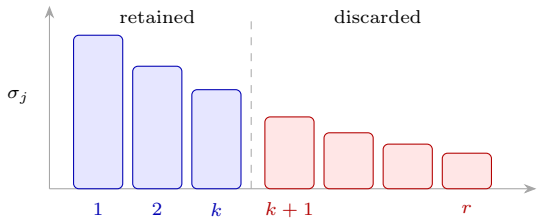

Figure 92: Bars left of the dashed divider form A_k; the right-hand bars satisfy $\|A - A_k\|_F^2 = \sum_{j=k+1}^{r} \sigma_j^2$.

Theorem 5.2.2. *Eckart–Young Low-Rank Approximation*
Let $A \in \operatorname{Mat}(m, n, \mathbb{F})$ have rank r, set $q := \min(m, n)$. Write $\sigma_1 \geq \cdots \geq \sigma_q \geq 0$ for its singular values, fix a full SVD $A = V\Sigma W^*$. Write $\mathbf{v}_j, \mathbf{w}_j$ for the columns of V, W, and set $(\forall j \in J_n \setminus J_q)\ \sigma_j := 0$. For $0 \leq k < q$, set $A_k := \sum_{j=1}^{k} \sigma_j \mathbf{v}_j \mathbf{w}_j^*$.

If $B \in \operatorname{Mat}(m, n, \mathbb{F})$ and $\operatorname{rank}(B) \leq k$, then:

(i) $\|A - A_k\|_2 \leq \|A - B\|_2$;

(ii) $\|A - A_k\|_F \leq \|A - B\|_F$.

Proof. If $k \geq r$, then $A_k = A$ and $\|A - A_k\|_2 = \|A - A_k\|_F = 0$, so both claims hold.
For $k < r$, the first r columns of V, W form a compact SVD of A by Theorem 4.2.14(i). Its rank-k truncation is A_k.

(i) $\dim \ker(B) \geq n - k$ by Corollary 3.3.1(i). $\ker(B) \cap \operatorname{span}(\mathbf{w}_1, \dots, \mathbf{w}_{k+1}) \neq \{\mathbf{0}\}$ by Corollary 2.3.3(i).

Fix a unit vector $\mathbf{x} = \sum_{i=1}^{k+1} c_i \mathbf{w}_i$ in this intersection. Then $\sum_{i=1}^{k+1} |c_i|^2 = 1$ and $\|A\mathbf{x}\|_2^2 = \sum_{i=1}^{k+1} \sigma_i^2 |c_i|^2 \geq \sigma_{k+1}^2$ by orthonormality.

$\|A - B\|_2 \geq \|(A - B)\mathbf{x}\|_2 = \|A\mathbf{x}\|_2 \geq \sigma_{k+1}$ by $B\mathbf{x} = \mathbf{0}$, spectral-norm definition. $\sigma_{k+1} = \|A - A_k\|_2$ by Proposition 5.2.1(iii).

(ii) $\dim \ker(B) \geq n - k$ by Corollary 3.3.1(i); choose $\mathcal{U} \subseteq \ker(B)$ with $\dim \mathcal{U} = n - k$.

An orthonormal basis $\mathbf{z}_1, \dots, \mathbf{z}_{n-k}$ of $\mathcal{U}$ exists by Corollary 1.3.11. Extend it to $\mathbf{z}_1, \dots, \mathbf{z}_n$ by Corollary 1.3.12.

For $Z := [\mathbf{z}_1 \ \cdots \ \mathbf{z}_n]$ and $P := P_{\mathcal{U}}$, Z is unitary by Theorem 2.6.8(i)–(ii). $\|A - B\|_F^2 = \|(A - B)Z\|_F^2$ by Proposition 5.1.7(iii).

$\|(A - B)Z\|_F^2 \geq \sum_{j=1}^{n-k} \|A\mathbf{z}_j\|_2^2$ by the column formula for $\|\cdot\|_F$ and $(\forall j \in J_{n-k})\ B\mathbf{z}_j = \mathbf{0}$.

Set $(\alpha_i)_{i \in J_n} := (\|P\mathbf{w}_i\|_2^2)_{i \in J_n}$. Then $\sum_{j=1}^{n-k} \|A\mathbf{z}_j\|_2^2 = \sum_{i=1}^{n} \sigma_i^2 \alpha_i$ by orthonormality and Proposition 2.2.3(ix).

$(\forall i \in J_n)\ 0 \leq \alpha_i \leq 1$ by Proposition 2.2.3(viii). $\sum_{i=1}^{n} \alpha_i = n - k$ by Theorem 1.4.7. Thus $\beta := \sum_{i=1}^{k} \alpha_i = \sum_{i=k+1}^{n} (1 - \alpha_i)$.

$\sum_{i=1}^{n} \sigma_i^2 \alpha_i - \sum_{i=k+1}^{n} \sigma_i^2 \geq \sigma_{k+1}^2 (\beta - \beta) = 0$ by singular-value ordering. $\|A - B\|_F^2 \geq \sum_{i=k+1}^{n} \sigma_i^2 = \|A - A_k\|_F^2$ by Proposition 5.2.1(ii).

Structural Commentary: Kernel intersection controls spectral loss; projection weights majorize the Frobenius tail.
Key Insight: Rank k preserves at most k singular directions. □

Computation Method 5.2.3. *Truncated SVD Approximation*
Given $A \in \mathrm{Mat}(m,n,\mathbb{F})$ with compact SVD $A = X\Sigma_r Y^*$ and $k \in \{0,\dots,r-1\}$:

(i) set $\mathcal{R}_k := \{B \in \mathrm{Mat}(m,n,\mathbb{F}) : \mathrm{rank}(B) \le k\}$;

(ii) form $A_k := \sum_{j=1}^{k} \sigma_j \mathbf{x}_j \mathbf{y}_j^* \in \mathcal{R}_k$;

(iii) compute $\|A - A_k\|_F^2 = \sum_{j=k+1}^{r} \sigma_j^2$ and $\|A - A_k\|_2 = \sigma_{k+1}$;

(iv) certify $(\forall \nu \in \{2, F\})\ \|A - A_k\|_\nu = \min_{B \in \mathcal{R}_k} \|A - B\|_\nu$ by (ii) and Theorem 5.2.2.

The same compact SVD data defines a canonical inverse on the nonzero singular subspaces.

Definition 5.2.4. *Moore–Penrose Pseudoinverse*
For $A \in \mathrm{Mat}(m,n,\mathbb{F})$, define $A^\dagger \in \mathrm{Mat}(n,m,\mathbb{F})$ by:

(i) $A = 0 \Longrightarrow A^\dagger := 0_{n,m}$;

(ii) $\mathrm{rank}(A) = r \ge 1 \Longrightarrow A^\dagger := Y\Sigma_r^{-1}X^*$ for a compact SVD $A = X\Sigma_r Y^*$.

The matrix $A^\dagger$ is the *pseudoinverse* or *Moore–Penrose pseudoinverse* of A.

Proposition 5.2.5. *Pseudoinverse is Well Defined*
The definition of $A^\dagger$ does not depend on the chosen compact SVD of A.

Proof. The assertion is immediate for $A = 0$. Suppose $\mathrm{rank}(A) = r \ge 1$. Let $A = X_1\Sigma_r Y_1^* = X_2\Sigma_r Y_2^*$ be compact SVDs.
Unitary U satisfies $X_1 = X_2U$, $Y_1 = Y_2U$, $U\Sigma_r = \Sigma_r U$ by Theorem 4.2.16. $U\Sigma_r^{-1}U^* = \Sigma_r^{-1}$; $Y_1\Sigma_r^{-1}X_1^* = Y_2U\Sigma_r^{-1}U^*X_2^* = Y_2\Sigma_r^{-1}X_2^*$.
Structural Commentary: Compact-SVD ambiguity commutes with reciprocal scaling and cancels between the singular bases.
Key Insight: Equal-value blocks also commute with Σ_r^{-1}. □

Corollary 5.2.6. *Pseudoinverse from a Full SVD*
Let $A = V\Sigma W^*$ be a full SVD of $A \in \mathrm{Mat}(m,n,\mathbb{F})$ with rank r, and set $D_r := \{(j,j) : j \in J_r\}$.
Define $\Sigma^\dagger \in \mathrm{Mat}(n,m,\mathbb{F})$ by $(\forall j \in J_r)\,(\Sigma^\dagger)_{jj} := \sigma_j^{-1}$. $(\forall (i,j) \in (J_n \times J_m) \setminus D_r)\,(\Sigma^\dagger)_{ij} := 0$. Then $A^\dagger = W\Sigma^\dagger V^*$.

Proof. If $r = 0$, then $A = 0$, $\Sigma^\dagger = 0_{n,m}$, and $W\Sigma^\dagger V^* = A^\dagger = 0_{n,m}$. Suppose $r \ge 1$, and write $V = [X\ X_0]$ and $W = [Y\ Y_0]$.
Then $A = X\Sigma_r Y^*$ and $W\Sigma^\dagger V^* = Y\Sigma_r^{-1}X^*$ by block multiplication. Hence $A^\dagger = W\Sigma^\dagger V^*$ by the defining compact-SVD formula.
Structural Commentary: Full-SVD block multiplication isolates the compact factors and their reciprocal scaling.
Key Insight: Only positive diagonal entries are inverted. □

Theorem 5.2.7. *Basic Properties of the Pseudoinverse*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$. Then:
(i) $\mathrm{col}(A^\dagger) = \mathrm{col}(A^*)$ and $\ker(A^\dagger) = \ker(A^*)$;
(ii) $AA^\dagger$ is the orthogonal projection of $\mathbb{F}^m$ onto $\mathrm{col}(A)$;
(iii) $A^\dagger A$ is the orthogonal projection of $\mathbb{F}^n$ onto $\mathrm{col}(A^*)$;
(iv) $AA^\dagger A = A$ and $A^\dagger AA^\dagger = A^\dagger$;
(v) $(A^\dagger)^\dagger = A$;
(vi) if $m = n$ and A is invertible, then $A^\dagger = A^{-1}$.

Proof. If $A = 0$, then (i)–(v) hold directly and the hypothesis of (vi) fails.
Suppose $\mathrm{rank}(A) = r \ge 1$. Fix a compact SVD $A = X\Sigma_r Y^*$; then $A^\dagger = Y\Sigma_r^{-1}X^*$ by the defining formula.

(i) $\mathrm{col}(A^\dagger) = \mathrm{col}(Y)$ by $A^\dagger = Y\Sigma_r^{-1}X^*$ and $A^\dagger X\Sigma_r = Y$. $\ker(A^\dagger) = \ker(X^*)$ by $Y^*A^\dagger = \Sigma_r^{-1}X^*$ and invertibility of Σ_r.
$A^* = Y\Sigma_r X^*$ is a compact SVD. $\mathrm{col}(A^*) = \mathrm{col}(Y)$ and $\ker(A^*) = \ker(X^*)$ by Theorem 4.2.15(i)–(ii).

(ii) $AA^\dagger = XX^* = P_{\mathrm{col}(X)} = P_{\mathrm{col}(A)}$ by Proposition 2.2.3(ix) and Theorem 4.2.15(i).

(iii) $A^\dagger A = YY^* = P_{\mathrm{col}(Y)} = P_{\mathrm{col}(A^*)}$ by Proposition 2.2.3(ix) and Theorem 4.2.15(i) for $A^* = Y\Sigma_r X^*$.

(iv) $AA^\dagger A = XX^*X\Sigma_r Y^* = A$ and $A^\dagger AA^\dagger = YY^*Y\Sigma_r^{-1}X^* = A^\dagger$ by $X^*X = Y^*Y = I_r$.

(v) Let $R \in \mathrm{Mat}(r,r,\mathbb{F})$ be the reversal permutation matrix, so $(\forall j \in J_r)\,R\mathbf{e}_j = \mathbf{e}_{r+1-j}$.
Then $A^\dagger = (YR)(R^*\Sigma_r^{-1}R)(XR)^*$ is a compact SVD with decreasing positive diagonal.
Hence $(A^\dagger)^\dagger = (XR)(R^*\Sigma_r R)(YR)^* = X\Sigma_r Y^* = A$ by the defining compact-SVD formula.

(vi) If A is square and invertible, then A^* is invertible by Proposition 2.3.9(i).
$\mathrm{col}(A) = \mathrm{col}(A^*) = \mathbb{F}^n$ by Corollary 3.6.2. $AA^\dagger = A^\dagger A = I_n$ by (ii)–(iii), so $A^\dagger = A^{-1}$.

Structural Commentary: Compact-SVD multiplication identifies the two projectors; reversed reciprocal scaling recovers A.
Key Insight: Positive singular coordinates invert; null coordinates remain zero. □

Figure 93 identifies the active inverse pair and the annihilated kernels.

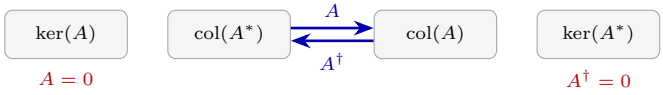

Figure 93: The arrows invert the active singular subspaces; the outer boxes mark $\ker(A)$ and $\ker(A^*)$.

Theorem 5.2.8. *Penrose Characterization of the Pseudoinverse*
Let $A \in \mathrm{Mat}(m,n,\mathbb{F})$, $B \in \mathrm{Mat}(n,m,\mathbb{F})$. Set $\mathsf{P}_A(B) := [ABA = A \wedge BAB = B \wedge (AB)^* = AB \wedge (BA)^* = BA]$; $B = A^\dagger \iff \mathsf{P}_A(B)$.

Proof.
(⇒) Suppose $B = A^\dagger$. The first two conjuncts hold by Theorem 5.2.7(iv).
Matrices AB and BA are orthogonal projections by Theorem 5.2.7(ii)–(iii). $(AB)^* = AB$ and $(BA)^* = BA$ by Theorem 2.5.6.

($\Leftarrow$) Suppose $\mathsf{P}_A(B)$, and set $\mathcal{C} := \mathrm{col}(A)$ and $\mathcal{D} := \mathrm{col}(A^*)$. Then $(AB)^2 = ABAB = AB$ and $(AB)^* = AB$.
The relations $\mathrm{range}(AB) \subseteq \mathcal{C}$ and $(\forall \mathbf{x} \in \mathbb{F}^n)\, AB(A\mathbf{x}) = A\mathbf{x}$ establish $\mathrm{range}(AB) = \mathcal{C}$.
$AB = P_{\mathcal{C}}$ by Theorem 2.5.6. For BA, $(BA)^2 = BABA = BA$ and $(BA)^* = BA$.
$\ker(BA) \subseteq \ker(A)$ by $(\forall \mathbf{x} \in \mathbb{F}^n)\, [BA\mathbf{x} = \mathbf{0} \Rightarrow A\mathbf{x} = ABA\mathbf{x} = \mathbf{0}]$.
$\ker(A) \subseteq \ker(BA)$ by $(\forall \mathbf{x} \in \mathbb{F}^n)\, [A\mathbf{x} = \mathbf{0} \Rightarrow BA\mathbf{x} = \mathbf{0}]$; hence $\ker(BA) = \ker(A)$.
$\mathrm{range}(BA) = (\ker(BA))^\perp = (\ker A)^\perp = \mathcal{D}$ by Proposition 2.3.10(iii)–(iv). $BA = P_{\mathcal{D}}$ by Theorem 2.5.6.
The identities $AB = AA^\dagger$ and $BA = A^\dagger A$ hold by Theorem 5.2.7(ii)–(iii).
$B = BAB = B(AA^\dagger) = (BA)A^\dagger = (A^\dagger A)A^\dagger = A^\dagger$ by $\mathsf{P}_A(B)$ and Theorem 5.2.7(iv).

Structural Commentary: Self-adjoint idempotence identifies both range projections; their product identities collapse B.
Key Insight: $AB = AA^\dagger$ and $BA = A^\dagger A$ force $B = A^\dagger$. □

Theorem 5.2.9. *Pseudoinverse and Minimum-Norm Least Squares*
For $A \in \mathrm{Mat}(m, n, \mathbb{F})$ and $\mathbf{y} \in \mathbb{F}^m$, set $\mathbf{x}_0 := A^\dagger \mathbf{y}$.
(i) $\mathbf{x}_0 \in \mathrm{LS}(A, \mathbf{y})$ *and* $\operatorname{arg\,min}_{\mathbf{x} \in \mathrm{LS}(A,\mathbf{y})} \|\mathbf{x}\|_2 = \{\mathbf{x}_0\}$.
(ii) If $\mathbf{y} \in \mathrm{col}(A)$, *then* $A\mathbf{x}_0 = \mathbf{y}$ *and* $\operatorname{arg\,min}_{\mathbf{x} \in \mathbb{F}^n :\, A\mathbf{x} = \mathbf{y}} \|\mathbf{x}\|_2 = \{\mathbf{x}_0\}$.

Proof. Set $P := AA^\dagger = P_{\mathrm{col}(A)}$ by Theorem 5.2.7(ii); then $A\mathbf{x}_0 = P\mathbf{y}$.
$\mathbf{x}_0 \in \mathrm{col}(A^\dagger) = \mathrm{col}(A^*) = (\ker A)^\perp$ by Theorem 5.2.7(i) and Proposition 2.3.10(iii).
(i) $\mathbf{x}_0 \in \mathrm{LS}(A, \mathbf{y})$ by $A\mathbf{x}_0 = P\mathbf{y}$ and Theorem 2.2.6. $P_{(\ker A)^\perp}\mathbf{x}_0 = \mathbf{x}_0$ by Proposition 2.2.3(ii).
The minimum-norm identity holds by Proposition 2.4.5(iii).
(ii) If $\mathbf{y} \in \mathrm{col}(A)$, then $A\mathbf{x}_0 = P\mathbf{y} = \mathbf{y}$ by Proposition 2.2.3(ii).
Thus $\mathrm{LS}(A, \mathbf{y}) = \{\mathbf{x} \in \mathbb{F}^n : A\mathbf{x} = \mathbf{y}\}$ by the zero minimum residual, and the claim holds by (i).

Structural Commentary: $AA^\dagger$ fits the data; $\mathrm{col}(A^\dagger) = (\ker A)^\perp$ selects the shortest preimage.
Key Insight: The pseudoinverse removes every kernel component. □

Computation Method 5.2.10. *Minimum-Norm Least Squares by Pseudoinverse*
Given $A \in \mathrm{Mat}(m, n, \mathbb{F})$ and $\mathbf{y} \in \mathbb{F}^m$, compute the minimum-norm least-squares solution as follows:
(i) if $A = 0$, set $A^\dagger = 0_{n,m}$;
(ii) if $\mathrm{rank}(A) = r \geq 1$, compute a compact SVD $A = X\Sigma_r Y^*$ and form $A^\dagger = Y\Sigma_r^{-1}X^*$;
(iii) set $\mathbf{x}_0 := A^\dagger \mathbf{y}$;
(iv) certify $\operatorname{arg\,min}_{\mathbf{x} \in \mathrm{LS}(A,\mathbf{y})} \|\mathbf{x}\|_2 = \{\mathbf{x}_0\}$ by Theorem 5.2.9(i);
(v) if $\mathbf{y} \in \mathrm{col}(A)$, report $A\mathbf{x}_0 = \mathbf{y}$ by Theorem 5.2.9(ii).

5.3 Conditioning

Throughout this subsection, $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, and all matrix dimensions are positive integers.

Definition 5.3.1. *Spectral Condition Number*
If $A \in \mathrm{Mat}(n, n, \mathbb{F})$ is invertible, its *spectral condition number* is $\kappa_2(A) := \|A\|_2 \left\|A^{-1}\right\|_2$. If A is singular, $\kappa_2(A)$ is undefined.

Proposition 5.3.2. *Properties of the Spectral Condition Number*
Let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$ be invertible and let $c \in \mathbb{F} \setminus \{0\}$. Let $U, V \in \mathrm{Mat}(n, n, \mathbb{F})$ be unitary.
(i) $\kappa_2(AB) \leq \kappa_2(A)\kappa_2(B)$;
(ii) $\kappa_2(A) = \frac{\sigma_{\max}(A)}{\sigma_{\min}(A)} \geq 1$, *with equality if and only if A is a nonzero scalar multiple of a unitary matrix;*
(iii) $\kappa_2(cA) = \kappa_2(A)$;
(iv) $\kappa_2(A) = \kappa_2(A^*) = \kappa_2(A^{-1})$; *over $\mathbb{C}$, these also equal $\kappa_2(\overline{A})$ and $\kappa_2(A^t)$;*
(v) $\kappa_2(A^*A) = \kappa_2(A)^2$;
(vi) $\kappa_2(UAV) = \kappa_2(A)$.

Proof.
(i) By Proposition 5.1.3(v), $\kappa_2(AB) = \|AB\|_2 \left\|B^{-1}A^{-1}\right\|_2 \leq \kappa_2(A)\kappa_2(B)$.
(ii) ($\Rightarrow$) Fix SVD $A = X\Sigma Y^*$ by Theorem 4.2.9. Since A invertible, $\sigma_n(A) > 0$ by Corollary 4.2.12(i)$\Rightarrow$(iii), $A^{-1} = Y\Sigma^{-1}X^*$.
Thus $\kappa_2(A) = \frac{\sigma_1(A)}{\sigma_n(A)} \geq 1$ by Theorem 5.1.2(i). For $s := \sigma_1(A) > 0$, equality forces $\Sigma = sI_n$, so $A = sXY^*$, a nonzero scalar multiple of a unitary matrix by Theorem 2.6.8(iv) and Proposition 2.6.12(i).
(ii) ($\Leftarrow$) If $A = dQ$ with $d \neq 0$ and Q unitary, then $Q^*Q = I_n$, so the singular values of Q are all 1.
Those of A are all $|d|$ by Proposition 4.2.11(iv); hence the quotient in part (ii) is 1.
(iii) Since $(cA)^{-1} = c^{-1}A^{-1}$, $\kappa_2(cA) = |c| \|A\|_2 |c|^{-1} \left\|A^{-1}\right\|_2 = \kappa_2(A)$ by Proposition 5.1.3(iii).
(iv) The singular values are unchanged under adjoint and, over $\mathbb{C}$, under transpose and conjugation by Proposition 4.2.11(iii).
Inversion reverses and reciprocates them by part (ii), so every stated condition number equals $\kappa_2(A)$ by part (ii).
(v) Matrix A^*A positive definite by Corollary 4.2.12(i)$\Leftrightarrow$(iv). Its eigenvalues are $\sigma_1(A)^2, \ldots, \sigma_n(A)^2$ by Proposition 4.2.11(i).
These are also its singular values by Theorems 6.1.12 and 6.1.11, as appropriate, and Proposition 5.1.7(i).
Hence $\kappa_2(A^*A) = \frac{\sigma_1(A)^2}{\sigma_n(A)^2} = \kappa_2(A)^2$ by part (ii).
(vi) The equality $\kappa_2(UAV) = \kappa_2(A)$ holds by Proposition 5.1.7(i) and part (ii).

Structural Commentary: Norm laws and singular-value transformations transfer directly to κ_2.
Key Insight: Only the ratio $\frac{\sigma_1(A)}{\sigma_n(A)}$ matters. □

Corollary 5.3.3. *Positive Definite Condition Number by Eigenvalues*
Let $A \in \mathrm{Mat}(n, n, \mathbb{F})$ satisfy $A \succ 0$ and have eigenvalues $0 < \lambda_1 \leq \cdots \leq \lambda_n$.
(i) $\|A\|_2 = \lambda_n$;
(ii) $\left\|A^{-1}\right\|_2 = \lambda_1^{-1}$;

(iii) $\kappa_2(A) = \frac{\lambda_n}{\lambda_1}$.

Proof.

(*i*) The matrix A is self-adjoint with positive eigenvalues by Theorem 2.1.8(i)⇒(ii).
Singular values are $\lambda_n, \dots, \lambda_1$ by Theorems 6.1.12, 6.1.11, as appropriate, Proposition 5.1.7(i); $\|A\|_2 = \lambda_n$ by Theorem 5.1.2(i).

(*ii*) The same diagonalization has diagonal entries $\lambda_1^{-1}, \dots, \lambda_n^{-1}$ for A^{-1}, so these are its singular values by Proposition 5.1.7(i).
Thus $\left\|A^{-1}\right\|_2 = \lambda_1^{-1}$ by Theorem 5.1.2(i).

(*iii*) The identity $\kappa_2(A) = \frac{\lambda_n}{\lambda_1}$ follows by parts (i)–(ii).

Structural Commentary: Diagonalization assigns the two operator norms to opposite endpoint eigenvalues.
Key Insight: Positive definiteness removes absolute values and makes λ_1 nonzero. □

Perspective 5.3.4. *Determinant is Not Conditioning*
Let $A \in \mathrm{Mat}(n, n, \mathbb{F})$ invertible, $c \in \mathbb{F} \setminus \{0\}$. Then $\kappa_2(cA) = \kappa_2(A)$ by Proposition 5.3.2(iii); $\det(cA) = c^n \det(A)$ by Theorem 3.8.2(ii). Thus determinant records volume scaling, not sensitivity under uniform rescaling.

Theorem 5.3.5. *Condition Number and Linear-System Error*
Let $A \in \mathrm{Mat}(n, n, \mathbb{F})$ be invertible, $\mathbf{x}, \Delta\mathbf{x}, \Delta\mathbf{y} \in \mathbb{F}^n$, $\mathbf{y} \in \mathbb{F}^n \setminus \{\mathbf{0}\}$. If $A\mathbf{x} = \mathbf{y}$ and $A\Delta\mathbf{x} = \Delta\mathbf{y}$, then $\frac{\|\Delta\mathbf{x}\|_2}{\|\mathbf{x}\|_2} \le \kappa_2(A) \frac{\|\Delta\mathbf{y}\|_2}{\|\mathbf{y}\|_2}$.

Proof. Since A is invertible and $\mathbf{y} \neq \mathbf{0}$, $\mathbf{x} \neq \mathbf{0}$.
By defining norm bound, $\|\mathbf{y}\|_2 \le \|A\|_2 \|\mathbf{x}\|_2$, $\|\Delta\mathbf{x}\|_2 = \left\|A^{-1}\Delta\mathbf{y}\right\|_2 \le \left\|A^{-1}\right\|_2 \|\Delta\mathbf{y}\|_2$. Claim follows by division and multiplication.
Structural Commentary: The equations bound $\|\mathbf{x}\|_2$ through A and $\|\Delta\mathbf{x}\|_2$ through A^{-1}.
Key Insight: The opposing operator norms multiply to $\kappa_2(A)$. □

Theorem 5.3.6. *Condition Number and Matrix Perturbation*
Let $A \in \mathrm{Mat}(n, n, \mathbb{F})$ be invertible, let $\Delta A \in \mathrm{Mat}(n, n, \mathbb{F})$, and let $\mathbf{x}, \Delta\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$.
Suppose $A\mathbf{x} = \mathbf{y}$, $(A + \Delta A)(\mathbf{x} + \Delta\mathbf{x}) = \mathbf{y}$, and $\mathbf{x} + \Delta\mathbf{x} \neq \mathbf{0}$. Then $\frac{\|\Delta\mathbf{x}\|_2}{\|\mathbf{x}+\Delta\mathbf{x}\|_2} \le \kappa_2(A) \frac{\|\Delta A\|_2}{\|A\|_2}$.

Proof. Set $\mathbf{z} := \mathbf{x} + \Delta\mathbf{x} \neq \mathbf{0}$. The system equations imply $\Delta\mathbf{x} = -A^{-1}\Delta A\mathbf{z}$.
Hence $\|\Delta\mathbf{x}\|_2 \le \left\|A^{-1}\right\|_2 \|\Delta A\|_2 \|\mathbf{z}\|_2$ by the defining norm bound and Proposition 5.1.3(v).
Since $\|A\|_2 > 0$ by Proposition 5.1.3(ii), the result follows by division by $\|\mathbf{z}\|_2$ and the defining formula for $\kappa_2(A)$.
Structural Commentary: Subtraction isolates $\Delta\mathbf{x}$ as $-A^{-1}\Delta A$ acting on the perturbed solution.
Key Insight: Matrix perturbation enters through the product $A^{-1}\Delta A$. □

Figure 94 depicts the ellipse determined by the extreme singular directions.

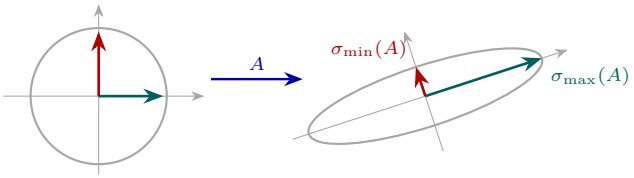

Figure 94: The unit circle maps to an ellipse with extreme-semiaxis ratio $\kappa_2(A) = \frac{\sigma_{\max}(A)}{\sigma_{\min}(A)}$.

5.4 Perturbation Bounds

Throughout this subsection, $n \in \mathbb{Z}_{>0}$.

Lemma 5.4.1. *Small Spectral-Norm Perturbations of the Identity*
If $E \in \mathrm{Mat}(n, n, \mathbb{C})$ and $\|E\|_2 < 1$, then $I_n + E$ is invertible.

Proof. $\rho(E) \le \|E\|_2 < 1$ by Theorem 5.1.12(ii), so $-1 \notin \mathrm{spec}(E)$.
For $p(z) = 1 + z$, $\mathrm{spec}(I_n + E) = \{1 + \lambda : \lambda \in \mathrm{spec}(E)\}$ by Corollary 3.4.2; $0 \notin \mathrm{spec}(I_n + E)$; $I_n + E$ invertible by Corollary 5.1.8.
Structural Commentary: The spectral-radius bound excludes -1, and spectral mapping transfers the exclusion to 0.
Key Insight: $\|E\|_2 < 1$ keeps -1 outside $\mathrm{spec}(E)$. □

Theorem 5.4.2. *Bauer–Fike Eigenvalue Perturbation Bound*
Let $A \in \mathrm{Mat}(n, n, \mathbb{C})$ be diagonalizable. Fix $S \in \mathrm{Mat}(n, n, \mathbb{C})^\times$ and $\Lambda = \mathrm{diag}(\lambda_1, \dots, \lambda_n)$ satisfying $A = S\Lambda S^{-1}$.
If $\Delta A \in \mathrm{Mat}(n, n, \mathbb{C})$ and $\mu \in \mathrm{spec}(A + \Delta A)$, then $\min_{j \in J_n} |\mu - \lambda_j| \le \kappa_2(S) \|\Delta A\|_2$.

Proof.

(i) *Separation*: If $(\exists\, j \in J_n)\, \mu = \lambda_j$, bound is immediate. Otherwise set $\delta := \min_{j \in J_n} |\mu - \lambda_j| > 0$, so $\Lambda - \mu I_n$ is invertible.

(ii) *Shift Factorization*: Since $\mu \in \mathrm{spec}(A + \Delta A)$, the matrix $A + \Delta A - \mu I_n$ is singular. Set $F := (\Lambda - \mu I_n)^{-1} S^{-1} \Delta A S$.
The identity $S^{-1}(A + \Delta A - \mu I_n)S = (\Lambda - \mu I_n)(I_n + F)$ holds. Thus $I_n + F$ is singular because S and $\Lambda - \mu I_n$ are invertible.

(iii) *Norm Obstruction*: The inequality $\|F\|_2 \ge 1$ holds by the contrapositive of Lemma 5.4.1.

(iv) *Resolvent Estimate*: Diagonal resolvent has singular values $(|\lambda_j - \mu|^{-1})_{j \in J_n}$. Thus $\left\|(\Lambda - \mu I_n)^{-1}\right\|_2 = \delta^{-1}$ by Theorem 5.1.2(i).
By part (iii) and Proposition 5.1.3(v), $1 \le \|F\|_2 \le \delta^{-1} \left\|S^{-1}\right\|_2 \|\Delta A\|_2 \|S\|_2 = \delta^{-1}\kappa_2(S) \|\Delta A\|_2$. Multiply by δ for bound.

Structural Commentary: Shift factorization converts a perturbed eigenvalue into failure of the small-norm invertibility lemma.
Key Insight: Singularity forces $\left\|(\Lambda - \mu I_n)^{-1} S^{-1} \Delta A S\right\|_2 \ge 1$. □

Computation Method 5.4.3. *Bauer–Fike Perturbation Method*
For diagonalizable $A \in \mathrm{Mat}(n, n, \mathbb{C})$ and $\Delta A \in \mathrm{Mat}(n, n, \mathbb{C})$, construct a spectral enclosure:

(i) choose a diagonalization $A = S\Lambda S^{-1}$ with S invertible and $\Lambda = \mathrm{diag}(\lambda_1, \dots, \lambda_n)$;

(ii) compute $\|\Delta A\|_2$;
(iii) compute $\kappa_2(S)$ and set $r := \kappa_2(S)\,\|\Delta A\|_2$;
(iv) output $\operatorname{spec}(A+\Delta A) \subseteq \bigcup_{j\in J_n} \{z \in \mathbb{C} : |z-\lambda_j| \le r\}$ by Theorem 5.4.2.

Definition 5.4.4. *Gersgorin Disks*
Let $A = [a_{ij}] \in \operatorname{Mat}(n,n,\mathbb{C})$.
(i) The *deleted absolute row sums* are defined by $(\forall\, k \in J_n)\; R_k^{\text{off}}(A) := \sum_{j\in J_n\setminus\{k\}} |a_{kj}|$.
(ii) The *absolute row sums* are defined by $(\forall\, k \in J_n)\; R_k(A) := \sum_{j\in J_n} |a_{kj}|$.
(iii) The *maximum absolute row sum* is $R_{\max}(A) := \max_{k\in J_n} R_k(A)$.
(iv) The *Gersgorin disks* are $(\forall\, k \in J_n)\; \operatorname{Ger}_k(A) := \{z \in \mathbb{C} : |z-a_{kk}| \le R_k^{\text{off}}(A)\}$. Their union is $\operatorname{Ger}(A) := \bigcup_{k\in J_n} \operatorname{Ger}_k(A)$.

Theorem 5.4.5. *Gersgorin Disk Theorem*
Let $A = [a_{ij}] \in \operatorname{Mat}(n,n,\mathbb{C})$. *Then* $\operatorname{spec}(A) \subseteq \operatorname{Ger}(A) = \bigcup_{k\in J_n} \operatorname{Ger}_k(A)$.

Proof. Fix $\lambda \in \operatorname{spec}(A)$ and $\mathbf{0} \neq \mathbf{x} = [x_1 \ \cdots \ x_n]^t \in E_\lambda(A)$. Choose $k \in J_n$ with $|x_k| = \max_{j\in J_n} |x_j| > 0$.
The kth row of $A\mathbf{x} = \lambda\mathbf{x}$ is $(\lambda - a_{kk})x_k = \sum_{j\in J_n\setminus\{k\}} a_{kj}x_j$.
Therefore $|\lambda - a_{kk}| \le \sum_{j\in J_n\setminus\{k\}} |a_{kj}| \left|\frac{x_j}{x_k}\right| \le R_k^{\text{off}}(A)$ by the triangle inequality and maximality of $|x_k|$; $\lambda \in \operatorname{Ger}_k(A) \subseteq \operatorname{Ger}(A)$.
Structural Commentary: The maximal eigenvector component converts one row identity into the deleted-row-sum bound.
Key Insight: $(\forall\, j \in J_n)\; \left|\frac{x_j}{x_k}\right| \le 1$ closes the disk estimate. □

Corollary 5.4.6. *Row-Column Gersgorin Refinement*
Let $A = [a_{ij}] \in \operatorname{Mat}(n,n,\mathbb{C})$.
(i) $\operatorname{spec}(A) \subseteq \operatorname{Ger}(A) \cap \operatorname{Ger}(A^t)$.
(ii) $\operatorname{spec}(A) \subseteq \{z \in \mathbb{C} : |z| \le \min(R_{\max}(A), R_{\max}(A^t))\}$.

Proof.
(i) The inclusion $\operatorname{spec}(A) \subseteq \operatorname{Ger}(A)$ holds by Theorem 5.4.5.
Since $\operatorname{spec}(A) = \operatorname{spec}(A^t)$ by Proposition 1.2.6(ii), $\operatorname{spec}(A) \subseteq \operatorname{Ger}(A^t)$ by Theorem 5.4.5; intersection is (i).
(ii) For $B = [b_{ij}] \in \{A, A^t\}$, $k \in J_n$, and $z \in \operatorname{Ger}_k(B)$, $|z| \le |b_{kk}| + R_k^{\text{off}}(B) = R_k(B) \le R_{\max}(B)$ by the triangle inequality.
Thus $\operatorname{Ger}(B) \subseteq \{z \in \mathbb{C} : |z| \le R_{\max}(B)\}$. The enclosure in (ii) follows from the two radial bounds by part (i).
Structural Commentary: Gersgorin applied to A and A^t supplies intersecting row and column enclosures.
Key Insight: The triangle inequality places each disk inside its row-sum radius. □

Computation Method 5.4.7. *Gersgorin Localisation Method*
For $A = [a_{ij}] \in \operatorname{Mat}(n,n,\mathbb{C})$, construct a row-column spectral enclosure as follows:
(i) Compute $(\forall\, k \in J_n)\; R_k^{\text{off}}(A) = \sum_{j\in J_n\setminus\{k\}} |a_{kj}|$. Form $\operatorname{Ger}(A) = \bigcup_{k\in J_n} \operatorname{Ger}_k(A)$.
(ii) Record the certified row enclosure $\operatorname{spec}(A) \subseteq \operatorname{Ger}(A)$ by Theorem 5.4.5.
(iii) Compute the deleted row sums of A^t, which are the deleted column sums of A, and form $\operatorname{Ger}(A) \cap \operatorname{Ger}(A^t)$.
The inclusion $\operatorname{spec}(A) \subseteq \operatorname{Ger}(A) \cap \operatorname{Ger}(A^t)$ holds by Corollary 5.4.6(i).
(iv) Interpret the output as an intersection of two unions; do not replace it by $\bigcup_{k\in J_n} (\operatorname{Ger}_k(A) \cap \operatorname{Ger}_k(A^t))$.

Figure 95 compares the row and column disks whose unions form the enclosure in Corollary 5.4.6(i).

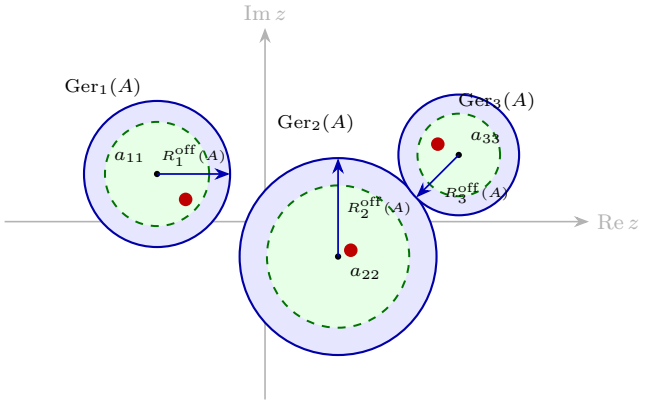

Figure 95: Solid blue row disks and dashed green column disks form $\operatorname{Ger}(A) \cap \operatorname{Ger}(A^t)$; red markers show candidate eigenvalues.

Definition 5.4.8. *Closed Spectral-Norm Pseudospectrum*
Let $\mathcal{M} := \operatorname{Mat}(n,n,\mathbb{C})$, $A \in \mathcal{M}$, and $\varepsilon \in \mathbb{R}_{\ge 0}$.
The *closed spectral-norm ε-pseudospectrum* of A is $\{z \in \mathbb{C} : (\exists\, \Delta A \in \mathcal{M})\; [\|\Delta A\|_2 \le \varepsilon \wedge z \in \operatorname{spec}(A+\Delta A)]\}$.

Let $A, \Delta A \in \mathrm{Mat}(n,n,\mathbb{C})$, let $\varepsilon \in \mathbb{R}_{\geq 0}$, and fix a diagonalization $A = S\Lambda S^{-1}$.
If $\|\Delta A\|_2 \leq \varepsilon$, then the Bauer–Fike disk radius is at most $\kappa_2(S)\varepsilon$ by Theorem 5.4.2.
The inclusion $\mathrm{spec}(A+\Delta A) \subseteq \mathrm{Ger}(A+\Delta A)$ holds by Theorem 5.4.5.
These bounds distinguish spectral location from perturbation sensitivity.

5.5 Diagonal Dominance and Definiteness

Throughout this subsection, $n \in \mathbb{Z}_{>0}$.

Definition 5.5.1. *Diagonal Dominance*
Let $A = [a_{ij}] \in \mathrm{Mat}(n,n,\mathbb{C})$.

(i) The matrix A is *diagonally dominant* iff $(\forall\, k \in J_n)\ |a_{kk}| \geq R_k^{\mathrm{off}}(A)$.
(ii) The matrix A is *strictly diagonally dominant* iff $(\forall\, k \in J_n)\ |a_{kk}| > R_k^{\mathrm{off}}(A)$.

Corollary 5.5.2. *Strict Diagonal Dominance Implies Invertibility*
Let $A = [a_{ij}] \in \mathrm{Mat}(n,n,\mathbb{C})$.

(i) If A is strictly diagonally dominant, then A is invertible.
(ii) If $\mathrm{spec}(A) \subseteq \mathbb{R}$, $(\forall\, k \in J_n)\, a_{kk} \in \mathbb{R}_{\geq 0}$, and A is diagonally dominant, then $\mathrm{spec}(A) \subseteq [0,\infty)$.
(iii) If $\mathrm{spec}(A) \subseteq \mathbb{R}$, $(\forall\, k \in J_n)\, a_{kk} \in \mathbb{R}_{\geq 0}$, and A is strictly diagonally dominant, then $\mathrm{spec}(A) \subseteq (0,\infty)$.

Proof.

(i) $0 \notin \mathrm{Ger}(A)$ by Definition 5.4.4 and strict diagonal dominance.
The relation $0 \notin \mathrm{spec}(A)$ holds by Theorem 5.4.5, and A is invertible by Corollary 5.1.8.
(ii) $(\forall\, k \in J_n)(\forall\, z \in \mathrm{Ger}_k(A))\ \mathrm{Re}(z) \geq a_{kk} - |z - a_{kk}| \geq a_{kk} - R_k^{\mathrm{off}}(A) \geq 0$ by Definition 5.4.4 and diagonal dominance.
The inclusion $\mathrm{spec}(A) \subseteq \mathrm{Ger}(A) \cap \mathbb{R} \subseteq [0,\infty)$ holds by the preceding bound, Theorem 5.4.5, and the real-spectrum hypothesis.
(iii) $(\forall\, k \in J_n)(\forall\, z \in \mathrm{Ger}_k(A))\ \mathrm{Re}(z) \geq a_{kk} - R_k^{\mathrm{off}}(A) > 0$ by Definition 5.4.4 and strict diagonal dominance.
The inclusion $\mathrm{spec}(A) \subseteq \mathrm{Ger}(A) \cap \mathbb{R} \subseteq (0,\infty)$ holds by the preceding bound, Theorem 5.4.5, and the real-spectrum hypothesis.

Structural Commentary: Disk exclusion handles (i); closed and open half-plane bounds handle (ii)–(iii).
Key Insight: Each Gersgorin radius is controlled by its nonnegative real center. □

Theorem 5.5.3. *Weak Diagonal Dominance with One Strict Row*
Let $A = [a_{ij}] \in \mathrm{Mat}(n,n,\mathbb{C})$ be diagonally dominant and satisfy $(\forall\, i,j \in J_n)\,[i \neq j \Longrightarrow a_{ij} \neq 0]$.
If $(\exists\, k \in J_n)\ |a_{kk}| > R_k^{\mathrm{off}}(A)$, then A is invertible.

Proof. Suppose $\mathbf{0} \neq \mathbf{x} \in \ker(A)$, $M := \|\mathbf{x}\|_\infty$. Choose $p \in J_n$ satisfying $|x_p| = M > 0$ by Proposition 1.1.21(iii).
$|a_{pp}|\, M = \left| \sum_{j \in J_n \setminus \{p\}} a_{pj} x_j \right| \leq \sum_{j \in J_n \setminus \{p\}} |a_{pj}|\, |x_j| \leq R_p^{\mathrm{off}}(A) M$ by $A\mathbf{x} = \mathbf{0}$, the triangle inequality, and maximality of $|x_p|$.
$R_p^{\mathrm{off}}(A) M \leq |a_{pp}|\, M$ by diagonal dominance; all preceding inequalities are equalities by their common endpoints.
The relation $(\forall\, j \in J_n)\ |x_j| = M$ holds by equality in the weighted bound, $|x_p| = M$, and the nonzero off-diagonal hypothesis.
Fix $k \in J_n$ satisfying $|a_{kk}| > R_k^{\mathrm{off}}(A)$ by the strict-row hypothesis.
$|a_{kk}|\, M = \left| \sum_{j \in J_n \setminus \{k\}} a_{kj} x_j \right| \leq R_k^{\mathrm{off}}(A) M$ by $A\mathbf{x} = \mathbf{0}$ and the preceding modulus identity.
$R_k^{\mathrm{off}}(A) M < |a_{kk}|\, M$ by strict dominance and $M > 0$, a contradiction.
The equality $\ker(A) = \{\mathbf{0}\}$ holds by contradiction, and A is invertible by Corollary 3.6.3(vi)⇒(i).
Structural Commentary: A maximal kernel coordinate propagates equal moduli before the strict row closes the contradiction.
Key Insight: Positive off-diagonal weights propagate one maximal modulus to every coordinate. □

Corollary 5.5.4. *Diagonal Dominance and Positive Semidefiniteness*
Let $A = [a_{ij}] \in \mathrm{Mat}(n,n,\mathbb{C})$ be Hermitian.
Suppose $(\forall\, k \in J_n)\, a_{kk} \in \mathbb{R}_{\geq 0}$.

(i) If A is diagonally dominant, then A is positive semidefinite.
(ii) If A is diagonally dominant and invertible, then A is positive definite.
(iii) If A is strictly diagonally dominant, then A is positive definite.

Proof. The induced $T_A \in \mathcal{L}(\mathbb{C}^n)$ is self-adjoint by Proposition 3.1.8, Theorems 2.3.7 and 3.4.5(i), and $A = A^*$.
The relation $\mathrm{spec}(A) = \mathrm{spec}(T_A) \subseteq \mathbb{R}$ holds by Definitions 3.1.7, 5.1.2, and 5.1.3, and Theorem 6.1.5.

(i) $\mathrm{spec}(A) \subseteq [0,\infty)$ by Corollary 5.5.2(ii), so $A \succeq 0$ by Theorem 2.1.3(ii).
(ii) $A \succeq 0$ by part (i), so $A \succ 0$ by Theorem 2.1.8(iii) and the invertibility hypothesis.
(iii) $\mathrm{spec}(A) \subseteq (0,\infty)$ by Corollary 5.5.2(iii), so $A \succ 0$ by Theorem 2.1.8(ii).

Structural Commentary: Hermitian reality activates Gersgorin bounds; spectral criteria transfer eigenvalue signs to definiteness.
Key Insight: Invertibility removes zero from the nonnegative Hermitian spectrum. □

5.6 Rayleigh Quotients and Minimax

Throughout this subsection, $n \in \mathbb{Z}_{>0}$.

Definition 5.6.1. *Hermitian Eigenvalue Order and Rayleigh Quotient*
Let $A \in \mathrm{Mat}(n,n,\mathbb{C})$ be Hermitian. Matrix A has real eigenvalues and admits an orthonormal eigenbasis by Theorems 6.1.5 and 6.1.11.

(i) Write eigenvalues with algebraic multiplicity as $\lambda_1(A) \leq \lambda_2(A) \leq \cdots \leq \lambda_n(A)$. If A is fixed, abbreviate $\lambda_i(A)$ to λ_i.
(ii) For $\mathbf{x} \in \mathbb{C}^n \setminus \{\mathbf{0}\}$, the *Rayleigh quotient* is $\mathrm{Ray}_A(\mathbf{x}) := \frac{\mathbf{x}^* A \mathbf{x}}{\mathbf{x}^* \mathbf{x}}$. If $\|\mathbf{x}\|_2 = 1$, then $\mathrm{Ray}_A(\mathbf{x}) = \mathbf{x}^* A \mathbf{x}$.

Theorem 5.6.2. *Rayleigh Quotient on a Spectral Interval*
Let $A \in \mathrm{Mat}(n,n,\mathbb{C})$ be Hermitian with increasing eigenvalues $\lambda_1 \leq \cdots \leq \lambda_n$ and corresponding orthonormal eigenvectors $\mathbf{u}_1, \ldots, \mathbf{u}_n$.
If $p, q \in J_n$, $p \leq q$, and $\mathbf{x} \in \mathrm{span}(\mathbf{u}_p, \ldots, \mathbf{u}_q)$ satisfies $\|\mathbf{x}\|_2 = 1$, then $\lambda_p \leq \mathrm{Ray}_A(\mathbf{x}) \leq \lambda_q$.

Proof. Write $\mathbf{x} = \sum_{i=p}^{q} c_i \mathbf{u}_i$; then $(\forall\, i \in \{p, \dots, q\})\ |c_i|^2 \geq 0$ and $\sum_{i=p}^{q} |c_i|^2 = 1$ by orthonormality.

The identity $\mathrm{Ray}_A(\mathbf{x}) = \sum_{i=p}^{q} \lambda_i |c_i|^2$ holds by the eigenvector relations and Definition 5.6.1(ii).

The bound $\lambda_p \leq \mathrm{Ray}_A(\mathbf{x}) \leq \lambda_q$ holds by $\lambda_p \leq \lambda_i \leq \lambda_q$ and the preceding weight relations.

Structural Commentary: Eigenbasis expansion reduces the quotient to a weighted average over its spectral support.

Key Insight: The spectral weights $|c_i|^2$ are nonnegative and sum to one. □

Corollary 5.6.3. *Rayleigh Extrema and Diagonal Entry Bounds*

Let $A = [a_{ij}] \in \mathrm{Mat}(n, n, \mathbb{C})$ be Hermitian with orthonormal eigenpairs $(\lambda_i, \mathbf{u}_i)_{i \in J_n}$, where $\lambda_1 \leq \cdots \leq \lambda_n$. For $p, q \in J_n$ with $p \leq q$, set $\mathcal{U}_{p,q} := \mathrm{span}(\mathbf{u}_p, \dots, \mathbf{u}_q)$.

(i) $\min_{\substack{\mathbf{x} \in \mathcal{U}_{p,q} \\ \|\mathbf{x}\|_2 = 1}} \mathrm{Ray}_A(\mathbf{x}) = \lambda_p$.

(ii) $\max_{\substack{\mathbf{x} \in \mathcal{U}_{p,q} \\ \|\mathbf{x}\|_2 = 1}} \mathrm{Ray}_A(\mathbf{x}) = \lambda_q$.

(iii) $(\forall\, \mathbf{x} \in \mathbb{C}^n)\ [\|\mathbf{x}\|_2 = 1 \implies \lambda_1 \leq \mathrm{Ray}_A(\mathbf{x}) \leq \lambda_n]$.

(iv) $(\forall\, i \in J_n)\ \lambda_1 \leq a_{ii} \leq \lambda_n$.

Proof.

(i) The lower bound and its attainment at $\mathbf{u}_p$ hold by Theorem 5.6.2 and $A\mathbf{u}_p = \lambda_p \mathbf{u}_p$, respectively.

(ii) The upper bound and its attainment at $\mathbf{u}_q$ hold by Theorem 5.6.2 and $A\mathbf{u}_q = \lambda_q \mathbf{u}_q$, respectively.

(iii) The asserted bound holds by (i)–(ii) with $(p, q) = (1, n)$ and $\mathcal{U}_{1,n} = \mathbb{C}^n$.

(iv) $(\forall\, i \in J_n)\ [\|\mathbf{e}_i\|_2 = 1 \wedge \mathrm{Ray}_A(\mathbf{e}_i) = a_{ii}]$ by Proposition 1.1.21(ii), Definition 5.6.1(ii), and coordinate multiplication. The relation $(\forall\, i \in J_n)\ \lambda_1 \leq a_{ii} \leq \lambda_n$ holds by the preceding identity and (iii).

Structural Commentary: Endpoint eigenvectors attain support bounds; coordinate vectors bound every diagonal entry.

Key Insight: Attainment turns spectral enclosures into exact extrema. □

Figure 96 places the quotient inside the eigenvalue interval determined by its spectral support, as asserted by Theorem 5.6.2.

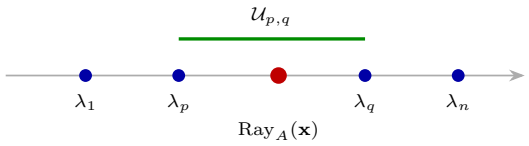

Figure 96: For ordered orthonormal eigenpairs of a Hermitian A, a unit vector supported on $\mathbf{u}_p, \dots, \mathbf{u}_q$ has $\mathrm{Ray}_A(\mathbf{x}) \in [\lambda_p, \lambda_q]$.

Computation Method 5.6.4. *Rayleigh Eigenbasis Method*

Given a Hermitian $A \in \mathrm{Mat}(n, n, \mathbb{C})$ and a unit vector $\mathbf{x} \in \mathbb{C}^n$, construct a certified spectral-support enclosure for $\mathrm{Ray}_A(\mathbf{x})$ as follows:

(i) compute an orthonormal eigenbasis $\mathbf{u}_1, \dots, \mathbf{u}_n$ in increasing eigenvalue order by Theorem 6.1.11 and Definition 5.6.1(i);

(ii) compute $c_i := \mathbf{u}_i^* \mathbf{x}$ for $i \in J_n$ and the nonempty support $I(\mathbf{x}) := \{i \in J_n : c_i \neq 0\}$;

(iii) evaluate $\mathrm{Ray}_A(\mathbf{x}) = \sum_{i \in J_n} \lambda_i |c_i|^2$;

(iv) set $p := \min I(\mathbf{x})$ and $q := \max I(\mathbf{x})$, and output the certified enclosure $\lambda_p \leq \mathrm{Ray}_A(\mathbf{x}) \leq \lambda_q$ by Theorem 5.6.2.

Theorem 5.6.5. *Rayleigh Minimax Principle*

Let $A = A^* \in \mathrm{Mat}(n, n, \mathbb{C})$ have eigenvalues $\lambda_1 \leq \cdots \leq \lambda_n$. For $k \in J_n$:

(i) $\lambda_k = \min_{\substack{\mathcal{S} \leq \mathbb{C}^n \\ \dim(\mathcal{S}) = k}} \max_{\mathbf{0} \neq \mathbf{x} \in \mathcal{S}} \mathrm{Ray}_A(\mathbf{x})$.

(ii) $\lambda_k = \max_{\substack{\mathcal{T} \leq \mathbb{C}^n \\ \dim(\mathcal{T}) = n-k+1}} \min_{\mathbf{0} \neq \mathbf{x} \in \mathcal{T}} \mathrm{Ray}_A(\mathbf{x})$.

Proof. Fix an orthonormal eigenbasis $\mathbf{u}_1, \dots, \mathbf{u}_n$ in increasing eigenvalue order by Theorem 6.1.11 and Definition 5.6.1(i).
Set $E_k := \mathrm{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$ and $F_k := \mathrm{span}(\mathbf{u}_k, \dots, \mathbf{u}_n)$. $(\forall\, \mathbf{x} \in \mathbb{C}^n \setminus \{\mathbf{0}\})\ \mathrm{Ray}_A(\mathbf{x}) = \mathrm{Ray}_A(\mathbf{x}/\|\mathbf{x}\|_2)$ by Definition 5.6.1(ii).
Hence $\max_{\mathbf{0} \neq \mathbf{x} \in E_k} \mathrm{Ray}_A(\mathbf{x}) = \lambda_k$ and $\min_{\mathbf{0} \neq \mathbf{x} \in F_k} \mathrm{Ray}_A(\mathbf{x}) = \lambda_k$ by Corollary 5.6.3(ii),(i).

(i) If $\mathcal{S} \leq \mathbb{C}^n$ and $\dim(\mathcal{S}) = k$, then $\mathcal{S} \cap F_k \neq \{\mathbf{0}\}$ by Corollary 2.3.3(i) and $\dim(\mathcal{S}) + \dim(F_k) = n + 1$.
The bound $\max_{\mathbf{0} \neq \mathbf{x} \in \mathcal{S}} \mathrm{Ray}_A(\mathbf{x}) \geq \lambda_k$ holds by the preceding intersection, Theorem 5.6.2, and scale invariance.
The outer minimum equals λ_k by this bound and $\mathcal{S} = E_k$ in the preceding extremum identity.

(ii) If $\mathcal{T} \leq \mathbb{C}^n$ and $\dim(\mathcal{T}) = n - k + 1$, then $\mathcal{T} \cap E_k \neq \{\mathbf{0}\}$ by Corollary 2.3.3(i) and $\dim(\mathcal{T}) + \dim(E_k) = n + 1$.
The bound $\min_{\mathbf{0} \neq \mathbf{x} \in \mathcal{T}} \mathrm{Ray}_A(\mathbf{x}) \leq \lambda_k$ holds by the preceding intersection, Theorem 5.6.2, and scale invariance.
The outer maximum equals λ_k by this bound and $\mathcal{T} = F_k$ in the preceding extremum identity.

Structural Commentary: Spectral-flag intersections supply universal bounds; E_k and F_k attain them.

Key Insight: A dimension sum of $n + 1$ forces a shared comparison vector. □

5.7 Eigenvalue and Singular-Value Interlacing

Throughout this subsection, all matrix dimensions are positive integers.

Theorem 5.7.1. *Rank-One Positive Perturbation Interlacing*

Let $A, E \in \mathrm{Mat}(n, n, \mathbb{C})$ be Hermitian, with $E \succeq 0$ and $\mathrm{rank}(E) \leq 1$.

(i) $(\forall\, i \in J_n)\ \lambda_i(A) \leq \lambda_i(A + E)$.

(ii) $(\forall\, i \in J_{n-1})\ \lambda_i(A+E) \le \lambda_{i+1}(A)$.
(iii) $(\forall\, i \in J_n)\ \lambda_i(A-E) \le \lambda_i(A)$.
(iv) $(\forall\, i \in J_{n-1})\ \lambda_i(A) \le \lambda_{i+1}(A-E)$.

Proof. Fix ordered orthonormal eigenbases $(\mathbf{u}_j)_{j\in J_n}$ of A and $(\mathbf{v}_j)_{j\in J_n}$ of $A+E$ by Theorem 6.1.11 and Definition 5.6.1(i).

(i) Fix $i \in J_n$, and set $\mathcal{U} = \operatorname{span}(\mathbf{u}_i, \dots, \mathbf{u}_n)$ and $\mathcal{V} = \operatorname{span}(\mathbf{v}_1, \dots, \mathbf{v}_i)$.
Fix a unit $\mathbf{x} \in \mathcal{U} \cap \mathcal{V}$ by Corollary 2.3.3(i), normalization, and $\dim(\mathcal{U}) + \dim(\mathcal{V}) = n+1$.
The chain $\lambda_i(A) \le \mathbf{x}^*A\mathbf{x} \le \mathbf{x}^*(A+E)\mathbf{x} \le \lambda_i(A+E)$ holds by Theorem 5.6.2 and $E \succeq 0$.
(ii) Fix $i \in J_{n-1}$, and set $\mathcal{U} = \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_{i+1})$, $\mathcal{V} = \operatorname{span}(\mathbf{v}_i, \dots, \mathbf{v}_n)$, and $\mathcal{W} = \ker(E)$.
The bounds $\dim(\mathcal{U} \cap \mathcal{V}) \ge 2$ and $\dim(\mathcal{W}) \ge n-1$ hold by Corollaries 2.3.3(ii) and 3.3.1(i), respectively.
Fix a unit $\mathbf{x} \in \mathcal{U} \cap \mathcal{V} \cap \mathcal{W}$ by Corollary 2.3.3(i) and normalization.
The chain $\lambda_i(A+E) \le \mathbf{x}^*(A+E)\mathbf{x} = \mathbf{x}^*A\mathbf{x} \le \lambda_{i+1}(A)$ holds by Theorem 5.6.2.
(iii) $(\forall\, i \in J_n)\ \lambda_i(A-E) \le \lambda_i(A)$ by part (i) with $A-E$ in place of A.
(iv) $(\forall\, i \in J_{n-1})\ \lambda_i(A) \le \lambda_{i+1}(A-E)$ by part (ii) with $A-E$ in place of A.

Structural Commentary: Two flag intersections prove the $A+E$ bounds; substitution transfers them to $A-E$.
Key Insight: Membership in $\ker(E)$ removes the perturbation from the upper comparison. □

Corollary 5.7.2. *Signed Rank-Two Perturbation Interlacing*
Let $A, H \in \operatorname{Mat}(n,n,\mathbb{C})$ be Hermitian, with $n \ge 2$ and $\operatorname{rank}(H) \le 2$. Suppose that H has at most one positive and one negative eigenvalue.

(i) $(\forall\, i \in J_n \setminus \{1\})\ \lambda_{i-1}(A) \le \lambda_i(A+H)$.
(ii) $(\forall\, i \in J_{n-1})\ \lambda_i(A+H) \le \lambda_{i+1}(A)$.

Proof. Fix $H = Q\operatorname{diag}(\mu_1, \dots, \mu_n)Q^*$ with Q unitary and $\mu_1, \dots, \mu_n \in \mathbb{R}$ by Theorem 6.1.11.
Set $\mu_j^+ := \max\{\mu_j, 0\}$ and $\mu_j^- := \max\{-\mu_j, 0\}$ for $j \in J_n$, and set $E_\pm := Q\operatorname{diag}(\mu_1^\pm, \dots, \mu_n^\pm)Q^*$.
The relations $H = E_+ - E_-$, $E_\pm \succeq 0$, and $\operatorname{rank}(E_\pm) \le 1$ hold by construction and the sign hypothesis.
Set $B := A - E_-$, so $A = B + E_-$ and $A + H = B + E_+$.

(i) $(\forall\, i \in J_n \setminus \{1\})\ \lambda_{i-1}(A) \le \lambda_i(B) \le \lambda_i(A+H)$ by Theorem 5.7.1(ii),(i).
(ii) $(\forall\, i \in J_{n-1})\ \lambda_i(A+H) \le \lambda_{i+1}(B) \le \lambda_{i+1}(A)$ by Theorem 5.7.1(ii),(i).

Structural Commentary: The signed spectral split makes A and $A+H$ positive rank-one updates of a common base.
Key Insight: Comparison through B aligns the lower and upper index shifts. □

Theorem 5.7.3. *Cauchy Interlacing: One Principal Deletion*
Let $A \in \operatorname{Mat}(n+1, n+1, \mathbb{C})$ be Hermitian, and let $B \in \operatorname{Mat}(n,n,\mathbb{C})$ be its leading principal submatrix.

(i) $(\forall\, i \in J_n)\ \lambda_i(A) \le \lambda_i(B)$.
(ii) $(\forall\, i \in J_n)\ \lambda_i(B) \le \lambda_{i+1}(A)$.

Proof. Fix ordered orthonormal eigenbases $(\mathbf{u}_j)_{j\in J_{n+1}}$ of A and $(\mathbf{v}_j)_{j\in J_n}$ of B by Theorem 6.1.11 and Definition 5.6.1(i).
Define $\iota : \mathbb{C}^n \to \mathbb{C}^{n+1}$ by $\iota(\mathbf{z}) = (\mathbf{z}, 0)$. The identities $\|\iota(\mathbf{z})\|_2 = \|\mathbf{z}\|_2$ and $\iota(\mathbf{z})^*A\iota(\mathbf{z}) = \mathbf{z}^*B\mathbf{z}$ hold by coordinate multiplication.

(i) Fix $i \in J_n$, and set $\mathcal{S} = \operatorname{span}(\iota(\mathbf{v}_1), \dots, \iota(\mathbf{v}_i))$ and $\mathcal{T} = \operatorname{span}(\mathbf{u}_i, \dots, \mathbf{u}_{n+1})$.
Fix a unit $\mathbf{x} = \iota(\mathbf{z}) \in \mathcal{S} \cap \mathcal{T}$ by Corollary 2.3.3(i), normalization, and $\dim(\mathcal{S}) + \dim(\mathcal{T}) = n+2$.
The chain $\lambda_i(A) \le \mathbf{x}^*A\mathbf{x} = \mathbf{z}^*B\mathbf{z} \le \lambda_i(B)$ holds by Theorem 5.6.2.
(ii) Fix $i \in J_n$, and set $\mathcal{S} = \operatorname{span}(\iota(\mathbf{v}_i), \dots, \iota(\mathbf{v}_n))$ and $\mathcal{T} = \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_{i+1})$.
Fix a unit $\mathbf{x} = \iota(\mathbf{z}) \in \mathcal{S} \cap \mathcal{T}$ by Corollary 2.3.3(i), normalization, and $\dim(\mathcal{S}) + \dim(\mathcal{T}) = n+2$.
The chain $\lambda_i(B) \le \mathbf{z}^*B\mathbf{z} = \mathbf{x}^*A\mathbf{x} \le \lambda_{i+1}(A)$ holds by Theorem 5.6.2.

Structural Commentary: The embedding preserves quadratic forms; complementary spectral flags establish both inequalities.
Key Insight: One coordinate deletion leaves the dimension sum $n+2$. □

Corollary 5.7.4. *Cauchy Interlacing for Principal Submatrices*
Let $m \in \mathbb{Z}_{>0}$, and let $B \in \operatorname{Mat}(n,n,\mathbb{C})$ be a principal submatrix of a Hermitian $A \in \operatorname{Mat}(n+m, n+m, \mathbb{C})$.

(i) $(\forall\, i \in J_n)\ \lambda_i(A) \le \lambda_i(B)$.
(ii) $(\forall\, i \in J_n)\ \lambda_i(B) \le \lambda_{i+m}(A)$.

Proof. Choose a permutation matrix P such that B is the leading principal submatrix of $\widetilde{A} := P^*AP$.
The matrices A and $\widetilde{A}$ have the same ordered eigenvalues by Theorem 2.1.7(i).
For $r \in \{0, \dots, m\}$, let $A^{(r)}$ be the leading principal submatrix of $\widetilde{A}$ of size $n+m-r$; thus $A^{(0)} = \widetilde{A}$ and $A^{(m)} = B$.

(i) $(\forall\, i \in J_n)\ \lambda_i(A^{(0)}) \le \lambda_i(A^{(1)}) \le \cdots \le \lambda_i(A^{(m)})$ by successive applications of Theorem 5.7.3(i).
(ii) $(\forall\, i \in J_n)\ \lambda_i(A^{(m)}) \le \lambda_{i+1}(A^{(m-1)}) \le \cdots \le \lambda_{i+m}(A^{(0)})$ by successive applications of Theorem 5.7.3(ii).

Structural Commentary: Permutation makes B leading; chained one-coordinate deletions accumulate the upper-index shift.
Key Insight: Each deletion raises the upper comparison index by one. □

Corollary 5.7.5. *Singular Values Interlace After Deleting a Row or Column*
Let $n \ge 2$, and let B be obtained from $A \in \operatorname{Mat}(n,n,\mathbb{C})$ by deleting one row or one column.
With singular values ordered decreasingly, $(\forall\, i \in J_{n-1})\ \sigma_i(A) \ge \sigma_i(B) \ge \sigma_{i+1}(A)$.

Proof.

(i) *Row Gram Reduction*: In the row case, choose a permutation matrix P with B as the first $n-1$ rows of PA. Set $G := (PA)(PA)^*$.
The matrix BB^* is its leading principal submatrix, and PA and A have the same singular values by Proposition 5.1.7(i).
(ii) *Index Identification*: $(\forall\, j \in J_n)\ \lambda_j(G) = \sigma_{n-j+1}(A)^2$ by Proposition 4.2.11(i) and Definition 4.2.8.
The identity $(\forall\, j \in J_{n-1})\ \lambda_j(BB^*) = \sigma_{n-j}(B)^2$ holds by Proposition 4.2.11(i) and Definition 4.2.8.
(iii) *Cauchy Transfer*: Fix $i \in J_{n-1}$ and set $j := n-i$. The chain $\sigma_{i+1}(A)^2 \le \sigma_i(B)^2 \le \sigma_i(A)^2$ holds by Theorem 5.7.3(i)–(ii).
The row-deletion claim follows by taking nonnegative square roots.
(iv) *Column Reduction*: If B is obtained by deleting a column, then B^* is obtained from A^* by deleting a row.
The stated inequalities hold by the row-deletion claim and Proposition 4.2.11(iii).

Structural Commentary: A principal Gram block proves row deletion; adjoints transfer the result to columns.
Key Insight: $j = n - i$ matches increasing Gram eigenvalues with decreasing singular values. □

Figure 97 compares the interlacing windows from Theorem 5.7.1 and Corollary 5.7.4.

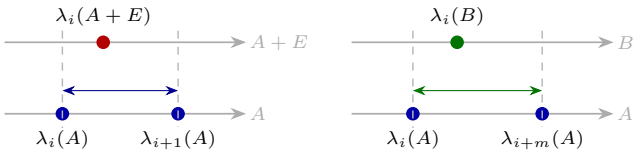

Figure 97: $\lambda_i(A+E)$ lies in $[\lambda_i(A), \lambda_{i+1}(A)]$, while $\lambda_i(B)$ lies in $[\lambda_i(A), \lambda_{i+m}(A)]$.

Theorem 5.7.6. *Schur Majorization of the Diagonal*
Let $A \in \mathrm{Mat}(n, n, \mathbb{C})$ be Hermitian, and let $d_1 \le \cdots \le d_n$ be its diagonal entries arranged increasingly.

(i) $(\forall\, k \in J_{n-1}) \sum_{i=1}^{k} \lambda_i(A) \le \sum_{i=1}^{k} d_i$.

(ii) $\sum_{i=1}^{n} \lambda_i(A) = \sum_{i=1}^{n} d_i$.

Proof. Choose a permutation matrix P such that the diagonal of $\widetilde{A} := P^* A P$ is $(d_1, \ldots, d_n)$.
The matrices A and $\widetilde{A}$ have the same ordered eigenvalues by Theorem 2.1.7(i).
Set A_k to be the leading $k \times k$ principal submatrix of $\widetilde{A}$ for $k \in J_n$.

(i) Fix $k \in J_{n-1}$. The inequalities $(\forall\, i \in J_k)\, \lambda_i(\widetilde{A}) \le \lambda_i(A_k)$ hold by Corollary 5.7.4(i).
The identity $\sum_{i=1}^{k} \lambda_i(A_k) = \mathrm{tr}(A_k) = \sum_{i=1}^{k} d_i$ holds by Proposition 1.1.14(i) and Definition 3.8.1.
Thus $\sum_{i=1}^{k} \lambda_i(A) \le \sum_{i=1}^{k} d_i$ by the preceding inequalities and the common ordered spectrum of A and $\widetilde{A}$.

(ii) $\sum_{i=1}^{n} \lambda_i(A) = \mathrm{tr}(A) = \sum_{i=1}^{n} d_i$ by Proposition 1.1.14(i) and Definition 3.8.1.

Structural Commentary: Cauchy bounds each leading-block eigenvalue before trace sums the inequalities.
Key Insight: Ordering the diagonal makes each partial sum a principal-block trace. □

Proof Method 5.7.7. *Eigenvalue Interlacing Proof Method*
Given a proposed Hermitian eigenvalue interlacing inequality, construct a proof route as follows:

(i) order every Hermitian spectrum increasingly and identify the requested lower and upper indices;
(ii) identify the lost or unaffected directions through perturbation rank, a kernel, or deleted coordinates;
(iii) choose lower and upper spectral flags whose dimensions force a nonzero intersection by Corollary 2.3.3;
(iv) normalize an intersection vector and certify the target eigenvalue chain by Theorem 5.6.2.

5.8 Weyl Eigenvalue Bounds

Throughout this subsection, $n \in \mathbb{Z}_{>0}$.

Theorem 5.8.1. *Weyl Eigenvalue Inequalities*
Let $A, B \in \mathrm{Mat}(n, n, \mathbb{C})$ be Hermitian.

(i) $(\forall\, i \in J_n)(\forall\, j \in J_{n-i} \cup \{0\})\, \lambda_i(A+B) \le \lambda_{i+j}(A) + \lambda_{n-j}(B)$.
(ii) $(\forall\, i \in J_n)(\forall\, j \in J_i)\, \lambda_{i-j+1}(A) + \lambda_j(B) \le \lambda_i(A+B)$.

Proof. Fix increasingly indexed orthonormal eigenbases $(\mathbf{u}_k)$, $(\mathbf{v}_k)$, and $(\mathbf{w}_k)$ of A, $A+B$, and B by Theorem 6.1.11, Definition 5.6.1(i).

(i) Fix $i \in J_n$ and $j \in J_{n-i} \cup \{0\}$. Set $\mathcal{U} = \mathrm{span}(\mathbf{u}_1, \ldots, \mathbf{u}_{i+j})$ and $\mathcal{V} = \mathrm{span}(\mathbf{v}_i, \ldots, \mathbf{v}_n)$.
Set $\mathcal{W} = \mathrm{span}(\mathbf{w}_1, \ldots, \mathbf{w}_{n-j})$. $\dim(\mathcal{U} \cap \mathcal{V}) \ge j + 1$ by Corollary 2.3.3(ii) with $\dim(\mathcal{U}) = i + j$ and $\dim(\mathcal{V}) = n - i + 1$.
Fix a unit $\mathbf{x} \in \mathcal{U} \cap \mathcal{V} \cap \mathcal{W}$ by Corollary 2.3.3(i), normalization, the preceding bound, and $\dim(\mathcal{W}) = n - j$.
The chain $\lambda_i(A+B) \le \mathbf{x}^*(A+B)\mathbf{x} = \mathbf{x}^* A \mathbf{x} + \mathbf{x}^* B \mathbf{x} \le \lambda_{i+j}(A) + \lambda_{n-j}(B)$ holds by Theorem 5.6.2.

(ii) Fix $i \in J_n$ and $j \in J_i$, and set $p := n - i + 1$ and $q := i - j$. $p \in J_n$ and $q \in J_{n-p} \cup \{0\}$ by index arithmetic.
$(\forall\, C \in \{A, B, A+B\})(\forall\, k \in J_n)\, \lambda_k(-C) = -\lambda_{n-k+1}(C)$ by Theorem 6.1.11 and Definition 5.6.1(i).
$-\lambda_i(A+B) \le -\lambda_j(B) - \lambda_{i-j+1}(A)$ by part (i) for $(-B, -A, p, q)$ and the reversal identity.
Claim (ii) holds by multiplying this inequality by -1.

Structural Commentary: Three-flag intersection establishes (i); spectral reversal and sign multiplication establish (ii).
Key Insight: $\dim(\mathcal{U}) + \dim(\mathcal{V}) + \dim(\mathcal{W}) = 2n + 1$ forces a common Rayleigh vector. □

Computation Method 5.8.2. *Weyl Eigenvalue-Bound Method*
Given Hermitian $A, B \in \mathrm{Mat}(n, n, \mathbb{C})$ and $i \in J_n$, compute a certified interval for $\lambda_i(A+B)$ as follows:

(i) compute the eigenvalues of A and B in increasing order;
(ii) set $U_i := \min_{j \in J_{n-i} \cup \{0\}} \{\lambda_{i+j}(A) + \lambda_{n-j}(B)\}$;
(iii) set $L_i := \max_{j \in J_i} \{\lambda_{i-j+1}(A) + \lambda_j(B)\}$;
(iv) output $[L_i, U_i]$, which satisfies $L_i \le \lambda_i(A+B) \le U_i$ by Theorem 5.8.1(i)–(ii);
(v) for structured B, simplify the candidates with any known sign or zero-eigenvalue data.
If $B \succeq 0$, then $\mathrm{spec}(B) \subseteq [0, \infty)$ by Theorem 2.1.3(ii).
If $\mathrm{rank}(B) = r$, then the algebraic multiplicity of 0 is $n - r$ by Corollary 3.3.1(i) and Theorem 6.1.11.

5.9 Brauer Rank-One Spectral Shifts

Throughout this subsection, $n \in \mathbb{Z}_{>0}$.

Theorem 5.9.1. *Brauer Rank-One Eigenvalue Shift*
Let $A \in \mathrm{Mat}(n,n,\mathbb{C})$, $\lambda \in \mathbb{C}$, and $\mathbf{x},\mathbf{y} \in \mathbb{C}^n$. Assume that $\mathbf{x} \neq \mathbf{0}$ and $A\mathbf{x} = \lambda\mathbf{x}$.
Let $\lambda_1,\dots,\lambda_n$ list the eigenvalues of A with algebraic multiplicity, where $\lambda_1 = \lambda$, and set $C := A + \mathbf{x}\mathbf{y}^*$.
(i) The eigenvalues of C, counted with algebraic multiplicity, are $\lambda + \mathbf{y}^*\mathbf{x}, \lambda_2, \dots, \lambda_n$.
(ii) $C\mathbf{x} = (\lambda + \mathbf{y}^*\mathbf{x})\mathbf{x}$.

Proof. Set $\mathbf{u} := \frac{\mathbf{x}}{\|\mathbf{x}\|_2}$. Then $\|\mathbf{u}\|_2 = 1$ and $A\mathbf{u} = \lambda\mathbf{u}$ by the hypotheses on $\mathbf{x}$.
Fix a unitary $U = [\mathbf{u}\ U_2]$ such that $T := U^*AU$ is upper triangular with diagonal $\lambda_1,\dots,\lambda_n$ by Theorem 2.1.9(i).
$U^*\mathbf{x} = \|\mathbf{x}\|_2 \mathbf{e}_1$ by the definition of $\mathbf{u}$ and $U = [\mathbf{u}\ U_2]$.
For $R := U^*(\mathbf{x}\mathbf{y}^*)U$, only its first row may be nonzero and $R_{11} = \mathbf{y}^*\mathbf{x}$ by the preceding identity and direct multiplication.
$U^*CU = T + R$ is upper triangular with diagonal $\lambda + \mathbf{y}^*\mathbf{x}, \lambda_2, \dots, \lambda_n$ by the definitions of C, T, and R.
(i) The displayed diagonal is the eigenvalue list of C by Proposition 2.1.6(iii) and Theorem 2.1.7(ii).
(ii) $C\mathbf{x} = A\mathbf{x} + \mathbf{x}(\mathbf{y}^*\mathbf{x}) = (\lambda + \mathbf{y}^*\mathbf{x})\mathbf{x}$ by the definition of C and $A\mathbf{x} = \lambda\mathbf{x}$.
Structural Commentary: Ordered Schur form isolates the eigenline; triangular multiplicities transfer back after one diagonal shift.
Key Insight: $U^*\mathbf{x} = \|\mathbf{x}\|_2 \mathbf{e}_1$ confines the update to the first Schur row. □

Figure 98 depicts the Schur-coordinate mechanism in Theorem 5.9.1.
The update replaces λ by $\lambda + \mathbf{y}^*\mathbf{x}$ and preserves the trailing Schur block T'.

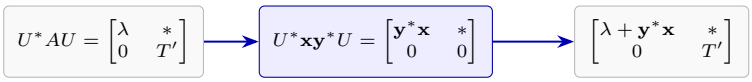

Figure 98: Brauer's aligned update replaces the leading Schur entry and preserves the trailing block T'.

Corollary 5.9.2. *Damped Rank-One Eigenvalue Reset*
Let $A \in \mathrm{Mat}(n,n,\mathbb{C})$, $\lambda,\tau \in \mathbb{C}$, and $\mathbf{x},\mathbf{y} \in \mathbb{C}^n$. Assume that $\mathbf{x} \neq \mathbf{0}$, $A\mathbf{x} = \lambda\mathbf{x}$, and $\mathbf{y}^*\mathbf{x} = 1$.
Let $\lambda_1,\dots,\lambda_n$ list the eigenvalues of A with algebraic multiplicity, where $\lambda_1 = \lambda$. Set $A_\tau := \tau A + (1-\tau)\lambda\mathbf{x}\mathbf{y}^*$.
Then the eigenvalues of A_τ are $\lambda, \tau\lambda_2, \dots, \tau\lambda_n$, counted with algebraic multiplicity.

Proof. The eigenvalues of τA are $\tau\lambda_1,\dots,\tau\lambda_n$ by Proposition 3.4.1 with $p(\zeta) = \tau\zeta$. Set $\mathbf{q} := (1-\overline{\tau})\overline{\lambda}\mathbf{y}$.
The identities $A_\tau = \tau A + \mathbf{x}\mathbf{q}^*$ and $(\tau A)\mathbf{x} = \tau\lambda\mathbf{x}$ hold by the definitions and $A\mathbf{x} = \lambda\mathbf{x}$. $\mathbf{q}^*\mathbf{x} = (1-\tau)\lambda\mathbf{y}^*\mathbf{x} = (1-\tau)\lambda$ by $\mathbf{y}^*\mathbf{x} = 1$.
The claimed eigenvalue list holds by Theorem 5.9.1(i) and $\tau\lambda + \mathbf{q}^*\mathbf{x} = \lambda$.
Structural Commentary: Scalar spectral mapping forms the damped spectrum; Brauer's aligned update restores its first entry.
Key Insight: $\mathbf{q}^*\mathbf{x} = (1-\tau)\lambda$ cancels the shift from λ to $\tau\lambda$. □

6 Numerical Linear Algebra

Numerical linear algebra turns matrix structure into algorithms for direct solves, least squares, eigenvalues, SVD, structured transforms, Krylov methods, iteration, and preconditioning.

6.1 Direct Linear-System Solves

Throughout this subsection, $n \in \mathbb{Z}_{>0}$ and $\mathbb{F} \in \{\mathbb{R},\mathbb{C}\}$.

Perspective 6.1.1. *Solve with Factors Before Forming Inverses*
Let $A \in \mathrm{Mat}(n,n,\mathbb{F})$ be invertible and $\mathbf{b} \in \mathbb{F}^n$. LU and QR factorisations are defined in Definitions 4.1.3 and 4.1.6.
Cholesky factorisation is established in Theorem 4.1.11.
Solve $A\mathbf{x} = \mathbf{b}$ by triangular solves and, for QR, a unitary transformation; do not form A^{-1}.
Reuse the factors for additional right-hand sides; fill-in limits exploitable sparsity.

Computation Method 6.1.2. *Iterative Refinement by Residual Correction*
Let $k \in \mathbb{Z}_{\geq 0}$, let $A \in \mathrm{Mat}(n,n,\mathbb{F})$ be invertible, and let $\mathbf{b} \in \mathbb{F}^n$. Given a current approximation $\mathbf{x}_k \in \mathbb{F}^n$, obtain $\mathbf{x}_{k+1}$ as follows:
(i) Set the residual $\mathbf{r}_k := \mathbf{b} - A\mathbf{x}_k$.
(ii) Compute a correction $\mathbf{d}_k$ for $A\mathbf{d}_k = \mathbf{r}_k$ with stored factors or a prescribed correction solver.
(iii) Set $\mathbf{x}_{k+1} := \mathbf{x}_k + \mathbf{d}_k$.

Proposition 6.1.3. *Exact Residual Correction*
Let $k \in \mathbb{Z}_{\geq 0}$, $A \in \mathrm{Mat}(n,n,\mathbb{F})$, and $\mathbf{b},\mathbf{x}_k,\mathbf{d}_k \in \mathbb{F}^n$. Set $\mathbf{r}_k := \mathbf{b} - A\mathbf{x}_k$ and $\mathbf{x}_{k+1} := \mathbf{x}_k + \mathbf{d}_k$. Then $A\mathbf{d}_k = \mathbf{r}_k \Rightarrow A\mathbf{x}_{k+1} = \mathbf{b}$.

Proof. If $A\mathbf{d}_k = \mathbf{r}_k$, then $A\mathbf{x}_{k+1} = A\mathbf{x}_k + A\mathbf{d}_k = A\mathbf{x}_k + \mathbf{r}_k = \mathbf{b}$ by the definitions of $\mathbf{x}_{k+1}$ and $\mathbf{r}_k$.
Structural Commentary: The update and correction substitutions reduce the claim to residual cancellation.
Key Insight: The correction exactly cancels the current residual. □

Perspective 6.1.4. *Finite-Precision Qualification*
Proposition 6.1.3 is the exact-correction case of Computation Method 6.1.2.
In finite precision, the computed residual and correction satisfy perturbed relations.
Improvement depends on residual evaluation, the correction solve, factor stability, and conditioning.
No quantitative convergence guarantee is asserted without a specified rounding-error model.

6.2 QR Least Squares

Throughout this subsection, $m, n \in \mathbb{Z}_{>0}$ satisfy $m \geq n$, and $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.

Proposition 6.2.1. *QR Route for Least Squares*
Let $A = QR \in \mathrm{Mat}(m, n, \mathbb{F})$ be a narrow QR factorisation and let $\mathbf{y} \in \mathbb{F}^m$. Assume $\mathrm{rank}(A) = n$. Then:

(i) *R is invertible;*
(ii) *$(\forall\, \mathbf{x} \in \mathbb{F}^n)\,[\mathbf{x} \in \mathrm{LS}(A, \mathbf{y}) \iff R\mathbf{x} = Q^*\mathbf{y}]$;*
(iii) *$P_{\mathrm{col}(A)} = QQ^*$.*

Proof.

(i) Inclusion $\ker(R) \subseteq \ker(A) = \{\mathbf{0}\}$ holds by $A = QR$, rank hypothesis, Corollary 3.3.1(i); R invertible by Corollary 3.6.3(vi)⇒(i).
(ii) ($\Rightarrow$) For $\mathbf{x} \in \mathrm{LS}(A, \mathbf{y})$, $R^*(R\mathbf{x} - Q^*\mathbf{y}) = \mathbf{0}$ by $A = QR$, $Q^*Q = I_n$, Theorem 2.4.4(i); $R\mathbf{x} = Q^*\mathbf{y}$ by invertibile R^* from (i).
(ii) ($\Leftarrow$) For $\mathbf{x} \in \mathbb{F}^n$ with $R\mathbf{x} = Q^*\mathbf{y}$, $A^*A\mathbf{x} = R^*R\mathbf{x} = R^*Q^*\mathbf{y} = A^*\mathbf{y}$ by $A = QR$, $Q^*Q = I_n$; $\mathbf{x} \in \mathrm{LS}(A, \mathbf{y})$ by Theorem 2.4.4(i).
(iii) Set $\mathcal{U} := \mathrm{col}(A)$. The equality $\mathcal{U} = \mathrm{col}(Q)$ holds by $A = QR$, $Q = AR^{-1}$, and (i).
Write $Q = [\mathbf{q}_1, \ldots, \mathbf{q}_n]$; its columns form an orthonormal basis of $\mathcal{U}$ by Definition 4.1.6.
For $\mathbf{z} \in \mathbb{F}^m$, $P_{\mathcal{U}}\mathbf{z} = \sum_{j=1}^{n} \langle \mathbf{z}, \mathbf{q}_j \rangle_{\mathbb{F}^m}\, \mathbf{q}_j = QQ^*\mathbf{z}$ by Proposition 2.2.3(ix) and matrix multiplication.
Thus $P_{\mathrm{col}(A)} = QQ^*$ by the definition of $\mathcal{U}$ and arbitrariness of $\mathbf{z}$.

Structural Commentary: Kernel transfer proves (i); cancellation and the orthonormal-column formula prove (ii)–(iii).
Key Insight: Invertible R separates projection from triangular coordinate recovery. □

Perspective 6.2.2. *Why Normal Equations Can Be Numerically Fragile*
For $A = QR$ as in Proposition 6.2.1, $A^*A = R^*R$ and R is invertible.
The identity $\kappa_2(A^*A) = \kappa_2(R^*R) = \kappa_2(R)^2$ holds by the preceding equality and Proposition 5.3.2(v).
Forming the normal equations therefore squares the spectral condition number of R. A QR route omits A^*A and this squaring.
Its finite-precision stability still depends on the factorisation or orthogonalisation implementation and the rounding-error model.

Algorithm 1: Classical Gram–Schmidt Least Squares in Exact Arithmetic

Require: $N \in \mathbb{Z}_{>0}$ and $p \in \mathbb{Z}_{\geq 0}$
Require: $X = [\mathbf{x}_0, \ldots, \mathbf{x}_p] \in \mathrm{Mat}(N, p+1, \mathbb{R})$ with $\mathrm{rank}(X) = p + 1$
Require: $\mathbf{y} \in \mathbb{R}^N$
Ensure: $\mathrm{LS}(X, \mathbf{y}) = \{\widehat{\boldsymbol{\beta}}\}$
  for $j = 0, \ldots, p$ **do**
    $\mathbf{z}_j \leftarrow \mathbf{x}_j$
    for $\ell = 0, \ldots, j-1$ **do**
      $r_{\ell j} \leftarrow \mathbf{q}_\ell^t \mathbf{x}_j$
      $\mathbf{z}_j \leftarrow \mathbf{z}_j - r_{\ell j}\mathbf{q}_\ell$
    end for
    $r_{jj} \leftarrow \|\mathbf{z}_j\|_2$
    $\mathbf{q}_j \leftarrow \frac{\mathbf{z}_j}{r_{jj}}$
  end for
  Set $r_{\ell j} \leftarrow 0$ for $0 \leq j < \ell \leq p$
  Form $Q = [\mathbf{q}_0, \ldots, \mathbf{q}_p]$ and $R = [r_{\ell j}]_{\ell, j=0}^{p}$
  Solve $R\widehat{\boldsymbol{\beta}} = Q^t\mathbf{y}$ by back-substitution

The loop is well-defined, $Q^tQ = I_{p+1}$, and $(\forall\, j \in \{0, \ldots, p\})\, r_{jj} > 0$ by the rank contract and Theorem 1.3.6.
The relation $(\forall\, j \in \{0, \ldots, p\})\, \mathbf{x}_j = \sum_{\ell=0}^{j} r_{\ell j}\mathbf{q}_\ell$ holds by the update assignments.
The identity $X = QR$ with upper-triangular R holds by this relation and the zero lower entries.
The postcondition holds by Proposition 6.2.1(i)–(ii) and the final triangular solve.
Both loops terminate by their finite bounds; the inner loop is empty for $j = 0$. The algorithm asserts no finite-precision stability.

Perspective 6.2.3. *Solve Least Squares with Factors*
Let $N, p \in \mathbb{Z}_{>0}$, let $X \in \mathrm{Mat}(N, p, \mathbb{R})$ satisfy $\mathrm{rank}(X) = p$, and let $\mathbf{y} \in \mathbb{R}^N$. Fix a narrow QR factorisation $X = QR$.
Matrix R is invertible by Proposition 6.2.1(i). The identity $X^tX = R^tR$ holds by $X = QR$ and $Q^tQ = I_p$.
The equality $\kappa_2(X^tX) = \kappa_2(R^tR) = \kappa_2(R)^2$ holds by this identity and Proposition 5.3.2(v). Let $\widehat{\boldsymbol{\beta}}$ be the unique solution of $R\widehat{\boldsymbol{\beta}} = Q^t\mathbf{y}$.
Then $\mathrm{LS}(X, \mathbf{y}) = \{\widehat{\boldsymbol{\beta}}\}$ by Proposition 6.2.1(i)–(ii). Compute $\widehat{\boldsymbol{\beta}}$ by triangular substitution rather than forming X^tX.
Use Cholesky on X^tX only when its conditioning and the required accuracy justify that route.
The exact-arithmetic algorithm above alone supplies no finite-precision guarantee.

6.3 Banded and Sparse Direct Methods

Throughout this subsection, $\mathbb{F}$ is a field.

Definition 6.3.1. *Half-Bandwidth and Tridiagonal Matrices*
Let $m \in \mathbb{Z}_{>0}$, $A = [a_{ij}] \in \mathrm{Mat}(m, m, \mathbb{F})$, $w \in J_m$. Matrix A has *half-bandwidth at most w* if $(\forall\, i, j \in J_m)[|i - j| \geq w \implies a_{ij} = 0]$.
Its *half-bandwidth* is the least such w, which exists because $w = m$ is admissible.
Matrices of half-bandwidth at most 1 are precisely diagonal matrices. Matrices of half-bandwidth at most 2 are *tridiagonal*.

Computation Method 6.3.2. *Banded Elimination without Row Exchanges*
Let $n \in \mathbb{Z}_{>0}$, $w \in J_n$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$ have half-bandwidth at most w. Assume every leading principal minor of A is nonzero.
Compute the unique exact-arithmetic factors $A = LU$, with L unit lower triangular and U upper triangular, as follows:

(i) Initialize $L \leftarrow I_n$, $U \leftarrow 0$, and a current active array $B = [b_{ij}] \leftarrow A$.

(ii) For $k = 1, \dots, n$ in order, set $u_{kj} \leftarrow b_{kj}$ for $k \le j \le \min(n, k+w-1)$.
For $i = k+1, \dots, \min(n, k+w-1)$, set $l_{ik} \leftarrow \frac{b_{ik}}{u_{kk}}$ and $b_{ik} \leftarrow 0$.
Then set $b_{ij} \leftarrow b_{ij} - l_{ik}u_{kj}$ for $k < j \le \min(n, k+w-1)$.
(iii) Return (L, U).
Let A_k be the leading $k \times k$ block and set $\det(A_0) := 1$. Prior row additions preserve $\det(A_k)$ and triangularise its first $k-1$ columns.
Hence $\det(A_k) = \left(\prod_{s=1}^{k-1} u_{ss}\right) b_{kk}$. The minor hypothesis and induction from $k = 1$ imply $u_{kk} = b_{kk} \neq 0$, so every division is defined.
An update requires $0 < i-k < w$ and $0 < j-k < w$, so $|i-j| < w$.
Thus induction preserves the band, and L and U have half-bandwidth at most w.
Reversing the stored row operations establishes $A = LU$. The returned pair is the unique factorisation by Theorem 4.1.4.
At pivot k, set $r_k := \min(w-1, n-k)$; the work is r_k divisions and r_k^2 multiply-subtract updates.
Thus the worst-case scalar-field operation count is $O(nw^2)$ by $r_k \le w-1$.
If $w = 1$, the inner ranges are empty and $(L, U) = (I_n, A)$; if $w = 2$, the cost is $O(n)$.
The finite loops terminate, but without a rounding-error model the method makes no stability claim.
Outside the stated hypotheses, preserving the band does not justify suppressing required row exchanges.

For tridiagonal input, Figure 99 depicts the factors from Computation Method 6.3.2.
Here L and U are lower and upper bidiagonal, respectively, and L has unit diagonal.

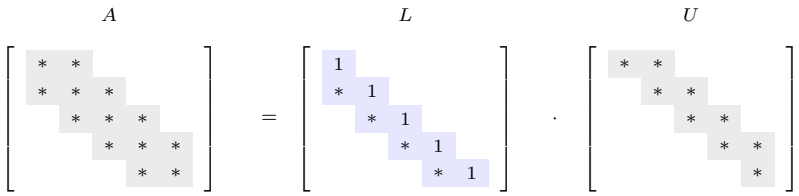

Figure 99: Possible nonzeros ($*$) in no-pivot tridiagonal elimination: L and U are bidiagonal.

Perspective 6.3.3. *Five-Point Stencils Are Sparse with Growing Bandwidth*
Let $N \in \mathbb{Z}_{\ge 2}$ and place the nodes of an $N \times N$ grid in row-major order.
Let $S_N \in \mathrm{Mat}(N^2, N^2, \mathbb{F})$ have nonzero entries precisely at self-couplings and grid-neighbour couplings.
Each row has at most five nonzeros, at offsets $0, \pm 1, \pm N$; boundary gaps remove horizontal wraparound.
Thus S_N has half-bandwidth $N+1$ by Definition 6.3.1. Its row sparsity is bounded independently of N.
An incomplete LU approximation may control fill by retaining a selected pattern or applying a drop rule.
Its quality depends on that rule and the ordering.

Figure 100 depicts the three offset classes.
Its ± 1 diagonals are schematic because row boundaries create periodic gaps that prevent wraparound couplings.

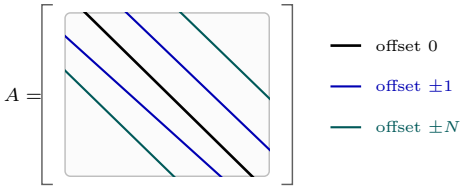

Figure 100: Row-major ordering places five-point couplings on the diagonals with offsets $0, \pm 1, \pm N$.

6.4 Krylov Subspace Methods

Throughout this subsection, $n \in \mathbb{Z}_{>0}$ and $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.

Definition 6.4.1. *Krylov Subspace*
Let $m \in \mathbb{Z}_{>0}$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$, and $\mathbf{b} \in \mathbb{F}^n$. Set $\mathcal{K}_m(A, \mathbf{b}) := \mathrm{span}\{\mathbf{b}, A\mathbf{b}, \dots, A^{m-1}\mathbf{b}\}$.
This is the mth *Krylov subspace* generated by $(A, \mathbf{b})$.

Computation Method 6.4.2. *Arnoldi, Lanczos, CG, and GMRES Templates*
Let $A \in \mathrm{Mat}(n, n, \mathbb{F})$ and work in exact arithmetic.
(i) *Arnoldi*: Let $\mathbf{b} \in \mathbb{F}^n \setminus \{\mathbf{0}\}$ and $m \in J_n$. Set $\mathbf{q}_1 := \mathbf{b}/\|\mathbf{b}\|_2$. For $j = 1, \dots, m$, set $\mathbf{v}_j := A\mathbf{q}_j$ and $h_{ij} := \mathbf{q}_i^* \mathbf{v}_j$ for $i \in J_j$.
Set $\mathbf{w}_j := \mathbf{v}_j - \sum_{i=1}^{j} h_{ij}\mathbf{q}_i$ and $\eta_j := \|\mathbf{w}_j\|_2$. If $\eta_j = 0$, set $s := j$ and stop; otherwise, set $h_{j+1,j} := \eta_j$ and $\mathbf{q}_{j+1} := \mathbf{w}_j/\eta_j$.
Write $Q_j := [\mathbf{q}_1 \ \cdots \ \mathbf{q}_j]$ and $H_j := [h_{i\ell}]_{i,\ell=1}^{j}$, where $h_{i\ell} := 0$ for $i > \ell + 1$.
The identities $\mathbf{q}_i^* \mathbf{w}_j = 0$ for $i \in J_j$ and $\mathbf{q}_{j+1} \in \mathcal{K}_{j+1}(A, \mathbf{b})$ imply inductively that $Q_j^* Q_j = I_j$ and $\mathrm{col}(Q_j) \subseteq \mathcal{K}_j(A, \mathbf{b})$.
Before breakdown, $\dim(\mathrm{col}(Q_j)) = j$ and $\dim(\mathcal{K}_j(A, \mathbf{b})) \le j$, so the inclusion is equality.
If no breakdown occurs through m, then $AQ_m = Q_m H_m + \eta_m \mathbf{q}_{m+1}\mathbf{e}_m^t$, and H_m is upper Hessenberg.
At breakdown s, the same relation becomes $AQ_s = Q_s H_s$, so $\mathcal{K}_s(A, \mathbf{b})$ is A-invariant and the construction terminates.
(ii) *Lanczos*: Suppose $A = A^*$ and Arnoldi does not break down through step m.
Then $H_m = Q_m^* A Q_m = H_m^*$, so its upper-Hessenberg structure is tridiagonal by Definition 6.3.1.
Set $\mathbf{q}_0 := \mathbf{0}$, $\beta_0 := 0$, $\alpha_j := h_{jj} \in \mathbb{R}$, and $\beta_j := \eta_j > 0$ for $j \in J_m$.
The Arnoldi relation becomes $(\forall\, j \in J_m)\ A\mathbf{q}_j = \beta_{j-1}\mathbf{q}_{j-1} + \alpha_j \mathbf{q}_j + \beta_j \mathbf{q}_{j+1}$.
At breakdown s, set $\beta_s := 0$; the recurrence through $j = s$ remains valid.

(iii) *CG, conjugate-direction form*: Suppose $A \succ 0$ and fix $\mathbf{b}, \mathbf{x}_0 \in \mathbb{F}^n$. Set $\mathbf{r}_0 := \mathbf{b} - A\mathbf{x}_0$. If $\mathbf{r}_0 = \mathbf{0}$, return $\mathbf{x}_0$.
Otherwise, let $k \in J_n$ satisfy $\dim(\mathcal{K}_k(A, \mathbf{r}_0)) = k$. Define $\langle \mathbf{u}, \mathbf{v} \rangle_A := \mathbf{v}^* A\mathbf{u}$, an inner product by $A \succ 0$.
Apply Gram–Schmidt in this inner product to $(\mathbf{r}_0, A\mathbf{r}_0, \dots, A^{k-1}\mathbf{r}_0)$, obtaining an A-orthogonal basis $\mathbf{p}_0, \dots, \mathbf{p}_{k-1}$ of $\mathcal{K}_k(A, \mathbf{r}_0)$.
For $i \in \{0, \dots, k-1\}$, set $c_i := \frac{\mathbf{p}_i^* \mathbf{r}_0}{\mathbf{p}_i^* A \mathbf{p}_i}$. The denominators are positive by $A \succ 0$. Set $\mathbf{x}_k := \mathbf{x}_0 + \sum_{i=0}^{k-1} c_i \mathbf{p}_i$ and $\mathbf{r}_k := \mathbf{b} - A\mathbf{x}_k$.
For $i \in \{0, \dots, k-1\}$, A-orthogonality reduces $\mathbf{p}_i^* \mathbf{r}_k$ to $\mathbf{p}_i^* \mathbf{r}_0 - c_i \mathbf{p}_i^* A \mathbf{p}_i = 0$. Hence $\mathbf{r}_k \perp \mathcal{K}_k(A, \mathbf{r}_0)$.
This correction is unique: if $\mathbf{z}, \mathbf{z}' \in \mathcal{K}_k(A, \mathbf{r}_0)$ both satisfy the residual condition, then $\mathbf{d} := \mathbf{z} - \mathbf{z}'$ lies in the same space.
Their residual difference is $-A\mathbf{d} \perp \mathcal{K}_k(A, \mathbf{r}_0)$, so $\mathbf{d}^* A \mathbf{d} = 0$ and $\mathbf{d} = \mathbf{0}$ by $A \succ 0$.

(iv) *GMRES*: Fix $\mathbf{b}, \mathbf{x}_0 \in \mathbb{F}^n$ and $k \in J_n$. Set $\mathbf{r}_0 := \mathbf{b} - A\mathbf{x}_0$. Set $\mathcal{A}_k := \mathbf{x}_0 + \mathcal{K}_k(A, \mathbf{r}_0)$.
If $\mathbf{r}_0 = \mathbf{0}$, return $\mathbf{x}_0$. Otherwise, set $s := \dim(\mathcal{K}_k(A, \mathbf{r}_0))$.
Choose an orthonormal basis matrix $Q_s \in \mathrm{Mat}(n, s, \mathbb{F})$ for this subspace and $\mathbf{y}_k \in \mathrm{LS}(AQ_s, \mathbf{r}_0)$ by Theorem 2.4.4(ii).
Set $\mathbf{x}_k := \mathbf{x}_0 + Q_s \mathbf{y}_k$. Since $\mathcal{A}_k = \{\mathbf{x}_0 + Q_s \mathbf{y} : \mathbf{y} \in \mathbb{F}^s\}$, $\mathbf{x}_k \in \operatorname{arg\,min}_{\mathbf{x} \in \mathcal{A}_k} \|\mathbf{b} - A\mathbf{x}\|_2$.

These templates access A through matrix-vector products. With stored products, a basis extension uses one new multiplication by A. The remaining work consists of inner products, vector updates, and reduced problems. The prescribed loops are finite because $m, k \le n$. In finite precision, orthogonality and convergence require a separate rounding-error analysis.

Perspective 6.4.3. *Projection Conditions across Krylov Methods*
Definition 6.4.1 supplies the common search spaces in Computation Method 6.4.2.
Arnoldi constructs orthonormal coordinates, and Lanczos reduces the recurrence when A is Hermitian.
CG uses A-orthogonal directions to impose residual orthogonality. GMRES instead minimizes the Euclidean residual norm.
These correspondences are exact-arithmetic statements; they do not supply finite-precision convergence guarantees.

6.5 Stationary Iterations and Splittings

Throughout this subsection, $n \in \mathbb{Z}_{>0}$.

Definition 6.5.1. *Matrix Splitting Iteration*
Let $A, S, T \in \mathrm{Mat}(n, n, \mathbb{C})$ satisfy $A = S - T$, with S invertible. Set $B := S^{-1}T$, and let $\mathbf{b}, \mathbf{x}_0 \in \mathbb{C}^n$.
The *splitting iteration* for $A\mathbf{x} = \mathbf{b}$ is $(\forall\, k \in \mathbb{Z}_{\ge 0})\, S\mathbf{x}_{k+1} = T\mathbf{x}_k + \mathbf{b}$. Equivalently, $(\forall\, k \in \mathbb{Z}_{\ge 0})\, \mathbf{x}_{k+1} = B\mathbf{x}_k + S^{-1}\mathbf{b}$.
If $A\mathbf{x}_* = \mathbf{b}$ and $\mathbf{e}_k := \mathbf{x}_k - \mathbf{x}_*$, then $(\forall\, k \in \mathbb{Z}_{\ge 0})\, \mathbf{e}_{k+1} = B\mathbf{e}_k$.

Theorem 6.5.2. *Splitting Convergence Criterion*
Let $A, S, T \in \mathrm{Mat}(n, n, \mathbb{C})$ satisfy $A = S - T$, with S invertible, and set $B := S^{-1}T$.
For $\mathbf{b}, \mathbf{x}_0 \in \mathbb{C}^n$, write $(\mathbf{x}_k(\mathbf{b}, \mathbf{x}_0))_{k \ge 0}$ for the splitting sequence in Definition 6.5.1.
Then $\rho(B) < 1$ if and only if A is invertible and $(\forall\, (\mathbf{b}, \mathbf{x}_0) \in (\mathbb{C}^n)^2)\, \mathbf{x}_k(\mathbf{b}, \mathbf{x}_0) \to A^{-1}\mathbf{b}$.

Proof.
($\Rightarrow$) By Theorem 3.3.5, $B^k \to 0$. If $(I_n - B)\mathbf{z} = \mathbf{0}$, then $B\mathbf{z} = \mathbf{z}$, so $\mathbf{z} = \mathbf{0}$ by $\rho(B) < 1$.
Thus $I_n - B$ is invertible by Corollary 3.6.3(vi)$\Rightarrow$(i), and $A = S(I_n - B)$ is invertible.
Fix $\mathbf{b}, \mathbf{x}_0 \in \mathbb{C}^n$, set $\mathbf{x}_* := A^{-1}\mathbf{b}$, $\mathbf{e}_k := \mathbf{x}_k(\mathbf{b}, \mathbf{x}_0) - \mathbf{x}_*$. Then $\mathbf{e}_k = B^k \mathbf{e}_0$ by Definition 6.5.1, induction, so $\mathbf{x}_k(\mathbf{b}, \mathbf{x}_0) \to A^{-1}\mathbf{b}$.
($\Leftarrow$) Fix $\mathbf{z} \in \mathbb{C}^n$, $(\mathbf{b}, \mathbf{x}_0) = (\mathbf{0}, \mathbf{z})$. Then $B^k \mathbf{z} = \mathbf{x}_k(\mathbf{0}, \mathbf{z}) \to \mathbf{0}$ by global-convergence hypothesis, Definition 6.5.1.
The convergence $B^k \to 0$ holds entrywise by specializing $\mathbf{z}$ to the standard basis vectors, and $\rho(B) < 1$ by Theorem 3.3.5.
Structural Commentary: The forward direction propagates errors by B^k; the reverse tests homogeneous iterations on a basis.
Key Insight: Arbitrary initial errors decay exactly when $B^k \to 0$. □

Corollary 6.5.3. *Singular Matrices Obstruct Splitting Convergence*
Let $A, S, T \in \mathrm{Mat}(n, n, \mathbb{C})$ satisfy $A = S - T$, with S invertible, and suppose A is singular. Then:
(i) $1 \in \mathrm{spec}(S^{-1}T)$;
(ii) $\rho(S^{-1}T) \ge 1$.

Proof.
(i) Choose $\mathbf{0} \ne \mathbf{x} \in \ker(A)$ by Corollary 3.6.3(i)$\Leftrightarrow$(vi). Then $(S - T)\mathbf{x} = \mathbf{0}$, so $S^{-1}T\mathbf{x} = \mathbf{x}$ and $1 \in \mathrm{spec}(S^{-1}T)$.
(ii) The inequality $\rho(S^{-1}T) \ge 1$ holds by (i) and Definition 3.3.3.
Structural Commentary: The identity $A\mathbf{x} = \mathbf{0}$ converts a null vector into a 1-eigenvector of $S^{-1}T$.
Key Insight: A fixed error mode prevents spectral-radius contraction. □

Computation Method 6.5.4. *Stationary Iterative Method*
Let $M \in \mathrm{Mat}(n, n, \mathbb{C})$ and $\mathbf{c}, \mathbf{x}_0 \in \mathbb{C}^n$.
(i) Generate $(\forall\, k \in \mathbb{Z}_{\ge 0})\, \mathbf{x}_{k+1} = M\mathbf{x}_k + \mathbf{c}$.
(ii) If $\rho(M) < 1$, then $I_n - M$ is invertible by Theorem 6.5.2, with $A = I_n - M$, $S = I_n$, and $T = M$.
The vector $\mathbf{x}_* := (I_n - M)^{-1}\mathbf{c}$ is the unique fixed point.
(iii) Under $\rho(M) < 1$, $\mathbf{x}_k - \mathbf{x}_* = M^k(\mathbf{x}_0 - \mathbf{x}_*) \to \mathbf{0}$ by Theorem 3.3.5.
This defines an infinite exact-arithmetic sequence. A finite implementation must additionally specify a stopping test and tolerance.

Computation Method 6.5.5. *Jacobi, Gauss–Seidel, and SOR Splittings*
Let $A = D + L + U \in \mathrm{Mat}(n, n, \mathbb{C})$, where D is diagonal and invertible, L is strictly lower triangular, and U is strictly upper triangular.
For a splitting $A = S - T$, use the iteration in Definition 6.5.1.
(i) *Jacobi*: $S = D$, $T = -(L + U)$, $B_J = -D^{-1}(L + U)$.
(ii) *Gauss–Seidel*: $S = D + L$, $T = -U$, $B_{\mathrm{GS}} = -(D + L)^{-1}U$.
(iii) *SOR*: For $\omega \in \mathbb{R} \setminus \{0\}$, $S_\omega = \frac{1}{\omega}D + L$, $T_\omega = \left(\frac{1}{\omega} - 1\right) D - U$, and $B_\omega = S_\omega^{-1} T_\omega$.
The transposes of $D + L$ and S_ω are upper triangular with nonzero diagonal entries.
The matrices $D + L$ and S_ω are invertible by Theorem 3.8.9(i) and Corollary 3.6.4.
Global convergence of listed scheme equivalent to $\rho(B) < 1$ for iteration matrix by Theorem 6.5.2. For $\omega = 1$, SOR is Gauss–Seidel.

Corollary 6.5.6. *Jacobi Convergence under Strict Diagonal Dominance*
Let $A = [a_{ij}] \in \mathrm{Mat}(n, n, \mathbb{C})$ be strictly diagonally dominant, $\mathbf{b}, \mathbf{x}_0 \in \mathbb{C}^n$, $(\mathbf{x}_k)$ be Jacobi sequence. Then $\mathbf{x}_k \to A^{-1}\mathbf{b}$.

Proof. The inequalities $|a_{ii}| > R_i^{\text{off}}(A) \geq 0$ hold for $i \in J_n$ by Definition 5.5.1, so D is invertible by Theorem 3.8.9(i).
From $A = D + L + U$, $B_J = -D^{-1}(L+U) = I_n - D^{-1}A$ and $(\forall\, i \in J_n)\,[(B_J)_{ii} = 0, \sum_{j \in J_n \setminus \{i\}} |(B_J)_{ij}| = \frac{R_i^{\text{off}}(A)}{|a_{ii}|} < 1]$.
Hence $\operatorname{spec}(B_J) \subseteq \{z \in \mathbb{C} : |z| < 1\}$ by Theorem 5.4.5, so $\rho(B_J) < 1$. Convergence $\mathbf{x}_k \to A^{-1}\mathbf{b}$ holds by Theorem 6.5.2.
Structural Commentary: Strict dominance becomes Gersgorin disks for B_J centered at 0 with radii below 1.
Key Insight: Row dominance confines the Jacobi error spectrum to the unit disk. □

Example 6.5.7. *Two-by-Two Jacobi and Gauss–Seidel*
For $A = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$, write $A = D + L + U$.
The Jacobi matrix is $B_J = -D^{-1}(L+U) = \left(\begin{smallmatrix} 0 & -\frac{1}{2} \\ -\frac{1}{2} & 0 \end{smallmatrix}\right)$, with $\rho(B_J) = \frac{1}{2}$.
The Gauss–Seidel matrix is $B_{\text{GS}} = -(D+L)^{-1}U = \left(\begin{smallmatrix} 0 & -\frac{1}{2} \\ 0 & \frac{1}{4} \end{smallmatrix}\right)$, with $\rho(B_{\text{GS}}) = \frac{1}{4}$.
Both schemes converge globally by Theorem 6.5.2.
Thus $\rho(B_{\text{GS}}) < \rho(B_J) < 1$; this spectral-radius comparison does not assert uniformly smaller transient error.

Example 6.5.8. *Poisson Tridiagonal Stationary Rates*
Let $A_n = \operatorname{tridiag}(-1, 2, -1)$ and $\theta_k := \frac{k\pi}{n+1}$ for $k \in J_n$.
For $\mathbf{v}^{(k)} = [\sin(\theta_k)\ \cdots\ \sin(n\theta_k)]^t$, $A_n\mathbf{v}^{(k)} = (2 - 2\cos(\theta_k))\mathbf{v}^{(k)}$ by the sine addition formulas.
These n eigenvalues are distinct, so $B_J = I_n - \frac{1}{2}A_n$ has eigenvalues $\cos(\theta_k)$ and $\rho(B_J) = \cos\left(\frac{\pi}{n+1}\right)$.
For $m \in J_n$, write $A_m = D_m + L_m + U_m$, and let $B_{J,m}$ and $B_{\text{GS},m}$ be its iteration matrices.
Set $p_m(\mu) := \det(\mu I_m - B_{J,m})$ and $q_m(\lambda) := \det(\lambda I_m - B_{\text{GS},m})$, with $p_0 = q_0 := 1$.
Since $\det(D_m + L_m) = 2^m$ and $\lambda I_m - B_{\text{GS},m} = (D_m + L_m)^{-1}(\lambda(D_m + L_m) + U_m)$, $q_m(\lambda) = 2^{-m}\det(\lambda(D_m + L_m) + U_m)$.
By tridiagonal determinant expansion, $p_1(\mu) = \mu$, $q_1(\lambda) = \lambda$, and, for $2 \leq m \leq n$,
$p_m(\mu) = \mu p_{m-1}(\mu) - \frac{1}{4}p_{m-2}(\mu)$, and $q_m(\lambda) = \lambda q_{m-1}(\lambda) - \frac{\lambda}{4}q_{m-2}(\lambda)$. The identity $(\forall\, \mu \in \mathbb{C})\, q_m(\mu^2) = \mu^m p_m(\mu)$ holds for $m = 0, 1$.
If it holds at $m-1, m-2$, then $q_m(\mu^2) = \mu^m(\mu p_{m-1}(\mu) - \frac{1}{4}p_{m-2}(\mu)) = \mu^m p_m(\mu)$, so it holds for $0 \leq m \leq n$ by induction.
For $\mu \neq 0$, $q_n(\mu^2) = 0 \iff p_n(\mu) = 0$; hence $\operatorname{spec}(B_{\text{GS}}) \setminus \{0\} = \{\lambda^2 : \lambda \in \operatorname{spec}(B_J) \setminus \{0\}\}$. Thus, $\rho(B_{\text{GS}}) = \rho(B_J)^2 = \cos^2\left(\frac{\pi}{n+1}\right)$.
As $n \to \infty$, both radii tend to 1, so the iterations become asymptotically slow and motivate acceleration or preconditioning.

Perspective 6.5.9. *Preconditioning Preview*
Let $A, M \in \operatorname{Mat}(n, n, \mathbb{C})$, with M invertible, and let $\mathbf{b} \in \mathbb{C}^n$.
The left-preconditioned system $M^{-1}A\mathbf{x} = M^{-1}\mathbf{b}$ is equivalent to $A\mathbf{x} = \mathbf{b}$.
The right-preconditioned system $AM^{-1}\mathbf{y} = \mathbf{b}$ is equivalent under $\mathbf{x} = M^{-1}\mathbf{y}$.
Favorable conditioning or iteration spectra and inexpensive solves with M are design goals, not consequences of invertibility alone.

6.6 Hessenberg Reduction and QR Eigenvalue Methods

Throughout this subsection, $n \in \mathbb{Z}_{>0}$ and $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.

Definition 6.6.1. *Upper Hessenberg Matrix*
Matrix $A = [a_{ij}] \in \operatorname{Mat}(n, n, \mathbb{F})$ is *upper Hessenberg* iff $(\forall\, (i,j) \in J_n^2)\,[i > j+1 \implies a_{ij} = 0]$.

Numerical eigenvalue methods introduce structural zeros by unitary similarity.
Upper Hessenberg form is the standard preliminary reduction for QR iteration.
Figure 101 separates unrestricted entries from forced zeros below the first subdiagonal.

$$\begin{bmatrix} * & * & * & * & * \\ * & * & * & * & * \\ 0 & * & * & * & * \\ 0 & 0 & * & * & * \\ 0 & 0 & 0 & * & * \end{bmatrix}$$

Figure 101: Upper Hessenberg pattern: asterisks are unrestricted and entries below the first subdiagonal are zero.

Theorem 6.6.2. *Unitary Upper Hessenberg Reduction*
Every $A \in \operatorname{Mat}(n, n, \mathbb{F})$ is unitarily similar to an upper Hessenberg matrix with real nonnegative subdiagonal entries.

Proof. For $n = 1$, take $U = I_1$. Assume $n \geq 2$ and set $A_0 := A$.
For $k \in J_{n-1}$ in increasing order, assume columns $1, \ldots, k-1$ have the required form.
This condition is vacuous for $k = 1$. Let $\mathbf{w}_k \in \mathbb{F}^{n-k}$ be the tail of column k of A_{k-1}.
If $\mathbf{w}_k = \mathbf{0}$, set $V_k := I_{n-k}$. Otherwise set $\mathbf{v}_k := \frac{\mathbf{w}_k}{\|\mathbf{w}_k\|_2}$; then $\|\mathbf{v}_k\|_2 = 1$.
Choose unitary V_k with $V_k\mathbf{e}_1 = \mathbf{v}_k$ by Corollary 2.7.4(iii) in the nonzero case.
In either case, $V_k^*\mathbf{w}_k = \|\mathbf{w}_k\|_2\,\mathbf{e}_1$ by the defining case and unitarity. Set $U_k := I_k \oplus V_k$ and $A_k := U_k^* A_{k-1} U_k$.
The identity $U_k^* U_k = I_n$ holds by block multiplication. The first $k-1$ columns are fixed by right multiplication with U_k.
They are fixed by left multiplication with U_k^* because only their zero tails are mixed.
Column k has the required zeros and subdiagonal entry $\|\mathbf{w}_k\|_2 \in \mathbb{R}_{\geq 0}$ by the tail identity.
For $U := U_1 \cdots U_{n-1}$, U is unitary by identities $U_k^* U_k = I_n$. Identity $A_{n-1} = U^* A U$ holds by iteration.
Matrix A_{n-1} has the required form by induction.
Structural Commentary: Trailing block similarities preserve completed columns while aligning the next column tail.
Key Insight: $V_k^*\mathbf{w}_k = \|\mathbf{w}_k\|_2\,\mathbf{e}_1$ installs both zeros and phase normalization. □

Perspective 6.6.3. *Why Hessenberg Form Matters*
Unitary similarity preserves p_A by Theorem 2.1.7(i), and hence the spectrum by Theorem 2.1.3(ii).
Upper Hessenberg form leaves only the first subdiagonal to eliminate in a QR factorisation.

Computation Method 6.6.4. *QR Eigenvalue Algorithm Preview*
Let $A \in \mathrm{Mat}(n,n,\mathbb{F})$. Choose unitary U such that $A_0 := U^*AU$ is upper Hessenberg by Theorem 6.6.2. For $k \in \mathbb{Z}_{\geq 0}$, perform:

(i) Choose $\mu_k \in \mathbb{F}$ and factor $A_k - \mu_k I_n = Q_k R_k$ by Theorem 4.1.7(i). Here Q_k is unitary and R_k is upper triangular.
(ii) Set $A_{k+1} = R_k Q_k + \mu_k I_n = Q_k^* A_k Q_k$.

$(\forall\, k \in \mathbb{Z}_{\geq 0})\ A_k \sim A$ by induction through the initialization and update similarities.
$(\forall\, k \in \mathbb{Z}_{\geq 0})\ \mathrm{spec}(A_k) = \mathrm{spec}(A)$ by the preceding relation, Theorem 2.1.7(i), and Theorem 2.1.3(ii).
No shift rule, deflation test, stopping criterion, or convergence claim is specified.

Computation Method 6.6.5. *Hessenberg QR Step by Plane Unitaries*
Assume $n \geq 2$. Let $H \in \mathrm{Mat}(n,n,\mathbb{C})$ be upper Hessenberg, and let $\mu \in \mathbb{C}$.

(i) Set $B_0 := H - \mu I_n$.
(ii) For $j \in J_{n-1}$, set $\mathbf{z}_j := \begin{pmatrix} (B_{j-1})_{jj} \\ (B_{j-1})_{j+1,j} \end{pmatrix}$. If $\mathbf{z}_j = \mathbf{0}$, set $\widehat{G}_j := I_2$. Otherwise set $\mathbf{u}_j := \frac{\mathbf{z}_j}{\|\mathbf{z}_j\|_2}$, so $\|\mathbf{u}_j\|_2 = 1$.
In the nonzero case, choose unitary $\widehat{G}_j$ with $\widehat{G}_j \mathbf{e}_1 = \mathbf{u}_j$ by Corollary 2.7.4(iii).
In either case, $\widehat{G}_j^* \mathbf{z}_j = \|\mathbf{z}_j\|_2 \mathbf{e}_1$ by the construction.
Let G_j act as $\widehat{G}_j$ on coordinates $j, j+1$ and as the identity elsewhere. Set $B_j := G_j^* B_{j-1}$.
(iii) Set $Q := G_1 \cdots G_{n-1}$ and $R := B_{n-1}$.
(iv) Define $H_+ := RQ + \mu I_n = Q^* H Q$.

Matrix B_0 is upper Hessenberg. At iteration j, the two mixed rows vanish in columns $1, \ldots, j-1$ by induction.
Their mixing preserves these zeros, and the tail identity annihilates entry $(j+1, j)$.
Thus B_j is upper Hessenberg with its first j columns upper triangular by induction.
Hence R is upper triangular and $H - \mu I_n = QR$ by $B_{n-1} = Q^*(H - \mu I_n)$.
Set $Q_0 := I_n$ and $Q_j := G_1 \cdots G_j$. Each Q_{j-1} acts only on the first j coordinates.
Thus $Q_{j-1}\mathbf{e}_{j+1} = \mathbf{e}_{j+1}$, and Q_j is upper Hessenberg by induction.
Matrix Q is unitary by the unitarity of each G_j. The identity $H_+ = Q^* H Q$ holds by the shifted factorisation.
For $i > j+1$, $(RQ)_{ij} = \sum_{\ell=1}^{n} r_{i\ell} q_{\ell j} = 0$ by $r_{i\ell} \neq 0 \Longrightarrow \ell \geq i$ and $q_{\ell j} \neq 0 \Longrightarrow \ell \leq j+1$. Hence $H_+ = RQ + \mu I_n$ is upper Hessenberg.
The identity $\mathrm{spec}(H_+) = \mathrm{spec}(H)$ holds by Theorem 2.1.7(i) and Theorem 2.1.3(ii).
The construction is exact-arithmetic; no floating-point stability or deflation claim is made.

6.7 Power and Shift-Invert Iterations

Throughout this subsection, $n \in \mathbb{Z}_{\geq 2}$.
For $\mathcal{E} \leq \mathbb{C}^n$, write $d(\mathbf{z}, \mathcal{E})$ for Euclidean distance, as in Definition 2.2.7.

Theorem 6.7.1. *Power Iteration toward a Dominant Eigenspace*
Let $A \in \mathrm{Mat}(n,n,\mathbb{C})$, and $(\mathbf{v}_1, \ldots, \mathbf{v}_n)$ bebasis of $\mathbb{C}^n$. Let $(\lambda_1, \ldots, \lambda_n) \in \mathbb{C}^n$ satisfy $(\forall\, j \in J_n)\ A\mathbf{v}_j = \lambda_j \mathbf{v}_j$ and $|\lambda_1| > \max_{2 \leq j \leq n} |\lambda_j|$.
Let $(c_1, \ldots, c_n) \in \mathbb{C}^n$ satisfy $c_1 \neq 0$, and set $\mathbf{u}_0 := \sum_{j=1}^{n} c_j \mathbf{v}_j$ and $\mathcal{E}_1 := \mathrm{span}\{\mathbf{v}_1\}$. As $k \longrightarrow \infty$:

(i) $\lambda_1^{-k} A^k \mathbf{u}_0 \longrightarrow c_1 \mathbf{v}_1$;
(ii) $\frac{d(A^k \mathbf{u}_0, \mathcal{E}_1)}{\|A^k \mathbf{u}_0\|_2} \longrightarrow 0$.

Proof. The relation $\lambda_1 \neq 0$ holds by the modulus gap. Set $\rho := \max_{2 \leq j \leq n} \left|\frac{\lambda_j}{\lambda_1}\right| < 1$. For $k \in \mathbb{Z}_{\geq 0}$, set $\mathbf{r}_k := \sum_{j=2}^{n} c_j \left(\frac{\lambda_j}{\lambda_1}\right)^k \mathbf{v}_j$.
For $k \in \mathbb{Z}_{\geq 0}$, $\lambda_1^{-k} A^k \mathbf{u}_0 = c_1 \mathbf{v}_1 + \mathbf{r}_k$ by induction and linearity. Estimate $\|\mathbf{r}_k\|_2 \leq \rho^k \sum_{j=2}^{n} |c_j| \|\mathbf{v}_j\|_2$ holds by triangle inequality.
The convergence $\mathbf{r}_k \longrightarrow \mathbf{0}$ holds by $0 \leq \rho < 1$.

(i) Claim (i) holds by the scaled identity and $\mathbf{r}_k \longrightarrow \mathbf{0}$.
(ii) $(\forall\, k \in \mathbb{Z}_{\geq 0})\ A^k \mathbf{u}_0 \neq \mathbf{0}$ by the nonzero eigenbasis coordinate $c_1 \lambda_1^k$.
For $k \geq 0$, $\frac{d(A^k \mathbf{u}_0, \mathcal{E}_1)}{\|A^k \mathbf{u}_0\|_2} \leq \frac{\|\mathbf{r}_k\|_2}{\|c_1 \mathbf{v}_1 + \mathbf{r}_k\|_2}$ by distance homogeneity and $c_1 \mathbf{v}_1 \in \mathcal{E}_1$.
The denominator converges to $\|c_1 \mathbf{v}_1\|_2 > 0$ by the reverse triangle inequality.
Claim (ii) holds by the vanishing numerator and positive denominator limit.

Structural Commentary: Eigenbasis scaling isolates a geometric remainder; distance homogeneity transfers its decay to directions.
Key Insight: The spectral gap contracts every nondominant eigenvalue ratio. □

Computation Method 6.7.2. *Inverse, Shift-Invert, and Shifted Power Iteration*
Let $A \in \mathrm{Mat}(n,n,\mathbb{C})$, and let $(\mathbf{v}_1, \ldots, \mathbf{v}_n)$ be a basis. Let $(\lambda_1, \ldots, \lambda_n) \in \mathbb{C}^n$ satisfy $(\forall\, j \in J_n)\ A\mathbf{v}_j = \lambda_j \mathbf{v}_j$.
Relabel target eigenpair as $(\lambda_1, \mathbf{v}_1)$. Let $(c_1, \ldots, c_n) \in \mathbb{C}^n$ satisfy $c_1 \neq 0$, set $\mathbf{x}_0 := \sum_{j=1}^{n} c_j \mathbf{v}_j$ and $\mathcal{E}_1 := \mathrm{span}\{\mathbf{v}_1\}$.
Set $\mathcal{N}(\mathbf{z}) := \frac{\mathbf{z}}{\|\mathbf{z}\|_2}$ for $\mathbf{z} \neq \mathbf{0}$. Define a transformed matrix B and eigenvalues $(\theta_j)_{j=1}^n$ by one branch:

(i) *Inverse*: Assume $0 \notin \mathrm{spec}(A)$ and $|\lambda_1| < \min_{2 \leq j \leq n} |\lambda_j|$. Matrix A is invertible by Corollary 5.1.8.
Set $B := A^{-1}$ and $(\theta_j)_{j=1}^n := (\lambda_j^{-1})_{j=1}^n$. Factor A once. For $k \in \mathbb{Z}_{\geq 0}$, solve $A\mathbf{y}_{k+1} = \mathbf{x}_k$ and set $\mathbf{x}_{k+1} := \mathcal{N}(\mathbf{y}_{k+1})$.
(ii) *Shift-Invert*: Choose $\sigma \in \mathbb{C} \setminus \mathrm{spec}(A)$ with $|\lambda_1 - \sigma| < \min_{2 \leq j \leq n} |\lambda_j - \sigma|$.
Matrix $A - \sigma I_n$ is invertible by Corollary 3.4.4 with $p(z) = z - \sigma$. Set $B := (A - \sigma I_n)^{-1}$ and $(\theta_j)_{j=1}^n := \big((\lambda_j - \sigma)^{-1}\big)_{j=1}^n$.
Factor $A - \sigma I_n$ once. For $k \in \mathbb{Z}_{\geq 0}$, solve $(A - \sigma I_n)\mathbf{y}_{k+1} = \mathbf{x}_k$ and set $\mathbf{x}_{k+1} := \mathcal{N}(\mathbf{y}_{k+1})$.
(iii) *Shifted Power*: Choose $\sigma \in \mathbb{C}$ with $|\lambda_1 - \sigma| > \max_{2 \leq j \leq n} |\lambda_j - \sigma|$. Set $B := A - \sigma I_n$ and $(\theta_j)_{j=1}^n := (\lambda_j - \sigma)_{j=1}^n$.
For $k \in \mathbb{Z}_{\geq 0}$, set $\mathbf{x}_{k+1} := \mathcal{N}\big((A - \sigma I_n)\mathbf{x}_k\big)$.

Each branch satisfies $(\forall\, j \in J_n)\, B\mathbf{v}_j = \theta_j \mathbf{v}_j$ by the original eigenpair identities.
It also satisfies $|\theta_1| > \max_{2 \le j \le n} |\theta_j|$ and $\theta_1 \neq 0$ by the branch hypothesis and the definition of θ_j.
$(\forall\, k \in \mathbb{Z}_{\ge 0})\, B^k \mathbf{x}_0 \neq \mathbf{0}$ by the nonzero eigenbasis coordinate $c_1 \theta_1^k$. $(\forall\, k \in \mathbb{Z}_{>0})(\exists\, \alpha_k \in \mathbb{C} \setminus \{0\})\, \mathbf{x}_k = \alpha_k B^k \mathbf{x}_0$ by induction.
The identity $(\forall\, k \in \mathbb{Z}_{>0})\ \|\mathbf{x}_k\|_2 = 1$ holds by the definition of $\mathcal{N}$.
The convergence $\frac{d(B^k \mathbf{x}_0, \mathcal{E}_1)}{\|B^k \mathbf{x}_0\|_2} \longrightarrow 0$ holds by Theorem 6.7.1(ii) with $A = B$ and $\lambda_j = \theta_j$.
Hence $d(\mathbf{x}_k, \mathcal{E}_1) \longrightarrow 0$ by homogeneity of distance and $\|\mathbf{x}_k\|_2 = 1$.
Branches (i) and (ii) reuse one factorization and never form the displayed inverse matrices.
These are exact-arithmetic iterations; no finite-precision stability, tolerance, or stopping rule is specified.

6.8 Numerical SVD Methods

Throughout this subsection, $m, n \in \mathbb{Z}_{>0}$ and $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.

Computation Method 6.8.1. *Bidiagonal Reduction and SVD Reconstruction*
Let $A \in \mathrm{Mat}(m, n, \mathbb{F})$ and set $q := \min\{m, n\}$.
A matrix $B = [b_{ij}] \in \mathrm{Mat}(m, n, \mathbb{F})$ is *upper bidiagonal* iff $(\forall\, (i, j) \in J_m \times J_n)\, j \notin \{i, i+1\} \Longrightarrow b_{ij} = 0$.
The method constructs unitary $P \in \mathrm{Mat}(m, m, \mathbb{F})$ and $Q \in \mathrm{Mat}(n, n, \mathbb{F})$ such that $B = P^* A Q$ is upper bidiagonal.
If $m \ge n$ and $\mathrm{rank}(A) = n$, the positive eigenvalues of $A^* A$ are $\sigma_1(A)^2, \ldots, \sigma_n(A)^2$ by Proposition 4.2.11(i).
Thus forming $A^* A$ squares the extremal singular-value ratio; for square invertible A, this is $\kappa_2(A^* A) = \kappa_2(A)^2$ by Proposition 5.3.2(v).
The reduction instead acts directly on A:

(i) Set $B_0 := A$, $P_0 := I_m$, and $Q_0 := I_n$.
(ii) For $k \in J_q$, construct a left unitary L_k and a right unitary R_k as follows:
  (a) Let $\mathbf{x}_k \in \mathbb{F}^{m-k+1}$ be column k of B_{k-1} in rows $k, \ldots, m$.
  If $\mathbf{x}_k = \mathbf{0}$, set $\widehat{L}_k := I_{m-k+1}$. Otherwise, choose a unitary $\widehat{L}_k$ satisfying $\widehat{L}_k \mathbf{e}_1 = \frac{\mathbf{x}_k}{\|\mathbf{x}_k\|_2}$ by Corollary 2.7.4(iii).
  Then $\widehat{L}_k^* \mathbf{x}_k = \|\mathbf{x}_k\|_2 \mathbf{e}_1$. Let L_k act as $\widehat{L}_k$ on rows $k, \ldots, m$ and as the identity on earlier coordinates, and set $C_k := L_k^* B_{k-1}$.
  (b) If $k = n$, set $R_k := I_n$. Otherwise, let $\mathbf{w}_k^*$ be row k of C_k in columns $k+1, \ldots, n$.
  If $\mathbf{w}_k = \mathbf{0}$, set $\widehat{R}_k := I_{n-k}$. Otherwise, choose a unitary $\widehat{R}_k$ satisfying $\widehat{R}_k \mathbf{e}_1 = \frac{\mathbf{w}_k}{\|\mathbf{w}_k\|_2}$ by Corollary 2.7.4(iii).
  Then $\mathbf{w}_k^* \widehat{R}_k = \|\mathbf{w}_k\|_2 \mathbf{e}_1^*$. Let R_k act as $\widehat{R}_k$ on columns $k+1, \ldots, n$ and as the identity on earlier coordinates.
  Set $B_k := L_k^* B_{k-1} R_k$, $P_k := P_{k-1} L_k$, and $Q_k := Q_{k-1} R_k$.
  Writing $B_k = [b_{ij}^{(k)}]$, the column invariant is $(\forall\, j \in J_k)(\forall\, i \in J_m)\, i > j \Longrightarrow b_{ij}^{(k)} = 0$.
  The row invariant is $(\forall\, i \in J_k)(\forall\, j \in J_n)\, j > i+1 \Longrightarrow b_{ij}^{(k)} = 0$; trailing-coordinate actions preserve both.
(iii) Set $P := P_q$, $Q := Q_q$, and $B := B_q$. The matrices P, Q are unitary by Proposition 2.6.12(i), and $B = P^* A Q$ by induction.
The invariant makes B upper bidiagonal, and A, B have the same singular values by Proposition 5.1.7(i).
(iv) Choose a full SVD $B = \widetilde{U} \Sigma \widetilde{V}^*$ by Theorem 4.2.9.
Set $U := P\widetilde{U}$ and $V := Q\widetilde{V}$. Then U, V are unitary by Proposition 2.6.12(i), and $A = U \Sigma V^*$ follows from $B = P^* A Q$.
These singular triples give optimal low-rank approximations by Theorem 5.2.2, and $A^\dagger = V \Sigma^\dagger U^*$ by Corollary 5.2.6.
For $\mathbf{y} \in \mathbb{F}^m$, $A^\dagger \mathbf{y}$ is the unique minimum-norm least-squares solution by Theorem 5.2.9(i).

The bidiagonal SVD solver, stopping rule, and rounding-error model remain unspecified.
No finite-precision stability, accuracy, or convergence guarantee is asserted.

6.9 Discrete Fourier Transforms and Circulant Matrices

Throughout this subsection, $n \in \mathbb{Z}_{>0}$.

Definition 6.9.1. *Discrete Fourier Matrix*
Set $\omega_n := e^{2\pi i / n}$, $F_n := [\omega_n^{jk}]_{j,k=0}^{n-1} \in \mathrm{Mat}(n, n, \mathbb{C})$, and $Q_n := n^{-1/2} F_n$.
For $\mathbf{c} \in \mathbb{C}^n$, $F_n \mathbf{c}$ is its unnormalized DFT and $Q_n \mathbf{c}$ its normalized DFT.

Definition 6.9.2. *Circulant Matrix*
Let $(\mathbf{e}_0, \ldots, \mathbf{e}_{n-1})$ be the 0-indexed standard basis of $\mathbb{C}^n$.
The *cyclic shift* is the matrix $P_n \in \mathrm{Mat}(n, n, \mathbb{C})$ defined by $(\forall\, j \in \{0, \ldots, n-1\})\, P_n \mathbf{e}_j = \mathbf{e}_{(j-1) \bmod n}$.
A matrix $C \in \mathrm{Mat}(n, n, \mathbb{C})$ is *circulant* iff $(\exists\, (a_0, \ldots, a_{n-1}) \in \mathbb{C}^n)\, C = \sum_{r=0}^{n-1} a_r P_n^r$.
If $(a_0, \ldots, a_{n-1}) \in \mathbb{C}^n$ satisfies this identity, set $p(z) := \sum_{r=0}^{n-1} a_r z^r \in \mathbb{C}[z]$; then $C = p(P_n)$.
Here $p(P_n)$ denotes the polynomial evaluation from Definition 3.8.5.

Theorem 6.9.3. *Fourier Diagonalization of Cyclic Shifts and Circulants*
Let F_n, Q_n be as in Definition 6.9.1 and P_n as in Definition 6.9.2. Set $\Omega_n := \mathrm{diag}(1, \omega_n, \ldots, \omega_n^{n-1})$.
For $(a_0, \ldots, a_{n-1}) \in \mathbb{C}^n$, set $p(z) := \sum_{r=0}^{n-1} a_r z^r$ and $C := p(P_n)$. Then:

(i) $F_n^* F_n = n I_n$, $Q_n^* Q_n = I_n$, and Q_n is unitary;
(ii) $P_n F_n = F_n \Omega_n$ and $Q_n^* P_n Q_n = \Omega_n$;
(iii) $Q_n^* C Q_n = p(\Omega_n) = \mathrm{diag}\big(p(1), p(\omega_n), \ldots, p(\omega_n^{n-1})\big)$.

Proof. For $k \in \{0, \ldots, n-1\}$, set $\mathbf{f}_k := (\omega_n^{jk})_{j=0}^{n-1}$. Then $F_n = [\mathbf{f}_0\ \cdots\ \mathbf{f}_{n-1}]$ by Definition 6.9.1.

(i) For $k, \ell \in \{0, \ldots, n-1\}$, $(F_n^* F_n)_{k\ell} = \sum_{r=0}^{n-1} \omega_n^{r(\ell - k)}$. This sum is n if $k = \ell$.
If $k \neq \ell$, then $W := \omega_n^{\ell - k}$ satisfies $W \neq 1$ by $0 < |\ell - k| < n$ and $W^n = 1$, so $\sum_{r=0}^{n-1} W^r = \frac{1 - W^n}{1 - W} = 0$.
Thus $F_n^* F_n = n I_n$ and $Q_n^* Q_n = n^{-1} F_n^* F_n = I_n$. Hence Q_n is unitary by Theorem 2.6.8(i).

(ii) For $k, j \in \{0, \dots, n-1\}$, $(P_n \mathbf{f}_k)_j = (\mathbf{f}_k)_{(j+1) \bmod n} = \omega_n^k (\mathbf{f}_k)_j$ by $\omega_n^{nk} = 1$.
Hence $P_n F_n = F_n \Omega_n$ and $P_n Q_n = Q_n \Omega_n$ by column comparison. Therefore $Q_n^* P_n Q_n = \Omega_n$ by (i).
(iii) Set $D := \operatorname{diag}\big(p(1), p(\omega_n), \dots, p(\omega_n^{n-1})\big)$. By (i),(ii), $P_n = Q_n \Omega_n Q_n^*$.
The identity $C = Q_n D Q_n^*$ holds by Theorem 1.1.1 with $(A, S, \Lambda) = (P_n, Q_n, \Omega_n)$.
The identity $p(\Omega_n) = D$ holds by the same theorem with $(A, S, \Lambda) = (\Omega_n, I_n, \Omega_n)$. Hence $Q_n^* C Q_n = D = p(\Omega_n)$ by (i).

Structural Commentary: Root orthogonality proves unitarity; shift eigenvectors transfer polynomial evaluation to the diagonal.
Key Insight: The Fourier modes form an orthonormal eigenbasis of the cyclic shift. □

Figure 102 summarizes Theorem 6.9.3. Horizontal arrows conjugate by Q_n, and vertical arrows evaluate p.

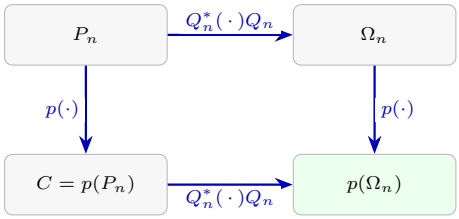

Figure 102: Fourier conjugation commutes with polynomial evaluation: P_n maps to Ω_n and $C = p(P_n)$ to $p(\Omega_n)$.

Proposition 6.9.4. *Inverse of the Fourier Matrix*
The Fourier matrix satisfies $F_n^{-1} = \frac{1}{n} F_n^*$.

Proof. The identity $\big(\frac{1}{n} F_n^*\big) F_n = I_n$ holds by Theorem 6.9.3(i). Hence $F_n^{-1} = \frac{1}{n} F_n^*$ by Theorem 3.4.2.
Structural Commentary: Fourier orthogonality supplies a left inverse; squareness identifies the two-sided inverse.
Key Insight: Normalization turns conjugate transpose into exact inversion. □

6.10 Fast Fourier Transform

Computation Method 6.10.1. *Radix-Two Fast Fourier Transform*
For $q \in \mathbb{Z}_{>0}$, let ω_q and F_q be as in Definition 6.9.1 with $n = q$. Let $\ell \in \mathbb{Z}_{\geq 0}$, set $n := 2^\ell$, and let $\mathbf{c} = (c_r)_{r=0}^{n-1} \in \mathbb{C}^n$.
Under exact complex arithmetic, the following recursion computes $\mathbf{y} = F_n \mathbf{c}$:

(i) If $\ell = 0$, set $\mathbf{y} := \mathbf{c}$ and stop.
(ii) If $\ell \geq 1$, set $m := \frac{n}{2} = 2^{\ell-1}$. Set $\mathbf{c}' := (c_{2r})_{r=0}^{m-1} \in \mathbb{C}^m$ and $\mathbf{c}'' := (c_{2r+1})_{r=0}^{m-1} \in \mathbb{C}^m$.
(iii) Recursively compute $\mathbf{y}' := F_m \mathbf{c}'$ and $\mathbf{y}'' := F_m \mathbf{c}''$.
(iv) Set $(\forall\, j \in \{0, \dots, m-1\})\, d_j := \omega_n^j$.
Set $(\forall\, j \in \{0, \dots, m-1\}) \big(y_j := y'_j + d_j y''_j,\ y_{j+m} := y'_j - d_j y''_j\big)$.

Termination: Each call decreases the exponent by 1, so the recursion reaches (i) after ℓ levels.
Correctness: If $\ell = 0$, then $F_1 = [1]$, and (i) returns $\mathbf{y} = F_1 \mathbf{c}$. Let $\ell \geq 1$, assume recursive calls return $\mathbf{y}' = F_m \mathbf{c}'$ and $\mathbf{y}'' = F_m \mathbf{c}''$.
Fix $j \in \{0, \dots, m-1\}$ and set $E_j := \sum_{r=0}^{m-1} \omega_m^{jr} c_{2r}$ and $O_j := \sum_{r=0}^{m-1} \omega_m^{jr} c_{2r+1}$. Then $E_j = y'_j$ and $O_j = y''_j$ by the recursive postconditions.
For $s \in \{0, 1\}$, the even-index contribution to $(F_n \mathbf{c})_{j+sm}$ is E_j by $\omega_n^2 = \omega_m$ and $\omega_n^{2m} = 1$.
The odd-index contribution is $(-1)^s d_j O_j$ by the same identities and $\omega_n^m = -1$. Hence $(F_n \mathbf{c})_{j+sm} = y'_j + (-1)^s d_j y''_j$.
Taking $s = 0, 1$ recovers (iv), so $\mathbf{y} = F_n \mathbf{c}$ by induction on ℓ.
Cost Model: Count unit-cost complex arithmetic with precomputed twiddle factors.
Exclude indexing, data movement, storage, and recursion overhead. Each butterfly reuses one multiplication in two additions.
Across each nonbase recursion depth, there are $\frac{n}{2}$ butterflies.
Thus the ℓ depths use $\frac{n\ell}{2}$ complex multiplications and $n\ell$ complex additions.
Dense multiplication by F_n uses n^2 complex multiplications and $n(n-1)$ complex additions.
Limitations: Only $n = 2^\ell$ is supported; no finite-precision accuracy or stability is asserted.

Let $\mathbf{c} = (c_0, c_1, c_2, c_3)^t \in \mathbb{C}^4$, and set $\mathbf{c}' := (c_0, c_2)^t$ and $\mathbf{c}'' := (c_1, c_3)^t$. Set $\mathbf{y}' := F_2 \mathbf{c}'$, $\mathbf{y}'' := F_2 \mathbf{c}''$, $\mathbf{y} := F_4 \mathbf{c}$, and $D := \operatorname{diag}(1, i)$.
Set $B_4(\mathbf{u}, \mathbf{v}) := \binom{\mathbf{u}+D\mathbf{v}}{\mathbf{u}-D\mathbf{v}}$ for $\mathbf{u}, \mathbf{v} \in \mathbb{C}^2$. Figure 103 instantiates the recurrence at $n = 4$.
It splits $\mathbf{c}$, applies two F_2 transforms, and recombines their outputs as $\mathbf{y} = B_4(\mathbf{y}', \mathbf{y}'')$.

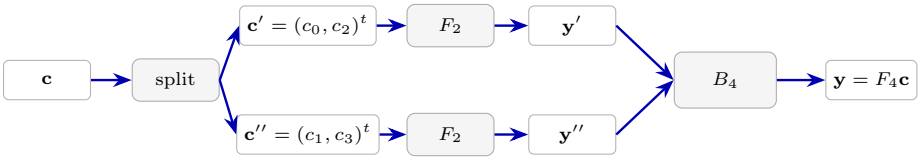

Figure 103: The $n = 4$ radix-two split: two F_2 transforms feed the butterfly B_4 and produce $F_4 \mathbf{c}$.

Part VII
Groups, Rings, and Fields

1 Algebraic Language and Categories

1.1 Universal Properties and Equivalence-Based Structure

1.2 Categories and Functors

1.3 Algebraic Structures as Objects

1.4 Exactness and Diagrams

2 Group Theory

2.1 Groups, Subgroups, and Cyclic Groups

Groups are the algebraic language of reversible operations. They appear here as the additive structure underlying rings and modules, and later as symmetry groups acting on mathematical objects.

Definition 2.1.1. *Groups*
A *group* is a nonempty set G with binary operation $(a,b)\mapsto ab$, identity element $e_G\in G$, and inversion map $g\mapsto g^{-1}$ such that:

(i) $(\forall\, a,b,c\in G)\,(ab)c=a(bc)$;
(ii) $(\forall\, g\in G)\,e_Gg=ge_G=g$;
(iii) $(\forall\, g\in G)\,gg^{-1}=g^{-1}g=e_G$.

The group is *abelian* if $(\forall\, a,b\in G)\,ab=ba$.
In an abelian group the operation is often written additively, with identity 0 and inverse $-a$.

Example 2.1.2. *Basic Groups*
Let S be a set, let $m,n\in\mathbb{N}$, and let $\mathbb{F}$ be a field.

(i) The bijections $S\to S$ form a group under composition; it is usually nonabelian.
(ii) $\mathrm{Mat}(m,n,\mathbb{F})$ is an abelian group under matrix addition.
(iii) $\mathrm{Mat}(n,n,\mathbb{F})^\times$, the invertible $n\times n$ matrices, is a group under multiplication.
(iv) $\mathbb{Z}/n\mathbb{Z}$ is a finite abelian group under addition modulo n.

Definition 2.1.3. *Subgroup*
Let G be a group. A subset $H\subseteq G$ is a *subgroup*, written $H\le G$, if $e_G\in H$, $(\forall\, a,b\in H)\,ab\in H$, and $(\forall\, a\in H)\,a^{-1}\in H$.

Proposition 2.1.4. *Subgroup Test*
Let G be a group and let $H\subseteq G$ be nonempty. Then $H\le G\iff(\forall\, a,b\in H)\,ab^{-1}\in H$.

Proof.
($\Rightarrow$) If $H\le G$ and $a,b\in H$, then $b^{-1}\in H$ and $ab^{-1}\in H$.
($\Leftarrow$) Assume $(\forall\, a,b\in H)\,ab^{-1}\in H$. Choose $h\in H$. Then $e_G=hh^{-1}\in H$. For $b\in H$, $b^{-1}=e_Gb^{-1}\in H$. For $a,c\in H$, since $c^{-1}\in H$, we have $ac=a(c^{-1})^{-1}\in H$. Hence $H\le G$.

Structural Commentary: Closure under one expression packages identity, inverses, and products.
Key Insight: In a group, subtraction-style closure is enough. □

Definition 2.1.5. *Generated and Cyclic Groups*
Let G be a group.

(i) For $a\in G$, define $a^0:=e_G$, $a^{n+1}:=a^na$ for $n\in\mathbb{N}_0$, and $a^{-n}:=(a^n)^{-1}$ for $n\in\mathbb{N}$.
(ii) For $a\in G$, the *subgroup generated by a* is $\langle a\rangle:=\{a^k:k\in\mathbb{Z}\}\le G$.
(iii) G is *cyclic* if $(\exists\, a\in G)\,G=\langle a\rangle$. If it exists, $\mathrm{ord}(a):=\min\{n\in\mathbb{N}:a^n=e_G\}$; then $\langle a\rangle=\{e_G,a,\dots,a^{\mathrm{ord}(a)-1}\}$.

2.2 Group Homomorphisms, Kernels, and Images

Definition 2.2.1. *Group Homomorphisms, Kernels, and Images*
Let G,H be groups.

(i) A *homomorphism* $\varphi:G\to H$ satisfies $(\forall\, a,b\in G)\,\varphi(ab)=\varphi(a)\varphi(b)$.
(ii) For a homomorphism $\varphi:G\to H$, $\ker\varphi:=\{g\in G:\varphi(g)=e_H\}$; and $\mathrm{im}\,\varphi:=\varphi(G)$. An *isomorphism* is a bijective homomorphism.

Proposition 2.2.2. *Basic Homomorphism Properties*
Let $\varphi:G\to H$ be a group homomorphism. Then:

(i) $\varphi(e_G)=e_H$;
(ii) $(\forall\, g\in G)\,\varphi(g^{-1})=\varphi(g)^{-1}$;
(iii) $\ker\varphi\le G$;
(iv) $\mathrm{im}\,\varphi\le H$.

Proof.
(i) Put $x:=\varphi(e_G)$. Then $x=x^2$, so $e_H=x^{-1}x=x^{-1}x^2=x$.
(ii) For $g\in G$, the identities $\varphi(g)\varphi(g^{-1})=e_H=\varphi(g^{-1})\varphi(g)$ hold by Definition 2.2.1. Thus $\varphi(g^{-1})=\varphi(g^{-1})\varphi(g)\varphi(g)^{-1}=\varphi(g)^{-1}$.
(iii) The identity $e_G\in\ker\varphi$ holds by (i). If $a,b\in\ker\varphi$, then $\varphi(ab^{-1})=\varphi(a)\varphi(b)^{-1}=e_H$ by Definition 2.2.1 and (ii). Hence $\ker\varphi\le G$ by Proposition 2.1.4.
(iv) The identity $e_H=\varphi(e_G)\in\mathrm{im}\,\varphi$ holds by (i). If $x=\varphi(a)$ and $y=\varphi(b)$ lie in $\mathrm{im}\,\varphi$, then $xy^{-1}=\varphi(ab^{-1})\in\mathrm{im}\,\varphi$ by Definition 2.2.1 and (ii). Hence $\mathrm{im}\,\varphi\le H$ by Proposition 2.1.4.

Structural Commentary: Homomorphisms preserve all group structure once they preserve multiplication.
Key Insight: $\varphi(ab) = \varphi(a)\varphi(b)$ preserves e, inverses, kernels, and images. □

Proposition 2.2.3. *Kernel Criterion for Injectivity*
Let $\varphi : G \to H$ be a group homomorphism. Then φ injective $\iff$ $\ker\varphi = \{e_G\}$.

Proof.
($\Rightarrow$) If φ injective, $g \in \ker\varphi$, then $\varphi(g) = e_H = \varphi(e_G)$ by Proposition 2.2.2, so $g = e_G$. Hence $\ker\varphi = \{e_G\}$.
($\Leftarrow$) If $\ker\varphi = \{e_G\}$ and $\varphi(a) = \varphi(b)$, then $\varphi(ab^{-1}) = \varphi(a)\varphi(b)^{-1} = e_H$ by Definition 2.2.1 and Proposition 2.2.2(ii). Thus $ab^{-1} = e_G$ and $a = (ab^{-1})b = b$.
Structural Commentary: Injectivity is detected by the identity fiber $\ker\varphi$.
Key Insight: The kernel measures exactly the failure of injectivity. □

2.3 Cosets, Normality, and Structure Theorems

2.4 Group Actions, Orbits, and Stabilizers

A group action packages the idea that elements of a group act as reversible motions of a set. The conjugation action is the finite-group ingredient used later in Wedderburn's theorem.

Definition 2.4.1. *Actions, Orbits, and Stabilizers*
Let G be a group and let $\mathcal{X}$ be a set.
(i) A *left action* of G on $\mathcal{X}$ is a map $G \times \mathcal{X} \to \mathcal{X}$, $(g, x) \mapsto gx$, satisfying $(\forall\, x \in \mathcal{X})\, e_G x = x$ and $(\forall\, g, h \in G)(\forall\, x \in \mathcal{X})\, (gh)x = g(hx)$.
(ii) The *orbit* of $x \in \mathcal{X}$ is $Gx := \{gx : g \in G\}$.
(iii) The *stabilizer* of $x \in \mathcal{X}$ is $G_x := \{g \in G : gx = x\}$.

Theorem 2.4.2. *Orbit-Stabilizer*
Let a finite group G act on $\mathcal{X}$. Then $(\forall\, x \in \mathcal{X})\, |Gx| = [G : G_x] = \frac{|G|}{|G_x|}$.

Proof. Define $\Phi : G/G_x \to Gx$, $\Phi(gG_x) = gx$. For $g, h \in G$, $gG_x = hG_x \iff h^{-1}g \in G_x \iff h^{-1}gx = x \iff gx = hx$. Thus Φ is well defined and injective. It is surjective by definition of Gx, hence bijective, so $|Gx| = |G/G_x| = [G : G_x]$.
Structural Commentary: Orbits are parametrized by cosets of the stabilizer.
Key Insight: Same orbit point $\iff$ same stabilizer coset. □

2.5 Conjugacy Classes and the Class Equation

Definition 2.5.1. *Conjugacy Classes and Centralizers*
Let G be a group.
(i) The *conjugation action* of G on itself is $g \cdot x := gxg^{-1}$.
(ii) The *conjugacy class* of $x \in G$ is $\{x\}^G := \{gxg^{-1} : g \in G\}$.
(iii) The *centralizer* of $x \in G$ is $C_G(x) := \{g \in G : gx = xg\}$.
(iv) The *center* of G is $Z(G) := \{g \in G : (\forall\, x \in G)\, gx = xg\}$.

Theorem 2.5.2. *Class Equation*
Let G be finite and let $S \subseteq G$ contain one representative of each noncentral conjugacy class. Then $|G| = |Z(G)| + \sum_{x \in S} [G : C_G(x)]$.

Proof. The conjugacy classes form a partition $G = Z(G) \sqcup \bigsqcup_{x \in S} \{x\}^G$. Indeed, $\left|\{x\}^G\right| = 1 \iff (\forall\, g \in G)\, gxg^{-1} = x \iff x \in Z(G)$.
For $x \in S$, $\left|\{x\}^G\right| = [G : C_G(x)]$ by Theorem 2.4.2 with conjugation action from Definition 2.5.1. Take cardinalities for formula.
Structural Commentary: G decomposes into central singleton classes and noncentral conjugacy classes.
Key Insight: Count conjugacy classes by orbit-stabilizer. □

2.6 Sylow Theory and Finite Groups

2.7 Representation-Theoretic Preview

3 Rings, Ideals, and Polynomial Rings

3.1 Rings, Identities, Fields, and Examples

Rings add multiplication to an abelian group.

Definition 3.1.1. *Rings, Identities, and Fields*
Let R be a set with binary operations $+$ and $\cdot$.
(i) R is a *ring* if $(R, +)$ is an abelian group, $(\forall\, a, b, c \in R)\, (ab)c = a(bc)$, and $(\forall\, a, b, c \in R)\, [a(b + c) = ab + ac \wedge (a + b)c = ac + bc]$. Denote the additive identity by 0_R and the additive inverse of a by $-a$.
(ii) A ring R is *commutative* if $(\forall\, a, b \in R)\, ab = ba$.
(iii) A ring R has *identity* if it is equipped with $1_R \in R$ satisfying $(\forall\, a \in R)\, 1_R a = a1_R = a$.
(iv) A *field* is a commutative ring with identity $1_R \neq 0_R$ equipped with an inversion map $R \setminus \{0_R\} \to R \setminus \{0_R\}$, $a \mapsto a^{-1}$, satisfying $(\forall\, a \in R \setminus \{0_R\})\, aa^{-1} = a^{-1}a = 1_R$.

Example 3.1.2. *Basic Rings*
Let $n \in \mathbb{N}$ and let $\mathbb{F}$ be a field.
(i) $(\mathbb{Z}, +, \cdot)$ and $(\mathbb{F}[x], +, \cdot)$ are commutative rings with identity 1.
(ii) $\mathrm{Mat}(n, n, \mathbb{F})$ is ing with identity under matrix addition and multiplication, with identity I_n; noncommutative for $n \geq 2$.
(iii) $2\mathbb{Z}$ is a commutative ring under inherited addition and multiplication, but has no identity.
(iv) $\mathbb{Z}/n\mathbb{Z}$ is a commutative ring under addition and multiplication modulo n, with identity $1 + n\mathbb{Z}$.

3.2 Ring Homomorphisms and Subrings

Definition 3.2.1. *Ring Homomorphisms and Subrings*
Let R, S be rings with identity.

(i) A *ring homomorphism* $\varphi : R \to S$ is a map satisfying $(\forall\, a, b \in R)\,[\varphi(a+b) = \varphi(a) + \varphi(b) \wedge \varphi(ab) = \varphi(a)\varphi(b)]$ and $\varphi(1_R) = 1_S$.
(ii) A *subring* of R is a subset $T \subseteq R$, written $T \leq R$, that is a ring under the inherited operations and has identity 1_R.

Proposition 3.2.2. *Subring Test*
Let R be a ring with identity and let $S \subseteq R$. Then $S \leq R \iff [1_R \in S \wedge (\forall\, a, b \in S)\,(a - b \in S \wedge ab \in S)]$.

Proof.
($\Rightarrow$) If $S \leq R$, then $1_R \in S$ and S is closed under subtraction and multiplication.
($\Leftarrow$) Assume $1_R \in S$ and $(\forall\, a, b \in S)\,(a-b \in S \wedge ab \in S)$. Then S is nonempty, $(S, +) \leq (R, +)$ by Proposition 2.1.4, and multiplication restricts to S. All ring laws and the identity 1_R are inherited from R, so $S \leq R$.
Structural Commentary: A subring is a subset stable under the operations and containing the ambient unit.
Key Insight: Subtraction handles the additive group part in one stroke. □

3.3 Ideals and Generated Ideals

Ideals are subsets by which quotient rings can be formed, just as subspaces are the subsets by which quotient vector spaces can be formed.

Definition 3.3.1. *Ideals and Generated Ideals*
Let R be a ring.

(i) A nonempty subset $\mathcal{I} \subseteq R$ is a *two-sided ideal*, written $\mathcal{I} \trianglelefteq R$, if $(\forall\, a, b \in \mathcal{I})\, a - b \in \mathcal{I}$ and $(\forall\, a \in \mathcal{I})(\forall\, r \in R)\,[ra \in \mathcal{I} \wedge ar \in \mathcal{I}]$.
(ii) If R is commutative with identity and $S \subseteq R$, the *ideal generated by S* is $\langle S \rangle := \left\{ \sum_{j=1}^{n} r_j s_j : n \in \mathbb{N}_0,\ r_j \in R,\ s_j \in S \right\}$, where $n = 0$ denotes the empty sum 0_R.
(iii) *Finite generated ideal notation*: if $n \in \mathbb{N}$ and $S = \{s_1, \ldots, s_n\}$, write $\langle s_1, \ldots, s_n \rangle := \langle S \rangle$.

For example, if $\mathbb{F}$ is a field and $p(x) \in \mathbb{F}[x]$, then $\langle p(x) \rangle = \{q(x)p(x) : q(x) \in \mathbb{F}[x]\}$ is the *principal* ideal generated by $p(x)$.

Proposition 3.3.2. *Generated Ideals Are Smallest*
Let R be a commutative ring with identity, $S \subseteq R$. Then $\langle S \rangle$ is an ideal, $S \subseteq \langle S \rangle$, and $\forall$ ideal $\mathcal{J} \subseteq R$, $S \subseteq \mathcal{J} \implies \langle S \rangle \subseteq \mathcal{J}$.

Proof. Let $x = \sum_{j=1}^{m} r_j s_j$ and $y = \sum_{k=1}^{n} t_k u_k$ lie in $\langle S \rangle$. By empty-sum convention, $0_R \in \langle S \rangle$. Moreover, $x - y = \sum_{j=1}^{m} r_j s_j + \sum_{k=1}^{n} (-t_k) u_k \in \langle S \rangle$.
For every $a \in R$, $ax = \sum_{j=1}^{m} (ar_j) s_j \in \langle S \rangle$ and $xa = ax$ by commutativity, so $\langle S \rangle$ is an ideal.
For every $s \in S$, $s = 1_R s \in \langle S \rangle$, so $S \subseteq \langle S \rangle$. If $\mathcal{J}$ is an ideal with $S \subseteq \mathcal{J}$, then $r_j s_j \in \mathcal{J}$ for every summand, while $(\mathcal{J}, +) \leq (R, +)$ by Proposition 2.1.4. Thus each finite sum lies in $\mathcal{J}$, so $\langle S \rangle \subseteq \mathcal{J}$, QED.
Structural Commentary: Generated ideals close a set under exactly the operations ideals must allow.
Key Insight: To force S into an ideal, one must include all ring-linear combinations of elements of S. □

Proposition 3.3.3. *Intersections and Chain Unions of Ideals*
Let R be a ring.

(i) If $\{\mathcal{I}_\alpha\}_{\alpha \in A}$ is a nonempty family of ideals of R, then $\bigcap_{\alpha \in A} \mathcal{I}_\alpha$ is an ideal of R.
(ii) If $A \neq \emptyset$ and $\{\mathcal{I}_\alpha\}_{\alpha \in A}$ is a chain of ideals of R under inclusion, then $\bigcup_{\alpha \in A} \mathcal{I}_\alpha$ is an ideal of R.

Proof.
(i) Let $\mathcal{I} = \bigcap_{\alpha \in A} \mathcal{I}_\alpha$. For every $\alpha \in A$, $0_R \in \mathcal{I}_\alpha$ by Proposition 2.1.4, so $0_R \in \mathcal{I}$.
If $a, b \in \mathcal{I}$ and $r \in R$, then $a - b, ra, ar \in \mathcal{I}_\alpha$ for every $\alpha \in A$, hence $a - b, ra, ar \in \mathcal{I}$.
(ii) Let $\mathcal{U} = \bigcup_{\alpha \in A} \mathcal{I}_\alpha$. Since $A \neq \emptyset$ and 0_R belongs to every ideal by Proposition 2.1.4, $0_R \in \mathcal{U}$.
If $a, b \in \mathcal{U}$, then $a \in \mathcal{I}_\alpha$ and $b \in \mathcal{I}_\beta$ for some α, β. Since the family is a chain, one of $\mathcal{I}_\alpha, \mathcal{I}_\beta$ contains both a, b; hence $a - b \in \mathcal{U}$.
If $a \in \mathcal{U}$ and $r \in R$, then $a \in \mathcal{I}_\alpha$ for some α, so $ra, ar \in \mathcal{I}_\alpha \subseteq \mathcal{U}$.
Structural Commentary: Chains avoid the usual failure of unions to preserve closure.
Key Insight: Comparability places any finite test inside one ideal. □

3.4 Quotient Rings and Maximal Ideals

Definition 3.4.1. *Quotient Rings*
Let R be a ring and let $\mathcal{I} \trianglelefteq R$ be a two-sided ideal.

(i) The underlying set is the additive quotient group $R/\mathcal{I} = \{a + \mathcal{I} : a \in R\}$.
(ii) For $a, b \in R$, addition and multiplication are $(a + \mathcal{I}) + (b + \mathcal{I}) = (a + b) + \mathcal{I}$ and $(a + \mathcal{I})(b + \mathcal{I}) = ab + \mathcal{I}$.
(iii) With these operations, $R/\mathcal{I}$ is the *quotient ring* of R by $\mathcal{I}$.

Proposition 3.4.2. *Ideals Make Quotient Multiplication Well Defined*
Let R be a ring and let $\mathcal{I} \leq (R, +)$. The rule $(a + \mathcal{I})(b + \mathcal{I}) := ab + \mathcal{I}$ for $a, b \in R$ is well defined on $R/\mathcal{I}$ iff $\mathcal{I} \trianglelefteq R$.

Proof.
($\Rightarrow$) If the rule is well defined and $i \in \mathcal{I}$, then $i + \mathcal{I} = 0_R + \mathcal{I}$.
For $r \in R$, $ri + \mathcal{I} = r0_R + \mathcal{I}$, and $ir + \mathcal{I} = 0_R r + \mathcal{I}$, so $ri, ir \in \mathcal{I}$. Thus $\mathcal{I} \trianglelefteq R$.
($\Leftarrow$) If $\mathcal{I} \trianglelefteq R$ and $a', a, b', b \in R$ satisfy $a' = a + i$, $b' = b + j$ with $i, j \in \mathcal{I}$, then $a'b' - ab = aj + ib + ij \in \mathcal{I}$.
Hence $a'b' + \mathcal{I} = ab + \mathcal{I}$, so the product is independent of representatives.

Structural Commentary: Ideals are exactly the additive subgroups compatible with multiplication of cosets.
Key Insight: Coset multiplication is well defined exactly for ideals. □

Definition 3.4.3. *Maximal Ideals*
Let R be a ring and let $\mathcal{M} \trianglelefteq R$.

(i) $\mathcal{M}$ is *proper* if $\mathcal{M} \neq R$.
(ii) $\mathcal{M}$ is *maximal* if $\mathcal{M} \neq R$ and $(\forall\, \mathcal{J} \trianglelefteq R)\,[\mathcal{M} \subseteq \mathcal{J} \subseteq R \Rightarrow (\mathcal{J} = \mathcal{M} \vee \mathcal{J} = R)]$.

Theorem 3.4.4. *Maximal Ideals and Fields*
Let R be a commutative ring with identity and let $\mathcal{I} \trianglelefteq R$. Then $R/\mathcal{I}$ is a field $\iff$ $\mathcal{I}$ is maximal.

Proof.
($\Rightarrow$) Suppose $R/\mathcal{I}$ is a field. Then $1_R + \mathcal{I} \neq 0_R + \mathcal{I}$, so $\mathcal{I} \neq R$. Let $\mathcal{I} \subsetneq \mathcal{J} \trianglelefteq R$ and choose $a \in \mathcal{J} \setminus \mathcal{I}$.
The nonzero coset $a + \mathcal{I}$ has an inverse $r + \mathcal{I}$, so $ra + \mathcal{I} = 1_R + \mathcal{I}$. Thus $1_R - ra \in \mathcal{I} \subseteq \mathcal{J}$ and $ra \in \mathcal{J}$, whence $1_R \in \mathcal{J}$.
For every $x \in R$, $x = x1_R \in \mathcal{J}$, so $\mathcal{J} = R$ and $\mathcal{I}$ is maximal.
($\Leftarrow$) Suppose $\mathcal{I}$ is maximal and let $a + \mathcal{I} \in R/\mathcal{I}$ satisfy $a + \mathcal{I} \neq 0_R + \mathcal{I}$. Then $a \notin \mathcal{I}$.
Set $\mathcal{K} := \langle \mathcal{I} \cup \{a\} \rangle$. Then $\mathcal{K} \trianglelefteq R$ and $\mathcal{I} \cup \{a\} \subseteq \mathcal{K}$ by Proposition 3.3.2, so $\mathcal{I} \subsetneq \mathcal{K}$. Maximality forces $\mathcal{K} = R$.
By Definition 3.3.1, an expression for $1_R \in \mathcal{K}$ can be regrouped as $1_R = i + ra$ for some $i \in \mathcal{I}$ and $r \in R$.
Hence $(r + \mathcal{I})(a + \mathcal{I}) = 1_R + \mathcal{I}$. The quotient ring is commutative with identity, and $\mathcal{I} \neq R$ because it is maximal.
Thus its zero and identity cosets are distinct, while every nonzero coset is invertible; hence $R/\mathcal{I}$ is a field.

Structural Commentary: Maximal ideals are exactly the proper ideals whose quotient rings are fields.
Key Insight: Maximality makes every nonzero coset invertible. □

Theorem 3.4.5. *Existence of Maximal Ideals*
If R is a commutative ring with identity and $1_R \neq 0_R$, then R has a maximal ideal.

Proof. Let $\mathcal{P} := \{\mathcal{I} \trianglelefteq R : \mathcal{I} \neq R\}$, ordered by inclusion. Then $\mathcal{P}$ is a poset by Proposition 6.1.5.
Also, $\{0_R\} = \langle \emptyset \rangle \trianglelefteq R$ by Proposition 3.3.2; as $1_R \neq 0_R$, $\{0_R\} \in \mathcal{P}$. Let $\mathcal{C} \subseteq \mathcal{P}$ be a chain. If $\mathcal{C} = \emptyset$, then $\{0_R\}$ upper bound for $\mathcal{C}$ in $\mathcal{P}$.
Assume $\mathcal{C} \neq \emptyset$ and set $\mathcal{U} := \bigcup_{\mathcal{I} \in \mathcal{C}} \mathcal{I}$. Then $\mathcal{U} \trianglelefteq R$ by Proposition 3.3.3.
Moreover, $\mathcal{U} \neq R$: if $1_R \in \mathcal{U}$, then $1_R \in \mathcal{I}$ for some $\mathcal{I} \in \mathcal{C}$, and $x = x1_R \in \mathcal{I}$ for every $x \in R$, contradicting $\mathcal{I} \in \mathcal{P}$.
Thus $\mathcal{U} \in \mathcal{P}$ is upper bound for $\mathcal{C}$. Every chain in $\mathcal{P}$ hence has an upper bound in $\mathcal{P}$, so $\mathcal{P}$ has a maximal element by Principle 6.1.3.
By Definition 3.4.3, this element is a maximal ideal of R.
Structural Commentary: Maximal ideals are produced by maximality, not by an explicit formula in general.
Key Insight: Chain unions keep properness because containing 1 is a finite obstruction. □

3.5 Integral Domains and Fields of Quotients

Definition 3.5.1. *Zero Divisors and Integral Domains*
Let R be a ring.

(i) A *zero divisor* is an element $a \in R \setminus \{0_R\}$ such that $(\exists\, b \in R \setminus \{0_R\})\,(ab = 0_R \vee ba = 0_R)$.
(ii) An *integral domain* is a commutative ring with identity $1_R \neq 0_R$ and no zero divisors.

Proposition 3.5.2. *Cancellation in Integral Domains*
Let R be a commutative ring with identity $1_R \neq 0_R$.
Then R is an integral domain $\iff$ $(\forall\, r, x, y \in R)\,[(r \neq 0_R \wedge rx = ry) \Rightarrow x = y]$.

Proof.
($\Rightarrow$) If $rx = ry$ and $r \neq 0_R$, then $r(x - y) = 0_R$. Since R has no zero divisors, $x - y = 0_R$, so $x = y$.
($\Leftarrow$) If $ab = 0_R$ and $a \neq 0_R$, then $ab = a0_R$, so the stated cancellation condition forces $b = 0_R$.
Commutativity therefore excludes zero divisors.

Structural Commentary: Domains are exactly cancellative commutative rings.
Key Insight: Zero divisors obstruct cancellation. □

Definition 3.5.3. *Field of Quotients*
Let R be an integral domain. For $a, c \in R$ and $b, d \in R \setminus \{0_R\}$, set $(a, b) \sim (c, d) \iff ad = bc$.
The *field of quotients* of R is $(R \times (R \setminus \{0_R\}))/\sim$; write $[(a, b)]_\sim = a/b$. Its operations are $\frac{a}{b} + \frac{c}{d} = \frac{ad+bc}{bd}$ and $\frac{a}{b}\frac{c}{d} = \frac{ac}{bd}$.

Proposition 3.5.4. *Domains Embed in Fields*
Let R be an integral domain with field of quotients K.
Then the map $\iota : R \to K$, $\iota(a) = a/1_R$, is an injective ring homomorphism.

Proof. By Definition 3.5.3, for $a, b \in R$, $\iota(a + b) = \frac{a+b}{1_R} = \frac{a}{1_R} + \frac{b}{1_R}$, $\iota(ab) = \frac{ab}{1_R} = \frac{a}{1_R}\frac{b}{1_R}$, and $\iota(1_R) = \frac{1_R}{1_R}$.
Thus ι is a ring homomorphism. If $\iota(a) = \iota(b)$, then $a/1_R = b/1_R$, so $a1_R = b1_R$ by Definition 3.5.3; hence $a = b$, and ι is injective.
Structural Commentary: The field of quotients formally adds denominators to a domain.
Key Insight: Integral domains are exactly the setting where fraction arithmetic is consistent. □

3.6 Ring Characteristic

Definition 3.6.1. *Characteristic*
Let R be a ring with identity. For $n \in \mathbb{N}$, define $n1_R := \underbrace{1_R + \cdots + 1_R}_{n \text{ summands}}$.
The *characteristic* of R is $\operatorname{char}(R) := 0$ if $(\forall\, n \in \mathbb{N})\, n1_R \neq 0_R$; otherwise, $\operatorname{char}(R) := \min\{n \in \mathbb{N} : n1_R = 0_R\}$.

Proposition 3.6.2. *Characteristic of Finite Rings and Domains*
Let R be a finite ring with identity.

(i) $\operatorname{char}(R) > 0$.
(ii) If R is an integral domain, then $\operatorname{char}(R)$ *is prime.*

Proof.

(i) Choose $m \in \mathbb{N}_0$ and a bijection $e : R \to J_m$ by Definition 6.2.4. Define $f : \mathbb{N} \to R$ by $f(n) := n1_R$.
The composite $e \circ f : \mathbb{N} \to J_m$ is not injective by Proposition 6.2.5(i), so f is not injective.
Choose $i, j \in \mathbb{N}$ with $i < j$ and $i1_R = j1_R$. Then $(j-i)1_R = 0_R$, and $\operatorname{char}(R) > 0$ by Definition 3.6.1.

(ii) Suppose R is an integral domain and set $c := \operatorname{char}(R)$. Then $c > 1$ by (i), Definition 3.6.1, and $1_R \neq 0_R$.
If c is composite, choose $a, b \in \mathbb{N}$ with $c = ab$ and $1 < a, b < c$.
Then $(a1_R)(b1_R) = ab1_R = c1_R = 0_R$, whereas $a1_R \neq 0_R$ and $b1_R \neq 0_R$ by minimality of c.
c is prime by this contradiction with the absence of zero divisors in R.

Structural Commentary: Finiteness creates an additive period; zero-divisor exclusion forces primality.
Key Insight: A composite characteristic factors zero through smaller nonzero multiples. □

3.7 Units, Divisibility, and Factorization Domains

Definition 3.7.1. *Units, Associates, Prime Elements, and Irreducible Elements*
Let R be an integral domain.

(i) *Units*: $R^\times := \{u \in R : (\exists v \in R)\, uv = 1_R\}$.
(ii) *Divisibility*: for $a, b \in R$, $a \mid b \iff (\exists c \in R)\, b = ac$.
(iii) *Associates*: for $a, b \in R \setminus \{0_R\}$, $a \sim b \iff (\exists u \in R^\times)\, a = ub$.
(iv) *Prime element*: $p \in R \setminus (R^\times \cup \{0_R\})$ is prime precisely when $(\forall a, b \in R)\,[p \mid ab \Rightarrow (p \mid a \vee p \mid b)]$.
(v) *Irreducible element*: $r \in R \setminus (R^\times \cup \{0_R\})$ is irreducible precisely when $(\forall a, b \in R)\,[r = ab \Rightarrow (a \in R^\times \vee b \in R^\times)]$.

Proposition 3.7.2. *Divisibility and Principal Ideals*
Let R be an integral domain and let $r, s \in R \setminus \{0_R\}$.

(i) $r \in R^\times \iff \langle r \rangle = R$.
(ii) $r \sim s \iff \langle r \rangle = \langle s \rangle$.
(iii) $r \mid s \iff \langle s \rangle \subseteq \langle r \rangle$.

Proof.

(i) ($\Rightarrow$) If $r \in R^\times$, choose $v \in R$ with $rv = 1_R$. Then $1_R \in \langle r \rangle$, so $\langle r \rangle = R$.
(i) ($\Leftarrow$) If $\langle r \rangle = R$, choose $a \in R$ with $1_R = ar = ra$. Then $r \in R^\times$ by Definition 3.7.1(i).
(ii) ($\Rightarrow$) If $r = us$ with $u \in R^\times$, choose $v \in R$ with $uv = 1_R$. Then $r = us \in \langle s \rangle$ and $s = (vu)s = v(us) = vr \in \langle r \rangle$, so $\langle r \rangle = \langle s \rangle$.
(ii) ($\Leftarrow$) If $\langle r \rangle = \langle s \rangle$, choose $a, b \in R$ with $r = as$ and $s = br$. The equality $r = (ab)r$ and $r \neq 0_R$ imply $ab = 1_R$ by Proposition 3.5.2.
Thus $a \in R^\times$ and $r \sim s$ by Definition 3.7.1(i), (iii).
(iii) ($\Rightarrow$) If $r \mid s$, choose $a \in R$ with $s = ar$ by Definition 3.7.1(ii). Then $\langle s \rangle = \{xs : x \in R\} = \{xar : x \in R\} \subseteq \langle r \rangle$.
(iii) ($\Leftarrow$) If $\langle s \rangle \subseteq \langle r \rangle$, then $s \in \langle r \rangle = \{ar : a \in R\}$, so $r \mid s$ by Definition 3.7.1(ii).

Structural Commentary: Generators prove containment; cancellation detects units and associates.
Key Insight: A principal ideal records its generator up to multiplication by a unit. □

3.8 Polynomial Rings, Division, and GCDs

Polynomial rings over fields support division with remainder, Euclidean gcds, and Bezout identities.

Definition 3.8.1. *Polynomials over a Field*
Let $\mathbb{F}$ be a field.

(i) $\mathbb{F}[x]$ denotes the ring of polynomials in one variable over $\mathbb{F}$.

(ii) If $n \in \mathbb{N}_0$, $a_0, \ldots, a_n \in \mathbb{F}$, $a_n \neq 0$, and $p(x) = \sum_{j=0}^{n} a_j x^j$, set $\operatorname{lc}(p) := a_n$ and $\deg p := n$.
The polynomial p is *monic* iff $\operatorname{lc}(p) = 1$; set $\deg 0 = -\infty$.

(iii) A polynomial $p \in \mathbb{F}[x] \setminus \{0\}$ *splits over* $\mathbb{F}$ iff $(\exists m \in \mathbb{N}_0)(\exists \alpha \in \mathbb{F}^\times)(\exists \lambda_1, \ldots, \lambda_m \in \mathbb{F})\, p(x) = \alpha \prod_{i=1}^{m} (x - \lambda_i)$.

Theorem 3.8.2. *Polynomial Division Algorithm*
Let $\mathbb{F}$ be a field and let $f, g \in \mathbb{F}[x]$ with $g \neq 0$.

(i) $(\exists q, r \in \mathbb{F}[x])\,[f = qg + r \wedge (r = 0 \vee \deg r < \deg g)]$.
(ii) Suppose $f = qg + r = q'g + r'$ for $(q, r), (q', r') \in \mathbb{F}[x]^2$. If $(r = 0 \vee \deg r < \deg g) \wedge (r' = 0 \vee \deg r' < \deg g)$, then $(q, r) = (q', r')$.

Proof. Set $d := \deg g$ and $\ell := \operatorname{lc}(g)$. Call (q, r) admissible for $h \in \mathbb{F}[x]$ if $h = qg + r$ and $(r = 0 \vee \deg r < d)$.

(i) The pair $(0, 0)$ is admissible for 0. Suppose some polynomial has no admissible pair.
The shift $k \mapsto k + 1$ sends the nonzero counterexample degrees into $\mathbb{N}$.
Choose a counterexample f of minimal degree by Assumption 2.6.1; set $n := \deg f$.
If $n < d$, then $(0, f)$ is admissible for f, so $n \geq d$. Set $a := \operatorname{lc}(f)$ and $f_1 := f - a\ell^{-1}x^{n-d}g$.
Coefficient of x^n in f_1 is $a - a\ell^{-1}\ell = 0$, so $f_1 = 0$ or $\deg f_1 < n$. Admissible pair (q_1, r) for f_1 exists by zero case or minimality.
Set $q := q_1 + a\ell^{-1}x^{n-d}$. Then $f = qg + r$, so (q, r) is admissible for f, a contradiction.

(ii) Suppose (q, r) and (q', r') are admissible for f. Then $(q - q')g = r' - r$.
If $q \neq q'$, then $\operatorname{lc}(q - q')\ell \neq 0$, so $\deg((q - q')g) = \deg(q - q') + d \geq d$.
Since both remainders are zero or have degree below d, $\deg(r' - r) < d$, a contradiction.
Therefore $q = q'$, and $(q - q')g = r' - r$ implies $r = r'$.

Structural Commentary: Minimal-degree descent proves existence; degree comparison proves uniqueness.
Key Insight: The inverse leading coefficient cancels exactly one highest-degree term. □

Definition 3.8.3. *Divisibility, GCDs, and Coprimality*
Let $\mathbb{F}$ be a field.

(i) *Divisibility*: for $p, q \in \mathbb{F}[x]$, $p \mid q \iff (\exists h \in \mathbb{F}[x])\, q = hp$.

(ii) *Greatest common divisor*: for $(f,g) \in \mathbb{F}[x]^2 \setminus \{(0,0)\}$, a monic $d \in \mathbb{F}[x]$ is a gcd iff
  (a) $d \mid f$ and $d \mid g$;
  (b) $(\forall h \in \mathbb{F}[x])\,[(h \mid f \wedge h \mid g) \Rightarrow h \mid d]$.

(iii) *Coprimality*: $f, g \in \mathbb{F}[x]$ are relatively prime iff 1 is a greatest common divisor of f and g.

Theorem 3.8.4. *Polynomial GCD and Bezout Identity*
Let $\mathbb{F}$ be a field and let $f, g \in \mathbb{F}[x]$ be not both zero.

(i) A monic greatest common divisor of f and g exists.
(ii) Any two monic greatest common divisors of f and g are equal.
(iii) Writing $d := \gcd(f,g)$ for this unique polynomial, $(\exists a, b \in \mathbb{F}[x])\, d = af + bg$.
(iv) For $d := \gcd(f,g)$, $d = 1 \iff (\exists a, b \in \mathbb{F}[x])\, af + bg = 1$.

Proof.

(i) If exactly one of f, g is zero, let h be the nonzero polynomial and set $d := \mathrm{lc}(h)^{-1}h$.
Then d is monic, $h = \mathrm{lc}(h)d$, $d \mid 0$, and every common divisor of f, g divides d. Now assume $f, g \neq 0$ and set $(r_0, r_1) := (f, g)$.
For $r_i \neq 0$, choose (q_i, r_{i+1}) by Theorem 3.8.2(i) with inputs (r_{i-1}, r_i).
Then $r_{i-1} = q_i r_i + r_{i+1}$ and $r_{i+1} = 0$ or $\deg r_{i+1} < \deg r_i$. The nonzero remainder degrees strictly decrease in $\mathbb{N}_0$.
Hence the process terminates with $r_N \neq 0$ and $r_{N+1} = 0$ by Assumption 2.6.1.
Since $r_{N-1} = q_N r_N$, $r_N \mid r_{N-1}$. Backward induction in recurrence proves $r_N \mid f$ and $r_N \mid g$. Let c be a common divisor of f, g.
If $c \mid r_{i-1}$ and $c \mid r_i$, then $c \mid r_{i+1} = r_{i-1} - q_i r_i$. Thus $c \mid r_N$ by induction on i from $c \mid r_0$ and $c \mid r_1$.
Thus $d := \mathrm{lc}(r_N)^{-1} r_N$ is a monic greatest common divisor.

(ii) Let d, e be monic greatest common divisors. Then $d \mid e$ and $e \mid d$ by Definition 3.8.3(ii).
Choose $h, k \in \mathbb{F}[x]$ with $e = hd$ and $d = ke$. Since $d, e \neq 0$, $\deg e = \deg h + \deg d$ and $\deg d = \deg k + \deg e$.
Thus $\deg h = \deg k = 0$ and $\deg d = \deg e$. Since d, e are monic, $\mathrm{lc}(h) = 1$, so $h = 1$ and $e = d$.

(iii) If one input is zero, the construction in (i) is an $\mathbb{F}[x]$-linear combination of f and g.
For $f, g \neq 0$, each r_i is an $\mathbb{F}[x]$-linear combination of f, g by induction on i.
The induction step uses $r_{i+1} = r_{i-1} - q_i r_i$. Therefore $(\exists a, b \in \mathbb{F}[x])\, d = \mathrm{lc}(r_N)^{-1} r_N = af + bg$.

(iv) ($\Rightarrow$) If $d = 1$, then $(\exists a, b \in \mathbb{F}[x])\, af + bg = 1$ by (iii).

(iv) ($\Leftarrow$) Suppose $a, b \in \mathbb{F}[x]$ satisfy $af + bg = 1$. Then $d \mid 1$ because $d \mid f$ and $d \mid g$; write $1 = hd$.
Then $\deg h + \deg d = 0$, so $\deg d = 0$; monicity forces $d = 1$.

Structural Commentary: Descent constructs the gcd; back-substitution constructs its Bezout form.
Key Insight: Euclidean remainders preserve common divisors until the last nonzero term. □

3.9 Irreducible Polynomials and Unique Factorization

Definition 3.9.1. *Irreducible Polynomials*
Let $\mathbb{F}$ be a field and let $p \in \mathbb{F}[x]$ be nonconstant.
The polynomial p is *irreducible over $\mathbb{F}$* iff $(\forall a, b \in \mathbb{F}[x])\,[p = ab \Rightarrow (a \in \mathbb{F}[x]^\times \vee b \in \mathbb{F}[x]^\times)]$.

Proposition 3.9.2. *Irreducibility and the Prime Property in $\mathbb{F}[x]$*
Let $\mathbb{F}$ be a field and let $p \in \mathbb{F}[x]$ be nonconstant. Then p is irreducible over $\mathbb{F}$ iff $(\forall f, g \in \mathbb{F}[x])\,[p \mid fg \Rightarrow (p \mid f \vee p \mid g)]$.

Proof.

($\Rightarrow$) Assume p is irreducible and $p \mid fg$. If $p \mid f$, the conclusion holds.
Otherwise set $d := \gcd(p, f)$ and choose $A, B \in \mathbb{F}[x]$ with $d = Ap + Bf$ by Theorem 3.8.4(iii).
By Definition 3.8.3(ii), $d \mid p$ and $d \mid f$; choose $e \in \mathbb{F}[x]$ with $p = de$. Either d or e is a unit by Definition 3.9.1.
If e is a unit, choose $v \in \mathbb{F}[x]$ with $ev = 1$. Then $d = vp$, so $d \mid f$ implies $p \mid f$, a contradiction. Thus d is a unit.
Choose $u \in \mathbb{F}[x]$ with $ud = 1$. Now $1 = (uA)p + (uB)f$, so $g = (uA)pg + (uB)fg$. Since $p \mid (uA)pg$ and $p \mid (uB)fg$, $p \mid g$.

($\Leftarrow$) Assume the divisibility property and write $p = ab$. Then $p \mid a$ or $p \mid b$.
If $p \mid a$, choose $h \in \mathbb{F}[x]$ with $a = ph$. Then $(1 - hb)p = 0$. The nonzero-product property and $p \neq 0$ imply $hb = 1$, so $b \in \mathbb{F}[x]^\times$.
If $p \mid b$, choose $k \in \mathbb{F}[x]$ with $b = pk$. Then $(1 - ak)p = 0$. The nonzero-product property and $p \neq 0$ imply $ak = 1$, so $a \in \mathbb{F}[x]^\times$.
Thus p is irreducible by Definition 3.9.1.

Structural Commentary: GCD reduction proves primality; polynomial cancellation proves the converse.
Key Insight: Bezout converts coprimality with f into divisibility of g. □

Theorem 3.9.3. *Unique Factorization in $\mathbb{F}[x]$*
Let $\mathbb{F}$ be a field and let $f \in \mathbb{F}[x]$ be nonconstant.

(i) f admits a factorization $f = c\prod_{i=1}^{m} p_i$ with $m \in \mathbb{N}$, $c \in \mathbb{F}^\times$, and monic irreducibles $p_1, \ldots, p_m \in \mathbb{F}[x]$.

(ii) Suppose $f = c\prod_{i=1}^{m} p_i = d\prod_{j=1}^{n} q_j$, where both factorizations have the form in (i).
Then $m = n$, $c = d$, and $(\exists \sigma \in \mathfrak{S}_m)(\forall i \in \{1, \ldots, m\})\, p_i = q_{\sigma(i)}$.

Proof.

(i) Suppose a nonconstant polynomial without a factorization in (i) exists. Its degree lies in $\mathbb{N}$.
Choose a counterexample w of minimal degree by Assumption 2.6.1. If w is irreducible, set $c := \mathrm{lc}(w)$ and $p_1 := c^{-1}w$.
Scalar c is a unit, so p_1 is monic, irreducible; hence $w = cp_1$, a contradiction. Thus $w = uv$ with $u, v \notin \mathbb{F}[x]^\times$ by Definition 3.9.1.
Since nonzero constants are units, $\deg u, \deg v > 0$. Since $w = uv \neq 0$, $\deg w = \deg u + \deg v$, so $\deg u, \deg v < \deg w$.
By minimality, u and v have factorizations of the form in (i). Their product is such a factorization of w, a contradiction.

(ii) Suppose $f = c\prod_{i=1}^{m} p_i = d\prod_{j=1}^{n} q_j$ has two factorizations of the form in (i). Since $c, d \in \mathbb{F}^\times$, $p_1 \mid \prod_{j=1}^{n} q_j$.
Then $(\exists j \in \{1, \ldots, n\})\, p_1 \mid q_j$ by induction on n with Proposition 3.9.2.
Write $q_j = p_1 h$. Since q_j is irreducible and p_1 is not a unit, $h \in \mathbb{F}[x]^\times$. Choose $k \in \mathbb{F}[x]$ with $hk = 1$.
Since $hk = 1$, $\deg h = 0$ by degree additivity; monicity of p_1, q_j then forces $h = 1$, so $q_j = p_1$.
Reindex the q-factors to place q_j first; the nonzero-product property permits cancellation of p_1.

Repeating this step removes one factor from each side.
A nonempty product of irreducibles has positive degree, so neither side retains factors after the other is exhausted.
Thus $m = n$; the matched indices define $\sigma \in \mathfrak{S}_m$, and the remaining scalar equality is $c = d$.

Structural Commentary: Degree descent proves existence; prime-factor cancellation proves uniqueness.
Key Insight: Primality matches each irreducible factor with one factor on the other side. □

3.10 Principal Ideal Domains and Unique Factorization

Definition 3.10.1. *Principal Ideal Domains and Unique Factorization Domains*
Let R be an integral domain.

(i) The ring R is a *principal ideal domain (PID)* iff $(\forall\, \mathcal{I} \trianglelefteq R)(\exists\, a \in R)\, \mathcal{I} = \langle a \rangle$.
(ii) The ring R is a *unique factorization domain (UFD)* iff both conditions hold:
  (a) Every $a \in R \setminus (R^\times \cup \{0_R\})$ admits a factorization $a = \prod_{i=1}^{m} p_i$ with $m \in \mathbb{N}$ and irreducible $p_1, \dots, p_m \in R$.
  (b) If $a = \prod_{i=1}^{m} p_i = \prod_{j=1}^{n} q_j$ are two such factorizations, then $m = n$ and $(\exists\, \sigma \in \mathfrak{S}_m)(\forall\, i \in \{1, \dots, m\})\, p_i \sim q_{\sigma(i)}$.

Theorem 3.10.2. *$\mathbb{Z}$ and $\mathbb{F}[x]$ Are Principal Ideal Domains*
Let $\mathbb{F}$ be a field.

(i) Every ideal of $\mathbb{Z}$ is principal.
(ii) If $\{0\} \neq \mathcal{I} \trianglelefteq \mathbb{Z}$, then $\mathcal{I}$ has the unique positive generator $d = \min(\mathcal{I} \cap \mathbb{N})$.
(iii) Every ideal of $\mathbb{F}[x]$ is principal.
(iv) If $\{0\} \neq \mathcal{I} \trianglelefteq \mathbb{F}[x]$, then its unique monic generator is the unique monic element of $\mathcal{I}$ having minimal degree.

Proof.

(i) The zero ideal is $\langle 0 \rangle$. Let $\{0\} \neq \mathcal{I} \trianglelefteq \mathbb{Z}$. Then $\mathcal{I} \cap \mathbb{N} \neq \emptyset$, because $\mathcal{I}$ contains the positive one of $a, -a$ whenever $0 \neq a \in \mathcal{I}$.
Choose $d = \min(\mathcal{I} \cap \mathbb{N})$ by Assumption 2.6.1. For $a \in \mathcal{I}$, choose $q, r \in \mathbb{Z}$ with $a = qd + r$ and $0 \leq r < d$.
Since $r = a - qd \in \mathcal{I}$, $r = 0$ by minimality of d. Thus $\mathcal{I} \subseteq \langle d \rangle$. The reverse inclusion holds by $d \in \mathcal{I}$.
(ii) Let e be a positive generator of $\mathcal{I}$. Then $d \leq e$ because $e \in \mathcal{I} \cap \mathbb{N}$.
Since $d \in \langle e \rangle$, choose $k \in \mathbb{Z}$ with $d = ke$. Then $k \in \mathbb{N}$ by $d, e > 0$, so $e \leq d$. Hence $e = d$.
(iii) The zero ideal is $\langle 0 \rangle$. Let $\{0\} \neq \mathcal{I} \trianglelefteq \mathbb{F}[x]$.
A monic element of $\mathcal{I}$ exists by scaling a nonzero element by the inverse of its leading coefficient.
Choose a monic $m \in \mathcal{I}$ of minimal degree by Assumption 2.6.1 for the shifted degrees.
For $p \in \mathcal{I}$, write $p = qm + r$, where $r = 0$ or $\deg r < \deg m$, by Theorem 3.8.2(i).
Since $r = p - qm \in \mathcal{I}$, a nonzero r could be scaled to a monic element of smaller degree.
Hence $r = 0$ by minimality of m, so $\mathcal{I} \subseteq \langle m \rangle$; the reverse inclusion holds by $m \in \mathcal{I}$.
(iv) Let m' be another monic element of $\mathcal{I}$ with $\deg m' = \deg m$.
Then $m - m' \in \mathcal{I}$ is zero or has degree less than $\deg m$, so $m = m'$ by minimality of m.
If g is a monic generator of $\mathcal{I}$, then $\deg m \leq \deg g$ by minimality of m.
Choose $h \in \mathbb{F}[x]$ with $m = gh$. Then $\deg m = \deg g + \deg h$, so $\deg g \leq \deg m$. Thus $g = m$ by the preceding uniqueness.

Structural Commentary: Minimal representatives and division remainders identify ideal generators.
Key Insight: A nonzero smaller remainder contradicts the selected representative. □

Corollary 3.10.3. *GCDs Generate Polynomial Ideals*
Let $\mathbb{F}$ be a field, let $n \in \mathbb{N}$, and let $0 \neq p_1, \dots, p_n \in \mathbb{F}[x]$. Set $\mathcal{I} := \langle p_1, \dots, p_n \rangle$.

(i) A monic $m \in \mathbb{F}[x]$ with $\mathcal{I} = \langle m \rangle$ exists.
(ii) The monic generator m in (i) is unique.
(iii) $(\forall\, i \in \{1, \dots, n\})\, m \mid p_i$.
(iv) If $q \in \mathbb{F}[x]$ satisfies $(\forall\, i \in \{1, \dots, n\})\, q \mid p_i$, then $q \mid m$. Consequently, $m = \gcd(p_1, \dots, p_n)$.

Proof.

(i) The ideal $\mathcal{I}$ is nonzero because $p_1 \in \mathcal{I}$. A monic m with $\mathcal{I} = \langle m \rangle$ exists by Theorem 3.10.2(iv).
(ii) The monic generator is unique by Theorem 3.10.2(iv).
(iii) Let $i \in \{1, \dots, n\}$. Since $p_i \in \mathcal{I} = \langle m \rangle$, $m \mid p_i$ by Definition 3.7.1(ii).
(iv) Suppose $(\forall\, i \in \{1, \dots, n\})\, q \mid p_i$. Then $q \neq 0$ by $p_1 \neq 0$ and $q \mid p_1$.
The inclusions $(\forall\, i \in \{1, \dots, n\})\, \langle p_i \rangle \subseteq \langle q \rangle$ hold by Proposition 3.7.2(iii), so $\mathcal{I} \subseteq \langle q \rangle$.
Thus $m \in \langle q \rangle$, and $q \mid m$ by Definition 3.7.1(ii). Therefore m has the asserted gcd property.

Structural Commentary: Principal generation constructs the gcd; containment verifies universality.
Key Insight: Divisibility reverses inclusion of the corresponding principal ideals. □

Counterexample 3.10.4. *A Polynomial Ring That Is Not a PID*
The PID conclusion for $\mathbb{F}[x]$ in Theorem 3.10.2(iii) does not extend to $\mathbb{F}[x, y]$. Let $\mathbb{F}$ be a field and set $\mathcal{I} := \langle x, y \rangle \trianglelefteq \mathbb{F}[x, y]$.
Suppose $\mathcal{I} = \langle p \rangle$. Since $x \in \mathcal{I}$ and $x \neq 0$, $p \neq 0$. Choose $q, r \in \mathbb{F}[x, y]$ with $x = pq$ and $y = pr$.
As both products nonzero, $0 = \deg_y p + \deg_y q$, $0 = \deg_x p + \deg_x r$. Thus $p \in \mathbb{F}[x] \cap \mathbb{F}[y] = \mathbb{F}$. Since $p \neq 0$, it is a unit, so $\mathcal{I} = \mathbb{F}[x, y]$.
This contradicts $1 \notin \mathcal{I}$, because every element of $\mathcal{I}$ has zero constant term. Hence $\mathbb{F}[x, y]$ is not a PID.

Proposition 3.10.5. *PIDs Satisfy the Ascending Chain Condition*
If R is a PID and $(\mathcal{I}_j)_{j \in \mathbb{N}}$ is an ascending chain of ideals, then $(\exists\, N \in \mathbb{N})(\forall\, j \in \mathbb{N})\, [j \geq N \Rightarrow \mathcal{I}_j = \mathcal{I}_N]$.

Proof. Set $\mathcal{I} := \bigcup_{j \in \mathbb{N}} \mathcal{I}_j$. The set $\mathcal{I}$ is an ideal by Proposition 3.3.3. Choose $a \in R$ with $\mathcal{I} = \langle a \rangle$ by Definition 3.10.1(i).
Choose $N \in \mathbb{N}$ with $a \in \mathcal{I}_N$. Then $\mathcal{I} = \langle a \rangle \subseteq \mathcal{I}_N \subseteq \mathcal{I}$. If $j \geq N$, then $\mathcal{I}_N \subseteq \mathcal{I}_j \subseteq \mathcal{I} = \mathcal{I}_N$, so $\mathcal{I}_j = \mathcal{I}_N$.
Structural Commentary: The union is principal, and its generator enters one finite stage.
Key Insight: That stage contains the entire union and stabilizes the chain. □

Theorem 3.10.6. *Prime, Irreducible, and Bezout Properties in a PID*
Let R be a principal ideal domain.

(i) For $r \in R \setminus (R^\times \cup \{0_R\})$, r is irreducible iff $\langle r \rangle$ is a maximal ideal of R.
(ii) Every irreducible element of R is prime.
(iii) For $a, b \in R$, $(\forall\, h \in R)\,[(h \mid a \wedge h \mid b) \Rightarrow h \in R^\times]$ iff $(\exists\, x, y \in R)\, xa + yb = 1_R$.

Proof.

(i) ($\Rightarrow$) Suppose r is irreducible. The ideal $\langle r \rangle$ is proper by Proposition 3.7.2(i).
Let $\langle r \rangle \subseteq \mathcal{I} \trianglelefteq R$, and choose $a \in R$ with $\mathcal{I} = \langle a \rangle$ by Definition 3.10.1(i).
Choose $x \in R$ with $r = xa$. Then x or a is a unit by Definition 3.7.1(v).
If x is a unit, then $\langle r \rangle = \langle a \rangle = \mathcal{I}$ by Proposition 3.7.2(ii). If a is a unit, then $\mathcal{I} = R$ by Proposition 3.7.2(i). Thus $\langle r \rangle$ is maximal.
(i) ($\Leftarrow$) Suppose $\langle r \rangle$ is maximal and write $r = ab$. Then $\langle r \rangle \subseteq \langle a \rangle$, so $\langle a \rangle = \langle r \rangle$ or $\langle a \rangle = R$.
In the second case, a is a unit by Proposition 3.7.2(i). In the first case, $a \sim r$ by Proposition 3.7.2(ii).
Choose $u \in R^\times$ with $a = ur$ by Definition 3.7.1(iii); $r = urb$, $ub = 1_R$ by Proposition 3.5.2. Hence b is a unit, so r is irreducible.
(ii) Let r be irreducible and suppose $r \mid ab$. Set $\mathcal{K} := \langle r, a \rangle$. The ideal $\langle r \rangle$ is maximal by (i), so $\mathcal{K} = \langle r \rangle$ or $\mathcal{K} = R$.
In the first case, $a \in \langle r \rangle$, so $r \mid a$ by Definition 3.7.1(ii). In the second case, choose $x, y \in R$ with $1_R = xr + ya$.
Then $b = xrb + yab$. Since $r \mid xrb$ and $r \mid yab$, $r \mid b$. Hence r is prime by Definition 3.7.1(iv).
(iii) ($\Rightarrow$) Suppose $(\forall\, h \in R)\,[(h \mid a \wedge h \mid b) \Rightarrow h \in R^\times]$. Choose $d \in R$ with $\langle a, b \rangle = \langle d \rangle$ by Definition 3.10.1(i).
Since $a, b \in \langle d \rangle$, $d \mid a$, $d \mid b$ by Definition 3.7.1(ii). Thus d is a unit, so $\langle a, b \rangle = R$ by Proposition 3.7.2(i); $(\exists\, x, y \in R)\, xa + yb = 1_R$.
(iii) ($\Leftarrow$) Choose $x, y \in R$ with $xa + yb = 1_R$, and let $h \in R$ satisfy $h \mid a$ and $h \mid b$. Then $h \mid 1_R$, so h is a unit by Definition 3.7.1(i).

Structural Commentary: Maximality-to-primality meets Bezout identities from two-generator ideals.
Key Insight: Principal ideal containment converts factors and common divisors into units. □

Theorem 3.10.7. *Every PID Is a UFD*
Let R be a principal ideal domain.

(i) Every $a \in R \setminus (R^\times \cup \{0_R\})$ admits a factorization $a = \prod_{i=1}^{m} p_i$ with $m \in \mathbb{N}$ and irreducible $p_1, \ldots, p_m \in R$.

(ii) If $a = \prod_{i=1}^{m} p_i = \prod_{j=1}^{n} q_j$ are two such factorizations, then $m = n$ and $(\exists\, \sigma \in \mathfrak{S}_m)(\forall\, i \in \{1, \ldots, m\})\, p_i \sim q_{\sigma(i)}$.

Proof.

(i) Suppose a has no irreducible factorization and set $s_1 := a$.
Recursively suppose s_j is a nonzero nonunit without an irreducible factorization.
Since an irreducible element is itself a factorization, s_j is not irreducible.
Choose nonunits $u_j, v_j \in R$ with $s_j = u_j v_j$ by Definition 3.7.1(v).
At least one of u_j, v_j is nonfactorable; otherwise their factorizations concatenate to one of s_j.
Let s_{j+1} be a nonfactorable factor and let t_j be the other factor, so $s_j = s_{j+1} t_j$. Both factors are nonzero because $s_j \neq 0_R$.
Then $\langle s_j \rangle \subseteq \langle s_{j+1} \rangle$ by Proposition 3.7.2(iii). If equality held, then $s_{j+1} \sim s_j$ by Proposition 3.7.2(ii).
Choose $w \in R^\times$ with $s_{j+1} = w s_j$ by Definition 3.7.1(iii). Now $s_{j+1} = w s_{j+1} t_j$, so $1_R = w t_j$ by Proposition 3.5.2.
This contradicts that t_j is a nonunit. Hence $\langle s_1 \rangle \subsetneq \langle s_2 \rangle \subsetneq \cdots$, which is impossible by Proposition 3.10.5.
Therefore every nonzero nonunit has an irreducible factorization.

(ii) The proof is by induction on m. The element p_1 is prime by Theorem 3.10.6(ii).
Then $(\exists\, j \in \{1, \ldots, n\})\, p_1 \mid q_j$ by induction on n with the prime property. Reindex q-factors, choose $u \in R^\times$ with $q_1 = u p_1$.
Choose $v \in R$ with $uv = 1_R$ by Definition 3.7.1(i). Suppose first that $m = 1$. Equality $1_R = u \prod_{j=2}^{n} q_j$ holds by Proposition 3.5.2.
If $n > 1$, then $1_R = q_2 \big(u \prod_{j=3}^{n} q_j\big)$, so $q_2 \in R^\times$ by Definition 3.7.1(i), a contradiction. Thus $n = 1$ and $p_1 \sim q_1$.
Now let $m > 1$ and suppose the conclusion holds for factorizations with $m - 1$ factors on the left.
If $n = 1$, then $\prod_{i=2}^{m} p_i = u$ by Proposition 3.5.2. Then $1_R = p_2 \big(v \prod_{i=3}^{m} p_i\big)$, so p_2 is a unit by Definition 3.7.1(i), a contradiction.
Hence $n > 1$. Then $\prod_{i=2}^{m} p_i = (uq_2) \prod_{j=3}^{n} q_j$ by Proposition 3.5.2.
The element uq_2 is a nonzero nonunit, because otherwise $q_2 = v(uq_2)$ would be zero or a unit.
If $uq_2 = bc$, then $q_2 = (vb)c$. Thus vb or c is a unit by Definition 3.7.1(v).
If vb is a unit, then $b = u(vb)$ is a unit. Hence uq_2 is irreducible by Definition 3.7.1(v).
By the induction hypothesis, $m - 1 = n - 1$, and the tail factors match up to permutation and associates.
Therefore $m = n$, and the first match combined with the tail permutation defines $\sigma \in \mathfrak{S}_m$ with $(\forall\, i \in \{1, \ldots, m\})\, p_i \sim q_{\sigma(i)}$.

Structural Commentary: ACC terminates factor descent; primality matches irreducible factors.
Key Insight: Strict principal-ideal growth obstructs endless factor refinement. □

3.11 Roots of Unity and Cyclotomic Polynomials

Definition 3.11.1. *Roots of Unity, Primitive Roots, and Euler's Totient*
Let $n \in \mathbb{N}$.

(i) The complex *nth roots of unity* are $U_n := \{z \in \mathbb{C}^\times : z^n = 1\}$.
(ii) A root $\omega \in U_n$ is *primitive* iff $\operatorname{ord}(\omega) = n$ in $\mathbb{C}^\times$; set $\Omega_n := \{\omega \in U_n : \operatorname{ord}(\omega) = n\}$.
(iii) *Euler's totient* is $\varphi(n) := |\{k \in \{1, \ldots, n\} : \gcd(k, n) = 1\}|$.

Proposition 3.11.2. *Cyclic Structure of Roots of Unity*
Let $n \in \mathbb{N}$ and set $\zeta_n := \exp\left(\frac{2\pi i}{n}\right)$.

(i) $U_n = \langle \zeta_n \rangle$.
(ii) $|U_n| = n$.
(iii) $\Omega_n = \{\zeta_n^k : k \in \{1, \ldots, n\},\ \gcd(k, n) = 1\}$.
(iv) $|\Omega_n| = \varphi(n)$.

(v) $U_n = \coprod_{d|n} \Omega_d$.

Proof.

(i) The roots of $x^n - 1$ in $\mathbb{C}$ are precisely ζ_n^k for $k \in \{1, \dots, n\}$. Hence $U_n = \{\zeta_n^k : k \in \{1, \dots, n\}\} = \langle \zeta_n \rangle$.

(ii) Suppose $1 \leq j < k \leq n$ and $\zeta_n^j = \zeta_n^k$. Then $\exp\left(\frac{2\pi i(k-j)}{n}\right) = 1$, so $\frac{k-j}{n} \in \mathbb{Z}$, contrary to $0 < k - j < n$.
Thus the n representatives in (i) are distinct, so $|U_n| = n$.

(iii) Fix $k \in \{1, \dots, n\}$, set $g := \gcd(k, n)$, and write $k = gk_0$ and $n = gn_0$.
Then $(\zeta_n^k)^{n_0} = 1$. If $(\zeta_n^k)^m = 1$ for $m \in \mathbb{N}$, then $n \mid km$, so $n_0 \mid k_0 m$.
The ring $\mathbb{Z}$ is a PID by Theorem 3.10.2(i) and Definition 3.10.1(i).
Since $\gcd(k_0, n_0) = 1$, choose $a, b \in \mathbb{Z}$ with $ak_0 + bn_0 = 1$ by Theorem 3.10.6(iii).
Then $n_0 \mid m$ by $m = ak_0 m + bn_0 m$. Therefore $\operatorname{ord}(\zeta_n^k) = n_0 = \frac{n}{\gcd(k,n)}$.
Hence $\zeta_n^k \in \Omega_n \iff \gcd(k, n) = 1$, which is the asserted description of Ω_n.

(iv) $|\Omega_n| = \varphi(n)$ by (iii) and Definition 3.11.1(iii).

(v) Let $z \in U_n$ and set $d := \operatorname{ord}(z)$. Choose $q, r \in \mathbb{Z}$ with $n = qd + r$ and $0 \leq r < d$.
Then $1 = z^n = (z^d)^q z^r = z^r$, so $r = 0$ by minimality of d. Thus $d \mid n$ and $z \in \Omega_d$.
Conversely, if $d \mid n$ and $\omega \in \Omega_d$, then $\omega^n = 1$, so $\omega \in U_n$. The union is disjoint by uniqueness of element order.

Structural Commentary: Root parametrization proves cyclicity; orders prove counting and partition.
Key Insight: $\gcd(k, n)$ determines the order of ζ_n^k. □

Definition 3.11.3. *Cyclotomic Polynomials*
Let $n \in \mathbb{N}$. The set Ω_n is finite by Proposition 3.11.2(iii). The *nth cyclotomic polynomial* is $\Phi_n(x) := \prod_{\omega \in \Omega_n} (x - \omega) \in \mathbb{C}[x]$.

Proposition 3.11.4. *Cyclotomic Factorization of $x^n - 1$*
For $n \in \mathbb{N}$, $x^n - 1 = \prod_{d|n} \Phi_d(x)$ in $\mathbb{C}[x]$.

Proof. The roots of $x^n - 1$ are U_n by Definition 3.11.1(i). Their number is n by Proposition 3.11.2(ii).
Since $x^n - 1$ is monic of degree n, $x^n - 1 = \prod_{z \in U_n} (x - z)$. The equality $\prod_{z \in U_n} (x - z) = \prod_{d|n} \prod_{\omega \in \Omega_d} (x - \omega)$ holds by Proposition 3.11.2(v).
Each inner product equals $\Phi_d(x)$ by Definition 3.11.3, so $x^n - 1 = \prod_{d|n} \Phi_d(x)$.

Structural Commentary: The order partition regroups linear factors into cyclotomic factors.
Key Insight: Each root belongs to exactly one primitive-order class. □

Proposition 3.11.5. *Cyclotomic Polynomials Have Integer Coefficients*
For $n \in \mathbb{N}$:

(i) Φ_n is monic.
(ii) $\Phi_n \in \mathbb{Z}[x]$.

Proof.

(i) The polynomial Φ_n is monic by Definition 3.11.3, because every factor $x - \omega$ is monic.

(ii) Suppose some Φ_n does not lie in $\mathbb{Z}[x]$, and choose the least such n by Assumption 2.6.1.
The identity $\Phi_1(x) = x - 1$ holds by Proposition 3.11.2(iii) and Definition 3.11.3, so $n > 1$. Set $D_n := \{d \in \mathbb{N} : d \mid n,\ d < n\}$.
If $d \in D_n$, then $\Phi_d \in \mathbb{Z}[x]$ by minimality and Φ_d is monic by (i). Hence $P_n(x) := \prod_{d \in D_n} \Phi_d(x)$ is a monic polynomial in $\mathbb{Z}[x]$.
The identity $x^n - 1 = \Phi_n(x) P_n(x)$ holds by Proposition 3.11.4.
Since P_n is monic, leading-term cancellation stays in $\mathbb{Z}[x]$, strictly lowers degree. Process terminates by Assumption 2.6.1.
Thus $h, r \in \mathbb{Z}[x]$ satisfy $x^n - 1 = hP_n + r$ with $r = 0$ or $\deg r < \deg P_n$.
Over $\mathbb{C}[x]$, $(\Phi_n, 0)$ is another quotient-remainder pair by the factorization identity.
Therefore $(h, r) = (\Phi_n, 0)$ by Theorem 3.8.2(ii). Thus $\Phi_n = h \in \mathbb{Z}[x]$, contrary to the choice of n.

Structural Commentary: Minimal divisors construct an integral quotient; uniqueness identifies Φ_n.
Key Insight: A monic divisor requires no coefficient division outside $\mathbb{Z}$. □

Lemma 3.11.6. *A Cyclotomic Size Estimate*
Let $n \in \mathbb{N}$ with $n > 1$ and let $z \in \mathbb{Z}$ with $z \geq 2$. Then $|\Phi_n(z)| > z - 1$.

Proof. Let $\omega \in \Omega_n$. Then $\omega \neq 1$ by $\operatorname{ord}(\omega) = n > 1$, $|\omega| = 1$ by $\omega^n = 1$. Since a point on unit circle has real part 1 only at 1, $\operatorname{Re}(\omega) < 1$.
Therefore $|z - \omega|^2 = z^2 - 2z\operatorname{Re}(\omega) + 1 > (z - 1)^2$, so $|z - \omega| > z - 1$. Relation $|\Omega_n| = \varphi(n) \geq 1$ holds by Proposition 3.11.2(iv), Definition 3.11.1(iii). By Definition 3.11.3, $|\Phi_n(z)| = \prod_{\omega \in \Omega_n} |z - \omega| > (z - 1)^{\varphi(n)} \geq z - 1$.

Structural Commentary: Unit-circle geometry bounds each factor; root counting bounds their product.
Key Insight: A primitive nth root with $n > 1$ cannot equal 1. □

4 Fields and Galois Theory

4.1 Field Extensions

4.2 Splitting Fields and Normality

4.3 Galois Groups

4.4 Finite Fields and Characteristic

Perspective 4.4.1. *Finite Fields and Characteristic*
Let F be a finite field. Then $\operatorname{char}(F)$ is prime by Proposition 3.6.2(ii).
If $\operatorname{char}(F) = 2$, then $(\forall\, a \in F)\, a + a = 0_F$, equivalently $(\forall\, a \in F)\, a = -a$.
Thus characteristic two identifies addition and subtraction in F-linear calculations.

Definition 4.4.2. *Linear Code and Hamming Weight*
Let $n, q \in \mathbb{N}$ and let $\mathbb{F}_q$ be a field with $|\mathbb{F}_q| = q$.

(i) Set $V(n,q) := \mathbb{F}_q^n$, the *ambient code space*.
(ii) A *linear code* of length n over $\mathbb{F}_q$ is a subspace $C \leq V(n,q)$.
(iii) The *Hamming weight* of $\mathbf{x} \in V(n,q)$ is $\mathrm{wt}(\mathbf{x}) := |\{j \in \{1,\dots,n\} : x_j \neq 0\}|$.

Example 4.4.3. *Even-Weight Code*
Let $n \in \mathbb{N}$ and define $\pi_n : V(n,2) \to \mathbb{F}_2$ by $\pi_n(\mathbf{x}) := \sum_{j=1}^{n} x_j$.

Then $(\forall\, \mathbf{x}, \mathbf{y} \in V(n,2))(\forall\, c \in \mathbb{F}_2)\, \pi_n(c\mathbf{x} + \mathbf{y}) = c\pi_n(\mathbf{x}) + \pi_n(\mathbf{y})$, so π_n is linear. Set $E_n := \ker(\pi_n) = \{\mathbf{x} \in V(n,2) : \sum_{j=1}^{n} x_j = 0\}$.

Then $E_n \leq V(n,2)$ by Proposition 1.6.3(i), so E_n is a linear code by Definition 4.4.2(ii).
Since $\mathbb{F}_2 = \{0,1\}$ and $1+1=0$, $(\forall\, \mathbf{x} \in V(n,2))\, [\mathbf{x} \in E_n \iff 2 \mid \mathrm{wt}(\mathbf{x})]$.
Structural Commentary: $E_n = \ker(\pi_n)$ supplies closure; binary addition supplies parity.
Key Insight: Over $\mathbb{F}_2$, coordinate summation records Hamming-weight parity.

4.5 Classical Applications

Part VIII
Modules, Multilinear Algebra, and Homological Methods

1 Module Theory

1.1 Modules and Submodules

Throughout this subsection, R is a nonzero commutative ring with identity 1_R.
Modules replace field scalars by ring scalars.
Nonzero scalars may therefore be noninvertible or annihilate nonzero vectors.

Definition 1.1.1. *R-Module*
An *R-module* is an abelian group $(M,+)$ equipped with an action $R\times M\to M$, $(r,u)\mapsto ru$.
For $(r,s,u,v)\in R^2\times M^2$, the following identities hold:

(i) $r(u+v)=ru+rv$.
(ii) $(r+s)u=ru+su$.
(iii) $(rs)u=r(su)$.
(iv) $1_Ru=u$.

The ring R is the *base ring* of M; denote the additive identity of M by 0_M.

Example 1.1.2. *Basic Module Models*
Fix $m,n\in\mathbb{N}$.

(i) R^n is an R-module under componentwise addition and scalar multiplication.
(ii) $\mathrm{Mat}(m,n,R)$ is an R-module under entrywise operations.
(iii) R is an R-module over itself by ring multiplication.
(iv) Every vector space over a field $\mathbb{F}$ is an $\mathbb{F}$-module.

The module axioms hold componentwise in (i) and entrywise in (ii). They are ring laws in (iii) and vector-space axioms in (iv).

Perspective 1.1.3. *The Base Ring Controls the Geometry*
The module axioms separate the additive group from the scalar ring.
Over a field, scalar division supports the usual theory of bases, dimension, and complements.
Over a general ring, nonunits and zero divisors can obstruct division and cancellation.
Consequently, bases, dimension, and complements need not retain their vector-space behavior.

Definition 1.1.4. *Submodule*
Let M be an R-module. A *submodule* $N\le M$ is a subset $N\subseteq M$ that is an R-module under the restricted operations.

Theorem 1.1.5. *Submodule Test*
Let M be an R-module and $\emptyset\neq N\subseteq M$. Then $N\le M\iff(\forall\,(r,s,u,v)\in R^2\times N^2)\,ru+sv\in N$.

Proof.
($\Rightarrow$) Assume $N\le M$. Fix $(r,s,u,v)\in R^2\times N^2$. Then $ru,sv,ru+sv\in N$ by scalar and additive closure.
($\Leftarrow$) Assume $(\forall\,(r,s,u,v)\in R^2\times N^2)\,ru+sv\in N$. $(\forall\,x\in M)\,0_Rx=0_M$ by $0_Rx=(0_R+0_R)x=0_Rx+0_Rx$, cancellation in $(M,+)$.
$(\forall\,x\in M)\,(-1_R)x=-x$ by $(-1_R)x+x=0_Rx=0_M$. Fix $n\in N$. Then $0_M=0_Rn+0_Rn\in N$ by the assumed closure.
$(\forall\,(x,y)\in N^2)\,x+y=1_Rx+1_Ry\in N$ by the assumed closure. $(\forall\,x\in N)\,-x=(-1_R)x+0_Rx\in N$ by the assumed closure.
$(\forall\,(r,x)\in R\times N)\,rx=rx+0_Rx\in N$ by the assumed closure. $N\le(M,+)$ by the preceding zero, addition, and inverse relations.
The set N is closed under R-scalar multiplication by the final relation.
$N\le M$ by Definition 1.1.4, since the remaining module axioms are inherited from M.

Structural Commentary: The reverse direction extracts every submodule operation from two-term closure.
Key Insight: Two-term R-linear combinations encode all submodule closure laws. □

Proposition 1.1.6. *Intersections and Sums of Submodules*
Let M be an R-module and $A,B\le M$. Define $\mathcal{S}_{A,B}:=\{N\le M:A\cup B\subseteq N\}$.

(i) $A\cap B\le M$.
(ii) $A+B:=\{a+b:(a,b)\in A\times B\}\le M$.
(iii) $A+B=\bigcap_{N\in\mathcal{S}_{A,B}}N$.

Proof.
(i) $0_M\in A\cap B$ by $A,B\le M$. For $(r,s,x,y)\in R^2\times(A\cap B)^2$, $rx+sy\in A\cap B$ by closure of A, B; $A\cap B\le M$ by Theorem 1.1.5.
(ii) $0_M=0_M+0_M\in A+B$. Fix $x=a+b$ and $y=a'+b'$ with $(a,a',b,b')\in A^2\times B^2$.
For $(r,s)\in R^2$, $rx+sy=(ra+sa')+(rb+sb')\in A+B$ by closure of A and B. Hence $A+B\le M$ by Theorem 1.1.5.
(iii) $(\forall\,a\in A)\,a=a+0_M\in A+B$ and $(\forall\,b\in B)\,b=0_M+b\in A+B$. $A\cup B\subseteq A+B$ by these inclusions, so $A+B\in\mathcal{S}_{A,B}$ by (ii).
$(\forall\,N\in\mathcal{S}_{A,B})\,A+B\subseteq N$ by additive closure in N. Hence $A+B\subseteq\bigcap_{N\in\mathcal{S}_{A,B}}N$ by the definition of intersection.
Conversely, $\bigcap_{N\in\mathcal{S}_{A,B}}N\subseteq A+B$ by $A+B\in\mathcal{S}_{A,B}$.

Structural Commentary: The closure test constructs both submodules; universal containment identifies their join.
Key Insight: $A+B$ contains exactly the additions forced by A and B. □

Proposition 1.1.7. *Ideals Are Submodules of the Regular Module*
Equip $(R,+)$ with the action $R\times R\to R$, $(r,x)\mapsto rx$. Write ${}_RR$ for this regular module. Then $(\forall\,N\subseteq R)\,[N\le{}_RR\iff N\trianglelefteq R]$.

Proof. The group $(R,+)$ is abelian by Definition 3.1.1. The ring laws make ${}_RR$ an R-module by Definition 1.1.1.
($\Rightarrow$) Assume $N\le{}_RR$. Then $N\neq\emptyset$ and $(\forall\,a,b\in N)\,a-b\in N$ by Definition 1.1.4.
$(\forall\,(r,n)\in R\times N)\,rn,nr\in N$ by scalar closure and commutativity of R. Hence $N\trianglelefteq R$ by Definition 3.3.1.

($\Leftarrow$) Assume $N \trianglelefteq R$. Then $N \leq (R,+)$ by Proposition 2.1.4 and Definition 3.3.1.
For $(r,s,u,v) \in R^2 \times N^2$, $ru, sv \in N$ by ideal absorption and $ru+sv \in N$ by additive closure. Hence $N \leq {}_RR$ by Theorem 1.1.5.

Structural Commentary: The regular action identifies scalar closure with ideal absorption; commutativity adds right absorption.
Key Insight: Submodules of ${}_RR$ and ideals share the same closure laws. □

1.2 Generated, Cyclic, and Finitely Generated Modules

Throughout this subsection, R is a nonzero commutative ring with identity 1_R. Fix an R-module M.

Definition 1.2.1. *Generated Submodule*

(i) For $S \subseteq M$, set $\langle\langle S \rangle\rangle_R := \left\{ \sum_{j=1}^{n} r_j s_j : n \in \mathbb{N}_0,\ (r_1,\dots,r_n) \in R^n,\ (s_1,\dots,s_n) \in S^n \right\}$.
Call this the *submodule generated by S*; the term $n=0$ denotes the empty sum 0_M. Hence $\langle\langle \emptyset \rangle\rangle_R = \{0_M\}$.
(ii) A subset $S \subseteq M$ *spans* or *generates* M if $\langle\langle S \rangle\rangle_R = M$.
(iii) For $n \in \mathbb{N}$ and $(s_1,\dots,s_n) \in M^n$, write $\langle\langle s_1,\dots,s_n \rangle\rangle_R := \langle\langle \{s_1,\dots,s_n\} \rangle\rangle_R$.

Proposition 1.2.2. *Generated Submodule Is Smallest*
Let $S \subseteq M$, $G := \langle\langle S \rangle\rangle_R$, and $\mathcal{S}_S := \{N \leq M : S \subseteq N\}$.
(i) $G \leq M$.
(ii) $S \subseteq G$.
(iii) $G = \bigcap_{N \in \mathcal{S}_S} N$.

Proof.
(i) $0_M \in G$ by the empty-sum convention.
Fix $x, y \in G$ and $a, b \in R$. Choose representations $x = \sum_{j=1}^{m} r_j s_j$ and $y = \sum_{k=1}^{n} t_k u_k$ by Definition 1.2.1(i).
Then $ax + by = \sum_{j=1}^{m} (ar_j)s_j + \sum_{k=1}^{n} (bt_k)u_k \in G$ by distributivity and Definition 1.2.1(i). Hence $G \leq M$ by Theorem 1.1.5.
(ii) $S \subseteq G$ by $(\forall\, s \in S)\, s = 1_R s \in G$.
(iii) $G \in \mathcal{S}_S$ by (i) and (ii). Fix $N \in \mathcal{S}_S$. Then $G \subseteq N$ by $S \subseteq N$ and scalar and additive closure in N.
Hence $G \subseteq \bigcap_{N \in \mathcal{S}_S} N$ by the arbitrariness of N. Conversely, $\bigcap_{N \in \mathcal{S}_S} N \subseteq G$ by $G \in \mathcal{S}_S$.

Structural Commentary: Closure is by the submodule test; minimality is by unit coefficients and containment.
Key Insight: Every containing submodule absorbs all finite R-linear combinations. □

Definition 1.2.3. *Cyclic and Finitely Generated Modules*

(i) For $v \in M$, the *cyclic submodule generated by v* is $\langle\langle v \rangle\rangle_R = Rv = \{rv : r \in R\}$.
(ii) M is *finitely generated* if $(\exists\, n \in \mathbb{N})(\exists\, (v_1,\dots,v_n) \in M^n)\, M = \langle\langle v_1,\dots,v_n \rangle\rangle_R$.
(iii) M is *cyclic* if $(\exists\, v \in M)\, M = Rv$.

Counterexample 1.2.4. *A Cyclic Module with a Non-Finitely Generated Submodule*
A submodule of a finitely generated module need not be finitely generated. Let $\mathbb{F}$ be a field and $R := \mathbb{F}[x_1, x_2, \dots]$.
This is the polynomial ring in countably many commuting indeterminates.
Every $f \in R$ involves only finitely many indeterminates, and ${}_RR = \langle\langle 1_R \rangle\rangle_R$ is cyclic.
Set $I := \langle \{x_j : j \in \mathbb{N}\} \rangle$ and $\mathcal{Z} := \{f \in R : f(0,0,\dots) = 0\}$. $I \trianglelefteq R$ by Proposition 3.3.2.
Hence $I \leq {}_RR$ by Proposition 1.1.7. $I \subseteq \mathcal{Z}$ by the zero constant terms of the generators.
Every $f \in \mathcal{Z}$ is a finite sum of nonconstant monomials.
Each such monomial lies in I because it is divisible by some x_j; hence $\mathcal{Z} \subseteq I$ and $I = \mathcal{Z}$. Assume I is finitely generated.
Choose $n \in \mathbb{N}$ and $(p_1,\dots,p_n) \in I^n$ satisfying $I = \langle\langle p_1,\dots,p_n \rangle\rangle_R$ by Definition 1.2.3(ii).
Only finitely many indeterminates occur among $p_1,\dots,p_n$. Choose $k \in \mathbb{N}$ such that x_k occurs in none of them.
Define $\varphi_k : R \to \mathbb{F}[x_k]$ by $\varphi_k|_{\mathbb{F}} = \mathrm{id}_{\mathbb{F}}$, $\varphi_k(x_k) = x_k$, and $(\forall\, j \in \mathbb{N} \setminus \{k\})\, \varphi_k(x_j) = 0$.
The map φ_k preserves sums, products, and identity by substitution. Hence φ_k is a ring homomorphism by Definition 3.2.1(i).
Each p_i has zero constant term by $p_i \in I = \mathcal{Z}$, and no p_i contains x_k. Hence $(\forall\, i \in \{1,\dots,n\})\, \varphi_k(p_i) = 0$.
$(\forall\, (r_1,\dots,r_n) \in R^n)\, \varphi_k\left(\sum_{i=1}^{n} r_i p_i\right) = \sum_{i=1}^{n} \varphi_k(r_i)\varphi_k(p_i) = 0$. $\varphi_k(I) = \{0\}$ by $I = \langle\langle p_1,\dots,p_n \rangle\rangle_R$ and the preceding identity.
However, $x_k \in I$ and $\varphi_k(x_k) = x_k \neq 0$, a contradiction. Therefore I is a non-finitely generated submodule of the cyclic module ${}_RR$.

1.3 Linear Independence in Modules

Throughout this subsection, R is a nonzero commutative ring with identity 1_R.
Fix an R-module M with additive identity 0_M.

Definition 1.3.1. *Linear Independence in a Module*

(i) $S \subseteq M$ is *R-linearly independent* if $(\forall\, F \subseteq S,\ |F| < \infty)(\forall\, (r_v)_{v \in F} \in R^F) \left[\sum_{v \in F} r_v v = 0_M \Rightarrow (\forall\, v \in F)\, r_v = 0_R \right]$.
(ii) $S \subseteq M$ is *R-linearly dependent* if it is not R-linearly independent.

Counterexample 1.3.2. *Dependence Without Solving for One Vector*
For distinct $u, v \in M$, dependence of $\{u, v\}$ need not imply $u \in Rv \vee v \in Ru$.
In the $\mathbb{Z}$-module $\mathbb{Z}$, the distinct elements $2, 3$ satisfy $3 \cdot 2 + (-2) \cdot 3 = 0$.
The set $\{2, 3\}$ is dependent by Definition 1.3.1(i)–(ii) with the nonzero coefficients $3, -2$.
Yet $2 \notin 3\mathbb{Z}$ and $3 \notin 2\mathbb{Z}$, so neither element is an integer multiple of the other.

Proposition 1.3.3. *Scaling Independent Sets over a Domain*
Assume R is integral domain. Let $S \subseteq M$ be finite, R-linearly independent, $r \in R \setminus \{0_R\}$. Then $rS := \{rv : v \in S\}$ is R-linearly independent.

Proof.

(i) *Reduction*: If $S = \emptyset$, then $rS = \emptyset$ is R-linearly independent by Definition 1.3.1(i).
Assume $S \neq \emptyset$ and write $S = \{v_1, \dots, v_n\}$ with $n \in \mathbb{N}$ and pairwise distinct $v_1, \dots, v_n$.

(ii) *Injective scaling*: If $rv_i = rv_j$ for $i \neq j$, then $rv_i + (-r)v_j = 0_M$.
Then $r = 0_R$ by Definition 1.3.1(i), contradicting $r \neq 0_R$; hence $rv_1, \dots, rv_n$ are distinct.

(iii) *Relation transfer*: A relation on $T \subseteq rS$ extends to rS by zero coefficients. Fix $(a_1, \dots, a_n) \in R^n$ satisfying $\sum_{i=1}^{n} a_i(rv_i) = 0_M$.
$0_M = \sum_{i=1}^{n} a_i(rv_i) = \sum_{i=1}^{n} (ra_i)v_i$ by Definition 1.1.1(iii), commutativity of R. $(\forall\, i \in \{1, \dots, n\})\, ra_i = 0_R$ by Definition 1.3.1(i).

(iv) *Coefficient cancellation*: $(\forall\, i \in \{1, \dots, n\})\, a_i = 0_R$ by Proposition 3.5.2 with $ra_i = 0_R = r0_R$ and $r \neq 0_R$.
Thus rS is R-linearly independent by Definition 1.3.1(i).

Structural Commentary: Relations on rS reduce to relations on S, followed by coefficient cancellation in R.
Key Insight: Each transferred coefficient has the cancellable factor $r \neq 0_R$. □

1.4 Module Homomorphisms, Kernels, and Images

Throughout this subsection, R is a nonzero commutative ring with identity 1_R.

Definition 1.4.1. *Module Homomorphism*
Let M, N be R-modules and let $\tau : M \to N$.

(i) The map τ is *R-linear* if $(\forall\, (r, s, u, v) \in R^2 \times M^2)\, \tau(ru + sv) = r\tau(u) + s\tau(v)$. An R-linear map is an *R-homomorphism*.
(ii) The set of all R-homomorphisms $M \to N$ is $\mathrm{Hom}_R(M, N)$.
(iii) An R-homomorphism $M \to M$ is an *endomorphism*.
(iv) If τ is an R-homomorphism, then:
  (a) τ is a *monomorphism* $\iff$ τ is injective;
  (b) τ is an *epimorphism* $\iff$ τ is surjective;
  (c) τ is an *isomorphism* $\iff$ τ is bijective.

Proposition 1.4.2. *Hom, Kernel, and Image*
Let M, N be R-modules with additive identities $0_M, 0_N$, and let $\tau \in \mathrm{Hom}_R(M, N)$.

(i) For $(\sigma, \rho, m) \in \mathrm{Hom}_R(M, N)^2 \times M$, set $(\sigma + \rho)(m) := \sigma(m) + \rho(m)$.
For $(a, \sigma, m) \in R \times \mathrm{Hom}_R(M, N) \times M$, set $(a\sigma)(m) := a\sigma(m)$. These pointwise operations make $\mathrm{Hom}_R(M, N)$ an R-module.
(ii) $\ker \tau := \tau^{-1}(\{0_N\}) \leq M$.
(iii) $\mathrm{im}\, \tau := \tau(M) \leq N$.
(iv) τ is a monomorphism $\iff \ker \tau = \{0_M\}$.

Proof. $(\forall\, a \in R)\, a0_N = 0_N$ by additive cancellation in $a0_N = a(0_N + 0_N) = a0_N + a0_N$.
$\tau(0_M) = 0_N$ by Definition 1.4.1(i) with $(r, s, u, v) = (1_R, 1_R, 0_M, 0_M)$ and additive cancellation in N.

(i) Set $\mathcal{F}(M, N) := \{f : f : M \to N\}$ and equip it with the pointwise operations in the statement.
Zero map $0_{\mathcal{F}} : M \to N$, $m \mapsto 0_N$, is additive identity. Module axioms hold pointwise in N and in $\mathcal{F}(M, N)$ by Assumption 3.1.2.
Thus $\mathcal{F}(M, N)$ is an R-module by Definition 1.1.1. The zero map is R-linear by $(\forall\, r, s \in R)\, r0_N + s0_N = 0_N$.
Fix $\sigma, \rho \in \mathrm{Hom}_R(M, N)$, $a, b, r, s \in R$, and $u, v \in M$.
$(a\sigma + b\rho)(ru + sv) = r(a\sigma + b\rho)(u) + s(a\sigma + b\rho)(v)$ by R-linearity of σ, ρ and ring commutativity.
Hence $a\sigma + b\rho \in \mathrm{Hom}_R(M, N)$ by Definition 1.4.1(i). Therefore $\mathrm{Hom}_R(M, N) \leq \mathcal{F}(M, N)$ by Theorem 1.1.5.

(ii) $0_M \in \ker \tau$ by $\tau(0_M) = 0_N$. For $(a, b, x, y) \in R^2 \times (\ker \tau)^2$, $\tau(ax + by) = a\tau(x) + b\tau(y) = a0_N + b0_N = 0_N$.
Thus $\ker \tau \leq M$ by Theorem 1.1.5.

(iii) $0_N \in \mathrm{im}\, \tau$ by $0_N = \tau(0_M)$. Fix $(a, b, y_1, y_2) \in R^2 \times (\mathrm{im}\, \tau)^2$.
Choose $x_1, x_2 \in M$ with $(y_1, y_2) = (\tau(x_1), \tau(x_2))$ by the definition of the image.
Then $ay_1 + by_2 = \tau(ax_1 + bx_2) \in \mathrm{im}\, \tau$ by Definition 1.4.1(i). Thus $\mathrm{im}\, \tau \leq N$ by Theorem 1.1.5.

(iv) ($\Rightarrow$) Assume τ is a monomorphism, hence injective by Definition 1.4.1(iv).
$(\forall\, m \in \ker \tau)\, m = 0_M$ by injectivity and $\tau(m) = 0_N = \tau(0_M)$. Therefore $\ker \tau = \{0_M\}$ by $\ker \tau \subseteq \{0_M\}$ and (ii).

(iv) ($\Leftarrow$) Assume $\ker \tau = \{0_M\}$ and fix $m, m' \in M$ with $\tau(m) = \tau(m')$. Then $\tau(m - m') = 0_N$ by Definition 1.4.1(i).
Thus $m - m' \in \ker \tau = \{0_M\}$ and $m = m'$. Thus τ is injective and hence a monomorphism by Definition 1.4.1(iv).

Structural Commentary: Hom closes pointwise; kernels use differences; images use lifted representatives.
Key Insight: R-linearity transports combinations and detects equality through kernel differences. □

1.5 Quotient Modules, Correspondence, and Isomorphism

Throughout this subsection, R is a nonzero commutative ring with identity 1_R.
Fix an R-module M with additive identity 0_M.

Definition 1.5.1. *Quotient Module*
Let $S \leq M$. For $(u, v) \in M^2$, define $u \equiv v \pmod{S} \iff u - v \in S$.
For $u \in M$, set $u + S := \{u + s : s \in S\}$, and set $M/S := \{u + S : u \in M\}$.
For $(u, v) \in M^2$, set $(u + S) + (v + S) := (u + v) + S$. For $(r, u) \in R \times M$, set $r(u + S) := ru + S$.

Proposition 1.5.2. *Quotient Operations Are Well-Defined*
Let $S \leq M$.

(i) For $(u, v) \in M^2$, $u + S = v + S \iff u - v \in S$. Consequently, congruence modulo S is an equivalence relation.
(ii) The operations of Definition 1.5.1 are well-defined and make M/S an R-module.
(iii) The additive identity is $0_{M/S} = S$. Quotient map $\pi : M \twoheadrightarrow M/S$, $\pi(u) := u + S$, is epimorphism with $\ker \pi = S$.

Proof.

(i) ($\Rightarrow$) Assume $u + S = v + S$. Then $u \in u + S = v + S$ by $0_M \in S$. Thus $(\exists\, s \in S)\, u = v + s$ by Definition 1.5.1, hence $u - v \in S$.

(i) ($\Leftarrow$) Assume $u - v \in S$ and fix $x \in u + S$. Choose $s \in S$ with $x = u + s$ by Definition 1.5.1.
$x = v + \big((u - v) + s\big) \in v + S$ by closure of S, so $u + S \subseteq v + S$. Fix $y \in v + S$, choose $t \in S$ with $y = v + t$ by Definition 1.5.1.
Then $y = u + \big((v - u) + t\big) \in u + S$ by $v - u = -(u - v) \in S$ and closure of S. Thus $v + S \subseteq u + S$ and $u + S = v + S$.
Congruence modulo S is an equivalence relation by this characterization and equality of cosets.
(ii) Assume $u + S = u' + S$ and $v + S = v' + S$. Then $u - u', v - v' \in S$ by (i). $(u + v) - (u' + v') = (u - u') + (v - v') \in S$.
For $r \in R$, $ru - ru' = r(u - u') \in S$. Hence $(u + v) + S = (u' + v') + S$ and $ru + S = ru' + S$ by (i).
Thus both operations are representative-independent.
Every module axiom holds on representatives by the corresponding axiom in M. Therefore M/S is an R-module.
(iii) The additive identity is $0_{M/S} = S$ by $0_M + S = S$.
For $(r, s, u, v) \in R^2 \times M^2$, $\pi(ru + sv) = (ru + sv) + S = r(u + S) + s(v + S) = r\pi(u) + s\pi(v)$.
Thus $\pi \in \mathrm{Hom}_R(M, M/S)$ by Definition 1.4.1(i). The map π is surjective by $M/S = \{u + S : u \in M\}$.
Hence π is an epimorphism by Definition 1.4.1(iv). Finally, $\ker \pi = \{u \in M : u + S = S\} = \{u \in M : u \in S\} = S$ by (i).

Structural Commentary: Coset equality controls representatives; module axioms descend from M.
Key Insight: Representatives agree exactly when their difference lies in S. □

Theorem 1.5.3. *Correspondence Theorem for Modules*
Let $S \leq M$ and let $\pi : M \twoheadrightarrow M/S$ be the quotient map. Set $\mathcal{A} := \{T \leq M : S \leq T\}$ and $\mathcal{B} := \{U : U \leq M/S\}$.
For $T \in \mathcal{A}$, define $\Phi(T) := T/S = \pi(T)$. For $U \in \mathcal{B}$, define $\Psi(U) := \pi^{-1}(U)$.

(i) $(\forall\, T \in \mathcal{A})\, \Phi(T) \in \mathcal{B}$ *and* $(\forall\, U \in \mathcal{B})\, \Psi(U) \in \mathcal{A}$.
(ii) $\Psi\Phi = \mathrm{id}_{\mathcal{A}}$ *and* $\Phi\Psi = \mathrm{id}_{\mathcal{B}}$.
(iii) Both Φ and Ψ preserve inclusion.

Consequently, $\Phi : \mathcal{A} \to \mathcal{B}$ is an order isomorphism with inverse Ψ.

Proof.

(i) Fix $T \in \mathcal{A}$; $0_{M/S} = S \in T/S$ by $S \leq T$. For $(r, s, t_1, t_2) \in R^2 \times T^2$, $r(t_1 + S) + s(t_2 + S) = (rt_1 + st_2) + S$ by Definition 1.5.1.
The coset $(rt_1 + st_2) + S$ lies in T/S by closure of T. Thus $\Phi(T) = T/S \leq M/S$ by Theorem 1.1.5. Fix $U \in \mathcal{B}$.
Then $0_M \in \pi^{-1}(U)$ by $\pi(0_M) = 0_{M/S} \in U$. Fix $(r, s, u, v) \in R^2 \times \pi^{-1}(U)^2$.
Then $\pi(ru + sv) = r\pi(u) + s\pi(v) \in U$ by Proposition 1.5.2(iii) and closure of U. Hence $\pi^{-1}(U) \leq M$ by Theorem 1.1.5.
$S = \ker \pi \subseteq \pi^{-1}(U)$ by Proposition 1.5.2(iii) and $0_{M/S} \in U$. Hence $\Psi(U) = \pi^{-1}(U) \in \mathcal{A}$ by the definition of $\mathcal{A}$.
(ii) Fix $T \in \mathcal{A}$. Then $(\forall\, t \in T)\, \pi(t) = t + S$ by Proposition 1.5.2(iii). Hence $T \subseteq \pi^{-1}(T/S)$ by the definition of T/S.
If $m \in \pi^{-1}(T/S)$, choose $t \in T$ with $m + S = t + S$ by the definition of T/S.
Then $m - t \in S \subseteq T$ by Proposition 1.5.2(i), so $m \in T$. Therefore $\Psi\Phi(T) = \pi^{-1}(T/S) = T$. Fix $U \in \mathcal{B}$.
Inclusion $\pi(\pi^{-1}(U)) \subseteq U$ holds by definition of preimage. If $x \in U$, choose $m \in M$ with $x = \pi(m)$ by Proposition 1.5.2(iii).
Then $m \in \pi^{-1}(U)$ and $x \in \pi(\pi^{-1}(U))$. Therefore $\Phi\Psi(U) = \pi(\pi^{-1}(U)) = U$.
(iii) If $T_1 \subseteq T_2$ in $\mathcal{A}$, then $\Phi(T_1) = \pi(T_1) \subseteq \pi(T_2) = \Phi(T_2)$. If $U_1 \subseteq U_2$ in $\mathcal{B}$, then $\Psi(U_1) = \pi^{-1}(U_1) \subseteq \pi^{-1}(U_2) = \Psi(U_2)$.
Thus both assignments preserve inclusion.

Thus $\Phi : \mathcal{A} \to \mathcal{B}$ is an order isomorphism with inverse Ψ by (ii)–(iii).
Structural Commentary: Closure constructs Φ, Ψ; lifting identifies inverses; set maps preserve order.
Key Insight: Preimages recover quotient images by surjectivity and kernel containment. □

Theorem 1.5.4. *Module Isomorphism Theorems*
The following canonical maps are R-module isomorphisms.

(i) Let N be R-module with additive identity 0_N, $\tau \in \mathrm{Hom}_R(M, N)$. For $m \in M$, $\overline{\tau}(m + \ker \tau) := \tau(m)$. Then $\overline{\tau} : M/\ker \tau \xrightarrow{\sim} \mathrm{im}\, \tau$.
(ii) For $S, T \leq M$ and $s \in S$, define $\theta\big(s + (S \cap T)\big) := s + T$. Then $\theta : S/(S \cap T) \xrightarrow{\sim} (S + T)/T$.
(iii) For $S \leq T \leq M$ and $m \in M$, define $\eta\big((m + S) + T/S\big) := m + T$. Then $\eta : (M/S)/(T/S) \xrightarrow{\sim} M/T$.

Proof.

(i) Assume $m + \ker \tau = m' + \ker \tau$. Then $m - m' \in \ker \tau$ by Proposition 1.5.2(i).
$\tau(m) - \tau(m') = \tau(m - m') = 0_N$ by Definition 1.4.1(i). Thus $\tau(m) = \tau(m')$ and $\overline{\tau}$ is well-defined.
Fix $(r, s, m, m') \in R^2 \times M^2$. Then $\overline{\tau}\big(r(m + \ker \tau) + s(m' + \ker \tau)\big) = \tau(rm + sm') = r\tau(m) + s\tau(m')$.
Therefore $\overline{\tau} \in \mathrm{Hom}_R(M/\ker \tau, \mathrm{im}\, \tau)$ by Definition 1.4.1(i). $\mathrm{im}\, \overline{\tau} = \mathrm{im}\, \tau$ by the definition of $\overline{\tau}$.
$\ker \overline{\tau} = \{m + \ker \tau : m \in \ker \tau\} = \{\ker \tau\} = \{0_{M/\ker \tau}\}$. Thus $\overline{\tau}$ is a monomorphism by Proposition 1.4.2(iv).
It is an epimorphism by $\mathrm{im}\, \overline{\tau} = \mathrm{im}\, \tau$ and Definition 1.4.1(iv). Hence $\overline{\tau}$ is an isomorphism by Definition 1.4.1(iv).
(ii) Assume $s + (S \cap T) = s' + (S \cap T)$. Then $s - s' \in S \cap T \subseteq T$ by Proposition 1.5.2(i).
Thus $s + T = s' + T$ by Proposition 1.5.2(i), so θ is well-defined. Fix $(r, q, s_1, s_2) \in R^2 \times S^2$.
Then $\theta\big(r(s_1 + (S \cap T)) + q(s_2 + (S \cap T))\big) = r(s_1 + T) + q(s_2 + T)$. Hence $\theta \in \mathrm{Hom}_R(S/(S \cap T), (S + T)/T)$ by Definition 1.4.1(i).
Fix $x \in (S + T)/T$, $y \in S + T$ with $x = y + T$ by Definition 1.5.1. Choose $(s, t) \in S \times T$ with $y = s + t$ by Proposition 1.1.6(ii).
Then $x = s + T = \theta\big(s + (S \cap T)\big)$, so θ is surjective. $\ker \theta = \{s + (S \cap T) : s \in S \cap T\} = \{S \cap T\}$ by Proposition 1.5.2(i).
Hence $\ker \theta = \{0_{S/(S \cap T)}\}$ by $0_{S/(S \cap T)} = S \cap T$. Thus θ is an isomorphism by Proposition 1.4.2(iv) and Definition 1.4.1(iv).
(iii) Assume $(m + S) + T/S = (m' + S) + T/S$. Then $(m - m') + S \in T/S$ by Proposition 1.5.2(i).
Choose $t \in T$ with $(m - m') + S = t + S$ by the definition of T/S. $m - m' - t \in S \subseteq T$ by Proposition 1.5.2(i), so $m - m' \in T$.
Thus $m + T = m' + T$ by Proposition 1.5.2(i), and η is well-defined. Fix $(r, s, m, m') \in R^2 \times M^2$.
Then $\eta\big(r((m + S) + T/S) + s((m' + S) + T/S)\big) = r(m + T) + s(m' + T)$; $\eta \in \mathrm{Hom}_R((M/S)/(T/S), M/T)$ by Definition 1.4.1(i).
η is surjective by $(\forall\, m \in M)\, \eta\big((m + S) + T/S\big) = m + T$. $\ker \eta = \{(m + S) + T/S : m \in T\} = \{T/S\}$ by Proposition 1.5.2(i).
Hence $\ker \eta = \{0_{(M/S)/(T/S)}\}$ by $0_{(M/S)/(T/S)} = T/S$. Thus η is isomorphism by Proposition 1.4.2(iv), Definition 1.4.1(iv).

Structural Commentary: Coset checks define maps; kernels and representatives certify bijectivity.
Key Insight: Each denominator is exactly the ambiguity annihilated by its canonical map. □

1.6 Torsion and Annihilators

Throughout this subsection, R is a nonzero commutative ring with identity 1_R and additive identity 0_R.
Fix an R-module M with additive identity 0_M.

Definition 1.6.1. *Torsion*

(i) An element $v \in M \setminus \{0_M\}$ is a *torsion element* if $(\exists\, r \in R \setminus \{0_R\})\, rv = 0_M$.
(ii) The module M is *torsion-free* if $(\forall\, (r, v) \in (R \setminus \{0_R\}) \times M)\, [rv = 0_M \Rightarrow v = 0_M]$.
(iii) The module M is a *torsion module* if $(\forall\, v \in M \setminus \{0_M\})(\exists\, r \in R \setminus \{0_R\})\, rv = 0_M$.
(iv) The *torsion set* of M is $M_{\text{tor}} := \{v \in M : (\exists\, r \in R \setminus \{0_R\})\, rv = 0_M\}$.

Example 1.6.2. *$\mathbb{Z}/n\mathbb{Z}$ as a Torsion Module*
Let $n \in \mathbb{N}$ with $n > 1$. Quotient $\mathbb{Z}/n\mathbb{Z}$ is $\mathbb{Z}$-module with $k\overline{a} := \overline{ka}$. $(\forall\, \overline{a} \in \mathbb{Z}/n\mathbb{Z})\, n\overline{a} = \overline{0}$; $\mathbb{Z}/n\mathbb{Z}$ is torsion module by Definition 1.6.1(iii). If $\overline{a} \neq \overline{0}$, then $n\overline{a} = \overline{0}$ with $n \neq 0_{\mathbb{Z}}$. Thus $\{\overline{a}\}$ is linearly dependent by Definition 1.3.1(i)–(ii).

Proposition 1.6.3. *Torsion Submodule over an Integral Domain*
Assume R is an integral domain.

(i) $M_{\text{tor}} \leq M$.
(ii) $(M/M_{\text{tor}})_{\text{tor}} = \{0_{M/M_{\text{tor}}}\} = \{M_{\text{tor}}\}$; *equivalently, M/M_{tor} is torsion-free.*

Proof.

(i) $0_M \in M_{\text{tor}}$ by $1_R 0_M = 0_M$ and Definition 1.6.1(iv). Fix $(r, s, x, y) \in R^2 \times M_{\text{tor}}^2$.
Choose $(a, b) \in (R \setminus \{0_R\})^2$ with $ax = by = 0_M$ by Definition 1.6.1(iv).
By Definition 3.5.1(ii), $ab \neq 0_R$. $ab(rx + sy) = rb(ax) + sa(by) = 0_M$.
Thus $rx + sy \in M_{\text{tor}}$ by Definition 1.6.1(iv). Hence $M_{\text{tor}} \leq M$ by Theorem 1.1.5.
(ii) Set $T := M_{\text{tor}}$ and fix $x \in (M/T)_{\text{tor}}$. Choose $m \in M$ with $x = m + T$ by Definition 1.5.1.
Choose $r \in R \setminus \{0_R\}$ with $rx = T$ by Definition 1.6.1(iv). Then $rm \in T$ by Proposition 1.5.2(i).
Choose $s \in R \setminus \{0_R\}$ with $srm = 0_M$ by Definition 1.6.1(iv). By Definition 3.5.1(ii), $sr \neq 0_R$.
Hence $m \in T$ by Definition 1.6.1(iv), so $x = T$ by Proposition 1.5.2(i).
Therefore $(M/T)_{\text{tor}} \subseteq \{0_{M/T}\}$. The reverse inclusion holds by Definition 1.6.1(iv).
Thus $(M/T)_{\text{tor}} = \{0_{M/T}\} = \{T\}$. Equivalently, M/T is torsion-free by Definition 1.6.1(ii).

Structural Commentary: Products of annihilators prove closure and eliminate quotient torsion.
Key Insight: Domain multiplication preserves nonzero annihilators. □

Definition 1.6.4. *Annihilators*

(i) For $v \in M$, the *annihilator* of v is $\text{Ann}_R(v) := \{r \in R : rv = 0_M\}$.
(ii) For $N \leq M$, the *annihilator* of N is $\text{Ann}_R(N) := \{r \in R : (\forall\, n \in N)\, rn = 0_M\}$.

Proposition 1.6.5. *Annihilator Properties*
Let $v \in M$ and $N \leq M$.

(i) $\text{Ann}_R(v) \trianglelefteq R$ *and* $\text{Ann}_R(N) \trianglelefteq R$.
(ii) v *is torsion* $\iff v \neq 0_M$ *and* $\text{Ann}_R(v) \neq \{0_R\}$.
(iii) If $A \leq B \leq M$, *then* $\text{Ann}_R(B) \subseteq \text{Ann}_R(A)$.

Proof.

(i) $0_R \in \text{Ann}_R(v)$ by $0_R v = 0_M$ and Definition 1.6.4(i). Fix $(r, s, a, b) \in R^2 \times \text{Ann}_R(v)^2$.
Then $(ra + sb)v = r(av) + s(bv) = 0_M$ by Definition 1.6.4(i). Thus $\text{Ann}_R(v) \leq {}_R R$ by Theorem 1.1.5.
Hence $\text{Ann}_R(v) \trianglelefteq R$ by Proposition 1.1.7. $(\forall\, n \in N)\, 0_R n = 0_M$, so $0_R \in \text{Ann}_R(N)$ by Definition 1.6.4(ii).
Fix $(r, s, a, b) \in R^2 \times \text{Ann}_R(N)^2$. $(\forall\, n \in N)\, [(ra + sb)n = r(an) + s(bn) = 0_M]$ by Definition 1.6.4(ii).
Thus $\text{Ann}_R(N) \leq {}_R R$ by Theorem 1.1.5. Hence $\text{Ann}_R(N) \trianglelefteq R$ by Proposition 1.1.7.
(ii) ($\Rightarrow$) Suppose v is torsion. Then $v \neq 0_M$, $(\exists\, r \in R \setminus \{0_R\})\, rv = 0_M$ by Definition 1.6.1(i); $\text{Ann}_R(v) \neq \{0_R\}$ by Definition 1.6.4(i).
(ii) ($\Leftarrow$) Suppose $v \neq 0_M$ and $\text{Ann}_R(v) \neq \{0_R\}$. Choose $r \in \text{Ann}_R(v) \setminus \{0_R\}$.
Then $rv = 0_M$ by Definition 1.6.4(i). Hence v is torsion by Definition 1.6.1(i).
(iii) Fix $A, B \leq M$ with $A \leq B$, and let $r \in \text{Ann}_R(B)$. Then $(\forall\, a \in A)\, ra = 0_M$ by $A \subseteq B$ and Definition 1.6.4(ii).
Hence $r \in \text{Ann}_R(A)$ by Definition 1.6.4(ii).

Structural Commentary: Closure establishes ideals; annihilators detect torsion and reverse containment.
Key Insight: Annihilation conditions strengthen as the tested subset grows. □

Proposition 1.6.6. *A Nonzero Annihilator from Torsion Generators over a Domain*
Assume R is an integral domain. Let $n \in \mathbb{N}$ and $M = \langle\!\langle u_1, \ldots, u_n \rangle\!\rangle_R$. If $(u_1, \ldots, u_n) \in M_{\text{tor}}^n$, then $\text{Ann}_R(M) \neq \{0_R\}$.

Proof. Choose $(a_1, \ldots, a_n) \in (R \setminus \{0_R\})^n$ with $(\forall\, i \in \{1, \ldots, n\})\, a_i u_i = 0_M$ by Definition 1.6.1(iv).
Set $a := \prod_{i=1}^{n} a_i$. By repeated application of Definition 3.5.1(ii), $a \neq 0_R$.
Fix $i \in \{1, \ldots, n\}$ and choose $b_i \in R$ with $a = b_i a_i$ by commutativity of R. Then $au_i = b_i(a_i u_i) = 0_M$.
Thus $(\forall\, i \in \{1, \ldots, n\})\, au_i = 0_M$. Fix $m \in M$. Choose $(r_1, \ldots, r_n) \in R^n$ with $m = \sum_{i=1}^{n} r_i u_i$ by Definition 1.2.1(i),(iii).
By commutativity of R, $am = \sum_{i=1}^{n} r_i(au_i) = 0_M$. Thus $a \in \text{Ann}_R(M) \setminus \{0_R\}$ by Definition 1.6.4(ii).

Structural Commentary: Generator annihilators multiply to a scalar killing all finite combinations.
Key Insight: Finite products stay nonzero because R is a domain. □

1.7 Direct Sums and Complements

Throughout this subsection, R denotes a nonzero commutative ring with identity 1_R.
The symbol M denotes an R-module with additive identity 0_M.

Definition 1.7.1. *Direct Sums and Direct Summands*

(i) For $m = (m_i)_{i \in I} \in \prod_{i \in I} M_i$, set $\text{supp}(m) := \{i \in I : m_i \neq 0_{M_i}\}$.
The *external direct sum* is $\bigoplus_{i \in I} M_i := \{m \in \prod_{i \in I} M_i : |\text{supp}(m)| < \infty\}$, with componentwise operations.

(ii) For a family $(S_i)_{i\in I}$ of submodules of M, define $\sum_{i\in I} S_i := \left\langle\left\langle \bigcup_{i\in I} S_i \right\rangle\right\rangle_R$.
Equivalently, $\sum_{i\in I} S_i = \{\sum_{i\in F} s_i : F \subseteq I,\ |F|<\infty,\ (s_i)_{i\in F} \in \prod_{i\in F} S_i\}$.
Here the empty sum is 0_M. The equivalence follows by absorbing coefficients into each submodule and collecting like indices.
Sum satisfies $\sum_{i\in I} S_i \le M$ by Proposition 1.2.2(i). It is *direct* if $(\forall\, k\in I)\, S_k \cap \sum_{i\in I\setminus\{k\}} S_i = \{0_M\}$.
If it is direct and equals M, write $M = \bigoplus_{i\in I} S_i$.

(iii) A submodule $S \le M$ is a *direct summand* if $(\exists\, T \le M)\, M = S \oplus T$. Such a T is a *complement* of S in M.

Proposition 1.7.2. *Direct Sum Characterizations*
For a family $(S_i)_{i\in I}$ of submodules of M, the following conditions are equivalent:

(i) $\sum_{i\in I} S_i$ *is direct.*

(ii) $(\forall\, F\subseteq I)\left[|F|<\infty \Rightarrow (\forall\,(x_i)_{i\in F}\in \prod_{i\in F} S_i)\left[\sum_{i\in F} x_i = 0_M \Rightarrow (\forall\, i\in F)\, x_i = 0_M\right]\right]$.

(iii) $(\forall\, x\in \sum_{i\in I} S_i)(\exists!\,(x_i)_{i\in I}\in \bigoplus_{i\in I} S_i)\, x = \sum_{i\in I} x_i$.

Proof.

(i) $\Rightarrow$ *(ii)* Assume (i). Fix $F\subseteq I$ with $|F|<\infty$ and $(x_i)_{i\in F}\in \prod_{i\in F} S_i$ with $\sum_{i\in F} x_i = 0_M$.
For $k\in F$, $x_k = -\sum_{i\in F\setminus\{k\}} x_i \in S_k \cap \sum_{i\in I\setminus\{k\}} S_i$. This intersection is $\{0_M\}$ by Definition 1.7.1(ii); hence $(\forall\, k\in F)\, x_k = 0_M$.

(ii) $\Rightarrow$ *(iii)* Fix $x\in \sum_{i\in I} S_i$. Choose $F\subseteq I$ with $|F|<\infty$ and $(x_i)_{i\in F}\in \prod_{i\in F} S_i$ with $x = \sum_{i\in F} x_i$ by Definition 1.7.1(ii).
Extend this family by 0_M. The resulting $(x_i)_{i\in I}$ lies in $\bigoplus_{i\in I} S_i$ by Definition 1.7.1(i), so a decomposition exists.
Suppose $(x_i)_{i\in I}, (y_i)_{i\in I}\in \bigoplus_{i\in I} S_i$ both sum to x, and set $H := \{i\in I : x_i\neq 0_M\}\cup\{i\in I : y_i\neq 0_M\}$.
Then $|H|<\infty$ by Definition 1.7.1(i), and $\sum_{i\in H}(x_i - y_i) = 0_M$.
Thus $(\forall\, i\in H)\, x_i = y_i$ by (ii), while $(\forall\, i\in I\setminus H)\, x_i = y_i = 0_M$ by the definition of H. Hence $(x_i)_{i\in I} = (y_i)_{i\in I}$.

(iii) $\Rightarrow$ *(i)* Fix $k\in I$ and $x\in S_k \cap \sum_{i\in I\setminus\{k\}} S_i$. Suppose $x\neq 0_M$.
Choose $F\subseteq I\setminus\{k\}$ with $|F|<\infty$ and $(y_i)_{i\in F}\in \prod_{i\in F} S_i$ with $x = \sum_{i\in F} y_i$ by Definition 1.7.1(ii).
Extend $(y_i)_{i\in F}$ by 0_M, and define $(z_i)_{i\in I}$ by $z_k = x$ and $(\forall\, i\in I\setminus\{k\})\, z_i = 0_M$.
These are distinct elements of $\bigoplus_{i\in I} S_i$ whose coordinates both sum to x, contrary to (iii).
Hence $x = 0_M$, so $(\forall\, k\in I)\, S_k \cap \sum_{i\in I\setminus\{k\}} S_i = \{0_M\}$.

Structural Commentary: Zero-sum rigidity turns the intersection criterion into coordinate uniqueness.
Key Insight: Decompositions are unique exactly when cross-summand cancellation is impossible. □

Counterexample 1.7.3. *Not Every Submodule Is Complemented*
The $\mathbb{Z}$-module $\mathbb{Z}$ refutes the assertion that every submodule of a module is complemented.
Each $S \le {}_{\mathbb{Z}}\mathbb{Z}$ is an ideal by Proposition 1.1.7. The zero submodule is $0\mathbb{Z}$.
Each nonzero S has a unique positive generator by Theorem 3.10.2(i),(ii). Hence $(\forall\, S\le {}_{\mathbb{Z}}\mathbb{Z})(\exists!\, n\in\mathbb{N}_0)\, S = n\mathbb{Z}$.
For $(m,n)\in\mathbb{N}^2$, $0\neq mn\in m\mathbb{Z}\cap n\mathbb{Z}$, so no two nonzero submodules form a direct sum.
Thus, for $k\in\mathbb{N}_0$, $k\mathbb{Z}$ is complemented only if $k\in\{0,1\}$; conversely, $\mathbb{Z} = \{0\}\oplus\mathbb{Z} = \mathbb{Z}\oplus\{0\}$.
Hence the complemented submodules of $\mathbb{Z}$ are exactly $\{0\}$ and $\mathbb{Z}$.

Theorem 1.7.4. *Complements and Quotients*
Let $S\le M$ and let $\pi : M \twoheadrightarrow M/S$ be the quotient map.

(i) If $T\le M$ and $M = S\oplus T$, then $\pi|_T : T \xrightarrow{\sim} M/S$, $t\mapsto t+S$.

(ii) If $T_1, T_2 \le M$ satisfy $M = S\oplus T_1 = S\oplus T_2$, then $T_1\cong T_2$.

Proof.

(i) Fix $T\le M$ and assume $M = S\oplus T$. Then $\pi|_T\in \mathrm{Hom}_R(T, M/S)$ by Proposition 1.5.2(iii).
The identity $\ker(\pi|_T) = T\cap S = \{0_M\}$ holds by Proposition 1.5.2(i) and Definition 1.7.1(ii).
Hence $\pi|_T$ is a monomorphism by Proposition 1.4.2(iv). Fix $m+S\in M/S$.
Choose $(s,t)\in S\times T$ with $m = s+t$ by $M = S+T$. Then $m+S = t+S = \pi|_T(t)$, so $\pi|_T$ is epimorphism by Definition 1.4.1(iv).
Therefore $\pi|_T$ is an isomorphism by Definition 1.4.1(iv).

(ii) Assume $M = S\oplus T_1 = S\oplus T_2$. Then $T_1\cong M/S\cong T_2$ by (i), and hence $T_1\cong T_2$.

Structural Commentary: Kernel and image tests transfer each complement to the common quotient model.
Key Insight: Its kernel on a complement is precisely the intersection with S. □

1.8 Retracts, One-Sided Inverses, and Split Maps

Throughout this subsection, R denotes a nonzero commutative ring with identity 1_R.
All modules are R-modules.

Theorem 1.8.1. *Direct Summands Extend Epimorphisms*
Let M, M_1 be R-modules, let $N\le M$, and let $\sigma\in\mathrm{Hom}_R(N, M_1)$ be an epimorphism.
Set $\mathcal{C}_N(M) := \{H\le M : M = N\oplus H\}$. Set $\mathcal{E}_\sigma := \{\tau\in\mathrm{Hom}_R(M,M_1) : \tau|_N = \sigma,\ \mathrm{im}\,\tau = M_1\}$.

(i) $(\forall\, H\in\mathcal{C}_N(M))(\exists!\,\overline{\sigma}_H\in\mathrm{Hom}_R(M,M_1))(\forall\,(n,h)\in N\times H)\,\overline{\sigma}_H(n+h) = \sigma(n)$.

(ii) $(\forall\, H\in\mathcal{C}_N(M))\,\overline{\sigma}_H\in\mathcal{E}_\sigma$.

(iii) $(\forall\, H \in \mathcal{C}_N(M))\ \ker \overline{\sigma}_H = \ker \sigma \oplus H$.
(iv) *If σ is an isomorphism, then $H \mapsto \overline{\sigma}_H$ is a bijection $\mathcal{C}_N(M) \to \mathcal{E}_\sigma$ with inverse $\tau \mapsto \ker \tau$.*

Proof.

(i) Fix $H \in \mathcal{C}_N(M)$. If $n + h = n' + h'$ for $(n, n', h, h') \in N^2 \times H^2$, then $(n - n') + (h - h') = 0_M$.
Hence $n = n'$ and $h = h'$ by Proposition 1.7.2(ii), so $\overline{\sigma}_H(n + h) := \sigma(n)$ is well-defined.
Fix $(r, s, n, n', h, h') \in R^2 \times N^2 \times H^2$. Then $\overline{\sigma}_H(r(n + h) + s(n' + h')) = \sigma(rn + sn') = r\sigma(n) + s\sigma(n')$.
Thus $\overline{\sigma}_H \in \mathrm{Hom}_R(M, M_1)$ by Definition 1.4.1(i). The extension is unique by the defining formula and Proposition 1.7.2(iii).
(ii) Fix $H \in \mathcal{C}_N(M)$. Then $\overline{\sigma}_H|_N = \sigma$ by the defining formula with $h = 0_M$.
The identity $\operatorname{im} \overline{\sigma}_H = \operatorname{im} \sigma = M_1$ holds by the same formula, so $\overline{\sigma}_H \in \mathcal{E}_\sigma$.
(iii) Fix $H \in \mathcal{C}_N(M)$. Then $\ker \overline{\sigma}_H = \{n + h : (n, h) \in N \times H,\ \sigma(n) = 0_{M_1}\} = \ker \sigma + H$.
Since $\ker \sigma \le N$ and $N \cap H = \{0_M\}$, $(\ker \sigma) \cap H = \{0_M\}$. Therefore $\ker \overline{\sigma}_H = \ker \sigma \oplus H$ by Definition 1.7.1(ii).
(iv) Suppose σ is an isomorphism. For $H \in \mathcal{C}_N(M)$, $\ker \overline{\sigma}_H = H$ by (iii) and $\ker \sigma = \{0_M\}$.
Conversely, fix $\tau \in \mathcal{E}_\sigma$. If $x \in N \cap \ker \tau$, then $0_{M_1} = \tau(x) = \sigma(x)$ and $x = 0_M$ by injectivity of σ.
For $m \in M$, set $n := \sigma^{-1}(\tau(m)) \in N$. Then $\tau(m - n) = 0_{M_1}$, so $m = n + (m - n) \in N + \ker \tau$.
Thus $\ker \tau \in \mathcal{C}_N(M)$ by Definition 1.7.1(ii). Starting with H recovers H by the first sentence.
Starting with τ, write $m = n + k$ with $(n, k) \in N \times \ker \tau$. Then $\tau(m) = \sigma(n) = \overline{\sigma}_{\ker \tau}(m)$, so $\overline{\sigma}_{\ker \tau} = \tau$.

Structural Commentary: Coordinates extend maps; kernels classify extensions when σ is invertible.
Key Insight: An isomorphic restriction makes the extension kernel recover its complement. □

Definition 1.8.2. *Retract*
Let $N \le M$.
(i) A *retraction* onto N is a map $\rho \in \mathrm{Hom}_R(M, N)$ such that $\rho|_N = \mathrm{id}_N$.
(ii) The submodule N is a *retract* of M if $(\exists\, \rho \in \mathrm{Hom}_R(M, N))\ \rho|_N = \mathrm{id}_N$.

Corollary 1.8.3. *Retracts Are Direct Summands*
For $N \le M$, N is a retract of $M \iff (\exists\, H \le M)\ M = N \oplus H$.

Proof.

(⇒) Choose $\rho \in \mathrm{Hom}_R(M, N)$ with $\rho|_N = \mathrm{id}_N$ by Definition 1.8.2(ii).
For $m \in M$, $\rho(m - \rho(m)) = \rho(m) - \rho(\rho(m)) = 0_N$ by $\rho(m) \in N$, $\rho|_N = \mathrm{id}_N$; $m = \rho(m) + (m - \rho(m)) \in N + \ker \rho$, so $M = N + \ker \rho$.
If $x \in N \cap \ker \rho$, then $x = \rho(x) = 0_N$; hence $N \cap \ker \rho = \{0_M\}$. Therefore $M = N \oplus \ker \rho$ by Definition 1.7.1(ii).
(⇐) Fix $H \le M$ with $M = N \oplus H$. Define $\rho : M \to N$ by $\rho(n + h) := n$. The map is well-defined by Proposition 1.7.2(ii).
For $(r, s, n, n', h, h') \in R^2 \times N^2 \times H^2$, $\rho(r(n + h) + s(n' + h')) = rn + sn' = r\rho(n + h) + s\rho(n' + h')$.
Thus $\rho \in \mathrm{Hom}_R(M, N)$ by Definition 1.4.1(i), and $\rho|_N = \mathrm{id}_N$. Hence N is a retract of M by Definition 1.8.2(ii).

Structural Commentary: Retraction kernels are complements; projections reverse the construction.
Key Insight: A retraction separates every element into image and kernel components. □

Definition 1.8.4. *One-Sided Inverses*
Let $\tau \in \mathrm{Hom}_R(A, B)$.
(i) A *left inverse* of τ is $\lambda \in \mathrm{Hom}_R(B, A)$ such that $\lambda\tau = \mathrm{id}_A$.
(ii) A *right inverse* of τ is $\rho \in \mathrm{Hom}_R(B, A)$ such that $\tau\rho = \mathrm{id}_B$.
(iii) A *two-sided inverse* of τ is $\upsilon \in \mathrm{Hom}_R(B, A)$ such that $\upsilon\tau = \mathrm{id}_A$ and $\tau\upsilon = \mathrm{id}_B$.

Theorem 1.8.5. *One-Sided Inverses and Complements*
Let $\sigma \in \mathrm{Hom}_R(M, M_1)$. For an R-module P and $S \le P$, set $\mathcal{C}_S(P) := \{H \le P : P = S \oplus H\}$.
Set $\mathcal{L}_\sigma := \{\lambda \in \mathrm{Hom}_R(M_1, M) : \lambda\sigma = \mathrm{id}_M\}$. Set $\mathcal{R}_\sigma := \{\rho \in \mathrm{Hom}_R(M_1, M) : \sigma\rho = \mathrm{id}_{M_1}\}$.
(i) If σ is injective, then $\lambda \mapsto \ker \lambda$ is a bijection $\mathcal{L}_\sigma \to \mathcal{C}_{\operatorname{im}\sigma}(M_1)$.
(ii) If σ is surjective, then $\rho \mapsto \operatorname{im} \rho$ is a bijection $\mathcal{R}_\sigma \to \mathcal{C}_{\ker\sigma}(M)$.

Proof.

(i) Assume σ is injective. Fix $H \in \mathcal{C}_{\operatorname{im}\sigma}(M_1)$. For $y \in M_1$, write $y = u + h$ with $(u, h) \in \operatorname{im}\sigma \times H$.
This pair is unique by Proposition 1.7.2(iii). Choose unique $m \in M$ with $u = \sigma(m)$ by $u \in \operatorname{im}\sigma$, injectivity of σ.
Define $\lambda_H(y) := m$. For $y = \sigma(m) + h$, $z = \sigma(m') + h'$, and $(r, s) \in R^2$, $\lambda_H(ry + sz) = rm + sm' = r\lambda_H(y) + s\lambda_H(z)$.
Thus $\lambda_H \in \mathrm{Hom}_R(M_1, M)$ by Definition 1.4.1(i). Identities $\lambda_H\sigma = \mathrm{id}_M$ and $\ker \lambda_H = H$ hold by defining formula, so $\lambda_H \in \mathcal{L}_\sigma$.
Conversely, fix $\lambda \in \mathcal{L}_\sigma$. If $y \in \operatorname{im}\sigma \cap \ker \lambda$, write $y = \sigma(m)$. Then $m = \lambda\sigma(m) = 0_M$, so $y = 0_{M_1}$.
For $y \in M_1$, $y = \sigma\lambda(y) + (y - \sigma\lambda(y))$ and $y - \sigma\lambda(y) \in \ker \lambda$. Hence $\ker \lambda \in \mathcal{C}_{\operatorname{im}\sigma}(M_1)$ by Definition 1.7.1(ii).
Start with H, recover H by $\ker \lambda_H = H$. Start with λ, recover λ by decomposition $y = \sigma\lambda(y) + (y - \sigma\lambda(y))$, injectivity of σ.
(ii) Assume σ is surjective. Fix $H \in \mathcal{C}_{\ker\sigma}(M)$ and set $\sigma_H := \sigma|_H : H \to M_1$.
The map σ_H is an R-homomorphism with $\ker \sigma_H = H \cap \ker \sigma = \{0_M\}$.
Fix $y \in M_1$. Choose $m \in M$ with $\sigma(m) = y$, and write $m = k + h$ with $(k, h) \in \ker\sigma \times H$.
Then $y = \sigma_H(h)$, so σ_H is an isomorphism by Proposition 1.4.2(iv) and Definition 1.4.1(iv).
For $y \in M_1$, define $\rho_H(y) := \sigma_H^{-1}(y) \in H \subseteq M$. For $(r, s, y, z) \in R^2 \times M_1^2$, $\sigma_H(r\rho_H(y) + s\rho_H(z)) = ry + sz = \sigma_H(\rho_H(ry + sz))$.
Hence $\rho_H(ry + sz) = r\rho_H(y) + s\rho_H(z)$ by injectivity of σ_H. Thus $\rho_H \in \mathrm{Hom}_R(M_1, M)$ by Definition 1.4.1(i).
The identities $\sigma\rho_H = \mathrm{id}_{M_1}$ and $\operatorname{im}\rho_H = H$ hold by construction, so $\rho_H \in \mathcal{R}_\sigma$.
Conversely, fix $\rho \in \mathcal{R}_\sigma$. The map ρ is injective by $\rho(y) = 0_M \Rightarrow y = \sigma\rho(y) = 0_{M_1}$.
If $x \in \operatorname{im}\rho \cap \ker\sigma$, write $x = \rho(y)$. Then $y = \sigma\rho(y) = \sigma(x) = 0_{M_1}$, so $x = 0_M$.
For $m \in M$, $m = (m - \rho\sigma(m)) + \rho\sigma(m)$ with $m - \rho\sigma(m) \in \ker\sigma$ and $\rho\sigma(m) \in \operatorname{im}\rho$. Thus $\operatorname{im}\rho \in \mathcal{C}_{\ker\sigma}(M)$ by Definition 1.7.1(ii).
Starting with H recovers H by $\operatorname{im}\rho_H = H$. Starting with ρ recovers ρ by $(\sigma|_{\operatorname{im}\rho})^{-1}(y) = \rho(y)$.

Structural Commentary: Coordinates construct inverses; decompositions recover their complements.
Key Insight: Left inverses split images; right inverses split kernels. □

2 Noetherian Modules and PID Structure Theorems

This section begins with the structure facts that make free modules and finite generation usable: rank, splitting maps onto free modules, Noetherian modules. It then develops the classification of finitely generated modules over a principal ideal domain. The guiding model is the abelian-group theorem over $\mathbb{Z}$ and, later, the polynomial-module classification behind rational canonical form.

2.1 Free Modules, Bases, and Universal Property

Throughout this subsection, R denotes a nonzero commutative ring with identity 1_R.
The symbol M denotes an R-module with additive identity 0_M.

Definition 2.1.1. *Free Module and Basis*

(i) A subset $\mathcal{B} \subseteq M$ is a *basis* of M if $\mathcal{B}$ is R-linearly independent and $\langle\langle \mathcal{B} \rangle\rangle_R = M$.
(ii) An R-module M is *free* if M has a basis.
(iii) If $\mathcal{B}$ is a basis of M, then M is *free on* $\mathcal{B}$.

The empty set is independent and generates $\{0_M\}$, so the zero module is free on $\emptyset$.

Theorem 2.1.2. *Basis Means Unique Finite Coordinates*
For $\mathcal{B} \subseteq M$, define $\Sigma_{\mathcal{B}} : \bigoplus_{b\in\mathcal{B}} R \to M$ by $\Sigma_{\mathcal{B}}((r_b)_{b\in\mathcal{B}}) := \sum_{b\in\mathcal{B}} r_b b$. Then $\mathcal{B}$ is a basis of M if and only if $\Sigma_{\mathcal{B}}$ is bijective.

Proof. The sum defining $\Sigma_{\mathcal{B}}$ is finite by membership in $\bigoplus_{b\in\mathcal{B}} R$, so $\Sigma_{\mathcal{B}}$ is well-defined.

($\Rightarrow$) Assume $\mathcal{B}$ is a basis. Then $\Sigma_{\mathcal{B}}$ is surjective by $\langle\langle \mathcal{B} \rangle\rangle_R = M$.
Fix $r = (r_b)_{b\in\mathcal{B}}$, $s = (s_b)_{b\in\mathcal{B}}$ with $\Sigma_{\mathcal{B}}(r) = \Sigma_{\mathcal{B}}(s)$, set $H := \operatorname{supp}(r) \cup \operatorname{supp}(s)$. Then $|H| < \infty$ and $\sum_{b\in H} (r_b - s_b)b = 0_M$.
Thus $(\forall\, b \in H)\, r_b = s_b$ by the R-linear independence of $\mathcal{B}$. Both families vanish on $\mathcal{B} \setminus H$, so $r = s$ and $\Sigma_{\mathcal{B}}$ is injective.
($\Leftarrow$) Assume $\Sigma_{\mathcal{B}}$ is bijective. Then $M = \operatorname{im} \Sigma_{\mathcal{B}} = \langle\langle \mathcal{B} \rangle\rangle_R$ by surjectivity and Definition 1.2.1(i), so $\mathcal{B}$ spans M.
Fix finite $F \subseteq \mathcal{B}$ and $(r_b)_{b\in F} \in R^F$ with $\sum_{b\in F} r_b b = 0_M$, and extend this family by 0_R to $\bar{r} \in \bigoplus_{b\in\mathcal{B}} R$.
Then $\Sigma_{\mathcal{B}}(\bar{r}) = 0_M = \Sigma_{\mathcal{B}}(0)$, so $\bar{r} = 0$ by injectivity. Thus $(\forall\, b \in F)\, r_b = 0_R$, so $\mathcal{B}$ is R-linearly independent by Definition 1.3.1(i).
Therefore $\mathcal{B}$ is a basis by Definition 2.1.1(i).

Structural Commentary: Surjectivity encodes spanning, while injectivity encodes rigidity of finite relations.
Key Insight: Coordinate families are the fibers of the summation map. □

Proposition 2.1.3. *Bases Are Minimal Spanning and Maximal Independent*
If $\mathcal{B}$ is a basis of M, then:
(i) $(\forall b \in \mathcal{B})\ \langle\langle \mathcal{B} \setminus \{b\} \rangle\rangle_R \neq M$;
(ii) $(\forall v \in M \setminus \mathcal{B})\ \mathcal{B} \cup \{v\}$ *is R-linearly dependent.*

Proof.

(i) Fix $b \in \mathcal{B}$ and suppose $b \in \langle\langle \mathcal{B} \setminus \{b\} \rangle\rangle_R$.
Then b has a coordinate family vanishing at b, whereas the singleton family with coefficient 1_R at b represents b.
These distinct families both map to b under $\Sigma_{\mathcal{B}}$, contrary to injectivity by Theorem 2.1.2. Hence $b \notin \langle\langle \mathcal{B} \setminus \{b\} \rangle\rangle_R$.
(ii) Fix $v \in M \setminus \mathcal{B}$. There is $r = (r_b)_{b\in\mathcal{B}} \in \bigoplus_{b\in\mathcal{B}} R$ with $\Sigma_{\mathcal{B}}(r) = v$ by Theorem 2.1.2.
Thus $1_R v - \sum_{b\in\mathcal{B}} r_b b = 0_M$ is a finite relation in $\mathcal{B} \cup \{v\}$ with nonzero coefficient 1_R at v.
Hence $\mathcal{B} \cup \{v\}$ is R-linearly dependent by Definition 1.3.1(ii).

Structural Commentary: Coordinate uniqueness obstructs deletion; coordinate existence creates dependence after enlargement.
Key Insight: Removing or adjoining one element destroys one basis condition. □

Theorem 2.1.4. *Maps Out of a Free Module*
Let M be free on $\mathcal{B}$, let N be an R-module, and let $f : \mathcal{B} \to N$. Then:
(i) $(\exists\, \widetilde{f} \in \operatorname{Hom}_R(M, N))\ \widetilde{f}|_{\mathcal{B}} = f$.
(ii) If $\phi, \psi \in \operatorname{Hom}_R(M, N)$ satisfy $\phi|_{\mathcal{B}} = \psi|_{\mathcal{B}} = f$, then $\phi = \psi$.

Proof.

(i) For $r = (r_b)_{b\in\mathcal{B}} \in \bigoplus_{b\in\mathcal{B}} R$, define $\widetilde{f}(\Sigma_{\mathcal{B}}(r)) := \sum_{b\in\mathcal{B}} r_b f(b)$.
This defines $\widetilde{f} : M \to N$ by the bijectivity in Theorem 2.1.2 and the finite support of r.
For $r, s \in \bigoplus_{b\in\mathcal{B}} R$ and $a, c \in R$, $\Sigma_{\mathcal{B}}(ar + cs) = a\Sigma_{\mathcal{B}}(r) + c\Sigma_{\mathcal{B}}(s)$ by the module laws.
Thus $\widetilde{f}(a\Sigma_{\mathcal{B}}(r) + c\Sigma_{\mathcal{B}}(s)) = a\widetilde{f}(\Sigma_{\mathcal{B}}(r)) + c\widetilde{f}(\Sigma_{\mathcal{B}}(s))$, so $\widetilde{f} \in \operatorname{Hom}_R(M, N)$.
The singleton coordinate families satisfy $(\forall\, b \in \mathcal{B})\ \widetilde{f}(b) = f(b)$, so $\widetilde{f}|_{\mathcal{B}} = f$.
(ii) Let $\phi, \psi \in \operatorname{Hom}_R(M, N)$ satisfy $\phi|_{\mathcal{B}} = \psi|_{\mathcal{B}} = f$. For $r = (r_b)_{b\in\mathcal{B}}$, $\phi(\Sigma_{\mathcal{B}}(r)) = \sum_{b\in\mathcal{B}} r_b f(b) = \psi(\Sigma_{\mathcal{B}}(r))$ by R-linearity.
Thus $\phi = \psi$ by the surjectivity of $\Sigma_{\mathcal{B}}$ and Assumption 3.1.2.

Structural Commentary: Coordinate evaluation constructs the extension; summation-map surjectivity globalizes basis agreement.
Key Insight: Agreement on a basis propagates through finite coordinate sums. □

Counterexample 2.1.5. *A Free Module with a Nonfree Submodule*
A submodule of a free module need not be free. Let $R = \mathbb{Z} \times \mathbb{Z}$ with componentwise operations, so $1_R = (1, 1)$ and $0_R = (0, 0)$.
Regular module R is free on $\{(1, 1)\}$ as $(\forall\, x \in R)(\exists!\, r \in R)\, x = r(1, 1)$. Set $N := \mathbb{Z} \times \{0\}$.
Then $N \trianglelefteq R$, so $N \leq {}_R R$ by Proposition 1.1.7. The nonzero scalar $(0, 1)$ satisfies $(\forall\, v \in N)\, (0, 1)v = 0_R$.
For $\emptyset \neq S \subseteq N$, fix $v \in S$; then $(0, 1)v = 0_R$ is a relation with nonzero coefficient.
Thus S is dependent by Definition 1.3.1(ii). The set $\emptyset$ does not span N because $(1, 0) \in N \setminus \{0_R\}$.
Hence N has no basis and is not free. Therefore $\emptyset$ is maximal independent but not spanning.

Counterexample 2.1.6. *A Quotient of a Free Module Need Not Be Free*
A quotient of a free module by a free submodule need not be free. Fix $n \in \mathbb{N}$ with $n > 1$.
As a $\mathbb{Z}$-module, $\mathbb{Z}$ is free on $\{1\}$, and $n\mathbb{Z}$ is free on $\{n\}$.
Set $Q := \mathbb{Z}/n\mathbb{Z}$ and $\overline{1} := 1 + n\mathbb{Z}$. Then $Q = \langle\!\langle \overline{1} \rangle\!\rangle_{\mathbb{Z}} \neq \{0_Q\}$, so $\{\overline{1}\}$ minimally spans Q.
However, $(\forall\, q \in Q)\, nq = 0_Q$ with $n \neq 0_{\mathbb{Z}}$. Thus each $\emptyset \neq S \subseteq Q$ is linearly dependent by Definition 1.3.1(ii).
Hence Q has no basis and is not free; the minimally spanning set $\{\overline{1}\}$ is therefore not a basis.

Principle 2.1.7. *Modules Are Not Just Vector Spaces with New Letters*
For a general ring R, the following vector-space implications fail:

(i) $N \leq M \nRightarrow (\exists\, H \leq M)\ M = N \oplus H$.
(ii) M finitely generated and $N \leq M \nRightarrow N$ finitely generated.
(iii) $M \neq \{0_M\} \nRightarrow (\exists\, \emptyset \neq S \subseteq M)\ S$ is linearly independent.
(iv) S minimally spans $M \nRightarrow S$ is a basis.
(v) S is maximal linearly independent in $M \nRightarrow S$ is a basis.
(vi) M free and $N \leq M \nRightarrow N$ free.
(vii) F free and $S \leq F \nRightarrow F/S$ free.

Counterexamples 1.7.3 and 1.2.4 witness (i) and (ii). Counterexample 2.1.5 witnesses (iii), (v), and (vi).
Counterexample 2.1.6 witnesses (iv) and (vii). Over a field, these obstructions vanish; algebraically, $R \setminus \{0_R\} \subseteq R^{\times}$.

2.2 Rank and Coordinate Models of Free Modules

Throughout this subsection, assume Principles 6.1.3 and 6.1.2.

Perspective 2.2.1. *Dimension as the Field Case of Rank*
An $\mathbb{F}$-vector space is a free $\mathbb{F}$-module by Theorem 1.3.17(ii) and Definition 2.1.1.
Finite basis cardinality is invariant by Theorem 1.4.1. Arbitrary Hamel-basis cardinality is invariant by Theorem 1.4.5.
Over general scalar rings, rank invariance requires additional hypotheses.

Theorem 2.2.2. *Rank Is Well Defined for Free Modules*
Let A be a nonzero commutative ring with identity 1_A, and let M be a free A-module.

(i) If B, B' are A-bases of M, then $|B| = |B'|$.
(ii) If B is an A-basis of M and $S \subseteq M$ satisfies $\langle\!\langle S \rangle\!\rangle_A = M$, then $|B| \leq |S|$.

Proof. Choose a maximal ideal $\mathfrak{m} \trianglelefteq A$ by Theorem 3.4.5. Set $\mathfrak{m}M := \langle\!\langle \{ax : (a, x) \in \mathfrak{m} \times M\} \rangle\!\rangle_A$, $K := A/\mathfrak{m}$, and $V := M/\mathfrak{m}M$.
The ring K is a field by Theorem 3.4.4. If $a - a' \in \mathfrak{m}$ and $x - x' \in \mathfrak{m}M$, then $ax - a'x' = (a - a')x + a'(x - x') \in \mathfrak{m}M$.
Hence $(a + \mathfrak{m})(x + \mathfrak{m}M) := ax + \mathfrak{m}M$ is well-defined, and the inherited module identities make V a K-vector space.
Fix an A-basis B of M, set $X_B := \{ \sum_{b \in B} i_b b : (i_b)_{b \in B} \in \bigoplus_{b \in B} \mathfrak{m} \}$. Inclusion $X_B \leq_A M$ holds by coefficientwise ideal closure.
If $i \in \mathfrak{m}$ and $x = \sum_{b \in B} r_b b$, then $ix = \sum_{b \in B} (ir_b)b \in X_B$. Thus $\mathfrak{m}M \subseteq X_B$ by Proposition 1.2.2(iii).
Conversely, $X_B \subseteq \mathfrak{m}M$ by Definition 1.2.1(i), so $\mathfrak{m}M = X_B$. Write $\overline{x} := x + \mathfrak{m}M$ for $x \in M$ and set $\overline{B} := \{\overline{b} : b \in B\}$.
The set $\overline{B}$ spans V by spanning of B. Let $F \subseteq B$ be finite and $(a_b)_{b \in F} \in A^F$ satisfy $\sum_{b \in F} (a_b + \mathfrak{m})\overline{b} = 0_V$.
Then $\sum_{b \in F} a_b b \in \mathfrak{m}M = X_B$. Consequently, $(\forall b \in F)\ a_b \in \mathfrak{m}$ by coordinate uniqueness in Theorem 2.1.2.
Thus $\overline{B}$ is K-linearly independent by Definition 1.3.1. If $\overline{b} = \overline{b'}$ for distinct $b, b' \in B$, then $b - b' \in X_B$.
The same coordinate uniqueness forces $1_A \in \mathfrak{m}$, contrary to $\mathfrak{m} \neq A$.
The map $b \mapsto \overline{b}$ is a bijection $B \to \overline{B}$ by the preceding injectivity and the definition of $\overline{B}$.
Hence $\overline{B}$ is a K-basis of V by spanning and independence.
Because B was arbitrary, the construction applies to every A-basis of M.

(i) If B, B' are A-bases of M, then $\overline{B}, \overline{B'}$ are K-bases of V. Thus $\left|\overline{B}\right| = \left|\overline{B'}\right|$ by Theorem 1.4.5.
$|B| = \left|\overline{B}\right| = \left|\overline{B'}\right| = |B'|$ by bijections above.

(ii) Fix an A-basis B of M and $S \subseteq M$ with $\langle\!\langle S \rangle\!\rangle_A = M$. Then $\overline{S} := \{\overline{s} : s \in S\}$ spans V by spanning of S.
Choose a K-basis $C \subseteq \overline{S}$ by Theorem 1.3.17(iv). Since $\overline{B}, C$ are K-bases, $\left|\overline{B}\right| = |C|$ by Theorem 1.4.5; $|B| = \left|\overline{B}\right| = |C| \leq \left|\overline{S}\right| \leq |S|$.

Structural Commentary: Reduction modulo $\mathfrak{m}$ transfers each A-basis to an equipotent K-basis for vector-space comparison.
Key Insight: Basis coordinates detect exactly which cosets vanish modulo $\mathfrak{m}$. □

Definition 2.2.3. *Rank of a Free Module*
Let A be a nonzero commutative ring with identity, let M be a free A-module, and fix an A-basis B of M.
Define the *rank* of M by $\mathrm{rk}_A(M) := |B|$. This value is independent of B by Theorem 2.2.2(i).
The empty basis of the zero module satisfies $\mathrm{rk}_A(\{0_M\}) = 0$.

Counterexample 2.2.4. *Why Commutativity Matters for Rank*
Commutativity cannot be omitted from Theorem 2.2.2. Here *basis* and *free* mean the left-module analogues of Definition 2.1.1.
Let $\mathbb{F}$ be a field, let $V = \bigoplus_{k \in \mathbb{N}_0} \mathbb{F}e_k$, and set $E := \mathcal{L}(V)$ with multiplication given by composition.
Define $p, u \in E$ by $p(e_0) = e_0$, $(\forall k \in \mathbb{N})\ p(e_k) = 0_V$, and $(\forall k \in \mathbb{N}_0)\ u(e_k) = e_{k+1}$. These operators exist uniquely by Theorem 2.1.4.
Ring E has identity id_V, $\mathrm{id}_V(e_0) = e_0 \neq 0_V$, so $\mathrm{id}_V \neq 0_E$. Since $(pu)(e_0) = 0_V \neq e_1 = (up)(e_0)$, ring E is noncommutative.
The left regular E-module E is free on $\{\mathrm{id}_V\}$ because $(\forall h \in E)(\exists! \alpha \in E)\ h = \alpha\, \mathrm{id}_V$.
Fix $n \in \mathbb{N}$ and define $\beta_0, \ldots, \beta_{n-1} \in E$ on the basis by $(\forall (k, s) \in \mathbb{N}_0 \times \{0, \ldots, n-1\})\ \beta_s(e_{kn+s}) = e_k$.
On the complementary residue classes, $(\forall (k, s, t) \in \mathbb{N}_0 \times \{0, \ldots, n-1\}^2)\, [s \neq t \Rightarrow \beta_s(e_{kn+t}) = 0_V]$.
These operators exist uniquely by Theorem 2.1.4, since Euclidean division indexes each basis vector exactly once.
If $(\alpha_s)_{s=0}^{n-1} \in E^n$ and $\sum_{s=0}^{n-1} \alpha_s \beta_s = 0_E$, then $(\forall (k, t) \in \mathbb{N}_0 \times \{0, \ldots, n-1\})\ \alpha_t(e_k) = 0_V$.
Hence $(\forall t \in \{0, \ldots, n-1\})\ \alpha_t = 0_E$ by uniqueness in Theorem 2.1.4. Thus $\{\beta_0, \ldots, \beta_{n-1}\}$ is E-linearly independent.
Fix $h \in E$ and define $\alpha_0, \ldots, \alpha_{n-1} \in E$ by $(\forall (k, s) \in \mathbb{N}_0 \times \{0, \ldots, n-1\})\ \alpha_s(e_k) := h(e_{kn+s})$.

These operators exist uniquely by Theorem 2.1.4. Then $(\forall (k,t) \in \mathbb{N}_0 \times \{0,\dots,n-1\})\ (\sum_{s=0}^{n-1} \alpha_s\beta_s)(e_{kn+t}) = h(e_{kn+t})$.
Hence $h = \sum_{s=0}^{n-1} \alpha_s\beta_s$ by the same uniqueness. Thus $\{\beta_0,\dots,\beta_{n-1}\}$ is an E-basis of E.
If $s,t \in \{0,\dots,n-1\}$ and $s \neq t$, then $\beta_s(e_s) = e_0 \neq 0_V = \beta_t(e_s)$. Therefore $|\{\beta_0,\dots,\beta_{n-1}\}| = n$.
Since $n \in \mathbb{N}$ was arbitrary, ${}_EE$ has bases of every positive finite cardinality. Thus rank invariance fails without commutativity.

Theorem 2.2.5. *Finite-Support Coordinate Modules*
Let A be a nonzero commutative ring with identity, let B be a set, and equip A^B with pointwise operations. Using Definition 3.1.4, set $A^{(B)} := \{f \in A^B : |\mathrm{supp}(f)| < \infty\}$. For $b \in B$, define $\delta_b \in A^{(B)}$ by $\delta_b(b) = 1_A$, $(\forall x \in B \setminus \{b\})\ \delta_b(x) = 0_A$.

(i) $A^{(B)} \leq_A A^B$.
(ii) The set $\{\delta_b : b \in B\}$ is an A-basis of $A^{(B)}$; equivalently, $A^{(B)} = \bigoplus_{b\in B} A\delta_b$.
(iii) $\mathrm{rk}_A(A^{(B)}) = |B|$.

Proof.

(i) The module identities in A^B hold pointwise, and equality is by Assumption 3.1.2. The zero function has empty support. $(\forall (a,c,f,g) \in A^2 \times (A^{(B)})^2)\ \mathrm{supp}(af+cg) \subseteq \mathrm{supp}(f) \cup \mathrm{supp}(g)$. Thus $A^{(B)} \leq_A A^B$ by Theorem 1.1.5.

(ii) $(\forall b \in B)\ \mathrm{supp}(\delta_b) = \{b\}$, so $\{\delta_b : b \in B\} \subseteq A^{(B)}$. The identity $f = \sum_{b\in\mathrm{supp}(f)} f(b)\delta_b$ holds for $f \in A^{(B)}$ by Assumption 3.1.2.
Hence the δ_b span $A^{(B)}$. Let $F \subseteq B$ be finite and $(a_b)_{b\in F} \in A^F$ satisfy $\sum_{b\in F} a_b\delta_b = 0_{A^{(B)}}$.
Then $(\forall x \in F)\ a_x = 0_A$ by evaluation at x. Hence $\{\delta_b : b \in B\}$ is independent by Definition 1.3.1.
If $x_b \in A\delta_b$ for $b \in F$ and $\sum_{b\in F} x_b = 0_{A^{(B)}}$, write $x_b = a_b\delta_b$. Then $(\forall b \in F)\ x_b = 0_{A^{(B)}}$ by independence of $\{\delta_b : b \in B\}$.
Therefore $\sum_{b\in B} A\delta_b$ is direct by Proposition 1.7.2(ii). $A^{(B)} = \bigoplus_{b\in B} A\delta_b$ by the spanning established above.

(iii) The map $b \mapsto \delta_b$ is surjective onto $\{\delta_b : b \in B\}$ by definition. If $b \neq b'$, then $\delta_b(b) = 1_A \neq 0_A = \delta_{b'}(b)$, so the map is injective.
Thus $\mathrm{rk}_A(A^{(B)}) = |B|$ by Definition 2.2.3.

Structural Commentary: Support closure defines the submodule; delta evaluation proves independence, directness, and cardinality.
Key Insight: A delta coefficient equals the function value at its index. □

Proposition 2.2.6. *Free Modules Are Coordinate Modules*
Let A be a nonzero commutative ring with identity.

(i) If M is a free A-module with A-basis B, then $b \mapsto \delta_b$ extends to an isomorphism $\Phi_B : M \xrightarrow{\sim} A^{(B)}$.
(ii) If M, N are free A-modules, then $M \cong N \iff \mathrm{rk}_A(M) = \mathrm{rk}_A(N)$.

Proof.

(i) Assignment $b \mapsto \delta_b$ extends uniquely to $\Phi_B \in \mathrm{Hom}_A(M, A^{(B)})$ by Theorem 2.1.4. Set $\{\delta_b : b \in B\}$ is basis by Theorem 2.2.5(ii).
Thus $\delta_b \mapsto b$ extends uniquely to $\Psi_B \in \mathrm{Hom}_A(A^{(B)}, M)$ by Theorem 2.1.4.
The composites $\Psi_B\Phi_B$ and $\Phi_B\Psi_B$ restrict to the identity on their respective bases.
Therefore they equal identity maps by uniqueness in Theorem 2.1.4. Hence Φ_B is isomorphism with inverse Ψ_B.

(ii) $(\Rightarrow)$ Let $\psi : M \xrightarrow{\sim} N$ and fix an A-basis C of M. The set $\psi(C)$ spans N by surjectivity.
If $F \subseteq C$ is finite and $(a_c)_{c\in F} \in A^F$ satisfies $\sum_{c\in F} a_c\psi(c) = 0_N$, then $\sum_{c\in F} a_c c = 0_M$ by injectivity.
Thus $(\forall c \in F)\ a_c = 0_A$ by independence of C. Set $\psi(C)$ is A-basis of N by preceding spanning, independence.
Since $\psi|_C : C \to \psi(C)$ is a bijection, $\mathrm{rk}_A(M) = |C| = |\psi(C)| = \mathrm{rk}_A(N)$.

(ii) $(\Leftarrow)$ Assume $\mathrm{rk}_A(M) = \mathrm{rk}_A(N)$ and fix A-bases C, D. Then $|C| = |D|$ by Definition 2.2.3; choose bijection $u : C \to D$.
The maps u, u^{-1} extend to homomorphisms $\Phi : M \to N$ and $\Psi : N \to M$ by Theorem 2.1.4.
Their composites restrict to the identity on C, D, respectively.
Hence $\Psi\Phi = \mathrm{id}_M$ and $\Phi\Psi = \mathrm{id}_N$ by uniqueness in Theorem 2.1.4, so Φ is an isomorphism.

Structural Commentary: Basis-map extension constructs coordinate isomorphisms, while basis transport proves rank invariance.
Key Insight: A basis bijection extends to mutually inverse module maps. □

Theorem 2.2.7. *Independent Sets Are Bounded by Rank over a Domain*
Let A be integral domain with field of quotients Q, M be free A-module. If $S \subseteq M$ is A-linearly independent, then $|S| \leq \mathrm{rk}_A(M)$.

Proof. Fix an A-basis B of M and identify $M \cong A^{(B)}$ by Proposition 2.2.6(i).
The coordinate isomorphism preserves finite relations, so S remains A-linearly independent.
Identify A with its image in Q by Proposition 3.5.4; then $A^{(B)} \subseteq Q^{(B)}$. Fix $n \in \mathbb{N}$ and distinct $s_1,\dots,s_n \in S$.
Let $(q_1,\dots,q_n) \in Q^n$ satisfy $\sum_{i=1}^{n} q_i s_i = 0_{Q^{(B)}}$. For $i \in \{1,\dots,n\}$, choose $(c_i,e_i) \in A \times (A \setminus \{0_A\})$ with $q_i = \frac{c_i}{e_i}$ by Definition 3.5.3.
Set $d := \prod_{i=1}^{n} e_i$. Then $d \neq 0_A$ by integral-domain hypothesis, $(\forall i \in \{1,\dots,n\})\ dq_i \in A$.
Relation $\sum_{i=1}^{n} (dq_i)s_i = 0_{Q^{(B)}}$ holds by multiplication by d. Both sides lie in $A^{(B)}$, so the same equality holds in $A^{(B)}$.
Thus $(\forall i \in \{1,\dots,n\})\ dq_i = 0_A$ by A-linear independence. Since $d \neq 0_Q$, $(\forall i \in \{1,\dots,n\})\ q_i = 0_Q$.
Hence S is Q-linearly independent in $Q^{(B)}$ by Definition 1.3.1. Choose Q-basis C of $Q^{(B)}$ with $S \subseteq C$ by Theorem 1.3.17(iii).
Set $\{\delta_b : b \in B\}$ is Q-basis by Theorem 2.2.5(ii); $|C| = |B|$ by Theorem 1.4.5; $|S| \leq |C| = |B| = \mathrm{rk}_A(M)$ by $S \subseteq C$, Definition 2.2.3.
Structural Commentary: Coordinate embedding and denominator clearing preserve independence before vector-space basis comparison.
Key Insight: One common denominator converts each finite Q-relation into an A-relation. □

2.3 Free Quotients and Splittings

Theorem 2.3.1. *Free Quotients Split*
Assume the Choice Principle 6.1.2. Let A be a nonzero commutative ring with identity, and M, F be A-modules.

(i) If $\sigma : M \twoheadrightarrow F$ and F is free, then $(\exists\, \tau \in \mathrm{Hom}_A(F, M))[\sigma\tau = \mathrm{id}_F \wedge M = \ker\sigma \oplus \mathrm{im}\,\tau \wedge \mathrm{im}\,\tau \cong F]$.
(ii) If $S \leq M$ and M/S is free, then $(\exists\, T \leq M)[M = S \oplus T \wedge T \cong M/S]$ and $M \cong S \oplus M/S$.
(iii) If $S \leq M$ and $M, S, M/S$ are free, then $\mathrm{rk}_A(M) = \mathrm{rk}_A(S) + \mathrm{rk}_A(M/S)$, where $+$ denotes cardinal addition. If $\mathrm{rk}_A(M) \in \mathbb{N}_0$, then $\mathrm{rk}_A(M/S) = \mathrm{rk}_A(M) - \mathrm{rk}_A(S)$.

Proof.
(i) Fix A-basis B of F. Relation $(\forall b \in B)\, \sigma^{-1}(\{b\}) \neq \emptyset$ holds by surjectivity. Fix $(m_b)_{b\in B} \in \prod_{b\in B} \sigma^{-1}(\{b\})$ by Choice Principle.
The assignment $b \mapsto m_b$ extends uniquely to $\tau \in \mathrm{Hom}_A(F, M)$ by Theorem 2.1.4.
The equality $\sigma\tau = \mathrm{id}_F$ holds by $(\forall b \in B)\, \sigma\tau(b) = \sigma(m_b) = b$ and uniqueness in Theorem 2.1.4.
Decomposition $M = \ker\sigma \oplus \mathrm{im}\,\tau$ holds by Theorem 1.8.5(ii). Map τ is injective by $(\forall x \in F)[\tau(x) = 0_M \Rightarrow x = \sigma\tau(x) = 0_F]$.
Its corestriction $F \to \mathrm{im}\,\tau$ is an isomorphism by linearity and bijectivity.
(ii) Let $\pi : M \twoheadrightarrow M/S$ be the quotient map; $\ker\pi = S$ by Proposition 1.5.2(iii).
Fix a section $\tau \in \mathrm{Hom}_A(M/S, M)$ of π by (i), and set $T := \mathrm{im}\,\tau$. Relations $M = S \oplus T$, $T \cong M/S$ hold by (i) and $\ker\pi = S$.
Define $\Phi : S \oplus M/S \to M$ by $\Phi(s, q) := s + \tau(q)$. Map Φ is A-linear by linearity of τ, surjective by $M = S \oplus T$.
Identity $\ker\Phi = \{(0_M, 0_{M/S})\}$ holds by $S \cap T = \{0_M\}$, injectivity of τ. Map Φ injective by Proposition 1.4.2(iv), kernel identity.
It is an isomorphism by injectivity, surjectivity, and Definition 1.4.1(iv)(c). Relation $M \cong S \oplus M/S$ holds by $\Phi^{-1} : M \xrightarrow{\sim} S \oplus M/S$.
(iii) Fix $T \leq M$ with $M = S \oplus T$ and $\theta : T \xrightarrow{\sim} M/S$ by (ii). Fix A-bases B_S of S and B_Q of M/S, and set $B_T := \theta^{-1}(B_Q)$.
The set B_T is an A-basis of T, and $\theta|_{B_T} : B_T \to B_Q$ is a bijection, by bijectivity and linearity of θ.
Relation $B_S \cap B_T = \emptyset$ holds by $S \cap T = \{0_M\}$, $0_M \notin B_S \cup B_T$; $B_S \cup B_T$ spans M by $M = S \oplus T$, spanning properties of B_S, B_T.
It is A-linearly independent by Proposition 1.7.2(ii) and the independence of B_S, B_T.
The union $B_S \cup B_T$ is an A-basis of M by its spanning and independence.
The identities $|B_S \cup B_T| = |B_S| + |B_T|$ and $|B_T| = |B_Q|$ hold by disjointness and the bijection $\theta|_{B_T}$.
Rank equality in (iii) holds by Definition 2.2.3, identities. Under $\mathrm{rk}_A(M) \in \mathbb{N}_0$, both summand ranks lie in $\mathbb{N}_0$ by rank equality.
The formula $\mathrm{rk}_A(M/S) = \mathrm{rk}_A(M) - \mathrm{rk}_A(S)$ holds by subtraction in $\mathbb{N}_0$.

Structural Commentary: Choice lifts a free target basis to a section; direct-sum bases then add ranks.
Key Insight: The section image is simultaneously a kernel complement and quotient model. □

2.4 Noetherian Modules

Throughout this subsection, A denotes a nonzero commutative ring with identity 1_A.

Definition 2.4.1. *Noetherian Modules and Rings*
(i) An *ascending chain* in an A-module M is a sequence $(M_n)_{n\in\mathbb{N}}$ of submodules satisfying $(\forall\, n \in \mathbb{N})\, M_n \leq M_{n+1}$.
It *stabilizes* if $(\exists\, n_0 \in \mathbb{N})(\forall\, n \in \mathbb{N})\, [n \geq n_0 \Rightarrow M_n = M_{n_0}]$.
The module M is *Noetherian*, or satisfies the *ascending chain condition (ACC)*, if all its ascending chains stabilize.
(ii) The ring A is *Noetherian* if the regular A-module ${}_AA$ is Noetherian.
By Proposition 1.1.7, this means that all ascending chains of ideals of A stabilize.

Theorem 2.4.2. *Noetherian Means Finitely Generated Submodules*
Let M be an A-module.

(i) M is Noetherian $\iff (\forall\, N \leq M)\, N$ is finitely generated.
(ii) A is Noetherian $\iff (\forall\, \mathcal{I} \trianglelefteq A)\, \mathcal{I}$ is finitely generated as an A-module.

Proof.
(i) ($\Rightarrow$) Assume M is Noetherian and fix a non-finitely generated $N \leq M$. Set $\mathcal{C} := \{X \subseteq N : X \neq \emptyset\}$.
Fix $c : \mathcal{C} \to N$ satisfying $(\forall\, X \in \mathcal{C})\, c(X) \in X$ by Principle 6.1.2. Set $u_1 := c(N)$ and $N_1 := \langle\!\langle u_1 \rangle\!\rangle_A$.
Given $u_1, \ldots, u_n$, set $N_n := \langle\!\langle u_1, \ldots, u_n \rangle\!\rangle_A$. $N \setminus N_n \neq \emptyset$ by non-finite generation of N and finite generation of N_n.
Set $u_{n+1} := c(N \setminus N_n)$. These recursive clauses define $(u_n)_{n\in\mathbb{N}}$ by Principle 6.3.5(i).
$(\forall\, n \in \mathbb{N})\, N_n \leq N$ by Proposition 1.2.2(i). $(\forall\, n \in \mathbb{N})\, u_{n+1} \in N_{n+1} \setminus N_n$ by Definition 1.2.1(i),(iii).
$(\forall\, n \in \mathbb{N})\, N_n < N_{n+1} \leq M$ by the preceding containment and nonmembership. This contradicts ACC.
(i) ($\Leftarrow$) Suppose $(\forall\, N \leq M)\, N$ is finitely generated. Let $(M_n)_{n\in\mathbb{N}}$ be an ascending chain in M, and set $U := \bigcup_{n\in\mathbb{N}} M_n$.
$0_M \in U$ by $0_M \in M_1$. Fix $(a, b, x, y) \in A^2 \times U^2$. Choose $i, j \in \mathbb{N}$ with $x \in M_i$ and $y \in M_j$ by the definition of U.
For $k := \max\{i, j\}$, $ax + by \in M_k \subseteq U$ by $M_i, M_j \subseteq M_k$ and submodule closure.
Hence $U \leq M$ by Theorem 1.1.5. Fix $r \in \mathbb{N}$ and $(u_1, \ldots, u_r) \in U^r$ satisfying $U = \langle\!\langle u_1, \ldots, u_r \rangle\!\rangle_A$ by finite generation of U.
Fix $(k_1, \ldots, k_r) \in \mathbb{N}^r$ satisfying $(\forall\, j \in \{1, \ldots, r\})\, u_j \in M_{k_j}$. Set $k := \max\{k_1, \ldots, k_r\}$. Then $U \subseteq M_k$ by Proposition 1.2.2(iii).
$M_k \subseteq U$ by construction. $(\forall\, n \in \mathbb{N})\, [n \geq k \Rightarrow M_n = M_k]$ by $M_k \subseteq M_n \subseteq U \subseteq M_k$. Hence M is Noetherian by Definition 2.4.1(i).
(ii) ($\Rightarrow$) If A is Noetherian, then ${}_AA$ is Noetherian by Definition 2.4.1(ii). All ideals of A finitely generated by (i), Proposition 1.1.7.
(ii) ($\Leftarrow$) Suppose $(\forall\, \mathcal{I} \trianglelefteq A)\, \mathcal{I}$ is finitely generated as an A-module.
All submodules of ${}_AA$ are finitely generated by the supposition and Proposition 1.1.7.
Thus ${}_AA$ is Noetherian by (i), and A is Noetherian by Definition 2.4.1(ii).

Structural Commentary: Generator adjunction contradicts ACC; finite generation of the chain union forces stabilization.
Key Insight: Non-finite generation supplies a generator outside every current stage. □

2.5 Orders and Cyclic Modules over a PID

Convention 2.5.1. *Standing PID Notation*
In this and the subsequent PID-structure subsections, R denotes a principal ideal domain unless otherwise stated.
For $r \in R$, write $\langle r \rangle = Rr$; for an R-module M and $v \in M$, write $\langle\!\langle v \rangle\!\rangle_R = Rv$.

Motivation 2.5.2. *Scalar Arithmetic over a PID*
For a field F, $F \setminus \{0_F\} = F^\times$, so every nonzero scalar is invertible.
A PID need not permit universal inversion; divisibility, gcds, and lcms replace it. Module order records this scalar arithmetic.

Definition 2.5.3. *Order of a Submodule or Element*
Let M be R-module, $N \leq M$. An *order* of N is any $\alpha \in R$ satisfying $\operatorname{Ann}_R(N) = \{r \in R : (\forall\, n \in N)\, rn = 0_M\} = \langle \alpha \rangle$.
Write $o(N) = \alpha$; nonzero choices are understood up to associates. For $v \in M$, define $o(v) := o(\langle\!\langle v \rangle\!\rangle_R)$.

Proposition 2.5.4. *Orders and Direct Sums*
Let $n \in \mathbb{N}$, and let $M_1, \ldots, M_n$ be R-modules with $o(M_i) = \alpha_i$. Then $o(\bigoplus_{i=1}^{n} M_i) = \operatorname{lcm}(\alpha_1, \ldots, \alpha_n)$.

Proof. Set $I := \{1, \ldots, n\}$, $\lambda := \operatorname{lcm}(\alpha_1, \ldots, \alpha_n)$. For $r \in R$, $r \in \operatorname{Ann}_R(\bigoplus_{i \in I} M_i) \iff (\forall\, i \in I)\, \alpha_i \mid r \iff \lambda \mid r$.

Hence $\operatorname{Ann}_R(\bigoplus_{i=1}^{n} M_i) = \langle \lambda \rangle$. Thus $o(\bigoplus_{i=1}^{n} M_i) = \lambda$.
Structural Commentary: The direct-sum annihilator is the intersection of the summand annihilators.
Key Insight: Common annihilators are exactly multiples of the least common multiple. □

Theorem 2.5.5. *Cyclic Modules over a PID*
Let M be an R-module and let $v \in M$.

(i) If $\operatorname{Ann}_R(v) = \langle \alpha \rangle$, define $\phi_v : R/\langle \alpha \rangle \to \langle\!\langle v \rangle\!\rangle_R$ by $\phi_v(r + \langle \alpha \rangle) = rv$. Then ϕ_v is an R-module isomorphism.
(ii) If $C = \langle\!\langle v \rangle\!\rangle_R$ and $S \leq C$, then $(\exists\, s \in R)\, S = \langle\!\langle sv \rangle\!\rangle_R$.
(iii) Let $o(v) = \alpha$ and $\beta \in R$. If $(\alpha, \beta) \neq (0_R, 0_R)$, then $o(\beta v) = \frac{\alpha}{\gcd(\alpha, \beta)}$. If $\alpha = \beta = 0_R$, then $o(\beta v) = 1_R$.
(iv) Let $o(v) = \alpha$ and $\beta \in R$ satisfy $(\alpha, \beta) \neq (0_R, 0_R)$. Then $\langle\!\langle \beta v \rangle\!\rangle_R = \langle\!\langle v \rangle\!\rangle_R \iff \gcd(\alpha, \beta) \sim 1_R$.

Proof.

(i) Set $\psi : R \to \langle\!\langle v \rangle\!\rangle_R$, $\psi(r) = rv$. 1qThen $\operatorname{im} \psi = \langle\!\langle v \rangle\!\rangle_R$ and $\ker \psi = \operatorname{Ann}_R(v) = \langle \alpha \rangle$.
The induced map ϕ_v is an R-module isomorphism by Theorem 1.5.4(i).
(ii) Set $\psi : R \to C$, $\psi(r) = rv$, $I := \psi^{-1}(S) = \{r \in R : rv \in S\}$; $0_R \in I$ and $(\forall\, (a, b, x, y) \in R^2 \times I^2)\, \psi(ax + by) = a\psi(x) + b\psi(y) \in S$.
Thus $I \leq {}_R R$ by Theorem 1.1.5. Choose $s \in R$ with $I = \langle s \rangle$ by Definition 3.10.1(i).
The equality $S = \psi(I)$ holds by $S \leq \operatorname{im} \psi$, so $S = \psi(Rs) = R(sv) = \langle\!\langle sv \rangle\!\rangle_R$.
(iii) If $\alpha = \beta = 0_R$, then $\beta v = 0_M$ and $\operatorname{Ann}_R(\beta v) = R = \langle 1_R \rangle$, so $o(\beta v) = 1_R$. Suppose $(\alpha, \beta) \neq (0_R, 0_R)$, $d := \gcd(\alpha, \beta) \neq 0_R$.
Choose $\alpha', \beta' \in R$ with $\alpha = d\alpha'$, $\beta = d\beta'$, and $\gcd(\alpha', \beta') \sim 1_R$. Choose $x, y \in R$ with $x\alpha' + y\beta' = 1_R$ by Theorem 3.10.6(iii).
Fix $r \in R$. If $\alpha' \mid r\beta'$, then $\alpha' \mid (xr\alpha' + yr\beta') = r$; the reverse divisibility holds by multiplication by β'.
Thus $r\beta v = 0_M \iff \alpha \mid r\beta \iff \alpha' \mid r$ by Proposition 3.5.2 with $d \neq 0_R$. Hence $\operatorname{Ann}_R(\beta v) = \langle \alpha' \rangle$ and $o(\beta v) = \alpha' = \frac{\alpha}{d}$.
(iv) ($\Rightarrow$) Suppose $\langle\!\langle \beta v \rangle\!\rangle_R = \langle\!\langle v \rangle\!\rangle_R$. Choose $c \in R$ with $v = c\beta v$. Then $\alpha \mid (1_R - c\beta)$, so $(\exists\, q \in R)\, q\alpha + c\beta = 1_R$.
Hence $\gcd(\alpha, \beta) \sim 1_R$ by Theorem 3.10.6(iii).
(iv) ($\Leftarrow$) Suppose $\gcd(\alpha, \beta) \sim 1_R$. Choose $q, c \in R$ with $q\alpha + c\beta = 1_R$ by Theorem 3.10.6(iii).
Then $v = (q\alpha + c\beta)v = c\beta v$, so $\langle\!\langle v \rangle\!\rangle_R \leq \langle\!\langle \beta v \rangle\!\rangle_R$. plaThe reverse inclusion holds by $\beta v \in \langle\!\langle v \rangle\!\rangle_R$.

Structural Commentary: Kernel quotients and preimage ideals transfer cyclic questions to ideal arithmetic.
Key Insight: Annihilators convert cyclic-module questions into divisibility in R. □

Theorem 2.5.6. *Composing and Decomposing Cyclic Modules*
Let M be an R-module, let $n \in \mathbb{N}$, and set $I := \{1, \ldots, n\}$.
Let $(\alpha_1, \ldots, \alpha_n) \in (R \setminus \{0_R\})^n$ satisfy $(\forall\, i, j \in I)\, [i \neq j \Rightarrow \gcd(\alpha_i, \alpha_j) \sim 1_R]$.

(i) If $(u_1, \ldots, u_n) \in M^n$ and $(\forall\, i \in I)\, o(u_i) = \alpha_i$, then $o(\sum_{i=1}^{n} u_i) \sim \prod_{i=1}^{n} \alpha_i$.

(ii) Let $(u_1, \ldots, u_n) \in M^n$ satisfy $(\forall\, i \in I)\, o(u_i) = \alpha_i$. Then $\bigoplus_{i=1}^{n} \langle\!\langle u_i \rangle\!\rangle_R = \langle\!\langle \sum_{i=1}^{n} u_i \rangle\!\rangle_R$.

(iii) If $v \in M$ and $o(v) = \alpha = \prod_{i=1}^{n} \alpha_i$, then there is a tuple $(v_1, \ldots, v_n) \in M^n$ satisfying

(a) $v = \sum_{i=1}^{n} v_i$;
(b) $(\forall\, i \in I)\, o(v_i) \sim \alpha_i$;
(c) $\langle\!\langle v \rangle\!\rangle_R = \bigoplus_{i=1}^{n} \langle\!\langle v_i \rangle\!\rangle_R$.

Proof. Set $\alpha := \prod_{i=1}^{n} \alpha_i$ and $\beta_i := \frac{\alpha}{\alpha_i} = \prod_{j \in I \setminus \{i\}} \alpha_j$. Then $(\forall\, i \in I)\, \gcd(\alpha_i, \beta_i) \sim 1_R$ by Theorem 3.10.7(ii).

(i) Set $u := \sum_{i=1}^{n} u_i$. Then $\alpha u = 0_M$, so $\alpha \in \operatorname{Ann}_R(u)$. Suppose $ru = 0_M$, $i \in I$. Then $r\beta_i u_i = 0_M$ by $(\forall\, j \in I \setminus \{i\})\, \alpha_j \mid \beta_i$.
Thus $\alpha_i \mid r\beta_i$. Choose $a_i, b_i \in R$ with $a_i\alpha_i + b_i\beta_i = 1_R$ by Theorem 3.10.6(iii). Then $\alpha_i \mid r(a_i\alpha_i + b_i\beta_i) = r$.
Hence $(\forall\, i \in I)\, \alpha_i \mid r$. Thus $\alpha \mid r$ by Theorem 3.10.7(ii). Therefore $\operatorname{Ann}_R(u) = \langle \alpha \rangle$ and $o(u) \sim \alpha$.
(ii) Choose $((a_i, b_i))_{i=1}^{n} \in (R^2)^n$ with $(\forall\, i \in I)\, a_i\alpha_i + b_i\beta_i = 1_R$ by Theorem 3.10.6(iii).
Suppose $\sum_{i=1}^{n} x_i = 0_M$ with $(\forall\, i \in I)\, x_i \in \langle\!\langle u_i \rangle\!\rangle_R$, and fix $i \in I$.
Then $\alpha_i x_i = 0_M$ and $\beta_i x_i = 0_M$, the latter by multiplying $\sum_{j=1}^{n} x_j = 0_M$ by β_i.
Hence $x_i = (a_i\alpha_i + b_i\beta_i)x_i = 0_M$, and the sum is internal.
Set $u := \sum_{i=1}^{n} u_i$. The inclusion $\langle\!\langle u \rangle\!\rangle_R \leq \sum_{i=1}^{n} \langle\!\langle u_i \rangle\!\rangle_R$ holds by u belonging to the sum.
$(\forall\, i \in I)\, u_i = b_i\beta_i u$ by $\alpha_i u_i = 0_M$ and $(\forall\, j \in I \setminus \{i\})\, \beta_i u_j = 0_M$. Thus $\sum_{i=1}^{n} \langle\!\langle u_i \rangle\!\rangle_R \leq \langle\!\langle u \rangle\!\rangle_R$.

(iii) If $n = 1$, then $(\forall\, h \in R)\,[h \mid \beta_1 \Rightarrow h \in R^\times]$ by $\beta_1 = 1_R$. Suppose $n \geq 2$ and fix $h \in R \setminus R^\times$ satisfying $(\forall\, i \in I)\, h \mid \beta_i$.
Then $h \neq 0_R$ by $h \mid \beta_1 \neq 0_R$. Choose an irreducible $p \mid h$ by Theorem 3.10.7(i). Then p is prime by Theorem 3.10.6(ii).
By the prime property and $p \mid \beta_1$, choose $j \neq 1$ with $p \mid \alpha_j$. By the prime property and $p \mid \beta_j$, choose $k \neq j$ with $p \mid \alpha_k$.
This contradicts $\gcd(\alpha_j, \alpha_k) \sim 1_R$. Thus $(\forall\, h \in R)\,[(\forall\, i \in I)\, h \mid \beta_i \Rightarrow h \in R^\times]$.
Choose $d \in R$ with $\langle \beta_1, \ldots, \beta_n \rangle = \langle d \rangle$ by Definition 3.10.1(i).
The element d is a common divisor of the β_i, so $d \in R^\times$ and $\langle \beta_1, \ldots, \beta_n \rangle = R$.
Choose $c_1, \ldots, c_n \in R$ with $\sum_{i=1}^{n} c_i \beta_i = 1_R$, and set $v_i := c_i \beta_i v$.

(a) The identity $v = \sum_{i=1}^{n} v_i$ holds by $\sum_{i=1}^{n} c_i \beta_i = 1_R$.

(b) Fix $i \in I$. If $h \mid c_i$ and $h \mid \alpha_i$, then $(\forall\, j \in I)\, h \mid c_j \beta_j$, because $\alpha_i \mid \beta_j$ when $j \neq i$. Hence $h \mid 1_R$ and $\gcd(c_i, \alpha_i) \sim 1_R$.
Therefore $\gcd(\alpha, c_i \beta_i) \sim \beta_i$ by Theorem 3.10.7(ii). Thus $o(v_i) \sim \alpha_i$ by Theorem 2.5.5(iii).

(c) The equality $\langle\!\langle v \rangle\!\rangle_R = \bigoplus_{i=1}^{n} \langle\!\langle v_i \rangle\!\rangle_R$ holds by (ii), $v = \sum_{i=1}^{n} v_i$, and $(\forall\, i \in I)\, o(v_i) \sim \alpha_i$.

Structural Commentary: Bézout projections compose the summands; complementary products construct the reverse decomposition.
Key Insight: Coprime orders isolate each cyclic component from the total sum. □

Proposition 2.5.7. *Prime-Order Cyclic Submodules from Prime Divisors*
Let M be a finitely generated torsion R-module with $o(M) = \mu$. If $p \mid \mu$ is prime, then $(\exists\, w \in M)\,[o(w) \sim p \wedge Rw \cong R/\langle p \rangle]$.

Proof. $\mathrm{Ann}_R(M) \neq \{0_R\}$ by Proposition 1.6.6, so $\mu \neq 0_R$. Choose $q \in R$ with $\mu = pq$. If $q \in \langle \mu \rangle$, choose $a \in R$ with $q = \mu a = pqa$.
Then $1_R = pa$ by Proposition 3.5.2 with $q \neq 0_R$, contrary to $p \notin R^\times$. Thus $q \notin \mathrm{Ann}_R(M)$.
Choose $v \in M$ with $qv \neq 0_M$ by the definition of $\mathrm{Ann}_R(M)$, and set $w := qv$. Then $pw = \mu v = 0_M$, so $o(w) \mid p$.
The element $o(w)$ is a nonunit by $w \neq 0_M$. Write $p = o(w)c$. Then $p \mid o(w)$ or $p \mid c$ by primality of p.
If $p \mid c$, write $c = pe$; then $1_R = o(w)e$ by Proposition 3.5.2 in $p = o(w)pe$, contrary to $o(w) \notin R^\times$.
Thus $p \mid o(w)$, and $o(w) \sim p$ by Proposition 3.7.2(ii)–(iii). Finally, $Rw \cong R/\langle p \rangle$ by Theorem 2.5.5(i).
Structural Commentary: A complementary factor constructs a nonzero element annihilated by the selected prime.
Key Insight: The complementary factor is not a global annihilator. □

2.6 Submodules of Finite Free PID Modules

Definition 2.6.1. *Minimum Number of Module Generators*
For an R-module M, define $\mu_R(M) := \min\{|X| : X \subseteq M \wedge \langle\!\langle X \rangle\!\rangle_R = M\}$.

Theorem 2.6.2. *Submodules of Finite Free PID Modules*
Let $n \in \mathbb{N}_0$, let F be a free R-module with $\mathrm{rk}_R(F) = n$, and let $N \leq F$. Then $(\exists\, m \in \mathbb{N}_0)\,[m \leq n \wedge N \cong R^m]$.

Proof. Identify F with R^n by Proposition 2.2.6(ii).

(i) *Coordinate Ideals*: Set $J := \{1, \ldots, n\}$. For $k \in J$, set $E_k := R^k \times \{0_R\}^{n-k}$ and $N_k := N \cap E_k$.
The relation $E_k \leq R^n$ holds by coordinatewise closure, and $N_k \leq R^n$ by Proposition 1.1.6(i).
Let $\pi_k \in \mathrm{Hom}_R(N_k, R)$ be kth-coordinate map, set $I_k := \mathrm{im}(\pi_k)$. Then $I_k \trianglelefteq R$ by Propositions 1.4.2(iii) and 1.1.7.
Choose $(r_k)_{k \in J} \in R^J$ satisfying $(\forall k \in J)\, I_k = \langle r_k \rangle$ by Definition 3.10.1(i).

(ii) *Triangular Independence*: Set $K := \{k \in J : r_k \neq 0_R\}$.
For $k \in K$, choose $u_k \in N_k$ with $(u_k)_k = r_k$ by $r_k \in I_k = \mathrm{im}(\pi_k)$, and set $U := \{u_k : k \in K\}$.
Let $(c_k)_{k \in K} \in R^K$ satisfy $\sum_{k \in K} c_k u_k = 0_{R^n}$, and set $C := \{k \in K : c_k \neq 0_R\}$. If $C \neq \emptyset$, set $j := \max C$.
The equality $c_j r_j = 0_R$ holds in coordinate j by $c_k = 0_R$ for $k > j$ and $(u_k)_j = 0_R$ for $k < j$.
Then $c_j = 0_R$ by Proposition 3.5.2, $r_j \neq 0_R$, contrary to $j \in C$; $C = \emptyset$, so U is R-linearly independent by Definition 1.3.1.

(iii) *Height Descent*: For $x \in N$, set $\ell(x) := \max(\mathrm{supp}(x) \cup \{0\}) \in \mathbb{N}_0$.
The implication $\ell(x) = 0 \Rightarrow x = 0_{R^n} \in \langle\!\langle U \rangle\!\rangle_R$ holds by Definition 3.1.4.
For the inductive step, fix $x \in N$ with $\ell(x) = j > 0$ and assume $(\forall y \in N)\,[\ell(y) < j \Rightarrow y \in \langle\!\langle U \rangle\!\rangle_R]$.
Then $x \in N_j$ and $x_j \neq 0_R$ by the definition of ℓ. The membership $j \in K$ holds by $x_j \in I_j = \langle r_j \rangle$ and $x_j \neq 0_R$.
Choose $c \in R$ with $x_j = cr_j$ by $x_j \in I_j$. Then $x - cu_j \in N$ and $\ell(x - cu_j) < j$ by $u_j \in N_j$ and $(u_j)_j = r_j$.
The membership $x - cu_j \in \langle\!\langle U \rangle\!\rangle_R$ holds by the induction hypothesis. Then $x = (x - cu_j) + cu_j \in \langle\!\langle U \rangle\!\rangle_R$.
Therefore $N = \langle\!\langle U \rangle\!\rangle_R$ by strong induction and $U \subseteq N$.

(iv) *Rank Conclusion*: Set $m := |K| \in \mathbb{N}_0$ and enumerate $K = \{k_1 < \cdots < k_m\}$. Define $\Phi : R^m \to N$ by $\Phi((a_i)_{i=1}^m) := \sum_{i=1}^{m} a_i u_{k_i}$.
The map Φ is an isomorphism by R-linearity, independence, and spanning of U.
The inequalities $m \leq |J| = n$ hold by $K \subseteq J$, so $m \leq n$ and $N \cong R^m$.

Structural Commentary: Coordinate ideals construct triangular pivots; height descent proves they span N.
Key Insight: The largest nonzero coordinate isolates each pivot coefficient. □

Corollary 2.6.3. *Submodules Need No More Generators over a PID*
Let $n \in \mathbb{N}_0$, let M be an R-module, and let $S \leq M$. If $\mu_R(M) \leq n$, then $\mu_R(S) \leq n$.

Proof.

(i) *Free Cover*: Set $d := \mu_R(M) \in \mathbb{N}_0$; the inequality $d \leq n$ holds by hypothesis.
Choose $(x_i)_{i=1}^d \in M^d$ with $M = \langle\!\langle x_1, \ldots, x_d \rangle\!\rangle_R$ by Definition 2.6.1.
Extend this tuple to $(x_i)_{i=1}^n$ by $(\forall i \in \{1, \ldots, n\})\,[i > d \Rightarrow x_i = 0_M]$.
Then $M = \langle\!\langle x_1, \ldots, x_n \rangle\!\rangle_R$ by the preceding spanning relation. Define $\pi : R^n \to M$ by $\pi((a_i)_{i=1}^n) := \sum_{i=1}^{n} a_i x_i$.
The map π is an epimorphism by the module laws and the spanning relation.

(ii) *Pullback*: Set $P := \pi^{-1}(S)$. Then $0_{R^n} \in P$ and $(\forall (a, b, u, v) \in R^2 \times P^2)\, \pi(au + bv) = a\pi(u) + b\pi(v) \in S$.
Thus $P \leq R^n$ by Theorem 1.1.5. Choose $m \in \mathbb{N}_0$ and $\theta : R^m \xrightarrow{\sim} P$ with $m \leq n$ by Theorem 2.6.2.

(iii) *Generator Transfer*: Let $(e_i)_{i=1}^m$ be the standard basis of R^m and set $v_i := \theta(e_i)$.
The equality $P = \langle\!\langle v_1, \dots, v_m \rangle\!\rangle_R$ holds by surjectivity of θ. The equality $\pi(P) = S$ holds by surjectivity of π and $P = \pi^{-1}(S)$.
Thus $S = \langle\!\langle \pi(v_1), \dots, \pi(v_m) \rangle\!\rangle_R$ by the preceding equalities. The bound $\mu_R(S) \le m \le n$ holds by Definition 2.6.1.

Structural Commentary: Pullback to R^n transfers finite-free rank control through a surjection.
Key Insight: Images of a pullback basis generate S. □

Corollary 2.6.4. *Finitely Generated PID Modules Are Noetherian*
Let M be an R-module. If $\mu_R(M) \in \mathbb{N}_0$, then M is Noetherian.

Proof. Set $n := \mu_R(M)$. Then $(\forall\, N \le M)\, \mu_R(N) \le n$ by Corollary 2.6.3.
Every submodule of M is finitely generated by Definition 2.6.1 and the bound. Thus M is Noetherian by Theorem 2.4.2(i).
Structural Commentary: The generator bound verifies that every submodule is finitely generated.
Key Insight: One finite bound controls every submodule of M. □

Perspective 2.6.5. *Noetherian Modules over a PID*
Theorem 2.6.2 restores finite-rank control for submodules of finite free modules over a PID.
Corollary 2.6.3 transfers that control through free covers.
Corollary 2.6.4 deduces Noetherianity; neither result asserts a submodule complement.

Proposition 2.6.6. *A Full-Size Spanning Set Is a Basis*
Let $n \in \mathbb{N}_0$ and let F be a free R-module with $\mathrm{rk}_R(F) = n$. If $F = \langle\!\langle s_1, \dots, s_n \rangle\!\rangle_R$, then $(s_1, \dots, s_n)$ is an R-basis of F.

Proof.

(i) *Surjective Endomorphism*: Choose an R-basis $(b_i)_{i=1}^n$ of F.
The assignment $b_i \mapsto s_i$ extends to $\tau \in \mathrm{End}_R(F)$ by Theorem 2.1.4. The map τ is surjective by $F = \langle\!\langle s_1, \dots, s_n \rangle\!\rangle_R$.

(ii) *Splitting*: Choose $(a_i)_{i=1}^n \in F^n$ satisfying $(\forall i \in \{1, \dots, n\})\, \tau(a_i) = b_i$ by surjectivity of τ.
The assignment $b_i \mapsto a_i$ extends to $\rho \in \mathrm{End}_R(F)$ by Theorem 2.1.4.
The equality $\tau\rho = \mathrm{id}_F$ holds by basis agreement and uniqueness in Theorem 2.1.4.
Then $F = \ker\tau \oplus \mathrm{im}\,\rho$ by Theorem 1.8.5(ii). The map ρ is injective by $\tau\rho = \mathrm{id}_F$.
Its corestriction $F \to \mathrm{im}\,\rho$ is an isomorphism by R-linearity, injectivity, and the definition of image.

(iii) *Rank Cancellation*: Choose $r \in \mathbb{N}_0$ with $r \le n$ and $\ker\tau \cong R^r$ by Theorem 2.6.2.
The chain $R^n \cong F \cong \ker\tau \oplus \mathrm{im}\,\rho \cong R^r \oplus R^n$ holds by the preceding isomorphisms.
Thus $R^n \cong R^{r+n}$ by coordinate concatenation. Thus $n = r + n$ by Proposition 2.2.6(ii), so $r = 0$.

(iv) *Basis Transport*: The equality $\ker\tau = \{0_F\}$ holds by $r = 0$ and $\ker\tau \cong R^r$.
The map τ is injective by Proposition 1.4.2(iv). It is an isomorphism by Definition 1.4.1(iv) and surjectivity.
Therefore $(s_i)_{i=1}^n = (\tau(b_i))_{i=1}^n$ is an R-basis by bijectivity and linearity of τ.

Structural Commentary: A splitting isolates the kernel; finite-free rank comparison forces it to vanish.
Key Insight: The equality $n = r + n$ leaves only $r = 0$. □

2.7 Smith Normal Form and Module Presentations

Definition 2.7.1. *Finite Free Presentations and Cokernels*
Let $m, n \in \mathbb{N}_0$ and let $A \in \mathrm{Mat}(m, n, R)$ act by $A : R^n \to R^m$. The *cokernel* of A is $\mathrm{coker}(A) := R^m / \mathrm{im}(A)$.
The matrix A is *finite presentation matrix* for R-module M if $M \cong \mathrm{coker}(A)$. Notation $R^n \xrightarrow{A} R^m \to M \to 0$ records this presentation.

Proposition 2.7.2. *Finitely Generated PID Modules Are Finitely Presented*
Let M be a f.g. R-module. Then there are $m, n \in \mathbb{N}_0$ and $A \in \mathrm{Mat}(m, n, R)$ such that $M \cong \mathrm{coker}(A)$.

Proof.

(i) *Free Cover*: Choose generators $u_1, \dots, u_m$ of M and define $\varepsilon : R^m \to M$ by $\varepsilon((a_i)_{i=1}^m) = \sum_{i=1}^m a_i u_i$.
Its image contains every u_i, so it equals M by Proposition 1.2.2(iii). Thus ε is an epimorphism by Definition 1.4.1(iv).

(ii) *Relation Module*: Set $K := \ker\varepsilon \le R^m$ by Proposition 1.4.2(ii).
By Theorem 2.6.2, choose $n \in \mathbb{N}_0$ with $n \le m$ and an isomorphism $\theta : R^n \xrightarrow{\sim} K$.

(iii) *Presentation Matrix*: Let $A \in \mathrm{Mat}(m, n, R)$ be the matrix of the composite $R^n \xrightarrow{\theta} K \hookrightarrow R^m$ in the standard bases.
Then $\mathrm{im}(A) = K$, and $M \cong R^m / K = \mathrm{coker}(A)$ by Theorem 1.5.4(i).

Structural Commentary: A finite generating map has a finite free kernel over a PID.
Key Insight: The inclusion of the relation module is a finite presentation matrix. □

Definition 2.7.3. *Matrix Equivalence and Determinantal Ideals over a PID*
Let $m, n \in \mathbb{N}_0$, set $q := \min(m, n)$, and let $A, B \in \mathrm{Mat}(m, n, R)$.

(i) The matrices A and B are *equivalent*, written $A \sim_{\mathrm{eq}} B$.
This relation is defined by $(\exists P \in \mathrm{Mat}(m, m, R)^\times)(\exists Q \in \mathrm{Mat}(n, n, R)^\times)\, [B = PAQ]$.

(ii) Set $\Delta_0(A) := R$. For $1 \le k \le q$, the *kth determinantal ideal* $\Delta_k(A) \trianglelefteq R$ is generated by all $k \times k$ minors of A.

Theorem 2.7.4. *Smith Normal Form over a PID*
Let $m, n \in \mathbb{N}_0$, $A \in \mathrm{Mat}(m, n, R)$, $q := \min(m, n)$. For $0 \le r \le q$ and $\mathbf{d} = (d_i)_{i=1}^r$, set $D_{\mathbf{d}} := \mathrm{diag}(d_1, \dots, d_r, 0, \dots, 0) \in \mathrm{Mat}(m, n, R)$.

(i) $\exists\ 0 \le r \le q$ and $d_1, \dots, d_r \in R \setminus \{0_R\}$ such that $d_1 \mid \cdots \mid d_r$ and $A \sim_{\mathrm{eq}} D_{\mathbf{d}}$. For these data, $r = \mathrm{rk}_R(\mathrm{im}(A))$.

(ii) Suppose $A \sim_{\mathrm{eq}} D_{\mathbf{d}}$ and $A \sim_{\mathrm{eq}} D_{\mathbf{e}}$ for nonzero divisibility chains $\mathbf{d} = (d_i)_{i=1}^r$ and $\mathbf{e} = (e_i)_{i=1}^s$.
Then $r = s$ and $(\forall i \in \{1, \dots, r\})\, [\langle d_i \rangle = \langle e_i \rangle]$.

Proof.

(i)

(a) *Bézout Pivot*: The existence assertion is proved by induction on q.
If $q = 0$ or $A = 0$, take $r = 0$ and $D_{\mathbf{d}} = 0$. Then $A \sim_{\mathrm{eq}} D_{\mathbf{d}}$ and $\mathrm{rk}_R(\mathrm{im}(A)) = 0$.
Otherwise, invertible permutation matrices move a nonzero entry to position $(1, 1)$; denote the resulting pivot by p.
Suppose an entry a in the first column is not divisible by p.

Choose $g \in R$ with $\langle p, a\rangle = \langle g\rangle$ by Definition 3.10.1(i), and write $p = gu$ and $a = gv$.
Since $g \in \langle p, a\rangle$, choose $x, y \in R$ with $g = xp + ya = g(xu + yv)$. Then $xu + yv = 1_R$ by $g \neq 0_R$ and Proposition 3.5.2.
Set $U := \left(\begin{smallmatrix} x & y \\ -v & u \end{smallmatrix}\right)$. The matrix $U^{-1} = \left(\begin{smallmatrix} u & -y \\ v & x \end{smallmatrix}\right)$ is its inverse, and $U\left(\begin{smallmatrix} p \\ a \end{smallmatrix}\right) = \left(\begin{smallmatrix} g \\ 0_R \end{smallmatrix}\right)$.
Embedding U into the corresponding two rows replaces the pivot by g.
Right multiplication by the embedded transpose U^{T} is the analogous first-row reduction. Finally, $\langle p\rangle \subsetneq \langle p, a\rangle = \langle g\rangle$ as $p \nmid a$.

(b) *Termination*: For a fixed pivot, entries divisible by it are cleared from its row and column by invertible row and column additions. If an interior entry is not divisible by the pivot after this clearing, adding its row to the first row exposes it to the Bézout pivot operation. Every such pivot improvement strictly enlarges the principal pivot ideal.
Only finitely many improvements occur by Proposition 3.10.5. At termination, the pivot p divides every entry, so the first row and column can be cleared to obtain a matrix equivalent to $\operatorname{diag}(p, B)$. Every entry of B remains divisible by p.

(c) *Block Induction*: The complementary matrix B has $\min(m-1, n-1) = q - 1$. By the induction hypothesis, invertible operations internal to this block put it in Smith form with nonzero diagonal entries $d_2 \mid \cdots \mid d_r$.
Those operations take R-linear combinations of entries of B, so $(\forall i \in \{2, \ldots, r\})\,[p \mid d_i]$.
Setting $d_1 := p$ establishes $d_1 \mid \cdots \mid d_r$ and $A \sim_{\mathrm{eq}} D_{\mathbf{d}}$.

(d) *Rank*: If $D_{\mathbf{d}} = PAQ$, then $\operatorname{im}(D_{\mathbf{d}}) = P(\operatorname{im}(A))$ because Q is surjective. The vectors $d_1 e_1, \ldots, d_r e_r$ span $\operatorname{im}(D_{\mathbf{d}})$.
They are linearly independent because R is an integral domain and every d_i is nonzero.
Hence their inverse images under P form a basis of $\operatorname{im}(A)$, so $\operatorname{rk}_R(\operatorname{im}(A)) = r$.

(ii) Let $B = PAQ$ with P and Q invertible. Two applications of the Cauchy–Binet expansion express each $k \times k$ minor of B as an R-linear combination of the $k \times k$ minors of A. Thus $\Delta_k(B) \subseteq \Delta_k(A)$.
Same argument applied to $A = P^{-1}BQ^{-1}$ proves reverse inclusion, so matrix equivalence preserves every determinantal ideal.
For $1 \leq k \leq r$, each nonzero $k \times k$ minor of $D_{\mathbf{d}}$ is a product $d_{i_1} \cdots d_{i_k}$ with $i_j \geq j$.
It is therefore divisible by $d_1 \cdots d_k$, while the leading $k \times k$ minor equals this latter product.
Consequently, $\Delta_k(D_{\mathbf{d}}) = \langle d_1 \cdots d_k\rangle$ for $k \leq r$, while $\Delta_k(D_{\mathbf{d}}) = \{0_R\}$ for $r < k \leq q$. The same formulas hold for $D_{\mathbf{e}}$.
Since R is an integral domain, the nonzero determinantal ideals occur precisely for $k \leq r$ and for $k \leq s$, respectively; hence $r = s$.
If $r = 0$, the uniqueness assertion follows. Assume $r \geq 1$. Thus $\langle d_1\rangle = \langle e_1\rangle$ by equality of the first determinantal ideals.
Assume inductively that these principal ideals agree through index $k - 1$.
By Proposition 3.7.2(ii), the corresponding generators are associates.
After absorbing their unit factors, equality of the kth determinantal ideals becomes $\langle cd_k\rangle = \langle ce_k\rangle$, where $c = d_1 \cdots d_{k-1} \neq 0_R$.
Thus $\langle d_k\rangle = \langle e_k\rangle$ by mutual divisibility and Proposition 3.5.2, completing the induction.

Structural Commentary: Bézout pivot improvement supplies existence, while determinantal ideals are unchanged by invertible row and column operations.
Key Insight: The ideals $\Delta_k(A)$ recover the successive invariant factors up to associates. □

Theorem 2.7.5. *Adapted Bases for Submodules of Free Modules*
Let $n \in \mathbb{N}_0$, F be free R-module with $\operatorname{rk}_R(F) = n$, $N \leq F$. There are $k \in \mathbb{N}_0$ with $k \leq n$ and an R-basis $(v_i)_{i=1}^n$ of F. For these choices, there are $r_1, \ldots, r_k \in R \setminus \{0_R\}$ such that $r_1 \mid \cdots \mid r_k$ and $(r_i v_i)_{i=1}^k$ is an R-basis of N.

Proof.

(i) *Free Setup*: By Theorem 2.6.2, choose $k \in \mathbb{N}_0$ with $k \leq n$ and $N \cong R^k$.
Choose an R-basis $(w_j)_{j=1}^k$ of N and an R-basis $(f_i)_{i=1}^n$ of F.
Let $A \in \operatorname{Mat}(n, k, R)$ be the matrix of the inclusion $\iota : N \hookrightarrow F$ in these bases.

(ii) *Zero Case*: If $k = 0$, then $N = \{0_F\}$, chosen basis of F together with empty basis of N satisfies conclusion. Assume $k \geq 1$.

(iii) *Smith Reduction*: The Smith diagonal of A has k nonzero entries by Theorem 2.7.4(i), since $\operatorname{im}(\iota) = N$ has rank k.
Denote these entries by $r_1 \mid \cdots \mid r_k$ and set $D := \operatorname{diag}(r_1, \ldots, r_k, 0, \ldots, 0)$.
Choose $P \in \operatorname{Mat}(n, n, R)^\times$ and $Q \in \operatorname{Mat}(k, k, R)^\times$ with $PAQ = D$ by Definition 2.7.3(i).

(iv) *Basis Transport*: Define $w'_j := \sum_{\ell=1}^{k} Q_{\ell j} w_\ell$ for $1 \leq j \leq k$. Define $v_i := \sum_{\ell=1}^{n} (P^{-1})_{\ell i} f_\ell$ for $1 \leq i \leq n$.
Since Q and P^{-1} are invertible, $(w'_j)_{j=1}^k$ and $(v_i)_{i=1}^n$ are bases of N and F, respectively.
Identity $AQ = P^{-1}D$ implies $(\forall j \in \{1, \ldots, k\})\,[\iota(w'_j) = r_j v_j]$. Because ι is inclusion, $(r_j v_j)_{j=1}^k = (w'_j)_{j=1}^k$ is R-basis of N.

Structural Commentary: Smith reduction changes the domain and codomain bases of the inclusion.
Key Insight: In the transported bases, the inclusion sends the jth basis vector to $r_j v_j$. □

Corollary 2.7.6. *Smith Form Presents Finitely Generated PID Modules*
Let $A \in \operatorname{Mat}(m, n, R)$ be a finite presentation matrix for M. Suppose $A \sim_{\mathrm{eq}} D$, where $D := \operatorname{diag}(d_1, \ldots, d_r, 0, \ldots, 0)$. Assume $0 \leq r \leq \min(m, n)$, $d_1 \mid \cdots \mid d_r$ are nonzero. Set $I := \{i \in \{1, \ldots, r\} : d_i \notin R^\times\}$. Then $M \cong R^{m-r} \oplus \bigoplus_{i \in I} R/\langle d_i\rangle$.

Proof.

(i) *Equivalent Cokernels*: Choose invertible P, Q with $D = PAQ$ by Definition 2.7.3(i). As $Q(R^n) = R^n$, thus $\operatorname{im}(D) = P(\operatorname{im}(A))$.
Consequently, $x + \operatorname{im}(A) \mapsto Px + \operatorname{im}(D)$ is an isomorphism $\operatorname{coker}(A) \xrightarrow{\sim} \operatorname{coker}(D)$; its inverse is induced by P^{-1}.

(ii) *Diagonal Cokernel*: With $(e_i)_{i=1}^m$ the standard basis of R^m, $\operatorname{im}(D) = \bigoplus_{i=1}^r \langle d_i\rangle e_i$.
Thus, coordinatewise quotienting produces $\operatorname{coker}(D) \cong \left(\bigoplus_{i=1}^r R/\langle d_i\rangle\right) \oplus R^{m-r}$.

(iii) *Unit Factors*: If $d_i \in R^\times$, then $R/\langle d_i\rangle = \{0_R\}$.
Removing these zero summands and using $M \cong \operatorname{coker}(A)$ proves the asserted decomposition.

Structural Commentary: Smith form turns presentations into direct sums.
Key Insight: Diagonal relations create cyclic torsion summands, and zero rows create free summands. □

Perspective 2.7.7. *Smith Form as Diagonalized Relations*
Proposition 2.7.2 encodes generators and relations as a finite matrix cokernel.
Theorem 2.7.4 changes bases to isolate those relations.
Corollary 2.7.6 reads off the resulting cyclic and free summands.
This mechanism concerns finite presentations; it does not classify arbitrary non-f.g. modules.

Example 2.7.8. *Smith Form for a Finite Abelian Group*
Let $M = \mathbb{Z}^2/\langle\!\langle (6, 0), (0, 10), (2, 4)\rangle\!\rangle_{\mathbb{Z}}$. Its three displayed relations are the columns of the finite presentation matrix $A = \left(\begin{smallmatrix} 6 & 0 & 2 \\ 0 & 10 & 4 \end{smallmatrix}\right)$.
The entries generate $\Delta_1(A) = \langle 6, 10, 2, 4\rangle = \langle 2\rangle$.

The 2×2 minors from the three column pairs are 60, 24, and -20, so $\Delta_2(A) = \langle 60, 24, -20 \rangle = \langle 4 \rangle$.
The Smith form has two nonzero invariant factors by the determinantal-ideal formulas in the proof of Theorem 2.7.4.
Those factors satisfy $d_1 \sim 2$ and $d_1 d_2 \sim 4$ by same formulas. Hence $d_2 \sim 2$ by cancellation; $M \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$ by Corollary 2.7.6.
Key Insight: The first two determinantal ideals recover the two cyclic summands.

2.8 Finitely Generated PID Modules

Theorem 2.8.1. *Finitely Generated Torsion-Free Modules Are Free*
Let M be a f.g. R-module. Then M is free $\iff$ M is torsion-free.

Proof.
($\Rightarrow$) Let $\mathcal{B}$ be an R-basis of M, $a \in R \setminus \{0_R\}$, $am = 0_M$. Choose finite $H \subseteq \mathcal{B}$, $(r_b)_{b \in H} \in R^H$ such that $m = \sum_{b \in H} r_b b$.
Then $\sum_{b \in H} (ar_b) b = 0_M$, so $(\forall b \in H)\,[ar_b = 0_R]$ by the independence of $\mathcal{B}$.
Since R is an integral domain and $a \neq 0_R$, $(\forall b \in H)\,[r_b = 0_R]$. Thus $m = 0_M$, and M is torsion-free by Definition 1.6.1(ii).
($\Leftarrow$) Assume M is torsion-free.
(a) *Independent Core*: Choose a finite generating set $G = \{u_1, \ldots, u_n\}$ of M.
Choose an inclusion-maximal R-linearly independent subset $S = \{v_1, \ldots, v_k\} \subseteq G$.
Set $L := \langle\!\langle S \rangle\!\rangle_R$. Then S is an R-basis of L, so L is finite free of rank k.
(b) *Common Scalar*: Set $W := G \setminus S$. Maximality makes $S \cup \{w\}$ dependent for $w \in W$.
The independence of S forces the coefficient of w in each nontrivial relation to be nonzero.
Choose coefficients $a_w \in R \setminus \{0_R\}$ and $b_{w,i} \in R$, indexed by $w \in W$, such that $(\forall w \in W)\,[a_w w = \sum_{i=1}^{k} b_{w,i} v_i]$.
Set $a := \prod_{w \in W} a_w$, with the empty product equal to 1_R. Then $a \neq 0_R$ because R is an integral domain.
Set $aM := \{am : m \in M\}$. For $w \in W$, write $a = c_w a_w$; then $aw = \sum_{i=1}^{k} c_w b_{w,i} v_i \in L$.
Together with $av_i \in L$ for $1 \leq i \leq k$, these relations imply $(\forall u \in G)\,[au \in L]$. Since G generates M, one has $aM \subseteq L$.
(c) *Free Image*: Define $\mu_a : M \to M$ by $\mu_a(m) := am$. Then $\mu_a \in \mathrm{Hom}_R(M, M)$ and $aM = \mathrm{im}(\mu_a)$.
Hence $aM \leq L$ by Proposition 1.4.2(iii) and the containment $aM \subseteq L$.
The module aM is free by Theorem 2.6.2, since L is finite free.
(d) *Transport*: The corestriction $\mu_a : M \to aM$ is surjective by the definition of aM.
It is injective because $a \neq 0_R$ and M is torsion-free. Thus $M \cong aM$, so M is free.

Structural Commentary: A maximal independent core produces a nonzero scalar sending M into a finite free span.
Key Insight: Multiplication by that nonzero product identifies M with the free submodule aM. □

Theorem 2.8.2. *Free Plus Torsion Decomposition*
Let M be a f.g. R-module and set $T := M_{\mathrm{tor}}$.
(i) There is a f.g. free submodule $F \leq M$ such that $M = T \oplus F$ and $F \cong M/T$.
(ii) If $M = T' \oplus G$, where $T' \leq M$ is torsion and $G \leq M$ is free, then $T' = T$ and $G \cong M/T$.

Proof.
(i) Set $Q := M/T$. Then $T \leq M$ and Q is torsion-free by Proposition 1.6.3(i)–(ii). Choose generators $u_1, \ldots, u_n$ of M.
Then $Q = \langle\!\langle u_1 + T, \ldots, u_n + T \rangle\!\rangle_R$, so Q is f.g. Hence Q is free by Theorem 2.8.1. Let $\pi : M \twoheadrightarrow Q$ be the quotient map.
Choose a section $\sigma : Q \to M$ of π by Theorem 2.3.1(i). Set $F := \mathrm{im}(\sigma)$. The identity $\ker \pi = T$ holds by Proposition 1.5.2(iii).
Hence $M = T \oplus F$ and $F \cong Q = M/T$ by Theorem 2.3.1(i). Since Q is free and $F \cong Q$, the module F is free.
The images under σ of the generators $u_i + T$ generate F, so F is f.g.
(ii) Assume $M = T' \oplus G$, where T' is torsion, G is free. Then $T' \subseteq T$ by Definition 1.6.1(iv). Fix $x \in T$, $x = t' + g$ with $(t', g) \in T' \times G$.
Since $T \leq M$ and $x, t' \in T$, one has $g = x - t' \in T \cap G$. Let $\rho : M \twoheadrightarrow G$, $t' + g \mapsto g$, be the coordinate projection.
The image under ρ of a finite generating set of M generates G, so G is f.g. Hence G is torsion-free by Theorem 2.8.1.
Since $g \in T \cap G$, one has $g = 0_M$. Thus $x = t' \in T'$, and hence $T = T'$. Finally, $G \cong M/T$ by Theorem 1.7.4(i).

Structural Commentary: The torsion-free quotient is free and splits; a free summand contains no nonzero torsion.
Key Insight: Every free complement is isomorphic to the common quotient model M/T. □

2.9 Primary Decomposition and Cyclic Primary Modules

Definition 2.9.1. *Primary Module*
Let $p \in R$ be prime. A torsion R-module M is *p-primary* if $(\exists e \in \mathbb{N})\,[\mathrm{Ann}_R(M) = \langle p^e \rangle]$.
Equivalently, $(\exists e \in \mathbb{N})\,[o(M) \sim p^e]$ by Definition 2.5.3.

Theorem 2.9.2. *Primary Decomposition*
Let $n \in \mathbb{N}$, $M \neq \{0_M\}$ be f.g. torsion, $p_1, \ldots, p_n \in R$ be distinct nonassociate primes. Suppose $e_1, \ldots, e_n \in \mathbb{N}$ and $o(M) \sim \mu := \prod_{i=1}^{n} p_i^{e_i}$.
Set $I := \{1, \ldots, n\}$. For $i \in I$, set $q_i := p_i^{e_i}$, $\mu_i := \prod_{j \in I \setminus \{i\}} q_j$, and $M_{p_i} := \mu_i M$.
(i) $M = \bigoplus_{i=1}^{n} M_{p_i}$ and $(\forall i \in I)\,[M_{p_i} = \{v \in M : q_i v = 0_M\}]$.
(ii) Each M_{p_i} is f.g. and p_i-primary, with $o(M_{p_i}) \sim q_i$.
(iii) The unordered family $\{(p_i, M_{p_i}) : i \in I\}$, with primes taken up to associates, is determined by M.

Proof.

(i)

(a) *Spanning*: The elements $\mu_1, \dots, \mu_n$ have no common nonunit divisor by the distinct-prime factorization of μ.
Choose $a_1, \dots, a_n \in R$ with $\sum_{i=1}^{n} a_i\mu_i = 1_R$ by induction on n from Theorem 3.10.6(iii).
Thus $(\forall x \in M)\,[x = \sum_{i=1}^{n} a_i\mu_i x]$, so $M = \sum_{i=1}^{n} M_{p_i}$.

(b) *Kernel Description*: Since $q_i\mu_i = \mu$ and $\mu M = \{0_M\}$, $(\forall i \in I)\,[q_i M_{p_i} = \{0_M\}]$.
Fix $i \in I$ and $v \in M$ with $q_i v = 0_M$. The elements μ_i and q_i have no common nonunit divisor.
Choose $a, b \in R$ with $a\mu_i + bq_i = 1_R$ by Theorem 3.10.6(iii).
Then $v = a\mu_i v + bq_i v = a\mu_i v \in M_{p_i}$. Hence $M_{p_i} = \{v \in M : q_i v = 0_M\}$.

(c) *Directness*: Let $(x_i)_{i=1}^{n} \in \prod_{i=1}^{n} M_{p_i}$ satisfy $\sum_{i=1}^{n} x_i = 0_M$, and fix $i \in I$.
If $j \neq i$, then $q_j \mid \mu_i$ and $q_j x_j = 0_M$, so $\mu_i x_j = 0_M$. By multiplying the displayed sum by μ_i, $\mu_i x_i = 0_M$.
Together with $q_i x_i = 0_M$ and the Bézout identity for μ_i, q_i, this implies $x_i = 0_M$. Thus the sum is direct.

(ii) The image $M_{p_i} = \mu_i M$ is f.g. because the μ_i-multiples of a finite generating set of M generate it. For $i \in I$, let $\alpha_i := o(M_{p_i})$.
Since $q_i M_{p_i} = \{0_M\}$, $(\forall i \in I)\,[\alpha_i \mid q_i]$. By Theorem 3.10.7(i)–(ii), choose $f_i \in \{0, \dots, e_i\}$ with $\alpha_i \sim p_i^{f_i}$ $(i \in I)$.
By part (i), Proposition 2.5.4, $o(M) \sim \operatorname{lcm}(\alpha_1, \dots, \alpha_n)$. Hence $\operatorname{lcm}(\alpha_1, \dots, \alpha_n) \sim \prod_{i=1}^{n} q_i$.
Unique factorization forces $(\forall i \in I)\,[f_i = e_i]$. Since $q_i \neq 0_R$ and $q_i M_{p_i} = \{0_M\}$, the module M_{p_i} is torsion.
Thus $o(M_{p_i}) \sim q_i$, so M_{p_i} is p_i-primary by Definition 2.9.1.

(iii) The prime-power factors q_i of $o(M)$ are determined up to associates and permutation by Theorem 3.10.7(ii).
If $q_i' \sim q_i$, then $\{v \in M : q_i' v = 0_M\} = \{v \in M : q_i v = 0_M\}$ because the associate factor is a unit.
Part (i) therefore makes each primary component intrinsic.

Structural Commentary: Bézout isolates prime-power kernels; their order lcm recovers every primary exponent.
Key Insight: Each intrinsic component is exactly $\ker(q_i : M \to M)$. □

Definition 2.9.3. *p-Power and p-Torsion Submodules*
Let $p \in R$ be prime and let M be an R-module.

(i) For $j \in \mathbb{N}_0$, the *jth p-power submodule* is $p^j M := \{p^j v : v \in M\} = \operatorname{im}(p^j \operatorname{id}_M) \leq M$.
(ii) The *first p-torsion layer* is $M[p] := \ker(p \operatorname{id}_M) = \{v \in M : pv = 0_M\} \leq M$.

Lemma 2.9.4. *The First p-Torsion Layer*
Let $p \in R$ be prime, let $\kappa := R/\langle p\rangle$, and let M be an R-module.

(i) If N is an R-module and $pN = \{0_N\}$, then $(r + \langle p\rangle)n := rn$ $(r \in R, n \in N)$ defines a κ-vector-space structure on N. In particular, $M[p]$ is a κ-vector space.
(ii) If $M = S \oplus T$, then $M[p] = S[p] \oplus T[p]$.

Proof.

(i) The prime element p is irreducible, so $\langle p\rangle$ is maximal by Theorem 3.10.6(i). Hence κ is a field by Theorem 3.4.4.
Suppose $r + \langle p\rangle = r' + \langle p\rangle$ and fix $n \in N$. Choose $c \in R$ satisfying $r - r' = cp$. Then $(r - r')n = c(pn) = 0_N$.
Thus the scalar action is well-defined. The vector-space axioms follow from the R-module axioms and the quotient-ring operations.
The submodule $M[p]$ satisfies $p(M[p]) = \{0_M\}$ by Definition 2.9.3(ii), so the particular case follows.

(ii) Let $M = S \oplus T$ and fix $v \in M[p]$. Write $v = s + t$ with $(s, t) \in S \times T$. Then $ps + pt = 0_M$.
Since $ps \in S$, $pt \in T$, and $S \cap T = \{0_M\}$, one has $ps = pt = 0_M$. Hence $v \in S[p] + T[p]$.
Conversely, $s \in S[p]$ and $t \in T[p]$ imply $p(s + t) = 0_M$. Finally, $S[p] \cap T[p] \subseteq S \cap T = \{0_M\}$, so the sum is direct.

Structural Commentary: Annihilation by p permits residue-class scalars; direct-sum intersections separate the p-killed coordinates.
Key Insight: The functor $M \mapsto M[p]$ preserves finite internal direct sums. □

Definition 2.9.5. *Primary Layer Dimensions*
Let $p \in R$ be prime, let $\kappa := R/\langle p\rangle$, and let M be an R-module. For $k \in \mathbb{N}$, one has $p^k M \leq p^{k-1} M$ because $(\forall v \in M)\,[p^k v = p^{k-1}(pv)]$.
Every class $p^{k-1}v + p^k M$ is annihilated by p. Thus $p^{k-1}M/p^k M$ is a κ-vector space by Lemma 2.9.4(i).
Define the *kth primary layer dimension* by $\lambda_k(M) := \dim_\kappa(p^{k-1}M/p^k M)$.

Proposition 2.9.6. *Layer Counts Recover Primary Exponents*
Let $p \in R$ be prime, $\kappa := R/\langle p\rangle$, $m \in \mathbb{N}$, $e_1 \geq \cdots \geq e_m \geq 1$. Suppose $M \cong \bigoplus_{i=1}^{m} R/\langle p^{e_i}\rangle$.

(i) $(\forall k \in \mathbb{N})\,[\lambda_k(M) = \#\{i \in \{1, \dots, m\} : e_i \geq k\}]$.
(ii) $(\forall k \in \mathbb{N})\,[\#\{i \in \{1, \dots, m\} : e_i = k\} = \lambda_k(M) - \lambda_{k+1}(M)]$.

Proof.

(i) Fix $(e, k) \in \mathbb{N}^2$ and set $C_e := R/\langle p^e\rangle$ and $L_{e,k} := p^{k-1}C_e/p^k C_e$. If $k > e$, then $L_{e,k} = \{0_{L_{e,k}}\}$.
Assume $k \leq e$ and define $\phi_{e,k} : \kappa \to L_{e,k}$ by $\phi_{e,k}(r + \langle p\rangle) := p^{k-1}(r + \langle p^e\rangle) + p^k C_e$.
If $r - r' = ps$, then the two images differ by $p^k(s + \langle p^e\rangle) \in p^k C_e$, so $\phi_{e,k}$ is well-defined.
The map $\phi_{e,k}$ is κ-linear and surjective by its formula. If $\phi_{e,k}(r + \langle p\rangle) = 0$, choose $s, t \in R$ satisfying $p^{k-1}(r - ps) = p^e t$.
By cancellation in the domain, $r = ps + p^{e-k+1}t \in \langle p\rangle$. Thus $\phi_{e,k}$ is injective, and consequently $L_{e,k} \cong \kappa$ for $k \leq e$.
An R-module isomorphism maps p^j-power submodules isomorphically, induces isomorphisms on corresponding primary layers.
Thus λ_k is invariant under R-module isomorphism.
For the displayed cyclic direct sum, p^j-power submodules and their quotients are coordinatewise.
Set $I_k := \{i \in \{1, \dots, m\} : e_i \geq k\}$. Hence its kth primary layer is $\bigoplus_{i \in I_k} \kappa$, so $\lambda_k(M) = \#I_k$.

(ii) Fix $k \in \mathbb{N}$ and set $I_k := \{i \in \{1, \dots, m\} : e_i \geq k\}$. Then $I_{k+1} \subseteq I_k$ and $I_k \setminus I_{k+1} = \{i \in \{1, \dots, m\} : e_i = k\}$.
By part (i), $\#(I_k \setminus I_{k+1}) = \#I_k - \#I_{k+1} = \lambda_k(M) - \lambda_{k+1}(M)$.

Structural Commentary: A cyclic block contributes one residue-field dimension until its exponent is exhausted.
Key Insight: Consecutive layer-dimension differences count blocks ending at each exponent. □

Theorem 2.9.7. *Cyclic Decomposition of a Primary Module*
Let $p \in R$ be prime, let $e \in \mathbb{N}$, and let M be a f.g. p-primary module with $o(M) \sim p^e$.

(i) There are $m \in \mathbb{N}$, $v_1, \dots, v_m \in M$, and $e = e_1 \geq e_2 \geq \cdots \geq e_m \geq 1$. The vectors satisfy $M = \bigoplus_{i=1}^{m} \langle\langle v_i \rangle\rangle_R$.
Their annihilators satisfy $(\forall i \in \{1, \dots, m\})\,[\mathrm{Ann}_R(v_i) = \langle p^{e_i} \rangle]$.
(ii) The exponent multiset $\{e_1, \dots, e_m\}$ is determined by M. Consequently, so is the ordered chain $\langle p^{e_1} \rangle \subseteq \cdots \subseteq \langle p^{e_m} \rangle$.

Proof.
(i)

(a) *Diagonal Presentation*: Choose $R^a \xrightarrow{A} R^b \to M \to 0$ by Proposition 2.7.2. Choose Smith form D of A by Theorem 2.7.4.
Choose $s, t \in \mathbb{N}_0$ and nonunits $d_1, \dots, d_t \in R$ with $M \cong R^s \oplus \bigoplus_{\ell=1}^{t} R/\langle d_\ell \rangle$ by Corollary 2.7.6.
If $s > 0$, the free summand R^s contains a nonzero torsion-free element, contradicting that M is torsion.
Hence $s = 0$. Since $M \neq \{0_M\}$, one has $t \geq 1$.

(b) *Prime Powers*: The order identity $\mathrm{lcm}(d_1, \dots, d_t) \sim o(M) \sim p^e$ holds by Proposition 2.5.4.
Every prime factor of d_ℓ is associate to p. By Theorem 3.10.7(i)–(ii), choose $e_\ell \in \mathbb{N}$ with $d_\ell \sim p^{e_\ell}$ $(1 \leq \ell \leq t)$.
Set $m := t$ and reorder so $e_1 \geq \cdots \geq e_m$. The least-common-multiple identity implies $e_1 = e$.

(c) *Internal Summands*: Set $C := \bigoplus_{i=1}^{m} R/\langle p^{e_i} \rangle$. Since $\langle d_i \rangle = \langle p^{e_i} \rangle$, choose an isomorphism $\Psi : C \to M$.
Let $\mathbf{u}_i$ be the standard generator of the ith coordinate summand and set $v_i := \Psi(\mathbf{u}_i)$.
Since Ψ is an isomorphism, $M = \bigoplus_{i=1}^{m} \langle\langle v_i \rangle\rangle_R$. The standard generator of $R/\langle p^{e_i} \rangle$ has annihilator $\langle p^{e_i} \rangle$.
An isomorphism preserves annihilators, so $\mathrm{Ann}_R(v_i) = \langle p^{e_i} \rangle$.

(ii) The dimensions $\lambda_k(M)$ are intrinsic because module isomorphisms induce isomorphisms on the layer quotients.
By Proposition 2.9.6(ii), the multiplicity of the exponent k is $\lambda_k(M) - \lambda_{k+1}(M)$.
Thus M determines every exponent multiplicity and hence the exponent multiset.
Its decreasing order determines the annihilator chain.

Structural Commentary: Smith form supplies prime-power blocks; primary-layer differences recover their multiplicities.
Key Insight: The differences $\lambda_k(M) - \lambda_{k+1}(M)$ recover each exponent multiplicity. □

2.10 Elementary Divisors and Invariant Factors

Definition 2.10.1. *Elementary Divisors*
Set $\mathrm{ElemDiv}(0) := \emptyset$. Let $0 \neq M$ be f.g. torsion. Choose its intrinsic primary components by Theorem 2.9.2.
Choose their intrinsic exponent chains by Theorem 2.9.7. Suppose the resulting cyclic summands have annihilators $\langle p_i^{e_{i,j}} \rangle$.
Define the *elementary-divisor multiset* by $\mathrm{ElemDiv}(M) := \{p_i^{e_{i,j}}\}_{i,j}$, with entries taken up to associates.

Theorem 2.10.2. *Primary Cyclic Decomposition*
Let M be a f.g. torsion R-module.

(i) There is a finite set I, together with distinct nonassociate primes $(p_i)_{i \in I}$ and $(k_i)_{i \in I} \in \mathbb{N}^I$.
There are exponents $e_{i,1} \geq \cdots \geq e_{i,k_i} \geq 1$ and vectors $v_{i,j} \in M$ $(i \in I,\ 1 \leq j \leq k_i)$. These data satisfy $M = \bigoplus_{i \in I} \bigoplus_{j=1}^{k_i} \langle\langle v_{i,j} \rangle\rangle_R$.
Their annihilators satisfy $\mathrm{Ann}_R(v_{i,j}) = \langle p_i^{e_{i,j}} \rangle$ $(i \in I,\ 1 \leq j \leq k_i)$. For $M = \{0_M\}$, take $I = \emptyset$.
(ii) If N is f.g. torsion, then $M \cong N \iff \mathrm{ElemDiv}(M) = \mathrm{ElemDiv}(N)$.

Proof.
(i) If $M = \{0_M\}$, the empty direct sum has the asserted form. Suppose $M \neq \{0_M\}$.
By Theorem 2.9.2, there is a finite family of f.g. p_i-primary components. It satisfies $M = \bigoplus_{i \in I} M_{p_i}$.
By Theorem 2.9.7(i), each M_{p_i} has an internal cyclic decomposition. Its exponent chain and annihilators have the asserted form.
Substitution into the primary decomposition proves the displayed internal direct sum.
(ii) $(\Rightarrow)$ Suppose $\Phi : M \xrightarrow{\sim} N$. The map Φ identifies the intrinsic primary components by Theorem 2.9.2(iii).
Their exponent multisets agree by Theorem 2.9.7(ii), so $\mathrm{ElemDiv}(M) = \mathrm{ElemDiv}(N)$.
(ii) $(\Leftarrow)$ Suppose $\mathrm{ElemDiv}(M) = \mathrm{ElemDiv}(N)$. Set $C := \bigoplus_{q \in \mathrm{ElemDiv}(M)} R/\langle q \rangle$. Then $M \cong C \cong N$ by part (i) and Theorem 2.5.5(i).

Structural Commentary: Intrinsic primary kernels and exponent layers make the prime-power blocks independent of choices.
Key Insight: The elementary-divisor multiset determines the common quotient-sum model. □

Proposition 2.10.3. *Elementary Divisors of a Direct Sum*
Let A and B be f.g. torsion, and let $\uplus$ denote multiset union. Then $\mathrm{ElemDiv}(A \oplus B) = \mathrm{ElemDiv}(A) \uplus \mathrm{ElemDiv}(B)$.

Proof. Choose primary cyclic decompositions of A and B by Theorem 2.10.2(i). Write $A = \bigoplus_{i \in I} A_i$ and $B = \bigoplus_{j \in J} B_j$.
Then $A \oplus B = (\bigoplus_{i \in I} A_i) \oplus (\bigoplus_{j \in J} B_j)$. This is a primary cyclic decomposition, including when I or J is empty.
By Definition 2.10.1, its prime-power annihilators form the required multiset. That multiset is $\mathrm{ElemDiv}(A) \uplus \mathrm{ElemDiv}(B)$.
Structural Commentary: Concatenating primary cyclic decompositions concatenates their annihilator multisets.
Key Insight: Multiset union retains repeated prime-power blocks. □

Definition 2.10.4. *Invariant Factors*
Let M be f.g. torsion. If $\mathrm{ElemDiv}(M)=\emptyset$, define $\mathrm{Inv}(M):=()$. Suppose $\mathrm{ElemDiv}(M)\neq\emptyset$.
Group it as $\{p_i^{e_{i,j}} : i\in I,\ 1\le j\le k_i\}$; p_i are distinct nonassociate primes. Order each exponent row by $e_{i,1}\ge\cdots\ge e_{i,k_i}\ge 1$.
Set $m:=\max_{i\in I} k_i$ and extend every row by $e_{i,j}:=0$ for $k_i<j\le m$. Set $d_j:=\prod_{i\in I} p_i^{e_{i,j}}$ $(1\le j\le m)$.
Invariant-factor tuple is $\mathrm{Inv}(M):=(d_1,\dots,d_m)$, with entries taken up to associates. Entries are nonunits and satisfy $d_m\mid\cdots\mid d_1$.

Method 2.10.5. *From Elementary Divisors to Invariant Factors*
(i) If $\mathrm{ElemDiv}(M)=\emptyset$, return $\mathrm{Inv}(M)=()$. Otherwise, group the input multiset by associate prime.
(ii) Write the ith group as $p_i^{e_{i,1}},\dots,p_i^{e_{i,k_i}}$ with $e_{i,1}\ge\cdots\ge e_{i,k_i}$. Pad every exponent row by zeros to length $m:=\max_i k_i$.
(iii) Form $d_j:=\prod_i p_i^{e_{i,j}}$ for $1\le j\le m$.
(iv) Return $\mathrm{Inv}(M)=(d_1,\dots,d_m)$ and verify $d_{j+1}\mid d_j$ from $e_{i,j+1}\le e_{i,j}$.
Recover the input by extracting its maximal prime-power factors from each d_j.

Theorem 2.10.6. *Invariant Factor Decomposition*
Let M be f.g. torsion and write $\mathrm{Inv}(M)=(d_1,\dots,d_m)$, where $m\in\mathbb{N}_0$.
(i) $M\cong\bigoplus_{j=1}^{m} R/\langle d_j\rangle$. If $m\ge 1$, then $d_j\notin R^\times$ $(1\le j\le m)$ and $d_{j+1}\mid d_j$ $(1\le j<m)$.
(ii) If N is f.g. torsion, then $M\cong N\iff\mathrm{Inv}(M)=\mathrm{Inv}(N)$.

Proof.
(i) If $m=0$, then $\mathrm{ElemDiv}(M)=\emptyset$ by Definition 2.10.4.
Hence $M=\{0_M\}$ by Theorem 2.10.2(i), so the empty direct sum proves the claim. Suppose $m\ge 1$.
By Definition 2.10.4, $\mathrm{ElemDiv}(M)=\{p_i^{e_{i,j}} : i\in I,\ 1\le j\le k_i\}$. Pad exponent rows by zeros, set $d_j=\prod_{i\in I} p_i^{e_{i,j}}$.
By Theorem 2.10.2(i), M is a direct sum of the associated primary cyclic blocks.
Each block is isomorphic to its quotient model by Theorem 2.5.5(i).
Hence $M\cong\bigoplus_{i\in I}\bigoplus_{j=1}^{k_i} R/\langle p_i^{e_{i,j}}\rangle$. For $1\le j\le m$, set $C_j:=\bigoplus_{\substack{i\in I\\ e_{i,j}>0}} R/\langle p_i^{e_{i,j}}\rangle$. By finite reindexing, $M\cong\bigoplus_{j=1}^{m} C_j$.
The nonunit orders in C_j are pairwise coprime. By Theorem 2.5.6(i)–(ii), C_j is cyclic and has order associated to d_j.
Hence $C_j\cong R/\langle d_j\rangle$ by Theorem 2.5.5(i). Substitution proves the asserted decomposition.
The nonunit and divisibility properties hold by Definition 2.10.4.
(ii) ($\Rightarrow$) Suppose $M\cong N$. Then $\mathrm{ElemDiv}(M)=\mathrm{ElemDiv}(N)$ by Theorem 2.10.2(ii); $\mathrm{Inv}(M)=\mathrm{Inv}(N)$ by Definition 2.10.4.
(ii) ($\Leftarrow$) Suppose $\mathrm{Inv}(M)=\mathrm{Inv}(N)$. Factoring invariant factors recovers equal prime-power multisets by Theorem 3.10.7(ii).
Thus $\mathrm{ElemDiv}(M)=\mathrm{ElemDiv}(N)$. Hence $M\cong N$ by Theorem 2.10.2(ii).

Structural Commentary: Coprime cyclic composition packs a single block from each prime into a divisibility column.
Key Insight: Factoring the invariant factors reverses the column packing. □

Example 2.10.7. *Packing Elementary Divisors into Invariant Factors*
Let $R=\mathbb{R}[z]$ and $\mathrm{ElemDiv}(M)=\{(z-1)^3, z-1, (z^2+1)^2, z^2+1\}$. The polynomials $z-1$ and z^2+1 are nonassociate primes in R.
By Method 2.10.5, $d_1=(z-1)^3(z^2+1)^2$ and $d_2=(z-1)(z^2+1)$. Thus $\mathrm{Inv}(M)=(d_1,d_2)$ with $d_2\mid d_1$.
By Theorem 2.10.6(i), $M\cong R/\langle d_1\rangle\oplus R/\langle d_2\rangle$.
Structural Commentary: Separate prime rows become the two invariant-factor columns.
Key Insight: Align exponents by height before multiplying across primes.

Example 2.10.8. *Recombining Elementary Divisors*
As a $\mathbb{Z}$-module, let $G:=\mathbb{Z}/12\mathbb{Z}\oplus\mathbb{Z}/18\mathbb{Z}$. By the primary decompositions of its cyclic summands, $\mathrm{ElemDiv}(G)=\{2^2,2,3^2,3\}$.
The exponent rows are $(2,1)$ for both primes, so $d_1=2^2\cdot 3^2=36$ and $d_2=2\cdot 3=6$.
Thus $\mathrm{Inv}(G)=(36,6)$ and $G\cong\mathbb{Z}/36\mathbb{Z}\oplus\mathbb{Z}/6\mathbb{Z}$ by Theorem 2.10.6(i), with $6\mid 36$.
Structural Commentary: The 2- and 3-primary rows recombine into the divisibility chain $6\mid 36$.
Key Insight: Matching exponent ranks determines which prime powers multiply together.

Corollary 2.10.9. *Classification of Finitely Generated PID Modules*
Let M and N be f.g. R-modules. Set $T_X:=X_{\mathrm{tor}}$ and $\rho_X:=\mathrm{rk}_R(X/T_X)$ $(X\in\{M,N\})$.
(i) There are $r,m\in\mathbb{N}_0$ and nonunits $d_1,\dots,d_m\in R$ with $d_{j+1}\mid d_j$ $(1\le j<m)$. For these data, $M\cong R^r\oplus\bigoplus_{j=1}^{m} R/\langle d_j\rangle$.
(ii) $M\cong N\iff[\rho_M=\rho_N\wedge\mathrm{Inv}(T_M)=\mathrm{Inv}(T_N)]$.
(iii) $M\cong N\iff[\rho_M=\rho_N\wedge\mathrm{ElemDiv}(T_M)=\mathrm{ElemDiv}(T_N)]$.

Proof.
(i) By Theorem 2.8.2(i), choose f.g. free $F\le M$ with $M=T_M\oplus F$, $F\cong M/T_M$, $r:=\mathrm{rk}_R(F)\in\mathbb{N}_0$; $F\cong R^r$ by Proposition 2.2.6(i).
Coordinate projection $M\twoheadrightarrow T_M$ maps finite generating set of M onto generating set of T_M, so T_M is f.g.
Write $\mathrm{Inv}(T_M)=(d_1,\dots,d_m)$ with $m\in\mathbb{N}_0$. By Theorem 2.10.6(i), these data have the asserted properties for T_M.
Substitution proves the claim.
(ii) ($\Rightarrow$) Suppose $\Phi: M\xrightarrow{\sim} N$ and fix $x\in T_M$. Choose $a\in R\setminus\{0_R\}$ with $ax=0_M$. Then $a\Phi(x)=0_N$, so $\Phi(T_M)\subseteq T_N$.
The same argument for Φ^{-1} proves $\Phi(T_M)=T_N$. Thus Φ restricts to $T_M\xrightarrow{\sim}T_N$ and induces $M/T_M\xrightarrow{\sim}N/T_N$.
Hence $\rho_M=\rho_N$ by Proposition 2.2.6(ii). The invariant-factor tuples agree by Theorem 2.10.6(ii).
(ii) ($\Leftarrow$) Suppose $\rho_M=\rho_N$ and $\mathrm{Inv}(T_M)=\mathrm{Inv}(T_N)$. Then $M/T_M\cong N/T_N$ by Proposition 2.2.6(ii).
Torsion modules satisfy $T_M\cong T_N$ by Theorem 2.10.6(ii). As $M\cong T_M\oplus M/T_M$, $N\cong T_N\oplus N/T_N$ by Theorem 2.8.2(i), $M\cong N$.
(iii) ($\Rightarrow$) Suppose $M\cong N$. Then $\rho_M=\rho_N$ by part (ii). The given module isomorphism induces $T_M\cong T_N$.
Hence $\mathrm{ElemDiv}(T_M)=\mathrm{ElemDiv}(T_N)$ by Theorem 2.10.2(ii).
(iii) ($\Leftarrow$) Suppose $\rho_M=\rho_N$ and $\mathrm{ElemDiv}(T_M)=\mathrm{ElemDiv}(T_N)$. Then $M/T_M\cong N/T_N$ by Proposition 2.2.6(ii).
The torsion modules satisfy $T_M\cong T_N$ by Theorem 2.10.2(ii).
The free-plus-torsion decompositions therefore imply $M\cong N$ by Theorem 2.8.2(i).

Structural Commentary: The intrinsic torsion summand carries invariant factors; the free quotient carries the rank.
Key Insight: Isomorphism requires equality of both independent data sets. □

Method 2.10.10. *Reading a Module from Smith Form*

Let $R^n \xrightarrow{A} R^m \to M \to 0$ be a finite presentation. Set $D := \operatorname{diag}(d_1, \dots, d_r, 0, \dots, 0)$.
Suppose $A \sim_{\text{eq}} D$ and $0 \le r \le \min\{m, n\}$. If $r \ge 1$, suppose $(d_1, \dots, d_r) \in (R \setminus \{0_R\})^r$ and $d_1 \mid \cdots \mid d_r$.

(i) Record the torsion-coordinate quotients $(R/\langle d_i\rangle)_{i=1}^r$ and the free-coordinate module R^{m-r}.
(ii) Delete the zero quotients indexed by $d_i \in R^\times$. Remaining list, together with R^{m-r}, is decomposition from Corollary 2.7.6.
(iii) If every d_i is a unit, return $\operatorname{Inv}(M_{\text{tor}}) = ()$. Otherwise, if nonunit entries are $d_s, \dots, d_r$, return $\operatorname{Inv}(M_{\text{tor}}) = (d_r, \dots, d_s)$.
(iv) In nonempty case, factor each d_i into pairwise nonassociate maximal prime powers. Retain multiplicities for $\operatorname{ElemDiv}(M_{\text{tor}})$.

Key Insight: Reverse the nonunit Smith entries for the repository's largest-first invariant-factor tuple.

Perspective 2.10.11. *Largest Invariant Factor and Product*

Let $0 \ne M$ be f.g. torsion with $\operatorname{Inv}(M) = (d_1, \dots, d_m)$. Decomposition $M \cong \bigoplus_{j=1}^m R/\langle d_j\rangle$ holds by Theorem 2.10.6(i).

Thus $\operatorname{Ann}_R(M) = \langle \operatorname{lcm}(d_1, \dots, d_m)\rangle$ by Proposition 2.5.4. Since $d_m \mid \cdots \mid d_1$, this ideal is $\langle d_1\rangle$.

The column construction in Definition 2.10.4 uses each elementary divisor once. Hence $\prod_{j=1}^m d_j \sim \prod_{q \in \operatorname{ElemDiv}(M)} q$.

Thus the largest invariant factor controls the annihilator, whereas the total product records every elementary-divisor block.

Theorem 2.10.12. *Characterizing Cyclic Torsion Modules*
Let $n \in \mathbb{N}$, let $0 \ne M$ be f.g. torsion, and let $p_1, \dots, p_n$ be distinct nonassociate primes.
Suppose $e_1, \dots, e_n \in \mathbb{N}$ and $o(M) \sim \mu := \prod_{i=1}^n p_i^{e_i}$. Set $I := \{1, \dots, n\}$. The following are equivalent:

(i) M is cyclic.
(ii) The primary components M_{p_i} are cyclic ($i \in I$).
(iii) $\operatorname{ElemDiv}(M) = \{p_i^{e_i} : i \in I\}$.
(iv) $M \cong R/\langle\mu\rangle$.

Proof.

(i) ⇒ (ii) Suppose $M = \langle\!\langle x\rangle\!\rangle_R$ and choose the order representative $o(x) = \mu$. By Theorem 2.5.6(iii), choose $x_1, \dots, x_n \in M$.
These vectors satisfy $M = \bigoplus_{i=1}^n \langle\!\langle x_i\rangle\!\rangle_R$. These vectors satisfy $o(x_i) \sim p_i^{e_i}$ ($i \in I$).
Hence $M_{p_i} = \langle\!\langle x_i\rangle\!\rangle_R$ by Theorem 2.9.2(iii), so every primary component is cyclic.

(ii) ⇒ (iii) By Theorem 2.9.2(i)–(ii), the primary decomposition is indexed by I. It satisfies $M = \bigoplus_{i=1}^n M_{p_i}$ and $o(M_{p_i}) \sim p_i^{e_i}$ ($i \in I$).
Choose generators $(y_i)_{i\in I}$ with $M_{p_i} = \langle\!\langle y_i\rangle\!\rangle_R$. Then $\operatorname{Ann}_R(y_i) = \operatorname{Ann}_R(M_{p_i}) = \langle p_i^{e_i}\rangle$ ($i \in I$).
Hence $M_{p_i} \cong R/\langle p_i^{e_i}\rangle$ by Theorem 2.5.5(i). Thus $\operatorname{ElemDiv}(M_{p_i}) = \{p_i^{e_i}\}$ by Definition 2.10.1.
By Proposition 2.10.3, iterated over the primary components, $\operatorname{ElemDiv}(M) = \{p_i^{e_i} : i \in I\}$.

(iii) ⇒ (iv) By Definition 2.10.4, $\operatorname{Inv}(M)$ has unique entry d_1. It satisfies $d_1 \sim \prod_{i=1}^n p_i^{e_i} \sim \mu$; $M \cong R/\langle d_1\rangle = R/\langle\mu\rangle$ by Theorem 2.10.6(i).

(iv) ⇒ (i) The module $R/\langle\mu\rangle$ is generated by $1 + \langle\mu\rangle$. Hence its image under any isomorphism to M generates M.

Structural Commentary: Coprime primary generators combine into single generator exactly when each prime contributes a single block.
Key Insight: Repeated same-prime blocks obstruct cyclicity. □

Definition 2.10.13. *Indecomposable Module*
A nonzero R-module M is *indecomposable* if $(\forall A, B \le M)\,[M = A \oplus B \Rightarrow A = \{0_M\} \vee B = \{0_M\}]$.

Theorem 2.10.14. *Indecomposable Finitely Generated Torsion Modules*
Let $0 \ne M$ be f.g. torsion. The following are equivalent:

(i) M is indecomposable.
(ii) M is primary cyclic.
(iii) $(\exists\, p \in R)(\exists\, e \in \mathbb{N})$ such that p is prime and $\operatorname{ElemDiv}(M) = \{p^e\}$.

Proof.

(i) ⇒ (ii) By Theorem 2.10.2(i), M has a finite nonempty primary cyclic decomposition. Its summands are nonzero.
After finite reindexing, write $M \cong \bigoplus_{\ell=1}^m C_\ell$ with $m \in \mathbb{N}$. Transport the coordinate summands into M.
If $m \ge 2$, a coordinate summand and the sum of the others form a nontrivial decomposition, contrary to indecomposability.
Hence $m = 1$, so M is primary cyclic.

(ii) ⇒ (iii) Choose a prime $p \in R$ and $e \in \mathbb{N}$ such that M is cyclic, p-primary, and $o(M) \sim p^e$.
Then $M \cong R/\langle p^e\rangle$ by Theorem 2.5.5(i). Thus $\operatorname{ElemDiv}(M) = \{p^e\}$ by Definition 2.10.1.

(iii) ⇒ (i) Suppose $M = A \oplus B$. Coordinate projections map a finite generating set of M onto generating sets of A and B.
Hence both summands are f.g.; they are torsion as submodules of M.
By Proposition 2.10.3, $\{p^e\} = \operatorname{ElemDiv}(A) \uplus \operatorname{ElemDiv}(B)$. Thus $\operatorname{ElemDiv}(A) = \emptyset$ or $\operatorname{ElemDiv}(B) = \emptyset$.
The corresponding summand is zero by Theorem 2.10.2(i), so M is indecomposable.

Structural Commentary: Transported primary cyclic summands split M unless the elementary-divisor multiset is a singleton.
Key Insight: A singleton elementary divisor is exactly an indecomposable block. □

3 Linear Operators as Modules

3.1 Polynomial Modules from Operators

Throughout this subsection, $\mathcal{V}$ is finite-dimensional over $\mathbb{F}$ unless explicitly stated otherwise.

Definition 3.1.1. *The Module Attached to an Operator*
For $T \in \mathcal{L}(\mathcal{V})$, the *operator module* attached to T is the $\mathbb{F}[z]$-module $\mathcal{V}_T$ whose underlying $\mathbb{F}$-vector space is $\mathcal{V}$. Its scalar action is $p(z) \cdot \mathbf{v} := p(T)\mathbf{v}$. For $A \in \mathrm{Mat}(n, n, \mathbb{F})$, define $(\mathbb{F}^n)_A$ by $p(z) \cdot \mathbf{x} := p(A)\mathbf{x}$.

Proposition 3.1.2. *Operator Modules Are Finitely Generated Torsion Modules*
Let $0 < \dim \mathcal{V} < \infty$ and $T \in \mathcal{L}(\mathcal{V})$.

(i) $\mathcal{V}_T$ is finitely generated over $\mathbb{F}[z]$.
(ii) $\mathcal{V}_T$ is a torsion $\mathbb{F}[z]$-module.

Proof.

(i) Let $(\mathbf{v}_1, \dots, \mathbf{v}_n)$ be an $\mathbb{F}$-basis of $\mathcal{V}$. Then $\mathcal{V}_T = \langle\langle \mathbf{v}_1, \dots, \mathbf{v}_n \rangle\rangle_{\mathbb{F}[z]}$ by $\mathbb{F} \subseteq \mathbb{F}[z]$.
(ii) Choose $0 \neq p \in \mathbb{F}[z]$ with $p(T) = 0$ by Proposition 1.1.7; $(\forall\, \mathbf{v} \in \mathcal{V})\, p \cdot \mathbf{v} = p(T)\mathbf{v} = \mathbf{0}$, so $\mathcal{V}_T$ is torsion by Definition 1.6.1(iii).

Structural Commentary: An $\mathbb{F}$-basis handles generation; one operator annihilator handles torsion.
Key Insight: One nonzero polynomial annihilates every vector. □

Theorem 3.1.3. *Submodules Are Invariant Subspaces*
Let $T \in \mathcal{L}(\mathcal{V})$ and $\mathcal{S} \subseteq \mathcal{V}$. Then $\mathcal{S} \leq_{\mathbb{F}[z]} \mathcal{V}_T \iff (\mathcal{S} \leq_{\mathbb{F}} \mathcal{V} \wedge T\mathcal{S} \subseteq \mathcal{S})$.

Proof.

($\Rightarrow$) Suppose $\mathcal{S} \leq_{\mathbb{F}[z]} \mathcal{V}_T$. Then $\mathcal{S} \leq_{\mathbb{F}} \mathcal{V}$ by $\mathbb{F} \subseteq \mathbb{F}[z]$. Hence $T\mathcal{S} \subseteq \mathcal{S}$ by $(\forall\, \mathbf{s} \in \mathcal{S})\, T\mathbf{s} = z \cdot \mathbf{s} \in \mathcal{S}$.
($\Leftarrow$) Suppose $\mathcal{S} \leq_{\mathbb{F}} \mathcal{V}$ and $T\mathcal{S} \subseteq \mathcal{S}$. Then $(\forall\, j \in \mathbb{Z}_{\geq 0})\, T^j\mathcal{S} \subseteq \mathcal{S}$ by induction on j.
For $p(z) = \sum_{j=0}^{m} a_j z^j \in \mathbb{F}[z]$ and $\mathbf{s} \in \mathcal{S}$, $p \cdot \mathbf{s} = \sum_{j=0}^{m} a_j T^j \mathbf{s} \in \mathcal{S}$. Thus $\mathcal{S} \leq_{\mathbb{F}[z]} \mathcal{V}_T$.

Structural Commentary: Restriction to constants recovers linearity; closure under z extends to every polynomial.
Key Insight: The scalar z acts exactly as T. □

Theorem 3.1.4. *Similarity Is Module Isomorphism*
Let $T, S \in \mathcal{L}(\mathcal{V})$.

(i) For $\Phi \in \mathrm{GL}(\mathcal{V})$, $\Phi \in \mathrm{Hom}_{\mathbb{F}[z]}(\mathcal{V}_T, \mathcal{V}_S) \iff \Phi T = S\Phi$.
(ii) $\mathcal{V}_T \cong_{\mathbb{F}[z]} \mathcal{V}_S \iff T \sim S$.

Proof.

(i) ($\Rightarrow$) If $\Phi : \mathcal{V}_T \to \mathcal{V}_S$ is $\mathbb{F}[z]$-linear, then $(\forall\, \mathbf{v} \in \mathcal{V})\, \Phi T\mathbf{v} = \Phi(z \cdot \mathbf{v}) = z \cdot \Phi\mathbf{v} = S\Phi\mathbf{v}$. Hence $\Phi T = S\Phi$.
(i) ($\Leftarrow$) Suppose $\Phi T = S\Phi$. Then $(\forall\, j \in \mathbb{Z}_{\geq 0})\, \Phi T^j = S^j \Phi$ by induction on j.
Thus $(\forall\, (p, \mathbf{v}) \in \mathbb{F}[z] \times \mathcal{V})\, \Phi(p \cdot \mathbf{v}) = \Phi(p(T)\mathbf{v}) = p(S)\Phi\mathbf{v} = p \cdot \Phi\mathbf{v}$, so Φ is $\mathbb{F}[z]$-linear.
(ii) ($\Rightarrow$) Let $\Phi : \mathcal{V}_T \xrightarrow{\sim} \mathcal{V}_S$ be an $\mathbb{F}[z]$-module isomorphism. Then $\Phi \in \mathrm{GL}(\mathcal{V})$ by $\mathbb{F} \subseteq \mathbb{F}[z]$, and $\Phi T = S\Phi$ by part (i).
Hence $S = \Phi T \Phi^{-1}$, so $T \sim S$ by Definition 6.2.6.
(ii) ($\Leftarrow$) Choose $\Phi \in \mathrm{GL}(\mathcal{V})$ with $S = \Phi T \Phi^{-1}$ by Definition 6.2.6.
Then $\Phi T = S\Phi$, so Φ is $\mathbb{F}[z]$-linear by part (i). Since Φ is bijective, $\Phi : \mathcal{V}_T \xrightarrow{\sim} \mathcal{V}_S$.

Structural Commentary: Intertwining the action of z extends to every polynomial and characterizes conjugacy.
Key Insight: Module linearity is exactly the equation $\Phi T = S\Phi$. □

Corollary 3.1.5. *Matrix Similarity Is Matrix-Module Isomorphism*
Let $n \geq 1$ and $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) For $X \in \mathrm{GL}_n(\mathbb{F})$, $T_X \in \mathrm{Hom}_{\mathbb{F}[z]}((\mathbb{F}^n)_A, (\mathbb{F}^n)_B) \iff XA = BX$.
(ii) $(\mathbb{F}^n)_A \cong_{\mathbb{F}[z]} (\mathbb{F}^n)_B \iff A \sim B$.

Proof.

(i) ($\Rightarrow$) If T_X is $\mathbb{F}[z]$-linear, then $T_X T_A = T_B T_X$ by Theorem 3.1.4(i). Hence $(\forall\, \mathbf{x} \in \mathbb{F}^n)\, XA\mathbf{x} = BX\mathbf{x}$, so $XA = BX$.
(i) ($\Leftarrow$) If $XA = BX$, then $T_X T_A = T_B T_X$ by Definition 3.1.7. Thus T_X is $\mathbb{F}[z]$-linear by Theorem 3.1.4(i).
(ii) ($\Rightarrow$) Let $\Psi : (\mathbb{F}^n)_A \xrightarrow{\sim} (\mathbb{F}^n)_B$. Choose $X, Y \in \mathrm{Mat}(n, n, \mathbb{F})$ with $\Psi = T_X$ and $\Psi^{-1} = T_Y$ by Theorem 3.4.5(i).
For $\mathbf{x} \in \mathbb{F}^n$, $XY\mathbf{x} = YX\mathbf{x} = \mathbf{x}$ by the inverse identities and Definition 3.1.7. Hence $XY = YX = I_n$ and $X \in \mathrm{GL}_n(\mathbb{F})$.
Then $XA = BX$ by part (i), and $A \sim B$ by $B = XAX^{-1}$ and Definition 6.2.1.
(ii) ($\Leftarrow$) Choose $X \in \mathrm{GL}_n(\mathbb{F})$ with $B = XAX^{-1}$ by Definition 6.2.1.
Then $XA = BX$, so the bijection T_X is $\mathbb{F}[z]$-linear by part (i) and is an $\mathbb{F}[z]$-module isomorphism.

Structural Commentary: Coordinate intertwiners translate module isomorphisms into the conjugation equation $XA = BX$.
Key Insight: Matrix similarity is polynomial-module isomorphism in coordinates. □

Definition 3.1.6. *Operator-Module Annihilator*
Let $0 < \dim \mathcal{V} < \infty$ and $T \in \mathcal{L}(\mathcal{V})$. The *annihilator* of $\mathcal{V}_T$ is $\mathrm{Ann}_{\mathbb{F}[z]}(\mathcal{V}_T) := \{p \in \mathbb{F}[z] : p(T) = 0_{\mathcal{L}(\mathcal{V})}\}$.

Proposition 3.1.7. *Minimal Polynomial as Module Order*
Let $0 < \dim \mathcal{V} < \infty$ and $T \in \mathcal{L}(\mathcal{V})$.

(i) $\mathrm{Ann}_{\mathbb{F}[z]}(\mathcal{V}_T) = \langle \mu_T \rangle$. Equivalently, μ_T is unique monic polynomial of minimal degree in $\{p \in \mathbb{F}[z] : p(T) = 0\}$.
(ii) If $S \in \mathcal{L}(\mathcal{V})$ and $S \sim T$, then $\mu_S = \mu_T$.
(iii) If $n \geq 1$ and $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$ are similar, then $\mu_A = \mu_B$.

Proof.

(i) $\mathrm{Ann}_{\mathbb{F}[z]}(\mathcal{V}_T) = \{p \in \mathbb{F}[z] : p(T) = 0\}$ by Definition 3.1.6.
For $p \neq 0$, $p(T) = 0 \iff \mu_T \mid p$ by Theorem 2.2.4; the zero polynomial belongs to both ideals.
Hence $\mathrm{Ann}_{\mathbb{F}[z]}(\mathcal{V}_T) = \langle \mu_T \rangle$, and the characterization of μ_T follows by Definition 2.2.2.

(ii) Choose $\Phi \in \mathrm{GL}(\mathcal{V})$ with $S = \Phi T \Phi^{-1}$ by Definition 6.2.6. Then $(\forall\, p \in \mathbb{F}[z])\, p(S) = \Phi p(T) \Phi^{-1}$, so $\mathrm{Ann}_{\mathbb{F}[z]}(\mathcal{V}_S) = \mathrm{Ann}_{\mathbb{F}[z]}(\mathcal{V}_T)$.
Hence $\mu_S = \mu_T$ by part (i).

(iii) $\mu_A = \mu_B$ by Theorem 2.2.5(ii).

Structural Commentary: Annihilator divisibility identifies μ_T; conjugation transports the resulting principal ideal.
Key Insight: The module order is invariant under intertwiners. □

Definition 3.1.8. *Cyclic Subspace and Vector Annihilator*
Let $T \in \mathcal{L}(\mathcal{V})$ and $\mathbf{v} \in \mathcal{V}$.

(i) The *T-cyclic subspace generated by $\mathbf{v}$* is $\mathcal{C}_T(\mathbf{v}) := \mathrm{span}\{T^j \mathbf{v} : j \in \mathbb{Z}_{\geq 0}\}$.
(ii) The vector $\mathbf{v}$ is a *cyclic vector* for T if $\mathcal{C}_T(\mathbf{v}) = \mathcal{V}$.
(iii) The *annihilator of $\mathbf{v}$ for T* is $\mathrm{ann}_T(\mathbf{v}) := \{p \in \mathbb{F}[z] : p(T)\mathbf{v} = \mathbf{0}\}$.

Proposition 3.1.9. *Cyclic Subspaces Are Smallest Invariant Hosts*
Let $T \in \mathcal{L}(\mathcal{V})$ and $\mathbf{v} \in \mathcal{V}$.

(i) $\mathcal{C}_T(\mathbf{v}) = \{p(T)\mathbf{v} : p \in \mathbb{F}[z]\}$.
(ii) $\mathcal{C}_T(\mathbf{v})$ *is the smallest T-invariant subspace containing* $\mathbf{v}$.
(iii) $\mathrm{ann}_T(\mathbf{v}) \trianglelefteq \mathbb{F}[z]$.

Proof.

(i) For $p(z) = \sum_{j=0}^{m} a_j z^j \in \mathbb{F}[z]$, $p(T)\mathbf{v} = \sum_{j=0}^{m} a_j T^j \mathbf{v}$. Both inclusions hold by this identity.

(ii) $T(p(T)\mathbf{v}) = (zp)(T)\mathbf{v} \in \mathcal{C}_T(\mathbf{v})$ by part (i), so $\mathcal{C}_T(\mathbf{v})$ is T-invariant.
Let $\mathcal{U} \leq_{\mathbb{F}} \mathcal{V}$ contain $\mathbf{v}$ and satisfy $T\mathcal{U} \subseteq \mathcal{U}$. By induction, $(\forall\, j \in \mathbb{Z}_{\geq 0})\, T^j \mathbf{v} \in \mathcal{U}$, so $\mathcal{C}_T(\mathbf{v}) \subseteq \mathcal{U}$.

(iii) The zero polynomial belongs to $\mathrm{ann}_T(\mathbf{v})$.
For $a, b \in \mathbb{F}[z]$ and $p, q \in \mathrm{ann}_T(\mathbf{v})$, $(ap + bq)(T)\mathbf{v} = a(T)p(T)\mathbf{v} + b(T)q(T)\mathbf{v} = \mathbf{0}$ by Proposition 1.1.6(i).
Thus $\mathrm{ann}_T(\mathbf{v}) \leq_{\mathbb{F}[z]} \mathbb{F}[z]$ by Theorem 1.1.5, and $\mathrm{ann}_T(\mathbf{v}) \trianglelefteq \mathbb{F}[z]$ by Proposition 1.1.7.

Structural Commentary: Orbit-polynomial equality controls minimal invariance; evaluation closure controls the ideal property.
Key Insight: Polynomial evaluation packages every finite orbit combination. □

Perspective 3.1.10. *An Operator as a Polynomial Action*
Definition 3.1.1 interprets z as T. Proposition 3.1.9(i) identifies the cyclic module generated by $\mathbf{v}$ with $\mathcal{C}_T(\mathbf{v})$.
Figure 104 illustrates how iteration under T forms this cyclic span; the cited formal owners establish the identities.

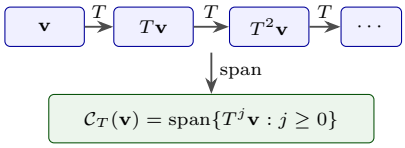

Figure 104: Iteration under T forms the orbit whose finite linear span is $\mathcal{C}_T(\mathbf{v})$.

Definition 3.1.11. *Order of a Vector under an Operator*
Let $T \in \mathcal{L}(\mathcal{V})$ and $\mathbf{v} \in \mathcal{V} \setminus \{\mathbf{0}\}$. Then $\{0\} \neq \mathrm{ann}_T(\mathbf{v}) \trianglelefteq \mathbb{F}[z]$ by Proposition 3.1.2(ii), Definition 1.6.1(iii), Proposition 3.1.9(iii).
This ideal has a unique monic generator by Theorem 3.10.2(iii)–(iv).
Specializing Definition 2.5.3, the *order of $\mathbf{v}$ under T* is this generator $m_{\mathbf{v}}$; equivalently, $\mathrm{ann}_T(\mathbf{v}) = \langle m_{\mathbf{v}} \rangle$.

Definition 3.1.12. *Companion Matrix*
Let $n \geq 1$ and let $f(z) = z^n + c_{n-1} z^{n-1} + \cdots + c_1 z + c_0$ be monic. For $n \geq 2$, the *companion matrix* of f is

$$C_f := \begin{bmatrix} 0 & 0 & \cdots & 0 & -c_0 \\ 1 & 0 & \cdots & 0 & -c_1 \\ 0 & 1 & \cdots & 0 & -c_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1 & -c_{n-1} \end{bmatrix}.$$

For $n = 1$, set $C_f = [-c_0]$.

Theorem 3.1.13. *Companion Matrix Realises a Polynomial*
Let $n \geq 1$, let $f(z) = z^n + \sum_{i=0}^{n-1} c_i z^i$ be monic, and let C_f be its companion matrix.

(i) $\mu_{C_f} = f$.
(ii) $p_{C_f} = f$.

Proof.

(i) Let $(\mathbf{e}_1, \ldots, \mathbf{e}_n)$ be the standard basis. Then $(\forall\, j \in \{0, \ldots, n-1\})\, C_f^j \mathbf{e}_1 = \mathbf{e}_{j+1}$.

The last column satisfies $C_f^n \mathbf{e}_1 = -\sum_{i=0}^{n-1} c_i C_f^i \mathbf{e}_1$, so $f(C_f)\mathbf{e}_1 = \mathbf{0}$.

For $j \in \{1, \ldots, n\}$, $f(C_f)\mathbf{e}_j = C_f^{j-1} f(C_f)\mathbf{e}_1 = \mathbf{0}$ by $\mathbf{e}_j = C_f^{j-1}\mathbf{e}_1$ and commutation with C_f. Thus $f(C_f) = 0$.

If $0 \neq g(z) = \sum_{i=0}^{m} b_i z^i$ with $m < n$, then $g(C_f)\mathbf{e}_1 = \sum_{i=0}^{m} b_i \mathbf{e}_{i+1} \neq \mathbf{0}$ by linear independence of the standard basis.
Therefore no nonzero polynomial of degree less than n annihilates C_f.
Since f is a monic degree-n annihilator, $\mu_{C_f} = f$ by Definition 2.2.3.

(ii) Work over the rational-function field $\mathbb{F}(z)$ and set $M(z) := zI_n - C_f$.

Row operation $R_1 \leftarrow R_1 + \sum_{k=2}^{n} z^{k-1} R_k$ preserves $\det M(z)$ by Theorem 3.8.2(ii)–(iv),(ix). New first row is $(0, \dots, 0, f(z))$.

Moving it below the other rows uses $n-1$ swaps and produces an upper-triangular matrix with diagonal $(-1, \dots, -1, f(z))$.
Hence $(-1)^{n-1} \det M(z) = (-1)^{n-1} f(z)$ by Theorem 3.8.2(iii),(v), so $p_{C_f}(z) = \det M(z) = f(z)$ by Definition 2.1.2.

Structural Commentary: The orbit basis fixes the least annihilator; determinant-preserving row reduction computes p_{C_f}.
Key Insight: One last-column relation controls both polynomial invariants. □

Theorem 3.1.14. *Cyclic Subspaces as Polynomial Quotients*

Let $\dim \mathcal{V} < \infty$, $T \in \mathcal{L}(\mathcal{V})$, *and* $0 \neq \mathbf{v} \in \mathcal{V}$. *Let* $m_{\mathbf{v}}(z) = z^d + \sum_{i=0}^{d-1} c_i z^i$ *be the order of* $\mathbf{v}$, *where* $d \geq 1$.

Define $\Phi_{\mathbf{v}} : \mathbb{F}[z] \to \mathcal{C}_T(\mathbf{v})$ *by* $\Phi_{\mathbf{v}}(p) = p(T)\mathbf{v}$. *Set* $\mathcal{B}_{\mathbf{v}} := (\mathbf{v}, T\mathbf{v}, \dots, T^{d-1}\mathbf{v})$. *Then*

(i) $\Phi_{\mathbf{v}}$ *is a surjective* $\mathbb{F}[z]$*-module homomorphism with* $\ker \Phi_{\mathbf{v}} = \langle m_{\mathbf{v}} \rangle$, *and* $\mathbb{F}[z]/\langle m_{\mathbf{v}} \rangle \cong \mathcal{C}_T(\mathbf{v})$;
(ii) $\mathcal{B}_{\mathbf{v}}$ *is a basis of* $\mathcal{C}_T(\mathbf{v})$;
(iii) $[T|_{\mathcal{C}_T(\mathbf{v})}]_{\mathcal{B}_{\mathbf{v}} \leftarrow \mathcal{B}_{\mathbf{v}}} = C_{m_{\mathbf{v}}}$.

Proof.

(i) For $a, b, p, q \in \mathbb{F}[z]$, $\Phi_{\mathbf{v}}(ap + bq) = a \cdot \Phi_{\mathbf{v}}(p) + b \cdot \Phi_{\mathbf{v}}(q)$ by Proposition 1.1.6(i).
Thus $\Phi_{\mathbf{v}}$ is $\mathbb{F}[z]$-linear by Definition 1.4.1(i). Its image is $\mathcal{C}_T(\mathbf{v})$ by Proposition 3.1.9(i).
Its kernel is $\operatorname{ann}_T(\mathbf{v}) = \langle m_{\mathbf{v}} \rangle$ by Definition 3.1.11. The quotient isomorphism follows by Theorem 1.5.4(i).

(ii) If $\sum_{j=0}^{d-1} a_j T^j \mathbf{v} = \mathbf{0}$, set $q(z) := \sum_{j=0}^{d-1} a_j z^j \in \langle m_{\mathbf{v}} \rangle$. If $q \neq 0$, then $m_{\mathbf{v}} \mid q$ and $d \leq \deg q < d$, a contradiction.
Thus $q = 0$, so $\mathcal{B}_{\mathbf{v}}$ is independent. For $p \in \mathbb{F}[z]$, choose $h, r \in \mathbb{F}[z]$ with $p = hm_{\mathbf{v}} + r$ and $\deg r < d$ or $r = 0$ by Theorem 3.8.2(i).
Then $p(T)\mathbf{v} = r(T)\mathbf{v} \in \operatorname{span} \mathcal{B}_{\mathbf{v}}$, so $\mathcal{B}_{\mathbf{v}}$ spans.

(iii) For $0 \leq j < d-1$, $T(T^j\mathbf{v}) = T^{j+1}\mathbf{v}$. The relation $T^d\mathbf{v} = -\sum_{i=0}^{d-1} c_i T^i \mathbf{v}$ holds by $m_{\mathbf{v}}(T)\mathbf{v} = \mathbf{0}$.

These are precisely the columns of $C_{m_{\mathbf{v}}}$ by Definitions 3.2.3 and 3.1.12.

Structural Commentary: The evaluation kernel forms the quotient; division selects the basis; the order relation fixes the matrix.
Key Insight: The first orbit relation becomes the companion column. □

Perspective 3.1.15. *The Translation Dictionary*
Definitions 3.1.1, 3.1.8, and 3.1.11 identify the module objects.
Proposition 3.1.7 and Theorems 3.1.3 and 3.1.14 establish the corresponding operator structures:

$\mathbb{F}[z]$-module $\mathcal{V}_T$	$\mathbb{F}$-vector space $\mathcal{V}$
$p(z) \cdot \mathbf{v}$	$p(T)\mathbf{v}$
submodule	T-invariant subspace
$\operatorname{Ann}_{\mathbb{F}[z]}(\mathcal{V}_T) = \langle \mu_T \rangle$	minimal polynomial of T
$\langle\langle \mathbf{v} \rangle\rangle_{\mathbb{F}[z]}$	$\mathcal{C}_T(\mathbf{v})$
$\mathbb{F}[z]/\langle m_{\mathbf{v}} \rangle$	cyclic block with companion matrix $C_{m_{\mathbf{v}}}$

This dictionary is local to $\mathcal{V}_T$; classification of arbitrary operator modules requires the subsequent PID decomposition results.

3.2 Invariant Factors

Definition 3.2.1. *Invariant Factors and Elementary Divisors*
Let $0 < \dim \mathcal{V} < \infty$, $T \in \mathcal{L}(\mathcal{V})$. Then $\mathcal{V}_T$ is a finitely generated torsion $\mathbb{F}[z]$-module by Proposition 3.1.2(i)–(ii).

(i) For $r \in \mathbb{N}$, a *cyclic decomposition* of T is $\mathcal{V} = \bigoplus_{j=1}^{r} \mathcal{C}_T(\mathbf{v}_j)$ with $(\mathbf{v}_1, \dots, \mathbf{v}_r) \in (\mathcal{V} \setminus \{\mathbf{0}\})^r$.
(ii) The *invariant factors* of T are the unique monic representatives of $\operatorname{Inv}(\mathcal{V}_T)$ from Definition 2.10.4.
Write $\operatorname{InvFact}(T) = (f_1, \dots, f_r)$. Then each f_j is monic and nonconstant, and $f_r \mid \cdots \mid f_1$.
(iii) The *elementary divisors* of T are the unique monic representatives of $\operatorname{ElemDiv}(\mathcal{V}_T)$ from Definition 2.10.1.
Denote the resulting multiset by $\operatorname{ElemDiv}(T)$.
(iv) Let $\mathcal{I}$ be finite, $(\mathbf{v}_\alpha)_{\alpha \in \mathcal{I}} \in (\mathcal{V} \setminus \{\mathbf{0}\})^{\mathcal{I}}$, $\mathcal{V} = \bigoplus_{\alpha \in \mathcal{I}} \mathcal{C}_T(\mathbf{v}_\alpha)$. For $\alpha \in \mathcal{I}$, set $d_\alpha := \deg m_{\mathbf{v}_\alpha}$ and $\mathcal{B}_\alpha := (\mathbf{v}_\alpha, T\mathbf{v}_\alpha, \dots, T^{d_\alpha - 1}\mathbf{v}_\alpha)$.
After choosing an ordering of $\mathcal{I}$, the corresponding concatenation of the $\mathcal{B}_\alpha$ is an *elementary divisor basis* if $\{m_{\mathbf{v}_\alpha} : \alpha \in \mathcal{I}\} = \operatorname{ElemDiv}(T)$ as multisets.
(v) For $n \geq 1$ and $A \in \operatorname{Mat}(n, n, \mathbb{F})$, set $\operatorname{InvFact}(A) := \operatorname{InvFact}(T_A)$. Set $\operatorname{ElemDiv}(A) := \operatorname{ElemDiv}(T_A)$.

Theorem 3.2.2. *Invariant-Factor Skeleton for Operators*
Let $0 < \dim \mathcal{V} < \infty$, $T \in \mathcal{L}(\mathcal{V})$, $r \in \mathbb{N}$, *and* $\operatorname{InvFact}(T) = (f_1, \dots, f_r)$.

(i) $(\exists \mathbf{v}_1, \dots, \mathbf{v}_r \in \mathcal{V} \setminus \{\mathbf{0}\})$ *such that, for* $\mathcal{C}_j := \mathcal{C}_T(\mathbf{v}_j)$, $\mathcal{V} = \bigoplus_{j=1}^{r} \mathcal{C}_j$. *Then* $m_{\mathbf{v}_j} = f_j$, $\mathcal{C}_j \cong \mathbb{F}[z]/\langle f_j \rangle$ *for* $j \in \{1, \dots, r\}$.

(ii) Set $\mathcal{B}_j := (\mathbf{v}_j, T\mathbf{v}_j, \dots, T^{\deg f_j - 1}\mathbf{v}_j)$ *and* $\mathcal{B} := (\mathcal{B}_1, \dots, \mathcal{B}_r)$. *Then* $\mathcal{B}$ *is a basis of* $\mathcal{V}$ *and* $[T]_{\mathcal{B} \leftarrow \mathcal{B}} = \bigoplus_{j=1}^{r} C_{f_j}$.

(iii) $\mu_T = f_1$.

(iv) $q_T = \prod_{j=1}^{r} f_j$.

Proof.

(i) The module $\mathcal{V}_T$ is finitely generated and torsion by Proposition 3.1.2(i)–(ii).

Choose an $\mathbb{F}[z]$-module isomorphism $\Psi : \bigoplus_{j=1}^{r} \mathbb{F}[z]/\langle f_j\rangle \to \mathcal{V}_T$ by Theorem 2.10.6(i).

Let $\mathbf{e}_j$ have jth coordinate $1 + \langle f_j\rangle$ and all other coordinates zero. Set $\mathbf{v}_j := \Psi(\mathbf{e}_j)$ and $\mathcal{C}_j := \Psi(\mathbb{F}[z]\mathbf{e}_j)$.
Since f_j is nonconstant and Ψ is injective, $\mathbf{e}_j \neq \mathbf{0}$ and $\mathbf{v}_j \neq \mathbf{0}$. For $p \in \mathbb{F}[z]$, $\Psi(p\mathbf{e}_j) = p(T)\mathbf{v}_j$ by $\mathbb{F}[z]$-linearity.

$\mathcal{C}_j = \mathcal{C}_T(\mathbf{v}_j)$ by the definitions of $\mathcal{C}_j$ and $\mathcal{C}_T(\mathbf{v}_j)$. Since Ψ is bijective, $\mathcal{V} = \bigoplus_{j=1}^{r} \mathcal{C}_j$ and $\mathcal{C}_j \cong \mathbb{F}[z]/\langle f_j\rangle$.

The annihilator of $\mathbf{e}_j$ is $\langle f_j\rangle$, so $\operatorname{ann}_T(\mathbf{v}_j) = \langle f_j\rangle$ by Ψ. Hence $m_{\mathbf{v}_j} = f_j$ by Definition 3.1.11.

(ii) For $j \in \{1,\dots,r\}$, $\mathcal{B}_j$ is a basis of $\mathcal{C}_j$ by Theorem 3.1.14(ii). $[T|_{\mathcal{C}_j}]_{\mathcal{B}_j \leftarrow \mathcal{B}_j} = C_{f_j}$ by Theorem 3.1.14(iii).
The concatenation $\mathcal{B}$ is a basis of $\mathcal{V}$ by part (i) and Definition 2.3.5.

Since $(\forall\, j \in \{1,\dots,r\})\, T\mathcal{C}_j \subseteq \mathcal{C}_j$, all off-diagonal blocks vanish. Thus $[T]_{\mathcal{B}\leftarrow\mathcal{B}} = \bigoplus_{j=1}^{r} C_{f_j}$.

(iii) For $j \in \{1,\dots,r\}$, $\operatorname{Ann}_{\mathbb{F}[z]}(\mathcal{C}_j) = \langle f_j\rangle$ because $\mathcal{C}_j = \mathbb{F}[z]\mathbf{v}_j$ and $m_{\mathbf{v}_j} = f_j$ by part (i).
$\operatorname{Ann}_{\mathbb{F}[z]}(\mathcal{V}_T) = \langle \operatorname{lcm}(f_1,\dots,f_r)\rangle$ by part (i), Proposition 2.5.4. Since $f_r \mid \cdots \mid f_1$, $\operatorname{lcm}(f_1,\dots,f_r) = f_1$ and $\operatorname{Ann}_{\mathbb{F}[z]}(\mathcal{V}_T) = \langle f_1\rangle$.
$\operatorname{Ann}_{\mathbb{F}[z]}(\mathcal{V}_T) = \langle \mu_T\rangle$ by Proposition 3.1.7(i). Since f_1 and μ_T are monic, $f_1 = \mu_T$.

(iv) Set $A := [T]_{\mathcal{B}\leftarrow\mathcal{B}}$. Then $q_T = p_A$ by Definition 2.1.15.

$A = \bigoplus_{j=1}^{r} C_{f_j}$ by part (ii), so $p_A = \prod_{j=1}^{r} p_{C_{f_j}}$ by repeated application of Proposition 2.1.8(i).

For $j \in \{1,\dots,r\}$, $p_{C_{f_j}} = f_j$ by Theorem 3.1.13(ii). Hence $q_T = \prod_{j=1}^{r} f_j$.

Structural Commentary: PID quotient generators produce cyclic bases; annihilators and determinants recover μ_T and q_T.
Key Insight: Cyclic quotient generators turn invariant factors into companion blocks. □

3.3 Elementary Divisors

Theorem 3.3.1. *Primary Cyclic Decomposition for an Operator*
Let $0 < \dim \mathcal{V} < \infty$, $T \in \mathcal{L}(\mathcal{V})$, $s \in \mathbb{N}$. Set $I := \{1,\dots,s\}$. Let $(p_i)_{i\in I} \in \mathbb{F}[z]^I$ be distinct monic irreducibles and $(e_i)_{i\in I} \in \mathbb{N}^I$.
Suppose $\mu_T = \prod_{i\in I} p_i^{e_i}$ and set $\mathcal{V}_{p_i} := \ker p_i(T)^{e_i}$ for $i \in I$.

(i) $\mathcal{V}_T = \bigoplus_{i\in I} \mathcal{V}_{p_i}$.

(ii) For $i \in I$, there are $k_i \in \mathbb{N}$ and exponents $e_i = e_{i,1} \geq \cdots \geq e_{i,k_i} \geq 1$. There are vectors $(\mathbf{v}_{i,j})_{j=1}^{k_i} \in (\mathcal{V}_{p_i} \setminus \{\mathbf{0}\})^{k_i}$.

These data satisfy $\mathcal{V}_{p_i} = \bigoplus_{j=1}^{k_i} \mathcal{C}_T(\mathbf{v}_{i,j})$. They satisfy $m_{\mathbf{v}_{i,j}} = p_i^{e_{i,j}}$ for $j \in \{1,\dots,k_i\}$.

(iii) For $i \in I$ and $j \in \{1,\dots,k_i\}$, set $d_{i,j} := \deg(p_i^{e_{i,j}})$. Set $\mathcal{B}_{i,j} := (\mathbf{v}_{i,j}, T\mathbf{v}_{i,j}, \dots, T^{d_{i,j}-1}\mathbf{v}_{i,j})$.
Then $\operatorname{ElemDiv}(T) = \{p_i^{e_{i,j}} : i \in I,\ 1 \leq j \leq k_i\}$ as multisets.
The lexicographically ordered concatenation of the $\mathcal{B}_{i,j}$ is an elementary divisor basis.

Proof.

(i) Since $\dim \mathcal{V} > 0$, $\mathcal{V}_T \neq \{\mathbf{0}\}$. It is finitely generated and torsion by Proposition 3.1.2(i)–(ii).
Its order satisfies $o(\mathcal{V}_T) \sim \mu_T$ by Proposition 3.1.7(i). For $i \in I$, set $M_i := \{\mathbf{v} \in \mathcal{V} : p_i^{e_i} \cdot \mathbf{v} = \mathbf{0}\}$.
Then M_i is the p_i-primary component and $\mathcal{V}_T = \bigoplus_{i\in I} M_i$ by Theorem 2.9.2(i).

The identity $p_i^{e_i} \cdot \mathbf{v} = p_i(T)^{e_i}\mathbf{v}$ holds by Definition 3.1.1. Hence $M_i = \ker p_i(T)^{e_i} = \mathcal{V}_{p_i}$.

(ii) For $i \in I$, $\mathcal{V}_{p_i}$ is finitely generated and p_i-primary by Theorem 2.9.2(ii). Its order satisfies $o(\mathcal{V}_{p_i}) \sim p_i^{e_i}$ by the same theorem.
Choose k_i, $(\mathbf{v}_{i,j})_{j=1}^{k_i}$, and $(e_{i,j})_{j=1}^{k_i}$ by Theorem 2.9.7(i).

They satisfy the exponent chain and $\mathcal{V}_{p_i} = \bigoplus_{j=1}^{k_i} \mathbb{F}[z]\mathbf{v}_{i,j}$ by the same theorem.

Their annihilators are $\langle p_i^{e_{i,j}}\rangle$ by the same theorem. Each $\mathbf{v}_{i,j}$ is nonzero because $\langle p_i^{e_{i,j}}\rangle \neq \mathbb{F}[z]$.
$\mathbb{F}[z]\mathbf{v}_{i,j} = \mathcal{C}_T(\mathbf{v}_{i,j})$ by Proposition 3.1.9(i). Thus $m_{\mathbf{v}_{i,j}} = p_i^{e_{i,j}}$ by Definition 3.1.11 and monicity.

(iii) $\operatorname{ElemDiv}(\mathcal{V}_T) = \{p_i^{e_{i,j}} : i \in I,\ 1 \leq j \leq k_i\}$ by part (ii) and Definition 2.10.1.
The multiset identity in (iii) follows by Definition 3.2.1(iii) and monicity. Each $\mathcal{B}_{i,j}$ is a basis of $\mathcal{C}_T(\mathbf{v}_{i,j})$ by Theorem 3.1.14(ii).
Their lexicographically ordered concatenation is basis of $\mathcal{V}$ by parts (i)–(ii). It is elementary divisor basis by Definition 3.2.1(iv).

Structural Commentary: Primary decomposition identifies kernels; cyclic decomposition refines each into annihilator blocks.
Key Insight: Each elementary divisor is one cyclic summand's monic annihilator. □

Theorem 3.3.2. *Reducing Decompositions Combine the Data*
Let $0 < \dim \mathcal{V} < \infty$, let $T \in \mathcal{L}(\mathcal{V})$, and suppose $\mathcal{V} = \mathcal{A} \oplus \mathcal{B}$.
Assume $\mathcal{A}$ and $\mathcal{B}$ are nonzero T-invariant subspaces. Set $T_{\mathcal{A}} := T|_{\mathcal{A}}$ and $T_{\mathcal{B}} := T|_{\mathcal{B}}$.

(i) $\mu_T = \operatorname{lcm}(\mu_{T_{\mathcal{A}}}, \mu_{T_{\mathcal{B}}})$.
(ii) $\operatorname{ElemDiv}(T) = \operatorname{ElemDiv}(T_{\mathcal{A}}) \uplus \operatorname{ElemDiv}(T_{\mathcal{B}})$. *Here $\uplus$ denotes multiset union.*
(iii) The multiset in (ii) is grouped and zero-padded as in Definition 2.10.4. Its column products form $\operatorname{InvFact}(T)$.

Proof.

(i) The subspaces $\mathcal{A}$ and $\mathcal{B}$ are $\mathbb{F}[z]$-submodules by Theorem 3.1.3. Hence $\mathcal{V}_T = \mathcal{A}_{T_{\mathcal{A}}} \oplus \mathcal{B}_{T_{\mathcal{B}}}$ by the assumed direct sum.
The order of this module sum is the least common multiple of the summand orders by Proposition 2.5.4.
They are μ_T, $\mu_{T_{\mathcal{A}}}$, and $\mu_{T_{\mathcal{B}}}$ by Proposition 3.1.7(i), proving (i).

(ii) Set $M_{\mathcal{A}} := \mathcal{A}_{T_{\mathcal{A}}}$ and $M_{\mathcal{B}} := \mathcal{B}_{T_{\mathcal{B}}}$. $\mathcal{V}_T = M_{\mathcal{A}} \oplus M_{\mathcal{B}}$ by the assumed direct sum and Theorem 3.1.3.
Hence $\operatorname{ElemDiv}(\mathcal{V}_T) = \operatorname{ElemDiv}(M_{\mathcal{A}} \oplus M_{\mathcal{B}})$. $\operatorname{ElemDiv}(M_{\mathcal{A}} \oplus M_{\mathcal{B}}) = \operatorname{ElemDiv}(M_{\mathcal{A}}) \uplus \operatorname{ElemDiv}(M_{\mathcal{B}})$ by Proposition 2.10.3.
The identity in (ii) follows by Definition 3.2.1(iii) after taking monic representatives.

(iii) Grouping, padding, and column multiplication produce $\mathrm{Inv}(\mathcal{V}_T)$ from (ii) by Definition 2.10.4.
Taking its unique monic representatives produces $\mathrm{InvFact}(T)$ by Definition 3.2.1(ii).

Structural Commentary: The reducing sum becomes a module sum; order and elementary-divisor laws separate its data.
Key Insight: Direct sums take least common multiples and multiset unions. □

Definition 3.3.3. *Characteristic Polynomial from Elementary Divisors*
Let $0 < \dim \mathcal{V} < \infty$ and $T \in \mathcal{L}(\mathcal{V})$. Define $\chi_T(z) := \prod_{q \in \mathrm{ElemDiv}(T)} q(z)$, retaining multiset multiplicities.
For $n \geq 1$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$, set $\chi_A := \chi_{T_A}$.

Theorem 3.3.4. *Minimal and Characteristic Polynomials from Elementary Divisors*
Let $0 < \dim \mathcal{V} < \infty$, $T \in \mathcal{L}(\mathcal{V})$, $s \in \mathbb{N}$. $I := \{1, \dots, s\}$. Let $(k_i)_{i \in I} \in \mathbb{N}^I$, $(p_i)_{i \in I} \in \mathbb{F}[z]^I$ be distinct monic irreducibles.
Let $e_{i,j} \in \mathbb{N}$ for $i \in I$, $j \in \{1, \dots, k_i\}$. Let $\mathrm{ElemDiv}(T) = \{p_i^{e_{i,j}} : i \in I,\ 1 \leq j \leq k_i\}$ be multisets. For $i \in I$, set $m_i := \max_{1 \leq j \leq k_i} e_{i,j}$.

(i) $\mu_T = \prod_{i \in I} p_i^{m_i}$.

(ii) $q_T = \chi_T = \prod_{i \in I} \prod_{j=1}^{k_i} p_i^{e_{i,j}}$.

(iii) $\deg \chi_T = \deg q_T = \dim \mathcal{V}$.

(iv) $\mu_T \mid q_T$, *and* μ_T, q_T, *and* χ_T *have the same monic irreducible factors.*

Proof.

(i) The module $\mathcal{V}_T$ is finitely generated and torsion by Proposition 3.1.2(i)–(ii).
Choose a primary cyclic decomposition of $\mathcal{V}_T$ by Theorem 2.10.2(i).
Its cyclic orders form $\mathrm{ElemDiv}(\mathcal{V}_T)$ by Definition 2.10.1. Their monic representatives form $\mathrm{ElemDiv}(T)$ by Definition 3.2.1(iii).
Set $\lambda := \mathrm{lcm}\{p_i^{e_{i,j}} : i \in I,\ 1 \leq j \leq k_i\}$. Then $o(\mathcal{V}_T) \sim \lambda$ by repeated application of Proposition 2.5.4.
The monic representative of this order is μ_T by Proposition 3.1.7(i).
Since the p_i are distinct and monic, this least common multiple is $\prod_{i \in I} p_i^{m_i}$.

(ii) Write $\mathrm{InvFact}(T) = (f_1, \dots, f_r)$. Then $q_T = \prod_{\ell=1}^{r} f_\ell$ by Theorem 3.2.2(iv).
The column construction uses every elementary divisor once by Definition 2.10.4.
Its monic column products are the f_ℓ by Definition 3.2.1(ii)–(iii).
Hence $\prod_{\ell=1}^{r} f_\ell = \prod_{i \in I} \prod_{j=1}^{k_i} p_i^{e_{i,j}}$. The latter product is χ_T by Definition 3.3.3.

(iii) $\deg q_T = \dim \mathcal{V}$ by Proposition 2.1.16(i). The equality $\deg \chi_T = \deg q_T$ holds by part (ii).

(iv) For $i \in I$, set $b_i := \sum_{j=1}^{k_i} e_{i,j}$. Then m_i is exponent of p_i in μ_T by part (i), b_i is its exponent in $q_T = \chi_T$ by part (ii).
Since $e_{i,j} \geq 1$, $1 \leq m_i \leq b_i$. Thus $\mu_T \mid q_T$, and all three polynomials have the monic irreducible factors $(p_i)_{i \in I}$.

Structural Commentary: Module orders take primewise maxima; invariant-factor products retain every primary exponent.
Key Insight: Minimal exponents take maxima; characteristic exponents take sums. □

Definition 3.3.5. *Nonderogatory Operators*
Let $0 < \dim \mathcal{V} < \infty$ and $T \in \mathcal{L}(\mathcal{V})$. The operator T is *nonderogatory* if $\mu_T = q_T$.
The equivalence $\mu_T = q_T \iff \mu_T = \chi_T$ holds by Theorem 3.3.4(ii).
The equivalence $\mu_T = q_T \iff \deg \mu_T = \dim \mathcal{V}$ holds by Theorem 3.3.4(iii)–(iv).
For $n \geq 1$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$, A is nonderogatory if T_A is.

Theorem 3.3.6. *Cyclic and Nonderogatory Are the Same*
Let $0 < \dim \mathcal{V} < \infty$, $T \in \mathcal{L}(\mathcal{V})$, $s \in \mathbb{N}$, $I := \{1, \dots, s\}$. Let $(p_i)_{i \in I} \in \mathbb{F}[z]^I$ be distinct monic irreducibles and $(e_i)_{i \in I} \in \mathbb{N}^I$.
Suppose $\mu_T = \prod_{i \in I} p_i^{e_i}$. The following are equivalent:

(i) $\mathcal{V}_T$ *is cyclic.*

(ii) T *has a cyclic vector.*

(iii) $\mathrm{ElemDiv}(T) = \{p_1^{e_1}, \dots, p_s^{e_s}\}$ *as multisets.*

(iv) T *is nonderogatory.*

Proof.

(i) $\Rightarrow$ *(ii)* Choose $\mathbf{v} \in \mathcal{V}$ with $\mathcal{V}_T = \mathbb{F}[z]\mathbf{v}$ by Definition 1.2.3(iii). Then $\mathcal{V} = \mathcal{C}_T(\mathbf{v})$ by Proposition 3.1.9(i).
Thus $\mathbf{v}$ is cyclic for T by Definition 3.1.8(ii).

(ii) $\Rightarrow$ *(iii)* Let $\mathbf{v}$ be cyclic for T. Then $\mathcal{V} = \mathcal{C}_T(\mathbf{v})$ by Definition 3.1.8(ii). Thus $\mathcal{V}_T = \mathbb{F}[z]\mathbf{v}$ by Proposition 3.1.9(i).
Since $\dim \mathcal{V} > 0$, $\mathcal{V}_T \neq \{\mathbf{0}\}$. It is finitely generated and torsion by Proposition 3.1.2(i)–(ii).
Its order satisfies $o(\mathcal{V}_T) \sim \mu_T$ by Proposition 3.1.7(i). Hence $\mathrm{ElemDiv}(\mathcal{V}_T) = \{p_i^{e_i} : i \in I\}$ by Theorem 2.10.12(i),(iii).
$\mathrm{ElemDiv}(T) = \{p_i^{e_i} : i \in I\}$ by Definition 3.2.1(iii) and monicity.

(iii) $\Rightarrow$ *(iv)* The identity $\mu_T = q_T = \prod_{i \in I} p_i^{e_i}$ holds by Theorem 3.3.4(i)–(ii). Thus T is nonderogatory by Definition 3.3.5.

(iv) $\Rightarrow$ *(i)* Choose $k_i \in \mathbb{N}$ and $e_i = e_{i,1} \geq \cdots \geq e_{i,k_i} \geq 1$ by Theorem 3.3.1(ii).
Then $\mathrm{ElemDiv}(T) = \{p_i^{e_{i,j}} : i \in I,\ 1 \leq j \leq k_i\}$ by Theorem 3.3.1(iii). Identity $\mu_T = q_T$ holds by condition (iv), Definition 3.3.5.
For $i \in I$, $e_i = \sum_{j=1}^{k_i} e_{i,j}$ by Theorem 3.3.4(i)–(ii). The inequalities $e_{i,j} \geq 1$ and $e_i = e_{i,1}$ force $k_i = 1$.
Hence $\mathrm{ElemDiv}(T) = \{p_i^{e_i} : i \in I\}$. $\mathrm{ElemDiv}(\mathcal{V}_T) = \{p_i^{e_i} : i \in I\}$ by Definition 3.2.1(iii); $\mathcal{V}_T$ is cyclic by Theorem 2.10.12(i),(iii).

Structural Commentary: Module generators become cyclic vectors; exponent sums detect multiple primary blocks.
Key Insight: Cyclicity fails exactly when one prime contributes multiple blocks. □

Perspective 3.3.7. *Elementary Divisors and Jordan Blocks*
Let $0 < \dim_{\mathbb{C}} \mathcal{V} < \infty$ and $T \in \mathcal{L}(\mathcal{V})$. Choose a Jordan form of T by Theorem 6.2.1.
Multiplication by z on $\mathbb{C}[z]/\langle (z-\lambda)^k \rangle$ has matrix $J_k(\lambda)$ in the reversed shifted-power basis.
Hence each Jordan block is cyclic with order $(z-\lambda)^k$. The Jordan direct sum is a primary cyclic decomposition.
Its elementary-divisor multiset is multiset of $(z-\lambda)^k$ by Definition 2.10.1; ElemDiv(T) records pairs (λ, k) by Definition 3.2.1(iii).
The prime-power polynomials and Jordan blocks encode corresponding data; they are not the same objects.

3.4 Operator Classification

Perspective 3.4.1. *Operator Modules and Similarity*
Let $0 < \dim \mathcal{V} < \infty$ and $S, T \in \mathcal{L}(\mathcal{V})$. Then $S \sim T \iff \mathcal{V}_S \cong_{\mathbb{F}[z]} \mathcal{V}_T$ by Theorem 3.1.4.
A cyclic summand of order f is isomorphic to $\mathbb{F}[z]/\langle f \rangle$, and its operator restriction has matrix C_f in a cyclic basis, by Theorem 3.1.14.

Theorem 3.4.2. *Complete Similarity Invariants*
Let $0 < \dim \mathcal{V} < \infty$, let $S, T \in \mathcal{L}(\mathcal{V})$, let $n \geq 1$, and let $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) $T \sim S \iff \mathcal{V}_T \cong_{\mathbb{F}[z]} \mathcal{V}_S \iff \mathrm{ElemDiv}(T) = \mathrm{ElemDiv}(S) \iff \mathrm{InvFact}(T) = \mathrm{InvFact}(S)$.
(ii) $A \sim_{\mathbb{F}} B \iff (\mathbb{F}^n)_A \cong_{\mathbb{F}[z]} (\mathbb{F}^n)_B \iff \mathrm{ElemDiv}(A) = \mathrm{ElemDiv}(B) \iff \mathrm{InvFact}(A) = \mathrm{InvFact}(B)$.
(iii) If $\mathcal{B}$ is a basis of $\mathcal{V}$ and $A = [T]_{\mathcal{B} \leftarrow \mathcal{B}}$, then $\mathrm{ElemDiv}(A) = \mathrm{ElemDiv}(T)$ *and* $\mathrm{InvFact}(A) = \mathrm{InvFact}(T)$.

Proof.
(i) ($\Rightarrow$) Suppose $T \sim S$. Then $\mathcal{V}_T \cong_{\mathbb{F}[z]} \mathcal{V}_S$ by Theorem 3.1.4.
Both divisor data sets agree by Theorems 2.10.2(ii) and 2.10.6(ii) with Definition 3.2.1(ii)–(iii).
(i) ($\Leftarrow$) Suppose either $\mathrm{ElemDiv}(T) = \mathrm{ElemDiv}(S)$ or $\mathrm{InvFact}(T) = \mathrm{InvFact}(S)$. Then $\mathcal{V}_T \cong_{\mathbb{F}[z]} \mathcal{V}_S$ by Theorem 2.10.2(ii) or Theorem 2.10.6(ii), respectively, with Definition 3.2.1(ii)–(iii).
Hence $T \sim S$ and $\mathrm{ElemDiv}(T) = \mathrm{ElemDiv}(S)$ by Theorems 3.1.4 and 2.10.2(ii) with Definition 3.2.1(iii).
(ii) ($\Rightarrow$) Suppose $A \sim_{\mathbb{F}} B$. Then $(\mathbb{F}^n)_A \cong_{\mathbb{F}[z]} (\mathbb{F}^n)_B$ by Corollary 3.1.5.
Both divisor data sets agree by Theorems 2.10.2(ii) and 2.10.6(ii) with Definition 3.2.1(ii)–(iii).
(ii) ($\Leftarrow$) Suppose either $\mathrm{ElemDiv}(A) = \mathrm{ElemDiv}(B)$ or $\mathrm{InvFact}(A) = \mathrm{InvFact}(B)$.
Then $(\mathbb{F}^n)_A \cong_{\mathbb{F}[z]} (\mathbb{F}^n)_B$ by Theorem 2.10.2(ii) or Theorem 2.10.6(ii), respectively, with Definition 3.2.1(ii)–(iii).
Hence $A \sim_{\mathbb{F}} B$ and $\mathrm{ElemDiv}(A) = \mathrm{ElemDiv}(B)$ by Corollary 3.1.5, Theorem 2.10.2(ii), and Definition 3.2.1(iii).
(iii) Set $\Phi(\mathbf{v}) := [\mathbf{v}]_{\mathcal{B}}$. The map Φ is bijective, and $(\forall\, (p, \mathbf{v}) \in \mathbb{F}[z] \times \mathcal{V})\, \Phi(p(T)\mathbf{v}) = p(A)\Phi(\mathbf{v})$ by $A = [T]_{\mathcal{B} \leftarrow \mathcal{B}}$.
Thus $\Phi : \mathcal{V}_T \to (\mathbb{F}^n)_A$ is an $\mathbb{F}[z]$-isomorphism by Definitions 3.1.1 and 1.4.1.
Both divisor data sets agree by Theorems 2.10.2(ii) and 2.10.6(ii) with Definition 3.2.1(ii)–(iii).

Structural Commentary: Similarity identifies the operator module; PID uniqueness fixes both divisor data sets.
Key Insight: Either divisor datum determines the module and its similarity class. □

Definition 3.4.3. *Rational Canonical Block Forms*
Let $\mathcal{P}$ be the set of monic nonconstant polynomials in $\mathbb{F}[z]$.
Let $\mathcal{Q}$ be the set of positive powers of monic irreducible polynomials in $\mathbb{F}[z]$. Let $n \geq 1$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) Matrix A is in *invariant-factor rational canonical form* if $(\exists\, r \in \mathbb{N})(\exists\, (s_1, \ldots, s_r) \in \mathcal{P}^r)\, [A = \mathrm{diag}(C_{s_1}, \ldots, C_{s_r}) \wedge s_r \mid \cdots \mid s_1]$.
(ii) Matrix A is in *elementary-divisor rational canonical form* if $(\exists\, m \in \mathbb{N})(\exists\, (q_1, \ldots, q_m) \in \mathcal{Q}^m)\, A = \mathrm{diag}(C_{q_1}, \ldots, C_{q_m})$.

Theorem 3.4.4. *Rational Canonical Form Skeleton*
Let $n \geq 1$, let $A \in \mathrm{Mat}(n, n, \mathbb{F})$, and write $\mathrm{InvFact}(A) = (s_1, \ldots, s_r)$. *Set $R_A := \mathrm{diag}(C_{s_1}, \ldots, C_{s_r})$. Then:*

(i) $r \in \mathbb{N}$, the s_j are monic and nonconstant, and $s_r \mid \cdots \mid s_1$.
(ii) $A \sim_{\mathbb{F}} R_A$.
(iii) $\mu_A = s_1$ and $p_A = \prod_{j=1}^{r} s_j$.

Proof.
(i) The tuple properties hold by Definition 3.2.1(ii).
(ii) Let $T_A : \mathbb{F}^n \to \mathbb{F}^n$, $\mathbf{x} \mapsto A\mathbf{x}$. There is a basis $\mathcal{B}$ with $[T_A]_{\mathcal{B} \leftarrow \mathcal{B}} = R_A$ by Theorem 3.2.2(ii). Hence $A \sim_{\mathbb{F}} R_A$ by Corollary 6.2.4.
(iii) Identities $\mu_{T_A} = s_1$ and $q_{T_A} = \prod_{j=1}^{r} s_j$ hold by Theorem 3.2.2(iii)–(iv). Thus $\mu_A = s_1$, $p_A = \prod_{j=1}^{r} s_j$ by Definitions 2.2.3, 2.1.15.

Structural Commentary: The invariant-factor decomposition supplies a cyclic basis whose coordinate blocks represent A.
Key Insight: The divisibility-ordered tuple fixes the companion-block representative. □

Theorem 3.4.5. *Rational Canonical Form: Two Versions*
Let $0 < \dim \mathcal{V} < \infty$, let $T \in \mathcal{L}(\mathcal{V})$, let $n \geq 1$, and let $A \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) If $\mathrm{ElemDiv}(T) = \{q_1, \ldots, q_m\}$, *then* $(\exists\, \mathcal{R})\, [T]_{\mathcal{R} \leftarrow \mathcal{R}} = \mathrm{diag}(C_{q_1}, \ldots, C_{q_m})$ *for a basis $\mathcal{R}$ of $\mathcal{V}$.*
(ii) The elementary-divisor form in (i) is unique up to block permutation.
(iii) If $\mathrm{InvFact}(T) = (s_1, \ldots, s_r)$, *then* $(\exists\, \mathcal{B})\, [T]_{\mathcal{B} \leftarrow \mathcal{B}} = \mathrm{diag}(C_{s_1}, \ldots, C_{s_r})$ *for a basis $\mathcal{B}$ of $\mathcal{V}$.*
(iv) The invariant-factor form in (iii) is unique under the order $s_r \mid \cdots \mid s_1$.
(v) The class $[A]_{\sim_{\mathbb{F}}}$ contains both forms, with the uniqueness in (ii) and (iv).

Proof.
(i) Basis $\mathcal{R}$ with displayed block matrix is obtained by concatenating cyclic bases in Theorem 3.3.1(ii)–(iii) and Theorem 3.1.14(iii).
(ii) Each block C_q is cyclic with order q by Definition 3.1.12, Theorem 3.1.13(i), and Proposition 3.1.7(i).
Hence an elementary-divisor block matrix has the multiset of its block orders by Proposition 2.10.3 and Definition 3.2.1(iii).
Every coordinate matrix of T has divisor data equal to those of T by Theorem 3.4.2(iii), so only the block order can vary.
(iii) A basis $\mathcal{B}$ with the displayed block matrix exists by Theorem 3.2.2(i)–(ii).
(iv) The companion blocks in an invariant-factor form are cyclic with their defining orders by Definition 3.1.12 and Theorem 3.1.13(i).
Their divisibility-ordered list is the invariant-factor tuple of the coordinate module by Theorem 2.10.6(i)–(ii).
It equals $\mathrm{InvFact}(T)$ by Theorem 3.4.2(iii), so the list is unique.

(v) Both forms for $T_A : \mathbb{F}^n \to \mathbb{F}^n$, $\mathbf{x} \mapsto A\mathbf{x}$, exist with the stated uniqueness by parts (i)–(iv).
Each resulting coordinate matrix is similar to A by Corollary 6.2.4.

Structural Commentary: Primary and invariant-factor decompositions concatenate cyclic bases in two intrinsic block orders.
Key Insight: The two forms preserve one module while exposing different divisor groupings. □

Computation Method 3.4.6. *Constructing an Operator from Elementary Divisors*

Given $m \in \mathbb{N}$ and a multiset $Q = \{q_1, \dots, q_m\}$ of monic nonconstant prime powers in $\mathbb{F}[z]$, set $n := \sum_{j=1}^{m} \deg q_j$.

The output is a matrix in $\mathrm{Mat}(n, n, \mathbb{F})$ with elementary-divisor multiset Q and its invariant-factor form.

(i) Set $R_Q := \mathrm{diag}(C_{q_1}, \dots, C_{q_m}) \in \mathrm{Mat}(n, n, \mathbb{F})$.
(ii) $(\forall\, j \in \{1, \dots, m\})\, \mathcal{C}_{T_{C_{q_j}}}(\mathbf{e}_1) = \mathbb{F}^{\deg q_j}$ by Definition 3.1.12. Identities $(\forall\, j \in \{1, \dots, m\})\, \mu_{C_{q_j}} = q_j$ hold by Theorem 3.1.13(i).
These polynomials represent the corresponding module orders by Proposition 3.1.7(i).
Hence $(\forall\, j \in \{1, \dots, m\})$ $\mathrm{ElemDiv}(T_{C_{q_j}}) = \{q_j\}$ by Theorem 2.10.12(i),(iii) and Definition 3.2.1(iii).
Therefore $\mathrm{ElemDiv}(T_{R_Q}) = Q$ by repeated application of Proposition 2.10.3.
(iii) Recombine Q into $\mathrm{InvFact}(T_{R_Q}) = (s_1, \dots, s_r)$ by Method 2.10.5. Then $\mathrm{diag}(C_{s_1}, \dots, C_{s_r}) \sim_{\mathbb{F}} R_Q$ by Theorem 3.4.4(ii).

Key Insight: Companion blocks realise cyclic summands; block sums realise direct sums.

Example 3.4.7. *Rational Canonical Possibilities from Degree Counts*
Let $T \in \mathcal{L}(\mathbb{R}^7)$ satisfy $\mu_T = (z-1)(z^2+1)^2$, and set $Q := \mathrm{ElemDiv}(T)$.
Then $\mathrm{lcm}\, Q = \mu_T$ and $\sum_{q \in Q} \deg q = 7$ by Theorem 3.3.4(i),(iii) and Definition 3.3.3.
Let a, b, c be the multiplicities in Q of $z-1$, z^2+1, and $(z^2+1)^2$, respectively.
The constraints are $a, c \geq 1$, $b \geq 0$, and $a + 2b + 4c = 7$, so $c = 1$ and $(a, b) \in \{(1,1), (3,0)\}$.
Thus $Q_1 = \{z-1, z^2+1, (z^2+1)^2\}$ or $Q_2 = \{z-1, z-1, z-1, (z^2+1)^2\}$.
The two possible elementary-divisor forms are $R_i = \bigoplus_{q \in Q_i} C_q$ $(i \in \{1, 2\})$, up to block order.

Theorem 3.4.8. *Determinant Form of the Characteristic Polynomial*
Let $n \geq 1$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$.

(i) $\chi_A = p_A$, so $\chi_A(z) = \det(zI_n - A)$.
(ii) If $0 < \dim \mathcal{V} = n$, $T \in \mathcal{L}(\mathcal{V})$, and $A = [T]_{\mathcal{B} \leftarrow \mathcal{B}}$ for a basis $\mathcal{B}$, then $\chi_T = q_T = \chi_A$.

Proof.

(i) $\chi_A = \chi_{T_A}$ by Definition 3.3.3. $\chi_{T_A} = q_{T_A} = p_A$ and $p_A(z) = \det(zI_n - A)$ hold by Theorem 3.3.4(ii), Definitions 2.1.15, 2.1.2.
(ii) The identity $\chi_T = q_T = p_A$ holds by Theorem 3.3.4(ii) and Definition 2.1.15. Hence $p_A = \chi_A$ by part (i).

Structural Commentary: Elementary-divisor products equal operator polynomial, which coordinates identify with shifted determinant.
Key Insight: The abstract block product is the concrete characteristic determinant. □

Theorem 3.4.9. *Changing the Base Field*
Let $\mathbb{F} \subseteq \mathbb{K}$ be fields, $n \geq 1$, $A \in \mathrm{Mat}(n, n, \mathbb{F})$. Subscripts on ElemDiv *and* InvFact *indicate the coefficient field.*
Let $s \in \mathbb{N}$, $(k_i)_{i=1}^{s} \in \mathbb{N}^s$, $p_i \in \mathbb{F}[z]$ be distinct monic irreducibles; $\mathrm{ElemDiv}_{\mathbb{F}}(A) = \{p_i^{e_{i,j}} : 1 \leq i \leq s,\ 1 \leq j \leq k_i\}$, *where $e_{i,j} \in \mathbb{N}$.*
For $i \in \{1, \dots, s\}$, let $m_i \in \mathbb{N}$, $(d_{i,\ell})_{\ell=1}^{m_i} \in \mathbb{N}^{m_i}$, $a_{i,\ell} \in \mathbb{K}[z]$ be pairwise distinct monic irreducibles. Suppose $p_i = \prod_{\ell=1}^{m_i} a_{i,\ell}^{d_{i,\ell}}$. Then:

(i) $\mathrm{ElemDiv}_{\mathbb{K}}(A) = \{a_{i,\ell}^{d_{i,\ell} e_{i,j}} : 1 \leq i \leq s,\ 1 \leq j \leq k_i,\ 1 \leq \ell \leq m_i\}$ *as multisets;*
(ii) $\mathrm{InvFact}_{\mathbb{K}}(A) = \mathrm{InvFact}_{\mathbb{F}}(A)$ *under the coefficient inclusion* $\mathbb{F}[z] \subseteq \mathbb{K}[z]$.

Proof.

(i) Set $R_{\mathbb{F}} := \bigoplus_{i=1}^{s} \bigoplus_{j=1}^{k_i} C_{p_i^{e_{i,j}}}$. The similarities $A \sim_{\mathbb{F}} R_{\mathbb{F}}$ and $A \sim_{\mathbb{K}} R_{\mathbb{F}}$ hold by Theorem 3.4.5(v) and $\mathrm{GL}_n(\mathbb{F}) \subseteq \mathrm{GL}_n(\mathbb{K})$.
Fix (i, j). The first standard vector is cyclic for $C_{p_i^{e_{i,j}}}$ by Definition 3.1.12.
Its order over $\mathbb{K}[z]$ is $p_i^{e_{i,j}}$ by Theorem 3.1.13(i) and Proposition 3.1.7(i).
The factors $a_{i,\ell}^{d_{i,\ell} e_{i,j}}$ are pairwise coprime, so $C_{p_i^{e_{i,j}}} \sim_{\mathbb{K}} \bigoplus_{\ell=1}^{m_i} C_{a_{i,\ell}^{d_{i,\ell} e_{i,j}}}$ by Theorems 2.5.6(iii) and 3.1.14(iii).
Replacing every block defines an elementary-divisor form $R_{\mathbb{K}}$ with $A \sim_{\mathbb{K}} R_{\mathbb{K}}$ by the direct sum of the blockwise similarity matrices.
Each block of $R_{\mathbb{K}}$ is cyclic with its displayed order by Definition 3.1.12, Theorem 3.1.13(i), and Proposition 3.1.7(i).
Thus the elementary divisors of $R_{\mathbb{K}}$ are its block orders by Proposition 2.10.3 and Definition 3.2.1(iii).
The asserted multiset is therefore $\mathrm{ElemDiv}_{\mathbb{K}}(A)$ by Theorem 3.4.2(ii).
(ii) Write $\mathrm{InvFact}_{\mathbb{F}}(A) = (s_1, \dots, s_r)$. Then $A \sim_{\mathbb{F}} \mathrm{diag}(C_{s_1}, \dots, C_{s_r})$ by Theorem 3.4.4(ii).
The same similarity holds over $\mathbb{K}$, and the s_j remain monic and nonconstant with $s_r \mid \cdots \mid s_1$, by coefficient inclusion.
This block matrix is invariant-factor form over $\mathbb{K}$ by Definition 3.4.3(i); claimed tuple equality holds by Theorem 3.4.5(iv)–(v).

Structural Commentary: Coprime factorization refines each elementary block; the original divisibility-ordered form remains valid.
Key Insight: Scalar extension splits prime powers without changing invariant-factor blocks. □

Corollary 3.4.10. *Nonderogatory Means One Companion Block*
Let $n \geq 1$ and $A \in \mathrm{Mat}(n, n, \mathbb{F})$. The following are equivalent:

(i) A is nonderogatory;
(ii) $(\mathbb{F}^n)_A$ is cyclic;
(iii) $A \sim_{\mathbb{F}} C_{\chi_A}$.

Proof.

(i) ⇒ *(ii)* The operator T_A is nonderogatory by condition (i) and Definition 3.3.5; $(\mathbb{F}^n)_A$ is cyclic by Theorem 3.3.6(iv),(i).

(*ii*) $\Rightarrow$ (*iii*) $\exists\, s \in \mathbb{F}[z]$ with $\mathrm{InvFact}(A) = (s)$ by condition (ii), Theorem 2.10.12(i),(iv), Theorem 2.10.6(i)–(ii), and Definition 3.2.1(ii). The identities $A \sim_{\mathbb{F}} C_s$ and $s = q_{T_A} = p_A = \chi_A$ hold by Theorem 3.2.2(ii)–(iv), Theorem 3.4.8(i), and Definition 2.1.15.
(*iii*) $\Rightarrow$ (*i*) The identity $\mu_A = \mu_{C_{\chi_A}} = \chi_A$ holds by condition (iii), Theorem 3.1.13(i), and Proposition 3.1.7(iii). Thus A is nonderogatory by Theorem 3.4.8(i) and Definitions 2.1.15 and 3.3.5.

Structural Commentary: Cyclic-module characterization reduces nonderogatoriness to one invariant-factor companion block.
Key Insight: A cyclic generator produces a single companion block. □

Corollary 3.4.11. *When the Elementary-Divisor Form Is Diagonal*
Let $0 < \dim \mathcal{V} < \infty$, *let* $T \in \mathcal{L}(\mathcal{V})$, *set* $Q := \mathrm{ElemDiv}(T)$, *and set* $R_{\mathrm{ed}} := \bigoplus_{q \in Q} C_q$. *The following are equivalent:*

(i) R_{ed} *is diagonal;*
(ii) $(\forall\, q \in Q)\ \deg q = 1$*;*
(iii) $(\exists\, \Lambda \subseteq \mathbb{F})\,[0 < |\Lambda| < \infty \wedge \mu_T = \prod_{\lambda \in \Lambda} (z - \lambda)]$.

Proof.
(*i*) $\Rightarrow$ (*ii*) Every companion block C_q is diagonal by condition (i). Hence $(\forall\, q \in Q)\ \deg q = 1$ by the nonzero subdiagonal in Definition 3.1.12 whenever $\deg q \geq 2$.
(*ii*) $\Rightarrow$ (*iii*) Polynomial μ_T is least common multiple of monic linear polynomials in Q by condition (ii) and Theorem 3.3.4(i). Hence condition (iii) holds for the finite nonempty set of their roots.
(*iii*) $\Rightarrow$ (*i*) The divisibility $(\forall\, q \in Q)\, q \mid \mu_T$ holds by condition (iii) and Theorem 3.3.4(i). Since the elements of Q are prime powers and μ_T is square-free, $(\forall\, q \in Q)(\exists\, \lambda \in \Lambda)\, q = z - \lambda$. Thus every C_q is a 1×1 diagonal matrix by Definition 3.1.12, so R_{ed} is diagonal.

Structural Commentary: Companion matrices of degree at least two have a nonzero subdiagonal; μ_T detects the remainder.
Key Insight: Diagonal companion blocks are exactly the linear elementary divisors. □

Example 3.4.12. *The Same Polynomial over Different Fields*
Set $\mu := (z^2 + 1)(z^2 - 2)$, $A := C_\mu \in \mathrm{Mat}(4, 4, \mathbb{Q})$. Then $\mu_A = p_A = \mu$ by Theorem 3.1.13(i)–(ii). Hence A is nonderogatory by Definitions 2.1.15 and 3.3.5.
The matrix $A = C_\mu$ is an invariant-factor form by Definition 3.4.3(i), so $\mathrm{InvFact}_{\mathbb{Q}}(A) = (\mu)$ by Theorem 3.4.5(iv)–(v). Thus the invariant-factor form over K is C_μ for $K \in \{\mathbb{Q}, \mathbb{R}, \mathbb{C}\}$ by Theorem 3.4.9(ii). The elementary divisors are:

K	$\mathrm{ElemDiv}_K(A)$
$\mathbb{Q}$	$\{z^2 + 1,\ z^2 - 2\}$
$\mathbb{R}$	$\{z^2 + 1,\ z - \sqrt{2},\ z + \sqrt{2}\}$
$\mathbb{C}$	$\{z - i,\ z + i,\ z - \sqrt{2},\ z + \sqrt{2}\}$

The elementary-divisor form over K is $\bigoplus_{q \in \mathrm{ElemDiv}_K(A)} C_q$.
Scalar extension refines these blocks while preserving C_μ; over $\mathbb{C}$, the elementary-divisor form is diagonal.

Perspective 3.4.13. *Crosswalk with the Spectral Presentation*
Let $0 < \dim_{\mathbb{C}} \mathcal{V} < \infty$ and $T \in \mathcal{L}(\mathcal{V})$. The module and spectral presentations encode the same data at different splitting levels:
(i) T is diagonalizable exactly when $(\forall\, q \in \mathrm{ElemDiv}(T))\ \deg q = 1$ by Theorem 3.2.1 and Corollary 3.4.11;
(ii) the elementary divisor $(z - \lambda)^k$ corresponds to the Jordan block $J_k(\lambda)$ by Theorem 6.2.1 and Perspective 3.3.7;
(iii) the rank drops of the $(z - \lambda)$-primary component recover the block exponents k by Proposition 2.9.6.

Key Insight: Rational form is Jordan form before irreducibles split.

Computation Method 3.4.14. *Moving Between Module and Spectral Data*
Let $\mathbb{F} \subseteq \mathbb{C}$, $0 < \dim_{\mathbb{F}} \mathcal{V} < \infty$, $T \in \mathcal{L}(\mathcal{V})$. Choose basis $\mathcal{B}$, set $A := [T]_{\mathcal{B} \leftarrow \mathcal{B}}$, and let $\mathbb{K} \subseteq \mathbb{C}$ be the splitting field of μ_T over $\mathbb{F}$. The outputs are a rational canonical form over $\mathbb{F}$ and the Jordan-block data of A over $\mathbb{K}$.

(i) Factor $\mu_T = \prod_{i=1}^{s} p_i^{e_i}$ into distinct monic irreducibles over $\mathbb{F}$, and set $\mathcal{V}_{p_i} := \ker p_i(T)^{e_i}$.
(ii) Decompose each $\mathcal{V}_{p_i}$ into cyclic summands of orders $p_i^{e_{i,j}}$ by Theorem 3.3.1(ii). These orders form $\mathrm{ElemDiv}(T)$ by part (iii) of that theorem.
(iii) Assemble the blocks $C_{p_i^{e_{i,j}}}$ into an elementary-divisor rational canonical form over $\mathbb{F}$ by Theorem 3.4.5(i).
(iv) Factor the p_i over $\mathbb{K}$ and refine the elementary divisors into powers $(z - \lambda)^k$ by Theorem 3.4.9(i) for A. In the reversed shifted-power basis of $\mathbb{K}[z]/\langle (z - \lambda)^k \rangle$, multiplication by z has matrix $J_k(\lambda)$. Hence each refined cyclic block is similar over $\mathbb{K}$ to $J_k(\lambda)$ by Theorem 3.1.14(i),(iii).
(v) If T is diagonalizable over $\mathbb{F}$, a diagonal coordinate matrix is a direct sum of blocks $C_{z-\lambda}$. Elementary divisors linear by Proposition 2.10.3, Definition 3.2.1(iii); $(\forall\, q \in \mathrm{ElemDiv}(T))\ \deg q = 1$ by Theorem 3.4.2(iii). Conversely, if every elementary divisor has degree one, form in (iii) is diagonal by Corollary 3.4.11; T is diagonalizable over $\mathbb{F}$.

Key Insight: Rational and Jordan forms encode the same elementary-divisor data over different fields.

Figure 105 tracks a similarity class through its operator module, divisor data, and companion-block representative.

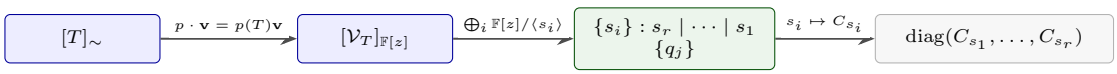

Figure 105: Similarity classes pass through operator modules and divisor data to companion-block representatives.

4 Associative Algebras

4.1 Associative Algebra Structures

The module viewpoint in Definition 3.1.1 encodes one operator at a time.
An algebra records a vector space of compatible products or operators.
The guiding example is $\mathcal{L}(\mathcal{V})$, whose vector-space operations are pointwise and whose multiplication is composition.

Definition 4.1.1. *Algebra over a Field*
Let $\mathbb{F}$ be a field. An *$\mathbb{F}$-algebra* is an $\mathbb{F}$-vector space $\mathcal{A}$ with multiplication $\mathcal{A}\times\mathcal{A}\to\mathcal{A}$, $(a,b)\mapsto ab$.
The structure $(\mathcal{A},+,\cdot)$ is a ring. Scalar compatibility is $(\forall\,\lambda\in\mathbb{F})(\forall\,a,b\in\mathcal{A})\;\lambda(ab)=(\lambda a)b=a(\lambda b)$.

Definition 4.1.2. *Unital Algebras and Basic Properties*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra.

(i) $\mathcal{A}$ is a *unital associative $\mathbb{F}$-algebra* if its underlying ring is equipped with an identity $1_{\mathcal{A}}$.
(ii) $\mathcal{A}$ is *finite-dimensional* iff $\dim_{\mathbb{F}}\mathcal{A}<\infty$.
(iii) $\mathcal{A}$ is *commutative* iff $(\forall\,a,b\in\mathcal{A})\;ab=ba$.
(iv) If $\mathcal{A}$ is unital, then $a\in\mathcal{A}$ is *invertible* iff $(\exists\,b\in\mathcal{A})\;ab=ba=1_{\mathcal{A}}$.

Convention 4.1.3. *Algebra Convention*
For a fixed field $\mathbb{F}$, *algebra* means unital associative $\mathbb{F}$-algebra unless stated otherwise.

Example 4.1.4. *Basic Algebras*

(i) If $\mathbb{F}\subseteq\mathbb{E}$ are fields, then $\mathbb{E}$ is an $\mathbb{F}$-algebra by $r\cdot x=rx$ and multiplication in $\mathbb{E}$.
(ii) $\mathbb{F}[x]$ is a commutative $\mathbb{F}$-algebra with unit 1 and scalar embedding $r\mapsto r$.
(iii) If $n\geq 1$, then $\mathrm{Mat}(n,n,\mathbb{F})$ is an $\mathbb{F}$-algebra with unit I_n and product AB.
(iv) If $\mathcal{V}$ is an $\mathbb{F}$-vector space, then $\mathcal{L}(\mathcal{V})=\mathrm{End}_{\mathbb{F}}(\mathcal{V})$ is an $\mathbb{F}$-algebra. Its unit is $I_{\mathcal{V}}$, and its product is composition $S\circ T$.

Definition 4.1.5. *Subalgebras and Generated Subalgebras*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra.

(i) A *subalgebra*, written $\mathcal{B}\leq_{\mathbb{F}\text{-alg}}\mathcal{A}$, is an $\mathbb{F}$-linear subspace $\mathcal{B}\leq_{\mathbb{F}}\mathcal{A}$ containing $1_{\mathcal{A}}$. It satisfies $(\forall\,b,b'\in\mathcal{B})\;bb'\in\mathcal{B}$.
(ii) For $X\subseteq\mathcal{A}$, the *subalgebra generated by X* is $\langle X\rangle_{\text{subalg}}:=\bigcap\{\mathcal{B}\leq_{\mathbb{F}\text{-alg}}\mathcal{A}:X\subseteq\mathcal{B}\}$.

Definition 4.1.6. *Center and Central Algebras*

(i) The *center* of an $\mathbb{F}$-algebra $\mathcal{A}$ is $Z(\mathcal{A}):=\{a\in\mathcal{A}:(\forall\,x\in\mathcal{A})\;ax=xa\}$.
(ii) $\mathcal{A}$ is *central over $\mathbb{F}$* iff $Z(\mathcal{A})=\mathbb{F}1_{\mathcal{A}}:=\{r1_{\mathcal{A}}:r\in\mathbb{F}\}$.

Proposition 4.1.7. *Centers and Central Scalar Embeddings*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra.

(i) $Z(\mathcal{A})\leq_{\mathbb{F}\text{-}alg}\mathcal{A}$.
(ii) If $1_{\mathcal{A}}\neq 0$, then $\iota_{\mathcal{A}}:\mathbb{F}\hookrightarrow Z(\mathcal{A})$, $r\mapsto r1_{\mathcal{A}}$, is an injective unital ring homomorphism.
(iii) If R is a unital ring and $\mathbb{F}\leq Z(R)$ is a subfield, then R is an $\mathbb{F}$-algebra via $r\cdot x:=rx$.

Proof.

(i) Identity belongs to $Z(\mathcal{A})$. If $(r,s,a,b,x)\in\mathbb{F}^2\times Z(\mathcal{A})^2\times\mathcal{A}$, then $(ra+sb)x=r(ax)+s(bx)=r(xa)+s(xb)=x(ra+sb)$.
Thus $Z(\mathcal{A})\leq_{\mathbb{F}}\mathcal{A}$. For $a,b\in Z(\mathcal{A})$ and $x\in\mathcal{A}$, $(ab)x=a(bx)=a(xb)=(ax)b=(xa)b=x(ab)$. Thus $Z(\mathcal{A})\leq_{\mathbb{F}\text{-alg}}\mathcal{A}$.
(ii) Set $\iota:=\iota_{\mathcal{A}}$. For $r,s\in\mathbb{F}$, $\iota(r+s)=\iota(r)+\iota(s)$, $\iota(rs)=\iota(r)\iota(s)$, and $\iota(1)=1_{\mathcal{A}}$ by the algebra axioms.
For $(r,a)\in\mathbb{F}\times\mathcal{A}$, $\iota(r)a=(r1_{\mathcal{A}})a=ra=a(r1_{\mathcal{A}})=a\iota(r)$, so $\operatorname{im}\iota\subseteq Z(\mathcal{A})$.
If $\iota(r)=0$ and $r\neq 0$, then $1_{\mathcal{A}}=\iota(r^{-1})\iota(r)=0$, contradiction; hence $\ker\iota=\{0\}$.
(iii) Set $r\cdot x:=rx$. Then R is an $\mathbb{F}$-vector space by the field laws in $\mathbb{F}\subseteq R$.
Scalar compatibility $(\forall\,r\in\mathbb{F})(\forall\,x,y\in R)\;r\cdot(xy)=(r\cdot x)y=x(r\cdot y)$ holds by $\mathbb{F}\subseteq Z(R)$. Thus R is an $\mathbb{F}$-algebra.

Structural Commentary: Center closure supports the scalar embedding, while a central subfield reconstructs the scalar action.
Key Insight: Scalar multiplication is multiplication by the corresponding central element. □

Definition 4.1.8. *Ideals, Simple Algebras, and Quotients*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra.

(i) A *two-sided ideal*, written $\mathcal{I}\triangleleft\mathcal{A}$, is an $\mathbb{F}$-linear subspace $\mathcal{I}\leq_{\mathbb{F}}\mathcal{A}$. It satisfies $(\forall\,a\in\mathcal{A})(\forall\,u\in\mathcal{I})\;au,ua\in\mathcal{I}$.
(ii) For $X\subseteq\mathcal{A}$, the *ideal generated by X* is $\langle X\rangle_{\text{ideal}}:=\bigcap\{\mathcal{I}\triangleleft\mathcal{A}:X\subseteq\mathcal{I}\}$.
(iii) $\mathcal{A}$ is *simple* iff $\mathcal{A}\neq\{0_{\mathcal{A}}\}$ and its only two-sided ideals are $\{0_{\mathcal{A}}\}$ and $\mathcal{A}$.
(iv) If $\mathcal{I}\triangleleft\mathcal{A}$, *quotient algebra* $\mathcal{A}/\mathcal{I}$ is quotient vector space. Product and identity are $(a+\mathcal{I})(b+\mathcal{I}):=ab+\mathcal{I}$ and $1_{\mathcal{A}/\mathcal{I}}:=1_{\mathcal{A}}+\mathcal{I}$.

Proposition 4.1.9. *Concrete Generated Substructures*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra and let $X\subseteq\mathcal{A}$. Set $\mathcal{W}_X:=\{1_{\mathcal{A}}\}\cup\{x_1\cdots x_m:m\in\mathbb{N},\;(x_1,\dots,x_m)\in X^m\}$.
Set $\mathcal{I}_X:=\{\sum_{j=1}^{n}a_jx_jb_j:n\in\mathbb{N}_0,\;(a_j,b_j,x_j)_{j=1}^{n}\in(\mathcal{A}\times\mathcal{A}\times X)^n\}$, with the empty sum at $n=0$.

(i) $\langle X\rangle_{\text{subalg}}=\mathrm{span}_{\mathbb{F}}(\mathcal{W}_X)$.
(ii) $\langle X\rangle_{\text{ideal}}=\mathcal{I}_X$.

Proof.

(i) Products of members of $\mathcal{W}_X$ belong to $\mathcal{W}_X$, so $\mathrm{span}_{\mathbb{F}}(\mathcal{W}_X)$ is a subalgebra containing X by bilinearity.
If $\mathcal{B}\leq_{\mathbb{F}\text{-alg}}\mathcal{A}$ and $X\subseteq\mathcal{B}$, then $\mathcal{W}_X\subseteq\mathcal{B}$ and $\mathrm{span}_{\mathbb{F}}(\mathcal{W}_X)\subseteq\mathcal{B}$. The equality follows by Definition 4.1.5(ii).
(ii) $\mathcal{I}_X\leq_{\mathbb{F}}\mathcal{A}$ by closure of finite sums under $\mathbb{F}$-linear combinations, and $X\subseteq\mathcal{I}_X$ by $x=1_{\mathcal{A}}x1_{\mathcal{A}}$.
For $(a,b)\in\mathcal{A}^2$ and $u=\sum_{j=1}^{n}a_jx_jb_j\in\mathcal{I}_X$, both $au=\sum_{j=1}^{n}(aa_j)x_jb_j$ and $ub=\sum_{j=1}^{n}a_jx_j(b_jb)$ belong to $\mathcal{I}_X$.
Thus $\mathcal{I}_X\triangleleft\mathcal{A}$. If $\mathcal{J}\triangleleft\mathcal{A}$ and $X\subseteq\mathcal{J}$, then $(\forall\,a,b\in\mathcal{A})(\forall\,x\in X)\;axb\in\mathcal{J}$, so $\mathcal{I}_X\subseteq\mathcal{J}$. The equality follows by Definition 4.1.8(ii).

Structural Commentary: Closure of words constructs the generated subalgebra; two-sided products construct the generated ideal.
Key Insight: Intersections agree with the explicit closures forced by their defining operations. □

Definition 4.1.10. *Algebra Homomorphisms*
Let $\mathcal{A}, \mathcal{B}$ be $\mathbb{F}$-algebras.

(i) An *algebra homomorphism* is an $\mathbb{F}$-linear map $\sigma \in \mathcal{L}(\mathcal{A}, \mathcal{B})$. It satisfies $(\forall\, a, b \in \mathcal{A})\, \sigma(ab) = \sigma(a)\sigma(b)$ and $\sigma(1_{\mathcal{A}}) = 1_{\mathcal{B}}$.
(ii) An algebra homomorphism is a *monomorphism* iff it is injective.
(iii) An algebra homomorphism is an *isomorphism* iff it is bijective.

Proposition 4.1.11. *Kernel, Image, and First Isomorphism Theorem*
Let $\sigma : \mathcal{A} \to \mathcal{B}$ be an $\mathbb{F}$-algebra homomorphism and set $K := \ker \sigma$.

(i) $K \lhd \mathcal{A}$.
(ii) $\operatorname{im} \sigma \leq_{\mathbb{F}\text{-}alg} \mathcal{B}$.
(iii) The map $\overline{\sigma} : \mathcal{A}/K \to \operatorname{im} \sigma$, $a + K \mapsto \sigma(a)$, is an $\mathbb{F}$-algebra isomorphism.

Proof.

(i) $K \leq_{\mathbb{F}} \mathcal{A}$ by linearity. If $(a, u) \in \mathcal{A} \times K$, then $\sigma(au) = \sigma(a)\sigma(u) = 0 = \sigma(u)\sigma(a) = \sigma(ua)$, so $au, ua \in K$ and $K \lhd \mathcal{A}$.
(ii) The image is an $\mathbb{F}$-linear subspace by linearity and contains $1_{\mathcal{B}} = \sigma(1_{\mathcal{A}})$.
It is closed under multiplication by $(\forall\, a, b \in \mathcal{A})\, \sigma(a)\sigma(b) = \sigma(ab)$. Thus $\operatorname{im} \sigma \leq_{\mathbb{F}\text{-alg}} \mathcal{B}$.
(iii) Define $\overline{\sigma}(a + K) := \sigma(a)$. The equivalence $a + K = a' + K \iff a - a' \in K$ holds by Proposition 1.5.2(i).
The equivalence $a - a' \in K \iff \sigma(a) = \sigma(a')$ holds by $K = \ker \sigma$.
Thus $\overline{\sigma}$ is well defined and injective; it is surjective by its codomain.
For $(a, a', r) \in \mathcal{A}^2 \times \mathbb{F}$, $\overline{\sigma}((a + K) + (a' + K)) = \sigma(a) + \sigma(a')$ and $\overline{\sigma}(r(a + K)) = r\sigma(a)$.
Multiplicativity is $\overline{\sigma}((a + K)(a' + K)) = \sigma(a)\sigma(a')$.
The identity $\overline{\sigma}(1_{\mathcal{A}} + K) = 1_{\mathcal{B}}$ completes the verification that $\overline{\sigma}$ is an $\mathbb{F}$-algebra isomorphism.

Structural Commentary: Kernel absorption forms the quotient, while image closure supplies the induced map's algebra codomain.
Key Insight: Cosets agree exactly when their representatives have the same image. □

Definition 4.1.12. *Left Regular Representation*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra. For $a \in \mathcal{A}$, the *left multiplication map* is $L_a : \mathcal{A} \to \mathcal{A}$, $x \mapsto ax$.
The map $L_{\mathcal{A}} : \mathcal{A} \to \mathcal{L}(\mathcal{A})$, $a \mapsto L_a$, is the *left regular representation* of $\mathcal{A}$.

Theorem 4.1.13. *Left Regular Representation*
If $\mathcal{A}$ is an $\mathbb{F}$-algebra, then $L_{\mathcal{A}} : \mathcal{A} \hookrightarrow \mathcal{L}(\mathcal{A})$, $a \mapsto L_a$, is an $\mathbb{F}$-algebra monomorphism.

Proof. For $(a, x, y, r) \in \mathcal{A}^3 \times \mathbb{F}$, $L_a(x + y) = L_a(x) + L_a(y)$ and $L_a(rx) = rL_a(x)$, so $L_a \in \mathcal{L}(\mathcal{A})$.
For $(a, b, r, x) \in \mathcal{A}^3 \times \mathbb{F}$, $L_{a+b}(x) = L_a(x) + L_b(x)$ and $L_{ra}(x) = rL_a(x)$. Hence $L_{\mathcal{A}}$ is $\mathbb{F}$-linear by Assumption 3.1.2.
For $a, b, x \in \mathcal{A}$, $L_{ab}(x) = a(bx) = (L_a L_b)(x)$ and $L_{1_{\mathcal{A}}}(x) = x$. Hence $L_{ab} = L_a L_b$ and $L_{1_{\mathcal{A}}} = I_{\mathcal{A}}$ by Assumption 3.1.2.
If $L_a = 0$, then $a = L_a(1_{\mathcal{A}}) = 0$, so $L_{\mathcal{A}}$ is injective.
Structural Commentary: Bilinearity defines the algebra map, while unit evaluation proves injectivity.
Key Insight: The identity recovers each element by $L_a(1_{\mathcal{A}}) = a$. □

Figure 106 records the multiplicativity and unit-evaluation identities used in the proof.

Figure 106: The left regular representation sends $a \in \mathcal{A}$ to $L_a : x \mapsto ax$; the identities $L_{ab} = L_a L_b$ and $L_a(1_{\mathcal{A}}) = a$ encode multiplicativity and injectivity.

Computation Method 4.1.14. *Building Multiplication from Structure Constants*
Input: A vector space $V = \bigoplus_{i \in I} \mathbb{F} b_i$ and coefficients $c_{ij}^k \in \mathbb{F}$. The support condition is $(\forall\, i, j \in I)\ \left|\{k \in I : c_{ij}^k \neq 0\}\right| < \infty$.
Output: A bilinear multiplication on V, together with coordinate tests for associativity, commutativity, and a basis identity.

(i) Define $b_i b_j := \sum_{k \in I} c_{ij}^k b_k$. Extend bilinearly by $(\sum_i r_i b_i)(\sum_j s_j b_j) := \sum_{i,j,k} r_i s_j c_{ij}^k b_k$.
(ii) The product is associative iff $(\forall\, i, j, k, m \in I)\ \sum_{\ell \in I} c_{ij}^{\ell} c_{\ell k}^{m} = \sum_{\ell \in I} c_{jk}^{\ell} c_{i\ell}^{m}$.
(iii) The product is commutative iff $(\forall\, i, j, k \in I)\, c_{ij}^k = c_{ji}^k$.
(iv) A basis vector b_e is an identity iff $(\forall\, j, m \in I)\, c_{ej}^m = \delta_j^m = c_{je}^m$.

Definition 4.1.15. *Group Algebra*
For a group G and field $\mathbb{F}$, the *group algebra* is $\mathbb{F}[G] := \{ \sum_{g \in G} r_g g : r_g \in \mathbb{F},\ |\{g \in G : r_g \neq 0\}| < \infty \}$.
Its vector-space operations are coefficientwise, and $(\sum_g r_g g)(\sum_h s_h h) := \sum_{g,h} r_g s_h (gh)$.

Proposition 4.1.16. *Structure of a Group Algebra*
Let G be a group and let $\mathbb{F}$ be a field.

(i) G is an $\mathbb{F}$-basis of $\mathbb{F}[G]$.
(ii) With the multiplication in Definition 4.1.15, $\mathbb{F}[G]$ is an $\mathbb{F}$-algebra with identity e_G.
(iii) $\mathbb{F}[G]$ is commutative iff G is abelian.
(iv) If G is finite, then $\dim_{\mathbb{F}} \mathbb{F}[G] = |G|$.

Proof.

(i) G is an $\mathbb{F}$-basis by the unique finite-support coefficient expansions in Definition 4.1.15.

(*ii*) The product is bilinear by construction. The two associative products are trilinear and agree on basis triples by $(gh)k = g(hk)$. The identity relation follows by bilinearity and $(\forall\, g \in G)\, e_G g = g = g e_G$.
(*iii*) ($\Rightarrow$) If $\mathbb{F}[G]$ is commutative, then $(\forall\, g, h \in G)\, gh = hg$, so G is abelian.
(*iii*) ($\Leftarrow$) If G is abelian, then $\mathbb{F}[G]$ is commutative by bilinearity and $(\forall\, g, h \in G)\, gh = hg$.
(*iv*) The dimension equals the cardinality of the basis G by part (i).

Structural Commentary: Basis multiplication transfers the group law to the algebra, while basis equality detects commutativity.
Key Insight: The group elements remain linearly independent inside $\mathbb{F}[G]$. □

Example 4.1.17. *Cyclic Group Algebras and Circulant Shifts*
Let $G = \langle \alpha \rangle$ have order n, and let $\mathcal{B} = (1, \alpha, \dots, \alpha^{n-1})$ be the ordered $\mathbb{F}$-basis of $\mathbb{F}[G]$.
With exponents read modulo n, $(\forall\, j, k \in \{0, \dots, n-1\})\, L_{\alpha^k}(\alpha^j) = \alpha^{j+k}$, so L_{α^k} is the k-fold cyclic shift of $\mathcal{B}$.
Set $P := [L_\alpha]_{\mathcal{B}}$. Then $(\forall\, k \in \{0, \dots, n-1\})\, [L_{\alpha^k}]_{\mathcal{B}} = P^k$. For $n \geq 5$, the following coordinate form displays the cyclic shift.

$$P = \begin{bmatrix} 0 & 0 & \cdots & 0 & 1 \\ 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & \ddots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1 & 0 \end{bmatrix}.$$

Thus $[L_{\sum_{k=0}^{n-1} c_k \alpha^k}]_{\mathcal{B}} = \sum_{k=0}^{n-1} c_k P^k$, and these are precisely the circulant matrices.

Proposition 4.1.18. *Endomorphisms and Matrices Are the Same Algebra after Choosing a Basis*
Let $\dim \mathcal{V} = n \geq 1$ and fix an ordered basis $\mathcal{B}$ of $\mathcal{V}$. Then $\mu_{\mathcal{B}} : \mathcal{L}(\mathcal{V}) \to \mathrm{Mat}(n, n, \mathbb{F})$, $T \mapsto [T]_{\mathcal{B}}$, is an $\mathbb{F}$-algebra isomorphism.

Proof. By Theorem 3.4.5, $\mu_{\mathcal{B}}$ is an $\mathbb{F}$-linear bijection. For $S, T \in \mathcal{L}(\mathcal{V})$, $\mu_{\mathcal{B}}(ST) = \mu_{\mathcal{B}}(S)\mu_{\mathcal{B}}(T)$ by Proposition 3.4.4.
Since $\mu_{\mathcal{B}}(I_{\mathcal{V}}) = I_n$, $\mu_{\mathcal{B}}$ is an $\mathbb{F}$-algebra isomorphism.
Structural Commentary: Linear coordinate encoding becomes algebra isomorphism by composition compatibility, identity preservation.
Key Insight: A fixed basis converts composition exactly into matrix multiplication. □

Theorem 4.1.19. *Center and Ideals of an Endomorphism Algebra*
Assume Zorn's lemma, and let $0 \neq \mathcal{V}$ be an $\mathbb{F}$-vector space. Set $\mathcal{F}(\mathcal{V}) := \{T \in \mathcal{L}(\mathcal{V}) : \dim \operatorname{im} T < \infty\}$.

(i) $Z(\mathcal{L}(\mathcal{V})) = \mathbb{F} I_{\mathcal{V}}$, so $\mathcal{L}(\mathcal{V})$ is central.
(ii) $\mathcal{F}(\mathcal{V}) \lhd \mathcal{L}(\mathcal{V})$.
(iii) $(\forall\, \mathcal{J} \lhd \mathcal{L}(\mathcal{V}))\, [\mathcal{J} \neq \{0\} \Rightarrow \mathcal{F}(\mathcal{V}) \subseteq \mathcal{J}]$.
(iv) $\mathcal{L}(\mathcal{V})$ is simple iff $\dim \mathcal{V} < \infty$.

Proof.

(*i*) For $(v, \varphi) \in \mathcal{V} \times \mathcal{V}'$, write $v \otimes \varphi \in \mathcal{L}(\mathcal{V})$ for $x \mapsto \varphi(x)v$. Fix $T \in Z(\mathcal{L}(\mathcal{V}))$.
For $0 \neq v \in \mathcal{V}$, choose $\varphi \in \mathcal{V}'$ with $\varphi(v) = 1$ by Proposition 4.1.7(iii), with $\{0\} \leq \mathcal{V}$.
Set $\lambda_v := \varphi(Tv)$. Then $Tv = T(v \otimes \varphi)(v) = (v \otimes \varphi)T(v) = \lambda_v v$. Fix $0 \neq v_0 \in \mathcal{V}$. If $v = cv_0 \neq 0$, then $\lambda_v = \lambda_{v_0}$ by linearity.
If v, v_0 are independent, then $\lambda_{v+v_0}(v + v_0) = \lambda_v v + \lambda_{v_0} v_0$, so $\lambda_v = \lambda_{v_0}$ by independence. Hence $T = \lambda_{v_0} I_{\mathcal{V}}$ by Assumption 3.1.2.
Since scalar operators commute with every endomorphism, $Z(\mathcal{L}(\mathcal{V})) = \mathbb{F} I_{\mathcal{V}}$.
(*ii*) The zero map belongs to $\mathcal{F}(\mathcal{V})$. For $(r, s, T, U) \in \mathbb{F}^2 \times \mathcal{F}(\mathcal{V})^2$, $\operatorname{im}(rT + sU) \subseteq \operatorname{im} T + \operatorname{im} U$.
Thus $\mathcal{F}(\mathcal{V}) \leq_{\mathbb{F}} \mathcal{L}(\mathcal{V})$. For $R, S \in \mathcal{L}(\mathcal{V})$ and $T \in \mathcal{F}(\mathcal{V})$, $\operatorname{im}(RTS) \subseteq R(\operatorname{im} T)$; $\mathcal{F}(\mathcal{V}) \lhd \mathcal{L}(\mathcal{V})$.
(*iii*) Let $\{0\} \neq \mathcal{J} \lhd \mathcal{L}(\mathcal{V})$. Choose $0 \neq S \in \mathcal{J}$, $e \in \mathcal{V}$ with $Se \neq 0$. Choose $\eta \in \mathcal{V}'$ with $\eta(Se) = 1$ by Proposition 4.1.7(iii), $\{0\} \leq \mathcal{V}$.
For $(v, \varphi) \in \mathcal{V} \times \mathcal{V}'$, $v \otimes \varphi = (v \otimes \eta)S(e \otimes \varphi) \in \mathcal{J}$, so $\mathcal{J}$ contains every rank-one map.
If $T \in \mathcal{F}(\mathcal{V})$ and $(w_1, \dots, w_m)$ is a basis of $\operatorname{im} T$, let ψ_j be its coordinate functionals.
For $x \in \mathcal{V}$, $T(x) = \sum_{j=1}^{m} \psi_j(Tx) w_j$. The identity $T = \sum_{j=1}^{m} w_j \otimes (\psi_j \circ T)$ holds by Assumption 3.1.2.
Each summand belongs to $\mathcal{J}$, so $T \in \mathcal{J}$ and $\mathcal{F}(\mathcal{V}) \subseteq \mathcal{J}$.
(*iv*) ($\Rightarrow$) Suppose $\mathcal{L}(\mathcal{V})$ is simple, $\dim \mathcal{V} = \infty$. Choose $0 \neq v \in \mathcal{V}$, $\varphi \in \mathcal{V}'$ with $\varphi(v) = 1$ by Proposition 4.1.7(iii), $\{0\} \leq \mathcal{V}$.
Then $0 \neq v \otimes \varphi \in \mathcal{F}(\mathcal{V})$, whereas $I_{\mathcal{V}} \notin \mathcal{F}(\mathcal{V})$; $\mathcal{F}(\mathcal{V})$ is nonzero proper ideal by part (ii), contradiction. Hence $\dim \mathcal{V} < \infty$.
(*iv*) ($\Leftarrow$) If $\dim \mathcal{V} < \infty$, then $\mathcal{F}(\mathcal{V}) = \mathcal{L}(\mathcal{V})$, so every nonzero two-sided ideal equals $\mathcal{L}(\mathcal{V})$ by part (iii).
Since $I_{\mathcal{V}} \neq 0$, the algebra $\mathcal{L}(\mathcal{V})$ is nonzero and therefore simple.

Structural Commentary: Rank-one probes force scalar central maps, while rank-one factorizations control every nonzero ideal.
Key Insight: Sandwiching one nonzero operator produces every rank-one operator. □

Perspective 4.1.20. *Operator Connection*
$T \in \mathcal{L}(\mathcal{V})$ determines an $\mathbb{F}[z]$-module by $z \cdot v = T(v)$.
The left regular map $L_{\mathcal{A}} : \mathcal{A} \hookrightarrow \mathcal{L}(\mathcal{A})$ identifies $\mathcal{A}$ with a subalgebra of its endomorphism algebra and supplies a faithful representation.

4.2 Algebraic Elements and Minimal Polynomials

Definition 4.2.1. *Evaluation and Algebraic Elements*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra and let $a \in \mathcal{A}$.

(i) For $p(x) = \sum_{j=0}^{n} c_j x^j \in \mathbb{F}[x]$, set $p(a) := \sum_{j=0}^{n} c_j a^j$, where $a^0 := 1_{\mathcal{A}}$. The *evaluation map at a* is $\mathrm{ev}_a : \mathbb{F}[x] \to \mathcal{A}$, $p \mapsto p(a)$.
(ii) The element a is *algebraic over $\mathbb{F}$* iff $(\exists\, p \in \mathbb{F}[x] \setminus \{0\})\, p(a) = 0$. Equivalently, a is algebraic over $\mathbb{F}$ iff $\ker \mathrm{ev}_a \neq \{0\}$.

Proposition 4.2.2. *Evaluation Is an Algebra Homomorphism*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra and let $a \in \mathcal{A}$.

(i) The map $\mathrm{ev}_a : \mathbb{F}[x] \to \mathcal{A}$ is an $\mathbb{F}$-algebra homomorphism.
(ii) If a is algebraic over $\mathbb{F}$, then $\ker \mathrm{ev}_a \lhd \mathbb{F}[x]$ is nonzero.

Proof.

(*i*) Let $p(x) = \sum_{i=0}^{m} c_i x^i$ and $q(x) = \sum_{j=0}^{n} d_j x^j$. Bilinearity and scalar centrality imply $(pq)(a) = \sum_{i=0}^{m}\sum_{j=0}^{n} c_i d_j a^{i+j} = p(a)q(a)$.
For $r \in \mathbb{F}$, the evaluation definition implies $(p+q)(a) = p(a) + q(a)$ and $(rp)(a) = rp(a)$.
Since $\mathrm{ev}_a(1) = 1_{\mathcal{A}}$, ev_a is an $\mathbb{F}$-algebra homomorphism by Definition 4.1.10(i).
(*ii*) If a is algebraic, then $\ker \mathrm{ev}_a \neq \{0\}$ by Definition 4.2.1(ii). $\ker \mathrm{ev}_a \lhd \mathbb{F}[x]$ by Proposition 4.1.11(i).

Structural Commentary: Multiplication verifies evaluation; its kernel is an ideal by kernel absorption.
Key Insight: Powers of one element commute, so evaluation preserves polynomial products in any algebra. □

Definition 4.2.3. *Minimal Polynomial of an Algebraic Element*
Let $\mathcal{A}$ be $\mathbb{F}$-algebra, $a \in \mathcal{A}$ algebraic. Ideal $\ker \mathrm{ev}_a$ nonzero by Proposition 4.2.2(ii). Has unique monic generator by Theorem 3.10.2(iv).

(i) The *minimal polynomial of a* is this generator $m_a \in \mathbb{F}[x]$.
Equivalently, m_a is the unique monic polynomial of least degree satisfying $m_a(a) = 0$.
(ii) The *polynomial annihilator of a* is $\mathrm{ann}_{\mathbb{F}[x]}(a) := \{f \in \mathbb{F}[x] : f(a) = 0\} = \ker \mathrm{ev}_a = \langle m_a \rangle$.

Theorem 4.2.4. *Finite-Dimensional Algebras Are Algebraic*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra with $\dim_{\mathbb{F}} \mathcal{A} < \infty$. Then $(\forall\, a \in \mathcal{A})$ a is algebraic over $\mathbb{F}$.

Proof. Let $n := \dim_{\mathbb{F}} \mathcal{A}$ and let $a \in \mathcal{A}$. The $n+1$ vectors $1_{\mathcal{A}}, a, \ldots, a^n$ are linearly dependent.
Thus $(\exists\,(c_0, \ldots, c_n) \in \mathbb{F}^{n+1} \setminus \{0\})$ $\sum_{j=0}^{n} c_j a^j = 0$; $p(x) := \sum_{j=0}^{n} c_j x^j$ is nonzero, satisfies $p(a) = 0$; a algebraic by Definition 4.2.1(ii).

Structural Commentary: Linear dependence among initial powers constructs an annihilating polynomial for arbitrary a.
Key Insight: Any list of more than $\dim_{\mathbb{F}} \mathcal{A}$ powers must contain a nontrivial linear relation. □

Example 4.2.5. *An Algebraic Infinite-Dimensional Algebra*
Let $\overline{\mathbb{Q}}_{\mathbb{C}} := \{z \in \mathbb{C} : (\exists\, p \in \mathbb{Q}[x] \setminus \{0\})\, p(z) = 0\}$. For $\alpha, \beta \in \overline{\mathbb{Q}}_{\mathbb{C}}$, choose nonzero $f, g \in \mathbb{Q}[x]$ with $f(\alpha) = g(\beta) = 0$.
Set $m := \deg f$ and $n := \deg g$. Reduction by $f(\alpha) = g(\beta) = 0$ proves $\mathbb{Q}[\alpha, \beta] = \mathrm{span}_{\mathbb{Q}}\{\alpha^i \beta^j : 0 \le i < m,\ 0 \le j < n\}$.
For $r \in \mathbb{Q}$, $\alpha + \beta, \alpha\beta, r\alpha \in \overline{\mathbb{Q}}_{\mathbb{C}}$ by Theorem 4.2.4. Since $1 \in \overline{\mathbb{Q}}_{\mathbb{C}}$, this set is a $\mathbb{Q}$-algebra.
For $n \in \mathbb{N}$, the polynomial $x^n - 2$ is Eisenstein at 2 and hence irreducible over $\mathbb{Q}$.
Any root $\alpha_n \in \mathbb{C}$ has $[\mathbb{Q}(\alpha_n) : \mathbb{Q}] = n$ and belongs to $\overline{\mathbb{Q}}_{\mathbb{C}}$. Thus $(\forall\, n \in \mathbb{N})$ $\dim_{\mathbb{Q}} \overline{\mathbb{Q}}_{\mathbb{C}} \ge n$.
Hence this algebra is infinite-dimensional although each of its elements is algebraic.

Proposition 4.2.6. *The Algebra Generated by One Algebraic Element*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra, let $a \in \mathcal{A}$ be algebraic, and set $d := \deg m_a$ and $\mathbb{F}[a] := \langle \{a\} \rangle_{\mathrm{subalg}}$.

(i) $\mathbb{F}[a] = \mathrm{im}\, \mathrm{ev}_a = \{p(a) : p \in \mathbb{F}[x]\}$.
(ii) $(\forall\, b \in \mathbb{F}[a])(\exists!\, r \in \mathbb{F}[x])\, [b = r(a) \wedge (r = 0 \vee \deg r < d)]$.
(iii) Set $\overline{\mathrm{ev}}_a : \mathbb{F}[x]/\langle m_a \rangle \to \mathbb{F}[a]$, $p + \langle m_a \rangle \mapsto p(a)$. Then $\overline{\mathrm{ev}}_a$ is an $\mathbb{F}$-algebra isomorphism.

Proof.

(*i*) The identity $\mathbb{F}[a] = \mathrm{span}_{\mathbb{F}}\{1_{\mathcal{A}}, a, a^2, \ldots\}$ holds by Proposition 4.1.9(i) with $X = \{a\}$.
This span equals $\{p(a) : p \in \mathbb{F}[x]\} = \mathrm{im}\, \mathrm{ev}_a$ by Definition 4.2.1(i).
(*ii*) For $p \in \mathbb{F}[x]$, choose $q, r \in \mathbb{F}[x]$ by Theorem 3.8.2(i) with $p = qm_a + r$ and $r = 0$ or $\deg r < d$.
Since $m_a(a) = 0$, $p(a) = r(a)$, so the reduced representation exists.
Suppose r, s satisfy the degree condition and $r(a) = s(a)$. Then $r - s \in \ker \mathrm{ev}_a = \langle m_a \rangle$.
If $r \neq s$, then $\deg(r - s) < d$, contradicting $\deg(hm_a) \ge d$ for $0 \neq h \in \mathbb{F}[x]$. Thus $r = s$.
(*iii*) $\ker \mathrm{ev}_a = \langle m_a \rangle$ by Definition 4.2.3(ii), and $\mathrm{im}\, \mathrm{ev}_a = \mathbb{F}[a]$ by (i). Asserted induced isomorphism holds by Proposition 4.1.11(iii).

Structural Commentary: Generated powers identify the image; division selects representatives; the kernel excludes duplicates.
Key Insight: Reduction modulo m_a converts polynomial division into unique normal forms for elements of $\mathbb{F}[a]$. □

Theorem 4.2.7. *Invertibility from the Constant Term*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra, $a \in \mathcal{A}$ be algebraic, m_a be its minimal polynomial. Then $a \in \mathcal{A}^{\times} \iff m_a(0) \neq 0$.

Proof.

($\Rightarrow$) Suppose $a \in \mathcal{A}^{\times}$ and $m_a(0) = 0$. Then $m_a = xq$ for a nonzero $q \in \mathbb{F}[x]$ with $\deg q < \deg m_a$.
Equality $0 = m_a(a) = aq(a)$ implies $q(a) = 0$ by multiplication by a^{-1}, contradicting minimality of $\deg m_a$, so $m_a(0) \neq 0$.
($\Leftarrow$) Suppose $m_a(0) \neq 0$, $m_a(x) = xq(x) + m_a(0)$. Then $0 = m_a(a) = aq(a) + m_a(0)1_{\mathcal{A}}$, so $b := -m_a(0)^{-1}q(a)$ satisfies $ab = 1_{\mathcal{A}}$.
Since $q(a) \in \mathbb{F}[a]$, $aq(a) = q(a)a$; hence $ba = ab = 1_{\mathcal{A}}$ and $a \in \mathcal{A}^{\times}$.

Structural Commentary: Factoring handles a zero constant term; separating a nonzero constant constructs the inverse.
Key Insight: A nonzero constant term constructs a^{-1}; a zero term lowers the annihilator degree. □

4.3 Zero Divisors and Spectra of Algebraic Elements

Definition 4.3.1. *Zero Divisors*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra and let $0 \neq a \in \mathcal{A}$.

(i) a is a *left zero divisor* iff $(\exists\, b \in \mathcal{A} \setminus \{0\})\, ab = 0$.
(ii) a is a *right zero divisor* iff $(\exists\, c \in \mathcal{A} \setminus \{0\})\, ca = 0$.

Theorem 4.3.2. *Invertibility and Zero Divisors*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra and let $0 \neq a \in \mathcal{A}$ be algebraic. The following conditions are equivalent.

(i) $a \in \mathcal{A}^{\times}$.
(ii) a is not a left zero divisor.
(iii) a is not a right zero divisor.

Proof.

(*i*) $\Rightarrow$ (*ii*) Suppose $a \in \mathcal{A}^{\times}$. If $ab = 0$, then $b = a^{-1}ab = 0$, so a is not a left zero divisor.

(*ii*) $\Rightarrow$ (*iii*) Suppose a is not a left zero divisor. If $a \notin \mathcal{A}^\times$, then $m_a(0) = 0$ by Theorem 4.2.7.
Write $m_a = xp$ with $0 \neq p \in \mathbb{F}[x]$, $\deg p < \deg m_a$. Then $p(a) \neq 0$ by minimality, while $0 = m_a(a) = ap(a) = p(a)a$, contradiction.
Hence $a \in \mathcal{A}^\times$. If $ca = 0$, then $c = caa^{-1} = 0$, so a is not a right zero divisor.
(*iii*) $\Rightarrow$ (*i*) Suppose a is not a right zero divisor. If $a \notin \mathcal{A}^\times$, then $m_a(0) = 0$ by Theorem 4.2.7.
Write $m_a = xp$ with $0 \neq p \in \mathbb{F}[x]$ and $\deg p < \deg m_a$.
Then $p(a) \neq 0$ by minimality, while $0 = m_a(a) = ap(a) = p(a)a$, a contradiction. Hence $a \in \mathcal{A}^\times$.

Structural Commentary: The implication cycle combines unit cancellation with minimal-polynomial factorization.
Key Insight: A zero constant term creates one nonzero polynomial witness annihilated by a on both sides. □

Corollary 4.3.3. *One-Sided Inverses Become Two-Sided*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra and let $a \in \mathcal{A}$ be algebraic. If $(\exists\, b \in \mathcal{A})\,[ba = 1_\mathcal{A} \vee ab = 1_\mathcal{A}]$, then $a \in \mathcal{A}^\times$.

Proof. If $1_\mathcal{A} = 0$, then $\mathcal{A} = \{0\}$ and $a = 1_\mathcal{A} \in \mathcal{A}^\times$. Assume $1_\mathcal{A} \neq 0$ and choose $b \in \mathcal{A}$ with $ba = 1_\mathcal{A}$ or $ab = 1_\mathcal{A}$.
If $ba = 1_\mathcal{A}$, then $a \neq 0$, and $ac = 0$ implies $c = bac = 0$. Thus a is not a left zero divisor, so $a \in \mathcal{A}^\times$ by Theorem 4.3.2.
If $ab = 1_\mathcal{A}$, then $a \neq 0$, and $ca = 0$ implies $c = cab = 0$. Thus a is not a right zero divisor, so $a \in \mathcal{A}^\times$ by Theorem 4.3.2.
Structural Commentary: The two cases convert a left or right inverse into the matching cancellation law.
Key Insight: Algebraicity upgrades either one-sided cancellation law to two-sided invertibility. □

Definition 4.3.4. *Spectrum*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra and let $a \in \mathcal{A}$ be algebraic. The *spectrum of a* is $\operatorname{spec}_\mathcal{A}(a) := \{r \in \mathbb{F} : m_a(r) = 0\}$.
An element of $\operatorname{spec}_\mathcal{A}(a)$ is an *algebraic eigenvalue of a*.

Theorem 4.3.5. *Spectrum Detected by Invertibility*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra, let $a \in \mathcal{A}$ be algebraic, and let $r \in \mathbb{F}$.
(i) $r \in \operatorname{spec}_\mathcal{A}(a) \iff a - r1_\mathcal{A} \notin \mathcal{A}^\times$.
(ii) $a \in \mathcal{A}^\times \iff 0 \notin \operatorname{spec}_\mathcal{A}(a)$.

Proof. Choose $q \in \mathbb{F}[x]$ and $c \in \mathbb{F}$ by Theorem 3.8.2(i) with $m_a = (x - r)q + c$. Then $c = m_a(r)$ by evaluation at r.
(*i*) ($\Rightarrow$) Suppose $r \in \operatorname{spec}_\mathcal{A}(a)$. Then $c = m_a(r) = 0$ by Definition 4.3.4; $m_a = (x - r)q$, where $q \neq 0$ and $\deg q < \deg m_a$.
The relation $0 = m_a(a) = (a - r1_\mathcal{A})q(a) = q(a)(a - r1_\mathcal{A})$ holds, and $q(a) \neq 0$ by minimality. Hence $a - r1_\mathcal{A} \notin \mathcal{A}^\times$.
(*i*) ($\Leftarrow$) Suppose $a - r1_\mathcal{A} \notin \mathcal{A}^\times$ and $r \notin \operatorname{spec}_\mathcal{A}(a)$. Then $c = m_a(r) \neq 0$ by Definition 4.3.4. Set $v := -c^{-1}q(a)$.
Since $m_a(a) = 0$ and $q(a)$ commutes with $a - r1_\mathcal{A}$, $v(a - r1_\mathcal{A}) = 1_\mathcal{A} = (a - r1_\mathcal{A})v$. This contradicts $a - r1_\mathcal{A} \notin \mathcal{A}^\times$, so $r \in \operatorname{spec}_\mathcal{A}(a)$.
(*ii*) ($\Rightarrow$) Suppose $a \in \mathcal{A}^\times$. Then $0 \notin \operatorname{spec}_\mathcal{A}(a)$ by (i) with $r = 0$.
(*ii*) ($\Leftarrow$) Suppose $0 \notin \operatorname{spec}_\mathcal{A}(a)$. Then $a \in \mathcal{A}^\times$ by (i) with $r = 0$.

Structural Commentary: Division isolates $m_a(r)$; zero supplies an annihilator, while nonzero constructs an inverse.
Key Insight: The scalar remainder is exactly the obstruction to invertibility of $a - r1_\mathcal{A}$. □

Theorem 4.3.6. *Polynomial Spectral Mapping for Algebraic Elements*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra and suppose $(\forall\, f \in \mathbb{F}[x])\,[\deg f \geq 1 \Rightarrow f$ splits over $\mathbb{F}]$. Let $a \in \mathcal{A}$ be algebraic and let $p \in \mathbb{F}[x]$.
(i) $p(a)$ is algebraic over $\mathbb{F}$.
(ii) $\operatorname{spec}_\mathcal{A}(p(a)) = p(\operatorname{spec}_\mathcal{A}(a)) := \{p(r) : r \in \operatorname{spec}_\mathcal{A}(a)\}$.

Proof.
(*i*) Set $d := \deg m_a$. Then $p(a) \in \mathbb{F}[a]$ and $\dim_\mathbb{F} \mathbb{F}[a] \leq d$ by Proposition 4.2.6(i)–(ii).
Hence $p(a)$ is algebraic by Theorem 4.2.4 for the $\mathbb{F}$-algebra $\mathbb{F}[a]$.
(*ii*)
(a) *Degenerate Cases*: If $1_\mathcal{A} = 0$, then $\mathcal{A} = \{0\}$ and $\ker \operatorname{ev}_a = \mathbb{F}[x] = \ker \operatorname{ev}_{p(a)}$. Thus $m_a = m_{p(a)} = 1$ by Definition 4.2.3(i).
Thus both spectra are empty, and the equality holds. Assume $1_\mathcal{A} \neq 0$.
If $p = c \in \mathbb{F}$, then m_a is nonconstant as $m_a(a) = 0$, $1_\mathcal{A} \neq 0$. It has a root in $\mathbb{F}$ by splitting hypothesis, so $\operatorname{spec}_\mathcal{A}(a) \neq \emptyset$.
If $\lambda \neq c$, then $(c - \lambda)^{-1}1_\mathcal{A}$ is the inverse of $(c - \lambda)1_\mathcal{A}$; if $\lambda = c$, then 0 is noninvertible because $1_\mathcal{A} \neq 0$.
Thus $\operatorname{spec}_\mathcal{A}(p(a)) = \{c\} = p(\operatorname{spec}_\mathcal{A}(a))$ by Theorem 4.3.5(i).
(b) *Forward Inclusion*: Suppose p is nonconstant, $\lambda \in \operatorname{spec}_\mathcal{A}(p(a))$. Then $p(a) - \lambda 1_\mathcal{A}$ noninvertible by Theorem 4.3.5(i).
Choose $N \in \mathbb{N}$, $c \in \mathbb{F}^\times$, and $r_1, \ldots, r_N \in \mathbb{F}$ by the splitting hypothesis with $p(x) - \lambda = c \prod_{j=1}^{N} (x - r_j)$.
If $(\forall\, j \in \{1, \ldots, N\})\, a - r_j 1_\mathcal{A} \in \mathcal{A}^\times$, then $p(a) - \lambda 1_\mathcal{A}$ is invertible. Hence $(\exists\, j \in \{1, \ldots, N\})\, a - r_j 1_\mathcal{A} \notin \mathcal{A}^\times$.
For such j, $r_j \in \operatorname{spec}_\mathcal{A}(a)$ by Theorem 4.3.5(i), and $p(r_j) = \lambda$. Therefore $\operatorname{spec}_\mathcal{A}(p(a)) \subseteq p(\operatorname{spec}_\mathcal{A}(a))$.
(c) *Reverse Inclusion*: Suppose p is nonconstant and let $r \in \operatorname{spec}_\mathcal{A}(a)$.
Choose $q \in \mathbb{F}[x]$ and $s \in \mathbb{F}$ by Theorem 3.8.2(i) with $p(x) - p(r) = (x - r)q(x) + s$.
$s = 0$ by evaluation at r, so $p(x) - p(r) = (x - r)q(x)$. The element $a - r1_\mathcal{A}$ is algebraic by (i) with the polynomial $x - r$.
If $p(a) - p(r)1_\mathcal{A} = (a - r1_\mathcal{A})q(a)$ were invertible with inverse w, then $q(a)w$ would be a right inverse of $a - r1_\mathcal{A}$.
Then $a - r1_\mathcal{A}$ would be invertible by Corollary 4.3.3. Yet $a - r1_\mathcal{A} \notin \mathcal{A}^\times$ by Theorem 4.3.5(i), a contradiction.
Thus $p(a) - p(r)1_\mathcal{A}$ is noninvertible; $p(r) \in \operatorname{spec}_\mathcal{A}(p(a))$ by Theorem 4.3.5(i). Hence $p(\operatorname{spec}_\mathcal{A}(a)) \subseteq \operatorname{spec}_\mathcal{A}(p(a))$.

Structural Commentary: Finite-dimensional reduction handles algebraicity; splitting and one-sided rigidity handle opposite inclusions.
Key Insight: Linear factors recover spectral preimages, while $x - r$ carries spectral membership forward. □

Proposition 4.3.7. *Spectra of ab and ba*
Let $\mathcal{A}$ be an $\mathbb{F}$-algebra with $\dim_\mathbb{F} \mathcal{A} < \infty$, $a, b \in \mathcal{A}$. Then $\operatorname{spec}_\mathcal{A}(ab) = \operatorname{spec}_\mathcal{A}(ba)$.

Proof. Every element of $\mathcal{A}$ is algebraic by Theorem 4.2.4. Let $r \in \mathbb{F}^\times$, $ba - r1_\mathcal{A} \in \mathcal{A}^\times$. Set $u := a(ba - r1_\mathcal{A})^{-1}b - 1_\mathcal{A}$.
Then $(ab - r1_\mathcal{A})u = a(ba - r1_\mathcal{A})(ba - r1_\mathcal{A})^{-1}b - ab + r1_\mathcal{A} = r1_\mathcal{A}$. Thus $r^{-1}u$ is a right inverse of $ab - r1_\mathcal{A}$.
The element $ab - r1_\mathcal{A}$ is invertible by Corollary 4.3.3. Hence $r \notin \operatorname{spec}_\mathcal{A}(ba) \Rightarrow r \notin \operatorname{spec}_\mathcal{A}(ab)$ by Theorem 4.3.5(i).
$\operatorname{spec}_\mathcal{A}(ab) \setminus \{0\} = \operatorname{spec}_\mathcal{A}(ba) \setminus \{0\}$ by symmetry. Suppose $ba \in \mathcal{A}^\times$ with inverse y. Then $b(ay) = 1_\mathcal{A}$ and $(yb)a = 1_\mathcal{A}$.
Thus $a, b \in \mathcal{A}^\times$ by Corollary 4.3.3, so $ab \in \mathcal{A}^\times$. The converse holds by symmetry, so $ab \in \mathcal{A}^\times \iff ba \in \mathcal{A}^\times$.
Thus $0 \in \operatorname{spec}_\mathcal{A}(ab) \iff 0 \in \operatorname{spec}_\mathcal{A}(ba)$ by Theorem 4.3.5(ii). Therefore $\operatorname{spec}_\mathcal{A}(ab) = \operatorname{spec}_\mathcal{A}(ba)$.
Structural Commentary: The resolvent calculation handles nonzero scalars; one-sided inverse rigidity handles the zero shift.
Key Insight: The resolvent correction $a(ba - r1_\mathcal{A})^{-1}b - 1_\mathcal{A}$ transfers invertibility across reversed products. □

4.4 Division Algebras

Definition 4.4.1. *Division Algebras*
An $\mathbb{F}$-algebra $\mathcal{D}$ is a *division algebra* iff $1_{\mathcal{D}} \neq 0$ and $\mathcal{D}^{\times} = \mathcal{D} \setminus \{0\}$.

Example 4.4.2. *Hamilton's Quaternions*
Hamilton's quaternion algebra is associative real algebra $\mathbb{H} := \mathbb{R}1 \oplus \mathbb{R}i \oplus \mathbb{R}j \oplus \mathbb{R}k$. Multiplication is $\mathbb{R}$-bilinear, and 1 is the identity.
The basis-unit products satisfy $i^2 = j^2 = k^2 = -1$, $ij = k = -ji$, $jk = i = -kj$, and $ki = j = -ik$.
The algebra is noncommutative by $ij = k = -ji$ and $k \neq 0$. For $q = r_0 + r_1 i + r_2 j + r_3 k$, set $\overline{q} := r_0 - r_1 i - r_2 j - r_3 k$.
Then $q\overline{q} = \overline{q}q = r_0^2 + r_1^2 + r_2^2 + r_3^2 := N(q)$. If $q \neq 0$, then $N(q) > 0$ and $q^{-1} = N(q)^{-1}\overline{q}$; hence $\mathbb{H}$ is a real division algebra.

Figure 107 records the oriented multiplication rules for the imaginary basis units.

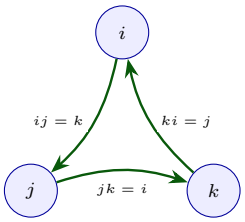

Figure 107: Quaternion basis products. The cycle $i \to j \to k \to i$ encodes $ij = k$, $jk = i$, and $ki = j$; reversed order negates each product. Each imaginary basis unit squares to -1, and 1 is the identity.

Theorem 4.4.3. *Division Algebras over Algebraically Closed Fields*
Let $\mathcal{D}$ be a division $\mathbb{F}$-algebra with $\dim_{\mathbb{F}} \mathcal{D} < \infty$. Suppose $(\forall\, f \in \mathbb{F}[x])\,[\deg f \geq 1 \Rightarrow f$ splits over $\mathbb{F}]$. Then $\mathcal{D} = \mathbb{F}1_{\mathcal{D}}$.

Proof. Fix $a \in \mathcal{D}$. The element a is algebraic by Theorem 4.2.4; let m_a be its minimal polynomial.
The polynomial m_a is nonconstant because $1_{\mathcal{D}} \neq 0$. Suppose $m_a = pq$ with $0 < \deg p, \deg q < \deg m_a$.
Then $p(a), q(a) \neq 0$ by minimality, whereas $q(a) = p(a)^{-1} m_a(a) = 0$, a contradiction.
Thus m_a is irreducible, and the splitting hypothesis forces $\deg m_a = 1$. Monicity fixes $m_a = x - r$ with $r \in \mathbb{F}$; hence $a = r1_{\mathcal{D}}$.
Thus $\mathcal{D} \subseteq \mathbb{F}1_{\mathcal{D}}$, while the reverse inclusion holds by the scalar action.
Structural Commentary: Algebraicity supplies a minimal polynomial; division makes it irreducible; splitting makes it linear.
Key Insight: A nontrivial factorization would create nonzero factors with zero product. □

Theorem 4.4.4. *Wedderburn's Theorem*
Every division algebra with finite underlying set is a field.

Proof.

(i) *Centralizer Data*: Suppose $\mathcal{D}$ is noncommutative and set $F := Z(\mathcal{D})$.
The set F is a finite field: every nonzero central element has a central inverse. Algebra $\mathcal{D}$ is F-algebra by Proposition 4.1.7(iii).
Set $z := |F| \geq 2$, $n := \dim_F \mathcal{D} > 1$, and $G := \mathcal{D}^{\times}$. Let B represent the noncentral conjugacy classes of G.
For $\beta \in B$, set $C_\beta := \{d \in \mathcal{D} : d\beta = \beta d\}$ and $k_\beta := \dim_F C_\beta$. Noncentrality implies $F \subsetneq C_\beta \subsetneq \mathcal{D}$.
The set C_β is a division subalgebra. Choose a right C_β-basis of $\mathcal{D}$ with r_β members.
Then $n = r_\beta k_\beta$ by expansion against F-basis of C_β. Thus $1 < k_\beta < n$, $k_\beta \mid n$. Identities $Z(G) = F^{\times}$, $C_G(\beta) = C_\beta^{\times}$ hold directly.
Finite vector-space counting therefore implies $|G| = z^n - 1$, $|Z(G)| = z - 1$, and $|C_G(\beta)| = z^{k_\beta} - 1$.

(ii) *Class Equation*: By Theorem 2.5.2, $z^n - 1 = z - 1 + \sum_{\beta \in B} \frac{z^n - 1}{z^{k_\beta} - 1}$.

(iii) *Cyclotomic Divisor*: Fix $\beta \in B$. Since $k_\beta \mid n$ and $k_\beta < n$, each divisor of k_β divides n but $n \nmid k_\beta$.
Thus $\Phi_n(z) \mid \frac{z^n - 1}{z^{k_\beta} - 1}$ by Propositions 3.11.4 and 3.11.5. The same propositions imply $\Phi_n(z) \mid z^n - 1$.

(iv) *Contradiction*: The class equation and (iii) imply $\Phi_n(z) \mid z - 1$. Yet $|\Phi_n(z)| > z - 1$ by Lemma 3.11.6, because $n > 1$ and $z \geq 2$.
This contradicts divisibility in $\mathbb{Z}$. Hence $\mathcal{D}$ is commutative and therefore is a finite field.

Structural Commentary: Centralizer dimensions convert the class equation into divisibility; the cyclotomic estimate excludes it.
Key Insight: The common cyclotomic divisor cannot divide the smaller integer $z - 1$. □

Theorem 4.4.5. *Frobenius Classification over $\mathbb{R}$*
If $\mathcal{D}$ is a finite-dimensional real division algebra, then $\mathcal{D} \cong \mathbb{R}$, $\mathcal{D} \cong \mathbb{C}$, or $\mathcal{D} \cong \mathbb{H}$.

Proof.

(i) *A Complex Unit*: The relation $\mathbb{R}1_{\mathcal{D}} \cong \mathbb{R}$ holds by Proposition 4.1.7(ii). If $\mathcal{D} = \mathbb{R}1_{\mathcal{D}}$, then $\mathcal{D} \cong \mathbb{R}$.
Otherwise choose $a \in \mathcal{D} \setminus \mathbb{R}1_{\mathcal{D}}$. The element a is algebraic by Theorem 4.2.4; let m_a be its minimal polynomial.
Suppose $m_a = pq$, $0 < \deg p, \deg q < \deg m_a$. Then $p(a), q(a) \neq 0$ by minimality, whereas $q(a) = p(a)^{-1} m_a(a) = 0$, contradiction.
Thus m_a is irreducible. Set $d := \deg m_a$, regard C_{m_a} as operator on $\mathbb{C}^d$. Characteristic polynomial is m_a by Theorem 3.1.13(ii).
Choose eigenvalue $\lambda \in \mathbb{C}$ by Theorem 5.3.2; $m_a(\lambda) = 0$ by Proposition 2.1.16(ii). If $\lambda \in \mathbb{R}$, then $x - \lambda \mid m_a$ by polynomial division.
Irreducibility and monicity would make $m_a = x - \lambda$ and $a = \lambda 1_{\mathcal{D}}$, contradiction. Thus $\lambda \notin \mathbb{R}$.
Set $h(x) := (x - \lambda)(x - \overline{\lambda}) \in \mathbb{R}[x]$. Then $h \mid m_a$ by polynomial division at the roots $\lambda, \overline{\lambda}$.
Hence $m_a = h$ by irreducibility and monicity. Set $r := \operatorname{Re}\lambda$ and $s := \operatorname{Im}\lambda$.
Then $s \neq 0$ and $m_a(x) = (x - r)^2 + s^2$. Set $i := s^{-1}(a - r1_{\mathcal{D}})$; then $i^2 = -1_{\mathcal{D}}$.

(ii) *Commuting and Anticommuting Parts*: Set $K := \mathbb{R}1_{\mathcal{D}} \oplus \mathbb{R}i$; then $K \cong \mathbb{C}$. Define the $\mathbb{R}$-linear map $\tau : \mathcal{D} \to \mathcal{D}$ by $\tau(x) := -ixi$.
The identity $\tau^2 = I_{\mathcal{D}}$ holds by $i^2 = -1_{\mathcal{D}}$. Set $\mathcal{D}_+ := \ker(\tau - I_{\mathcal{D}})$ and $\mathcal{D}_- := \ker(\tau + I_{\mathcal{D}})$. For $x \in \mathcal{D}$, $x = \frac{1}{2}(x + \tau(x)) + \frac{1}{2}(x - \tau(x))$.
The two summands lie in $\mathcal{D}_+$ and $\mathcal{D}_-$, respectively. Since $\mathcal{D}_+ \cap \mathcal{D}_- = \{0\}$, $\mathcal{D} = \mathcal{D}_+ \oplus \mathcal{D}_-$.
Equivalently, $\mathcal{D}_+ = \{x \in \mathcal{D} : xi = ix\}$ and $\mathcal{D}_- = \{x \in \mathcal{D} : xi = -ix\}$. The set $\mathcal{D}_+$ is a division subalgebra, and $K \subseteq Z(\mathcal{D}_+)$.
For $y \in \mathcal{D}_+$, the map L_y is complex-linear on the finite-dimensional complex space $\mathcal{D}_+$.
Choose $\mu \in K$ and $0 \neq x \in \mathcal{D}_+$ with $yx = \mu x$ by Theorem 5.3.2. Since $x^{-1} \in \mathcal{D}_+$, $y = \mu \in K$. Thus $\mathcal{D}_+ = K$.

(iii) *The Anticommuting Line*: If $\mathcal{D}_- = \{0\}$, then $\mathcal{D} = K \cong \mathbb{C}$. Otherwise choose $0 \neq j_0 \in \mathcal{D}_-$.
For $x \in \mathcal{D}_-$, $(xj_0^{-1})i = x(-ij_0^{-1}) = ixj_0^{-1}$; hence $xj_0^{-1} \in \mathcal{D}_+ = K$.
Conversely, $Kj_0 \subseteq \mathcal{D}_-$ by $j_0 i = -ij_0$, so $\mathcal{D}_- = Kj_0$. The relation $j_0^2 i = ij_0^2$ places j_0^2 in $\mathcal{D}_+ = K$.
Write $j_0^2 = u1_{\mathcal{D}} + vi$, $u, v \in \mathbb{R}$. Relations $j_0 i = -ij_0$ and $j_0 j_0^2 = j_0^2 j_0$ imply $0 = -2vij_0$, so $v = 0$; $j_0^2 = u1_{\mathcal{D}}$ with $u \neq 0$.
Suppose $u > 0$. Then $(j_0 - \sqrt{u}1_{\mathcal{D}})(j_0 + \sqrt{u}1_{\mathcal{D}}) = 0$. One factor vanishes by the absence of zero divisors, so j_0 is scalar.
This contradicts $\mathcal{D}_+ \cap \mathcal{D}_- = \{0\}$. Hence $u < 0$. Set $j := (-u)^{-1/2} j_0$; then $j^2 = -1_{\mathcal{D}}$ and $\mathcal{D}_- = Kj$.

(iv) *Quaternion Identification*: Now $\mathcal{D} = K \oplus Kj$ has real basis $(1_{\mathcal{D}}, i, j, ij)$. Set $k := ij$.
The relations $i^2 = j^2 = -1_{\mathcal{D}}$ and $ji = -ij$ imply $k^2 = -1_{\mathcal{D}}$.
They also imply $jk = i$ and $ki = j$; the reversed products are negated. Let $\varphi : \mathbb{H} \to \mathcal{D}$ send $(1, i, j, k)$ to $(1_{\mathcal{D}}, i, j, k)$ $\mathbb{R}$-linearly.
The map φ is bijective by the basis and multiplicative by the relations; hence $\mathcal{D} \cong \mathbb{H}$.

Structural Commentary: Quadratic minimal polynomial constructs K; conjugation splits $\mathcal{D}$ into commuting, anticommuting parts.
Key Insight: The anticommuting eigenspace is at most one-dimensional over K. □

5 Tensor Products

5.1 Tensor Products and Universal Properties

Tensor products linearize bilinear data.
Their construction combines free extension from Theorem 2.1.4 with quotient descent from Theorem 2.2.11.

Definition 5.1.1. *Bilinear Maps*
Let $\mathcal{U}, \mathcal{V}, \mathcal{W}$ be $\mathbb{F}$-vector spaces and $f : \mathcal{U} \times \mathcal{V} \to \mathcal{W}$.

(i) The map f is *bilinear* if $(\forall\, \mathbf{v} \in \mathcal{V})\, f(\,\cdot\,, \mathbf{v}) \in \mathcal{L}(\mathcal{U}, \mathcal{W})$ and $(\forall\, \mathbf{u} \in \mathcal{U})\, f(\mathbf{u}, \,\cdot\,) \in \mathcal{L}(\mathcal{V}, \mathcal{W})$.
(ii) $\mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{W}) := \{f : \mathcal{U} \times \mathcal{V} \to \mathcal{W} : f \text{ is bilinear}\}$.
(iii) If $\mathcal{W} = \mathbb{F}$, then $\mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathbb{F})$ is the set of *bilinear forms* from Definition 4.4.1.

Example 5.1.2. *Basic Bilinear Maps*

(i) For an $\mathbb{F}$-algebra A, define $\mu : A \times A \to A$ by $\mu(a, b) := ab$.
The map μ is bilinear by distributivity and compatibility of scalar and algebra multiplication.
(ii) Define $\mathrm{ev} : \mathcal{L}(\mathcal{V}, \mathcal{W}) \times \mathcal{V} \to \mathcal{W}$ by $\mathrm{ev}(T, \mathbf{v}) := T\mathbf{v}$. The map ev is bilinear by pointwise linearity in T and the linearity of T in $\mathbf{v}$.
(iii) For $\varphi \in \mathcal{V}'$, $\psi \in \mathcal{W}'$, define $B_{\varphi,\psi} : \mathcal{V} \times \mathcal{W} \to \mathbb{F}$ by $B_{\varphi,\psi}(\mathbf{v}, \mathbf{w}) := \varphi(\mathbf{v})\psi(\mathbf{w})$. Map $B_{\varphi,\psi}$ is bilinear by linearity of φ, ψ.

Definition 5.1.3. *Tensor Product by Universal Property*
Let $\mathcal{U}, \mathcal{V}, \mathcal{T}$ be $\mathbb{F}$-vector spaces and $t \in \mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{T})$.
Given any $\mathbb{F}$-vector space $\mathcal{W}$, define $t^*_{\mathcal{W}} : \mathcal{L}(\mathcal{T}, \mathcal{W}) \to \mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{W})$ by $t^*_{\mathcal{W}}(L) := L \circ t$.

(i) The pair $(\mathcal{T}, t)$ is a *tensor product* of $\mathcal{U}$ and $\mathcal{V}$ if every map $t^*_{\mathcal{W}}$ above is bijective.
(ii) For $f \in \mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{W})$, the map $\widetilde{f} := (t^*_{\mathcal{W}})^{-1}(f)$ is the *mediating map* for f; equivalently, $\widetilde{f} \circ t = f$.
(iii) For a chosen tensor product, write $\mathcal{T} = \mathcal{U} \otimes \mathcal{V}$ and $\mathbf{u} \otimes \mathbf{v} := t(\mathbf{u}, \mathbf{v})$. A tensor of the form $\mathbf{u} \otimes \mathbf{v}$ is *decomposable*.

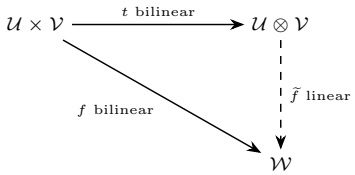

Figure 108: A tensor product is universal for bilinear maps out of $\mathcal{U} \times \mathcal{V}$.

Figure 108 depicts $f = \widetilde{f} \circ t$ from Definition 5.1.3. The definition owns existence and uniqueness of $\widetilde{f}$.

Theorem 5.1.4. *Quotient Construction of the Tensor Product*
Let $\mathcal{U}, \mathcal{V}$ be $\mathbb{F}$-vector spaces, $\mathcal{F} := \bigoplus^{\mathrm{ext}}_{(\mathbf{u},\mathbf{v}) \in \mathcal{U} \times \mathcal{V}} \mathbb{F}$. For $(\mathbf{u}, \mathbf{v}) \in \mathcal{U} \times \mathcal{V}$, let $[\mathbf{u}, \mathbf{v}] \in \mathcal{F}$ be coordinate family supported at $(\mathbf{u}, \mathbf{v})$ with value 1.
In the following relation families, $r, s \in \mathbb{F}$, $\mathbf{u}, \mathbf{u}_1, \mathbf{u}_2 \in \mathcal{U}$, and $\mathbf{v}, \mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}$.
Let $\mathcal{R}_{\mathcal{U}} \leq \mathcal{F}$ be spanned by all $r[\mathbf{u}_1, \mathbf{v}] + s[\mathbf{u}_2, \mathbf{v}] - [r\mathbf{u}_1 + s\mathbf{u}_2, \mathbf{v}]$. Let $\mathcal{R}_{\mathcal{V}} \leq \mathcal{F}$ be spanned by all $r[\mathbf{u}, \mathbf{v}_1] + s[\mathbf{u}, \mathbf{v}_2] - [\mathbf{u}, r\mathbf{v}_1 + s\mathbf{v}_2]$.
Set $\mathcal{R} := \mathcal{R}_{\mathcal{U}} + \mathcal{R}_{\mathcal{V}}$, $\mathcal{U} \otimes \mathcal{V} := \mathcal{F}/\mathcal{R}$, and $\mathbf{u} \otimes \mathbf{v} := [\mathbf{u}, \mathbf{v}] + \mathcal{R}$. Define $t : \mathcal{U} \times \mathcal{V} \to \mathcal{U} \otimes \mathcal{V}$ by $t(\mathbf{u}, \mathbf{v}) := \mathbf{u} \otimes \mathbf{v}$. Then:
(i) $\mathcal{U} \otimes \mathcal{V} = \mathrm{span}\{\mathbf{u} \otimes \mathbf{v} : \mathbf{u} \in \mathcal{U},\ \mathbf{v} \in \mathcal{V}\}$.
(ii) $(\mathcal{U} \otimes \mathcal{V}, t)$ is a tensor product of $\mathcal{U}$ and $\mathcal{V}$.

Proof. $\mathcal{F}$ is an $\mathbb{F}$-vector space by Proposition 2.1.19(ii). Let $\mathcal{B} := \{[\mathbf{u}, \mathbf{v}] : (\mathbf{u}, \mathbf{v}) \in \mathcal{U} \times \mathcal{V}\}$.
Every $\mathbf{x} = (x_{\mathbf{u},\mathbf{v}}) \in \mathcal{F}$ has a unique finite expansion $\mathbf{x} = \sum_{(\mathbf{u},\mathbf{v}) \in \mathrm{supp}(\mathbf{x})} x_{\mathbf{u},\mathbf{v}}[\mathbf{u}, \mathbf{v}]$ by Definition 2.1.18.
The set $\mathcal{B}$ is a basis by this expansion, and $\mathcal{F}$ is free on $\mathcal{B}$ by Definition 2.1.1.
Let $j : \mathcal{U} \times \mathcal{V} \to \mathcal{F}$ satisfy $j(\mathbf{u}, \mathbf{v}) := [\mathbf{u}, \mathbf{v}]$. Let $\pi : \mathcal{F} \to \mathcal{U} \otimes \mathcal{V}$ be the quotient map.

(i) Set $\mathcal{D} := \{\mathbf{u} \otimes \mathbf{v} : \mathbf{u} \in \mathcal{U},\ \mathbf{v} \in \mathcal{V}\}$. Then $\pi(\mathcal{B}) = \mathcal{D}$ by the definitions of π and decomposable tensors.
The equality $\mathcal{U} \otimes \mathcal{V} = \pi(\mathcal{F}) = \mathrm{span}(\pi(\mathcal{B})) = \mathrm{span}(\mathcal{D})$ holds by the linearity and surjectivity of π.
(ii) Fix $r, s \in \mathbb{F}$, $\mathbf{u}_1, \mathbf{u}_2 \in \mathcal{U}$, and $\mathbf{v} \in \mathcal{V}$. The identity $t(r\mathbf{u}_1 + s\mathbf{u}_2, \mathbf{v}) = rt(\mathbf{u}_1, \mathbf{v}) + st(\mathbf{u}_2, \mathbf{v})$ holds by the definition of $\mathcal{R}_{\mathcal{U}}$.
Fix $\mathbf{u} \in \mathcal{U}$ and $\mathbf{v}_1, \mathbf{v}_2 \in \mathcal{V}$. The identity $t(\mathbf{u}, r\mathbf{v}_1 + s\mathbf{v}_2) = rt(\mathbf{u}, \mathbf{v}_1) + st(\mathbf{u}, \mathbf{v}_2)$ holds by the definition of $\mathcal{R}_{\mathcal{V}}$.
The map $t = \pi \circ j$ is bilinear by these identities. Fix an $\mathbb{F}$-vector space $\mathcal{W}$ and $f \in \mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{W})$.
The assignment $[\mathbf{u}, \mathbf{v}] \mapsto f(\mathbf{u}, \mathbf{v})$ extends uniquely to $\alpha \in \mathcal{L}(\mathcal{F}, \mathcal{W})$ by Theorem 2.1.4.
Fix a displayed generator $x_{\mathcal{U}} := r[\mathbf{u}_1, \mathbf{v}] + s[\mathbf{u}_2, \mathbf{v}] - [r\mathbf{u}_1 + s\mathbf{u}_2, \mathbf{v}]$ of $\mathcal{R}_{\mathcal{U}}$.
Then $\alpha(x_{\mathcal{U}}) = rf(\mathbf{u}_1, \mathbf{v}) + sf(\mathbf{u}_2, \mathbf{v}) - f(r\mathbf{u}_1 + s\mathbf{u}_2, \mathbf{v}) = 0$ by bilinearity of f.
Fix a displayed generator $x_{\mathcal{V}} := r[\mathbf{u}, \mathbf{v}_1] + s[\mathbf{u}, \mathbf{v}_2] - [\mathbf{u}, r\mathbf{v}_1 + s\mathbf{v}_2]$ of $\mathcal{R}_{\mathcal{V}}$.

Then $\alpha(x_{\mathcal{V}}) = rf(\mathbf{u},\mathbf{v}_1) + sf(\mathbf{u},\mathbf{v}_2) - f(\mathbf{u}, r\mathbf{v}_1 + s\mathbf{v}_2) = 0$ by bilinearity of f.
$\mathcal{R} \leq \ker \alpha$ by the linearity of α and the two generator calculations.
Unique $\widetilde{f} \in \mathcal{L}(\mathcal{U} \otimes \mathcal{V}, \mathcal{W})$ satisfies $\widetilde{f} \circ \pi = \alpha$ by Theorem 2.2.11(i). Equality $\widetilde{f} \circ t = f$ holds by $(\widetilde{f} \circ t)(\mathbf{u},\mathbf{v}) = \alpha[\mathbf{u},\mathbf{v}] = f(\mathbf{u},\mathbf{v})$.
If $L \in \mathcal{L}(\mathcal{U} \otimes \mathcal{V}, \mathcal{W})$ satisfies $L \circ t = f$, then $L = \widetilde{f}$ by agreement on the spanning decomposable tensors from (i).

Structural Commentary: Free extension kills both relation subspaces and descends through their quotient.
Key Insight: The two relation subspaces encode linearity in the tensor factors. □

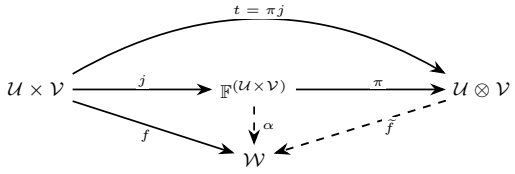

Figure 109: The free linear map α kills $\mathcal{R}$, so it descends uniquely to $\widetilde{f} : \mathcal{U} \otimes \mathcal{V} \to \mathcal{W}$.

Figure 109 records $j(\mathbf{u},\mathbf{v}) = [\mathbf{u},\mathbf{v}]$, $t = \pi \circ j$, and $\widetilde{f} \circ \pi = \alpha$ from Theorem 5.1.4.
The theorem owns the spanning and factorisation claims.

Corollary 5.1.5. *Tensor Products Are Unique up to Isomorphism*
If $(\mathcal{T}, t)$ and $(\mathcal{S}, s)$ are tensor products of $\mathcal{U}$ and $\mathcal{V}$, then a unique isomorphism $\Phi : \mathcal{T} \to \mathcal{S}$ satisfies $\Phi \circ t = s$.

Proof. Unique mediating maps $\Phi : \mathcal{T} \to \mathcal{S}$ and $\Psi : \mathcal{S} \to \mathcal{T}$ exist by Definition 5.1.3(i). They satisfy $\Phi \circ t = s$ and $\Psi \circ s = t$.
The identity $\Psi\Phi = I_{\mathcal{T}}$ holds by mediator uniqueness because $(\Psi\Phi) \circ t = \Psi \circ s = t = I_{\mathcal{T}} \circ t$.
Likewise, $\Phi\Psi = I_{\mathcal{S}}$ by mediator uniqueness because $(\Phi\Psi) \circ s = \Phi \circ t = s = I_{\mathcal{S}} \circ s$.
The map Φ is an isomorphism with inverse Ψ by these two identities.
If $\Theta : \mathcal{T} \to \mathcal{S}$ is linear and $\Theta \circ t = s$, then $\Theta = \Phi$ by uniqueness of the mediating map for s.
Structural Commentary: The two universal factorisations compose to the unique mediating identity maps.
Key Insight: Mediator uniqueness forces the comparison maps to be mutual inverses. □

Theorem 5.1.6. *Bilinearity Equals Linearity on a Tensor Product*
Let $\mathcal{U}, \mathcal{V}, \mathcal{W}$ be $\mathbb{F}$-vector spaces. Fix a tensor product $(\mathcal{U} \otimes \mathcal{V}, t)$ of $\mathcal{U}$ and $\mathcal{V}$.

(i) The set $\mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{W})$ is an $\mathbb{F}$-vector space under pointwise addition and scalar multiplication.
(ii) The assignment $f \mapsto \widetilde{f}$ defines an isomorphism $\Phi : \mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{W}) \to \mathcal{L}(\mathcal{U} \otimes \mathcal{V}, \mathcal{W})$.
For $f \in \mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{W})$, the map $\Phi(f) = \widetilde{f}$ is characterized by $\widetilde{f} \circ t = f$.

Proof.

(i) The zero map is bilinear by Definition 5.1.1(i). Fix $a, b \in \mathbb{F}$ and $f, g \in \mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{W})$.
For $\mathbf{u} \in \mathcal{U}$ and $\mathbf{v} \in \mathcal{V}$, $(af + bg)(\,\cdot\,, \mathbf{v}) \in \mathcal{L}(\mathcal{U}, \mathcal{W})$ and $(af + bg)(\mathbf{u}, \,\cdot\,) \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ by linearity of the corresponding partial maps.
$af + bg \in \mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{W})$ by Definition 5.1.1(i). The vector-space axioms hold by their pointwise counterparts in $\mathcal{W}$.

(ii) The assignment $\Phi(f) = \widetilde{f}$ is well-defined by Definition 5.1.3(i). Define $\Psi : \mathcal{L}(\mathcal{U} \otimes \mathcal{V}, \mathcal{W}) \to \mathrm{Bil}_{\mathbb{F}}(\mathcal{U}, \mathcal{V}; \mathcal{W})$ by $\Psi(L) := L \circ t$.
The map Ψ is well-defined by linearity of L and bilinearity of t.
The identity $\Psi(\Phi(f)) = f$ holds by $\widetilde{f} \circ t = f$, and $\Phi(\Psi(L)) = L$ by mediator uniqueness for $L \circ t$.
Hence $\Psi = \Phi^{-1}$ by these identities. Fix $a, b \in \mathbb{F}$ and bilinear f, g.
The equality $(a\Phi(f) + b\Phi(g)) \circ t = af + bg = \Phi(af + bg) \circ t$ holds by the definition of Φ.
Thus $\Phi(af + bg) = a\Phi(f) + b\Phi(g)$ by mediator uniqueness. Map Φ is linear isomorphism by this linearity and inverse above.

Structural Commentary: Mediator uniqueness constructs the inverse and transfers pointwise linear combinations through t.
Key Insight: Precomposition with t inverts bilinear linearization. □

Computation Method 5.1.7. *Constructing Maps from Tensor Products*
Fix $\mathbb{F}$-vector spaces $\mathcal{U}, \mathcal{V}, \mathcal{W}$ and a tensor product $(\mathcal{U} \otimes \mathcal{V}, t)$. To construct $L \in \mathcal{L}(\mathcal{U} \otimes \mathcal{V}, \mathcal{W})$, proceed as follows:

(i) specify a rule $f : \mathcal{U} \times \mathcal{V} \to \mathcal{W}$;
(ii) verify $(\forall\, \mathbf{v} \in \mathcal{V})\, f(\,\cdot\,, \mathbf{v}) \in \mathcal{L}(\mathcal{U}, \mathcal{W})$ and $(\forall\, \mathbf{u} \in \mathcal{U})\, f(\mathbf{u}, \,\cdot\,) \in \mathcal{L}(\mathcal{V}, \mathcal{W})$;
(iii) set $L := \Phi(f)$; then $L \circ t = f$ by Theorem 5.1.6(ii).

The decomposable tensors span $\mathcal{U} \otimes \mathcal{V}$ by Theorem 5.1.4(i), but are generally linearly dependent.
Assignments on decomposable tensors must therefore respect their linear relations.

5.2 Tensor Product Bases and Maps

Definition 5.2.1. *Finite-Coordinate Tensor Product Model*
Let $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_m)$ and $\gamma = (\mathbf{w}_1, \ldots, \mathbf{w}_n)$ be ordered bases of $\mathcal{V}$ and $\mathcal{W}$.
The *coordinate tensor model* is $\mathcal{V} \otimes_{\beta,\gamma} \mathcal{W} := \mathrm{Mat}(m, n, \mathbb{F})$. For $(\mathbf{v},\mathbf{w}) \in \mathcal{V} \times \mathcal{W}$, define $\mathbf{v} \otimes_{\beta,\gamma} \mathbf{w} := [\mathbf{v}]_\beta [\mathbf{w}]_\gamma^{\mathsf{T}}$.
The identity $\mathbf{v}_i \otimes_{\beta,\gamma} \mathbf{w}_j = E_{i,j}$ holds by the coordinate columns of the basis vectors.

Proposition 5.2.2. *Tensor Model Basis and Bilinear Evaluation*
In the coordinate tensor model associated to bases $\beta = (\mathbf{v}_1, \ldots, \mathbf{v}_m)$ and $\gamma = (\mathbf{w}_1, \ldots, \mathbf{w}_n)$:

(i) The matrices $E_{i,j} = \mathbf{v}_i \otimes_{\beta,\gamma} \mathbf{w}_j$ form a basis.
(ii) The map $(\mathbf{v},\mathbf{w}) \mapsto \mathbf{v} \otimes_{\beta,\gamma} \mathbf{w}$ is bilinear.
(iii) Let $\mathcal{X}$ be $\mathbb{F}$-vector space and let $f \in \mathrm{Bil}_{\mathbb{F}}(\mathcal{V}, \mathcal{W}; \mathcal{X})$.
A unique $\Theta_f \in \mathcal{L}(\mathrm{Mat}(m, n, \mathbb{F}), \mathcal{X})$ satisfies $(\forall\, (\mathbf{v},\mathbf{w}) \in \mathcal{V} \times \mathcal{W})\, \Theta_f(\mathbf{v} \otimes_{\beta,\gamma} \mathbf{w}) = f(\mathbf{v},\mathbf{w})$.

Proof.

(i) The matrices $E_{i,j}$ form the entry-matrix basis of $\mathrm{Mat}(m, n, \mathbb{F})$ by Proposition 3.1.5(ii).

(ii) Fix $a, b \in \mathbb{F}$, $\mathbf{v}, \mathbf{v}' \in \mathcal{V}$, and $\mathbf{w}, \mathbf{w}' \in \mathcal{W}$. The identity $(a\mathbf{v} + b\mathbf{v}') \otimes_{\beta,\gamma} \mathbf{w} = a(\mathbf{v} \otimes_{\beta,\gamma} \mathbf{w}) + b(\mathbf{v}' \otimes_{\beta,\gamma} \mathbf{w})$ holds by $\mathbb{F}$-linearity of $[\cdot]_\beta$. Likewise, $\mathbf{v} \otimes_{\beta,\gamma} (a\mathbf{w} + b\mathbf{w}') = a(\mathbf{v} \otimes_{\beta,\gamma} \mathbf{w}) + b(\mathbf{v} \otimes_{\beta,\gamma} \mathbf{w}')$ by $\mathbb{F}$-linearity of $[\cdot]_\gamma$.
(iii) The basis-value assignment $E_{i,j} \mapsto f(\mathbf{v}_i, \mathbf{w}_j)$ extends uniquely to $\Theta_f \in \mathcal{L}(\mathrm{Mat}(m, n, \mathbb{F}), \mathcal{X})$ by Proposition 1.5.8.
Write $\mathbf{v} = \sum_{i=1}^{m} x_i \mathbf{v}_i$ and $\mathbf{w} = \sum_{j=1}^{n} y_j \mathbf{w}_j$. The identity $\Theta_f(\mathbf{v} \otimes_{\beta,\gamma} \mathbf{w}) = \sum_{i=1}^{m} \sum_{j=1}^{n} x_i y_j f(\mathbf{v}_i, \mathbf{w}_j)$ holds by linearity of Θ_f.
Last sum equals $f(\mathbf{v}, \mathbf{w})$ by bilinearity of f. Uniqueness holds by agreement on the basis matrices $E_{i,j}$ and Proposition 1.5.8.

Structural Commentary: Entry matrices form the basis; coordinate expansion proves factorisation.
Key Insight: Each basis pair occupies one independent matrix coordinate. □

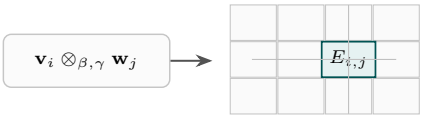

Figure 110: A basis pair occupies the (i, j) matrix slot.

Figure 110 illustrates the basis correspondence in Proposition 5.2.2(i). The proposition owns the basis and bilinearity claims.

Theorem 5.2.3. *Tensor Bases, Dimension, and Coordinate Rank*
Let $\mathcal{U}$ and $\mathcal{V}$ be finite-dimensional with bases $\beta = (\mathbf{u}_1, \ldots, \mathbf{u}_m)$ and $\gamma = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$.
(i) The tensors $\mathbf{u}_i \otimes \mathbf{v}_j$ form a basis of $\mathcal{U} \otimes \mathcal{V}$.
(ii) $\dim(\mathcal{U} \otimes \mathcal{V}) = \dim(\mathcal{U}) \dim(\mathcal{V})$.
(iii) Every $\mathbf{z} \in \mathcal{U} \otimes \mathcal{V}$ admits unique coefficients $r_{ij} \in \mathbb{F}$. They satisfy $\mathbf{z} = \sum_{i=1}^{m} \sum_{j=1}^{n} r_{ij}(\mathbf{u}_i \otimes \mathbf{v}_j)$.
(iv) Define $R_{\beta,\gamma}(\mathbf{z}) := [r_{ij}]$ from (iii). The value $\operatorname{rank} R_{\beta,\gamma}(\mathbf{z})$ is independent of the bases β, γ.

Proof.
(i) The coordinate tensor model is a tensor product by Proposition 5.2.2(i)–(iii) and Definition 5.1.3(i).
A unique comparison isomorphism $\Xi : \mathcal{U} \otimes \mathcal{V} \to \mathrm{Mat}(m, n, \mathbb{F})$ exists by Corollary 5.1.5.
It satisfies $\Xi(\mathbf{u}_i \otimes \mathbf{v}_j) = E_{i,j}$ by the same corollary. The tensors $\mathbf{u}_i \otimes \mathbf{v}_j$ form a basis by bijectivity of Ξ and Proposition 5.2.2(i).
(ii) $\dim(\mathcal{U} \otimes \mathcal{V}) = mn = \dim(\mathcal{U}) \dim(\mathcal{V})$ by the mn-element basis in (i).
(iii) The coefficients r_{ij} exist uniquely by the basis in (i).
(iv) Let β', γ' be other ordered bases and set $P := [I_{\mathcal{U}}]_{\beta' \leftarrow \beta}$ and $Q := [I_{\mathcal{V}}]_{\gamma' \leftarrow \gamma}$.
The identity $R_{\beta',\gamma'}(\mathbf{z}) = P R_{\beta,\gamma}(\mathbf{z}) Q^{\mathsf{T}}$ holds by factorwise coordinate substitution.
Matrices P, Q^{T} invertible by Theorem 3.5.2(i), Corollary 3.6.4. Equality $\operatorname{rank} R_{\beta',\gamma'}(\mathbf{z}) = \operatorname{rank} R_{\beta,\gamma}(\mathbf{z})$ holds by Theorem 3.6.6(ii).

Structural Commentary: Coordinates transfer the basis; invertible basis changes preserve rank.
Key Insight: Basis changes multiply coordinate matrices by invertible factors. □

Definition 5.2.4. *Tensor Coordinate Matrix and Rank*
Let $\mathcal{U}, \mathcal{V}$ be finite-dimensional, with bases $\beta = (\mathbf{u}_1, \ldots, \mathbf{u}_m)$ and $\gamma = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$.
(i) For $\mathbf{z} \in \mathcal{U} \otimes \mathcal{V}$, let r_{ij} be the unique coefficients from Theorem 5.2.3(iii). The *coordinate matrix* is $R_{\beta,\gamma}(\mathbf{z}) := [r_{ij}]$.
(ii) The *rank of the tensor* is $\operatorname{rank}(\mathbf{z}) := \operatorname{rank} R_{\beta,\gamma}(\mathbf{z})$. It is independent of β, γ by Theorem 5.2.3(iv).

Theorem 5.2.5. *Zero Tests and Decomposable Rank*
Let $\mathcal{U}, \mathcal{V}$ be $\mathbb{F}$-vector spaces.
(i) $(\forall\, \mathbf{u} \in \mathcal{U})(\forall\, \mathbf{v} \in \mathcal{V})\ \mathbf{0} \otimes \mathbf{v} = \mathbf{u} \otimes \mathbf{0} = \mathbf{0}$.
(ii) Assume Zorn's lemma, let $r \in \mathbb{Z}_{>0}$, and let $(\mathbf{u}_i)_{i=1}^{r} \in \mathcal{U}^r$ be linearly independent.
Let $(\mathbf{v}_i)_{i=1}^{r} \in \mathcal{V}^r$. If $\sum_{i=1}^{r} \mathbf{u}_i \otimes \mathbf{v}_i = \mathbf{0}$, then $\mathbf{v}_1 = \cdots = \mathbf{v}_r = \mathbf{0}$.
(iii) If $\dim \mathcal{U}, \dim \mathcal{V} < \infty$ and $\mathbf{z} \in (\mathcal{U} \otimes \mathcal{V}) \setminus \{\mathbf{0}\}$, then $\mathbf{z}$ is decomposable $\iff \operatorname{rank}(\mathbf{z}) = 1$.
(iv) Assume $\dim \mathcal{U}, \dim \mathcal{V} < \infty$ and let $\mathbf{z} \in \mathcal{U} \otimes \mathcal{V}$. For $r \in \mathbb{Z}_{\geq 0}$, define $\mathcal{D}_r := \{\sum_{i=1}^{r} \mathbf{x}_i \otimes \mathbf{y}_i : (\mathbf{x}_i, \mathbf{y}_i)_{i=1}^{r} \in (\mathcal{U} \times \mathcal{V})^r\}$.
Then $\operatorname{rank}(\mathbf{z}) = \min\{r \in \mathbb{Z}_{\geq 0} : \mathbf{z} \in \mathcal{D}_r\}$.

Proof.
(i) The tensor map is linear in each slot by Definition 5.1.3(i). The equality $\mathbf{0} \otimes \mathbf{v} = \mathbf{u} \otimes \mathbf{0} = \mathbf{0}$ holds by Proposition 1.5.3.
(ii) Fix $k \in \{1, \ldots, r\}$ and set $\mathcal{S}_k := \operatorname{span}\{\mathbf{u}_i : i \neq k\}$. The inclusion $\mathbf{u}_k \notin \mathcal{S}_k$ holds by linear independence.
A functional $\varphi_k \in \mathcal{U}'$ satisfies $\varphi_k|_{\mathcal{S}_k} = 0$ and $\varphi_k(\mathbf{u}_k) = 1$ by Proposition 4.1.7(iii).
The bilinear map $(\mathbf{u}, \mathbf{v}) \mapsto \varphi_k(\mathbf{u})\mathbf{v}$ induces $T_k \in \mathcal{L}(\mathcal{U} \otimes \mathcal{V}, \mathcal{V})$ by Theorem 5.1.6(ii).
Then $\mathbf{0} = T_k(\sum_{i=1}^{r} \mathbf{u}_i \otimes \mathbf{v}_i) = \sum_{i=1}^{r} \delta_{ki} \mathbf{v}_i = \mathbf{v}_k$. The equality $\mathbf{v}_1 = \cdots = \mathbf{v}_r = \mathbf{0}$ holds by the arbitrary choice of k.
(iii) ($\Rightarrow$) Fix ordered bases β, γ and write $\mathbf{z} = \mathbf{x} \otimes \mathbf{y} \neq \mathbf{0}$. The vectors $\mathbf{x}, \mathbf{y}$ are nonzero by (i).
The identity $R_{\beta,\gamma}(\mathbf{z}) = [\mathbf{x}]_\beta [\mathbf{y}]_\gamma^{\mathsf{T}}$ holds by Definition 5.2.4(i) and bilinearity.
The equality $\operatorname{rank}(\mathbf{z}) = 1$ holds by Definition 5.2.4(ii) and $\operatorname{col}(R_{\beta,\gamma}(\mathbf{z})) = \operatorname{span}([\mathbf{x}]_\beta) \neq \{\mathbf{0}\}$.
(iii) ($\Leftarrow$) Fix ordered bases β, γ and assume $\operatorname{rank} R_{\beta,\gamma}(\mathbf{z}) = 1$. Choose a nonzero column $\mathbf{a}$ spanning $\operatorname{col}(R_{\beta,\gamma}(\mathbf{z}))$.
A row $\mathbf{b}^{\mathsf{T}}$ satisfies $R_{\beta,\gamma}(\mathbf{z}) = \mathbf{a}\mathbf{b}^{\mathsf{T}}$ by Theorem 4.1.2(i). Let $[\mathbf{x}]_\beta = \mathbf{a}$ and $[\mathbf{y}]_\gamma = \mathbf{b}$. Then $\mathbf{z} = \mathbf{x} \otimes \mathbf{y}$ by Theorem 5.2.3(iii).
(iv) Fix ordered bases β, γ, set $R := R_{\beta,\gamma}(\mathbf{z})$, $r := \operatorname{rank}(R)$. If $r = 0$, then $\operatorname{col}(R) = \{\mathbf{0}\}$ by Definition 3.1.12(iii), Proposition 1.4.3(ii).
Then $R = 0$ by $\operatorname{col}(R) = \{\mathbf{0}\}$. Equalities $\mathbf{z} = \mathbf{0}$, $\mathbf{z} \in \mathcal{D}_0$ hold by Theorem 5.2.3(iii), empty-sum convention respectively.
Suppose $r \geq 1$, and let the columns of $X \in \mathrm{Mat}(\dim \mathcal{U}, r, \mathbb{F})$ form a basis of $\operatorname{col}(R)$. A matrix Y satisfies $R = XY$ by Theorem 4.1.2(i).
If $\mathbf{a}_i$ is column i of X and $\mathbf{b}_i^{\mathsf{T}}$ is row i of Y, then $R = \sum_{i=1}^{r} \mathbf{a}_i \mathbf{b}_i^{\mathsf{T}}$ by matrix multiplication.

Choose $[\mathbf{x}_i]_\beta = \mathbf{a}_i$ and $[\mathbf{y}_i]_\gamma = \mathbf{b}_i$. Then $\mathbf{z} = \sum_{i=1}^{r} \mathbf{x}_i \otimes \mathbf{y}_i$ by Theorem 5.2.3(iii).

Membership $\mathbf{z} \in \mathcal{D}_r$ holds by definition. If $\mathbf{z} \in \mathcal{D}_s$, choose $\mathbf{z} = \sum_{i=1}^{s} \mathbf{x}_i \otimes \mathbf{y}_i$. Every column of R lies in $\operatorname{span}\{[\mathbf{x}_1]_\beta, \dots, [\mathbf{x}_s]_\beta\}$.

The inequality $r \le s$ holds by Definition 3.1.12(iii), Proposition 1.4.3(i), and Theorem 1.3.11.
The minimum formula holds by $\mathbf{z} \in \mathcal{D}_r$ and $(\forall\, s \in \mathbb{Z}_{\ge 0})\,[\mathbf{z} \in \mathcal{D}_s \Rightarrow r \le s]$.

Structural Commentary: Linearity proves zeros; functionals isolate terms; matrix factors fix rank.
Key Insight: Tensor rank is the minimum number of decomposable summands. □

Theorem 5.2.6. *Tensor Product of Linear Maps*
Let $A \in \mathcal{L}(\mathcal{U},\mathcal{U}')$ and $B \in \mathcal{L}(\mathcal{V},\mathcal{V}')$.

(i) A unique $A \otimes B \in \mathcal{L}(\mathcal{U} \otimes \mathcal{V}, \mathcal{U}' \otimes \mathcal{V}')$ exists. It satisfies $(\forall\, \mathbf{u} \in \mathcal{U})(\forall\, \mathbf{v} \in \mathcal{V})\,(A \otimes B)(\mathbf{u} \otimes \mathbf{v}) = A\mathbf{u} \otimes B\mathbf{v}$.
(ii) Define $\tau : \mathcal{L}(\mathcal{U},\mathcal{U}') \times \mathcal{L}(\mathcal{V},\mathcal{V}') \to \mathcal{L}(\mathcal{U} \otimes \mathcal{V}, \mathcal{U}' \otimes \mathcal{V}')$ by $\tau(A,B) := A \otimes B$. The map τ is bilinear.
(iii) Let $A_i \in \mathcal{L}(\mathcal{U}_{i-1},\mathcal{U}_i)$ and $B_i \in \mathcal{L}(\mathcal{V}_{i-1},\mathcal{V}_i)$ for $i \in \{1,2\}$. Then $(A_2A_1) \otimes (B_2B_1) = (A_2 \otimes B_2)(A_1 \otimes B_1)$.
(iv) $I_\mathcal{U} \otimes I_\mathcal{V} = I_{\mathcal{U}\otimes\mathcal{V}}$.
(v) Suppose $\mathcal{U},\mathcal{V},\mathcal{U}',\mathcal{V}'$ are finite-dimensional with ordered bases $\beta,\gamma,\beta',\gamma'$, respectively.
For the lexicographically ordered tensor-product bases, $[A \otimes B]_{\beta'\otimes\gamma' \leftarrow \beta\otimes\gamma} = [A]_{\beta' \leftarrow \beta} \otimes [B]_{\gamma' \leftarrow \gamma}$.
The right-hand $\otimes$ denotes the matrix Kronecker product.

Proof.

(i) The map $(\mathbf{u},\mathbf{v}) \mapsto A\mathbf{u} \otimes B\mathbf{v}$ is bilinear by linearity of A, B and bilinearity of the tensor map.
The unique linear map $A \otimes B$ exists by Theorem 5.1.6(ii).

(ii) Fix $a,b \in \mathbb{F}$, $A, C \in \mathcal{L}(\mathcal{U},\mathcal{U}')$, and $B, D \in \mathcal{L}(\mathcal{V},\mathcal{V}')$.
On decomposable tensors, $\tau(aA + bC, B) = a\tau(A,B) + b\tau(C,B)$ by the linearity of A, C and the tensor map.
Likewise, $\tau(A, aB + bD) = a\tau(A,B) + b\tau(A,D)$ on decomposable tensors.
The identities extend to $\mathcal{U} \otimes \mathcal{V}$ by Theorem 5.1.4(i), and τ is bilinear by these identities.

(iii) For $(\mathbf{u},\mathbf{v}) \in \mathcal{U}_0 \times \mathcal{V}_0$, both sides send $\mathbf{u} \otimes \mathbf{v}$ to $A_2A_1\mathbf{u} \otimes B_2B_1\mathbf{v}$.
The composition identity holds by decomposable spanning in Theorem 5.1.4(i).

(iv) Both $I_\mathcal{U} \otimes I_\mathcal{V}$ and $I_{\mathcal{U}\otimes\mathcal{V}}$ fix every decomposable tensor. Their equality holds by decomposable spanning in Theorem 5.1.4(i).

(v) Fix expansions $A\mathbf{u}_j = \sum_i a_{ij}\mathbf{u}'_i$ and $B\mathbf{v}_\ell = \sum_k b_{k\ell}\mathbf{v}'_k$. Then $(A \otimes B)(\mathbf{u}_j \otimes \mathbf{v}_\ell) = \sum_{i,k} a_{ij}b_{k\ell}(\mathbf{u}'_i \otimes \mathbf{v}'_k)$ by bilinearity.
The claimed matrix identity holds by this Kronecker block-entry rule and Definition 3.2.3.

Structural Commentary: Linearization builds $A \otimes B$; spanning proves composition; bases fix the matrix.
Key Insight: Factorwise action becomes Kronecker multiplication in coordinates. □

Theorem 5.2.7. *Tensor Product of Spaces of Linear Maps*
Assume Zorn's lemma, and let $\mathcal{U},\mathcal{V},\mathcal{X},\mathcal{Y}$ be $\mathbb{F}$-vector spaces.

(i) A unique linear map $\Theta : \mathcal{L}(\mathcal{U},\mathcal{X}) \otimes \mathcal{L}(\mathcal{V},\mathcal{Y}) \to \mathcal{L}(\mathcal{U} \otimes \mathcal{V}, \mathcal{X} \otimes \mathcal{Y})$ exists. It is characterized by $\Theta(A \otimes B)(\mathbf{u} \otimes \mathbf{v}) = A\mathbf{u} \otimes B\mathbf{v}$.
(ii) The map Θ is injective.
(iii) If $\mathcal{U},\mathcal{V},\mathcal{X},\mathcal{Y}$ are finite-dimensional, then Θ is an isomorphism.
(iv) Define $\Delta(\varphi \otimes \psi)(\mathbf{u} \otimes \mathbf{v}) := \varphi(\mathbf{u})\psi(\mathbf{v})$. This rule determines an injective map $\Delta : \mathcal{U}' \otimes \mathcal{V}' \to (\mathcal{U} \otimes \mathcal{V})'$.
(v) If $\mathcal{U},\mathcal{V}$ are finite-dimensional, then Δ is an isomorphism.

Proof.

(i) The assignment $(A,B) \mapsto A \otimes B$ is bilinear by Theorem 5.2.6(ii).
The unique linear map Θ exists by Theorem 5.1.6(ii). Its characterization holds by Theorem 5.2.6(i).

(ii) Fix $0 \ne Z = \sum_{i=1}^{r} A_i \otimes B_i$ with r minimal. The relations $(\forall\, i \in \{1,\dots,r\})\,[A_i \ne 0 \wedge B_i \ne 0]$ hold by minimality.

If $(A_i)_{i=1}^r$ is dependent, reindex with $A_r = \sum_{i=1}^{r-1} c_iA_i$. Then $Z = \sum_{i=1}^{r-1} A_i \otimes (B_i + c_iB_r)$, contrary to minimality.

The family $(A_i)_{i=1}^r$ is independent by contradiction. If $(B_i)_{i=1}^r$ is dependent, reindex with $B_r = \sum_{i=1}^{r-1} d_iB_i$.

Then $Z = \sum_{i=1}^{r-1} (A_i + d_iA_r) \otimes B_i$, contrary to minimality. The family $(B_i)_{i=1}^r$ is independent by contradiction.

Choose $\mathbf{u} \in \mathcal{U}$ with $A_1\mathbf{u} \ne 0$. After reindexing, let $A_1\mathbf{u}, \dots, A_m\mathbf{u}$ be a basis of $\operatorname{span}\{A_i\mathbf{u} : 1 \le i \le r\}$.

For $m < j \le r$, write $A_j\mathbf{u} = \sum_{i=1}^{m} c_{ij}A_i\mathbf{u}$. Set $C_i := B_i + \sum_{j=m+1}^{r} c_{ij}B_j$ for $1 \le i \le m$. Then $C_i \ne 0$ by independence of $(B_i)_{i=1}^r$.

For $\mathbf{v} \in \mathcal{V}$, $\Theta(Z)(\mathbf{u} \otimes \mathbf{v}) = \sum_{i=1}^{m} (A_i\mathbf{u}) \otimes C_i\mathbf{v}$. If $\Theta(Z) = 0$, then $(\forall\, i \in \{1,\dots,m\})(\forall\, \mathbf{v} \in \mathcal{V})\, C_i\mathbf{v} = \mathbf{0}$ by Theorem 5.2.5(ii).

The conclusion $(\forall\, i \in \{1,\dots,m\})\, C_i = 0$ holds by Assumption 3.1.2, contrary to the preceding nonvanishing.
The inequality $\Theta(Z) \ne 0$ holds by contradiction, and Θ is injective.

(iii) Both spaces have dimension $\dim\mathcal{U}\dim\mathcal{V}\dim\mathcal{X}\dim\mathcal{Y}$ by Theorem 5.2.3(ii) and Theorem 3.4.5(ii).
The map Θ is an isomorphism by (ii) and Corollary 1.7.6(ii).

(iv) Set $\mathcal{X} = \mathcal{Y} = \mathbb{F}$. The multiplication map induces $\lambda : \mathbb{F} \otimes \mathbb{F} \to \mathbb{F}$ with $\lambda(a \otimes b) = ab$ by Theorem 5.1.6(ii).
The map λ is an isomorphism by the basis correspondence $\{1 \otimes 1\} \mapsto \{1\}$ and Theorem 5.2.3(i).
Postcomposition with λ is an isomorphism $\lambda_* : \mathcal{L}(\mathcal{U} \otimes \mathcal{V}, \mathbb{F} \otimes \mathbb{F}) \to (\mathcal{U} \otimes \mathcal{V})'$. Its inverse is postcomposition with λ^{-1}.
The identity $\Delta = \lambda_* \circ \Theta$ holds on decomposable tensors by the defining formulas. The map Δ is injective by (ii).

(v) If $\mathcal{U},\mathcal{V}$ are finite-dimensional, then Θ is an isomorphism by (iii).
The map Δ is an isomorphism by $\Delta = \lambda_* \circ \Theta$ and the isomorphisms λ_*, Θ.

Structural Commentary: Minimality proves injection; dimensions and multiplication prove isomorphism.
Key Insight: Independent operator factors are detected on one decomposable tensor. □

Proposition 5.2.8. *Scalar Extension by Tensor Product*
Let $K/\mathbb{F}$ be a field extension, regard K as an $\mathbb{F}$-vector space, and let $\mathcal{V}_\mathbb{F}$ be an $\mathbb{F}$-vector space.

(i) The $\mathbb{F}$-vector space $K \otimes_\mathbb{F} \mathcal{V}_\mathbb{F}$ is a K-vector space via $\alpha \cdot (\beta \otimes \mathbf{v}) := (\alpha\beta) \otimes \mathbf{v}$.
(ii) Define $\mu : \mathcal{V}_\mathbb{F} \to K \otimes_\mathbb{F} \mathcal{V}_\mathbb{F}$ by $\mu(\mathbf{v}) := 1 \otimes \mathbf{v}$. Let $\mathcal{Y}$ be a K-vector space and let $f : \mathcal{V}_\mathbb{F} \to \mathcal{Y}$ be $\mathbb{F}$-linear. A unique K-linear $\widetilde{f} : K \otimes_\mathbb{F} \mathcal{V}_\mathbb{F} \to \mathcal{Y}$ satisfies $\widetilde{f} \circ \mu = f$.

Proof.

(i) For $\alpha \in K$, set $m_\alpha(\beta, \mathbf{v}) := (\alpha\beta) \otimes \mathbf{v}$. The map m_α is $\mathbb{F}$-bilinear. It induces $M_\alpha \in \mathcal{L}_\mathbb{F}(K \otimes_\mathbb{F} \mathcal{V}_\mathbb{F})$ by Theorem 5.1.6(ii).
For $\alpha, \lambda \in K$, the identities $M_0 = 0$ and $M_{\alpha+\lambda} = M_\alpha + M_\lambda$ hold on decomposable tensors.
Identities $M_{\alpha\lambda} = M_\alpha M_\lambda$ and $M_1 = I$ likewise hold there. They extend to tensor product by Theorem 5.1.4(i).
The map $\alpha \mapsto M_\alpha$ is a unital ring homomorphism $K \to \mathrm{End}_\mathbb{F}(K \otimes_\mathbb{F} \mathcal{V}_\mathbb{F})$ by these identities.
The action $\alpha \cdot \mathbf{z} := M_\alpha \mathbf{z}$ defines the claimed K-vector space by this unital ring homomorphism.
(ii) The map μ is $\mathbb{F}$-linear by bilinearity of the tensor map. Set $g(\beta, \mathbf{v}) := \beta f(\mathbf{v})$.
The map g is $\mathbb{F}$-bilinear by the $\mathbb{F}$-linearity of f and scalar multiplication on $\mathcal{Y}$.
A unique $\mathbb{F}$-linear map $\widetilde{f}$ satisfies $\widetilde{f}(\beta \otimes \mathbf{v}) = \beta f(\mathbf{v})$ by Theorem 5.1.6(ii).
For $\alpha, \beta \in K$ and $\mathbf{v} \in \mathcal{V}_\mathbb{F}$, $\widetilde{f}(\alpha \cdot (\beta \otimes \mathbf{v})) = \alpha\beta f(\mathbf{v}) = \alpha \widetilde{f}(\beta \otimes \mathbf{v})$.
The map $\widetilde{f}$ is K-linear by Theorem 5.1.4(i). The identity $\widetilde{f} \circ \mu = f$ holds by $\widetilde{f}(1 \otimes \mathbf{v}) = f(\mathbf{v})$.
If h is K-linear, $h \circ \mu = f$, then $h(\beta \otimes \mathbf{v}) = \beta h(1 \otimes \mathbf{v}) = \beta f(\mathbf{v}) = \widetilde{f}(\beta \otimes \mathbf{v})$. Equality $h = \widetilde{f}$ holds by Theorem 5.1.4(i).

Structural Commentary: Field-action maps define K-scalars; bilinear extension proves universality.
Key Insight: The factor K freely supplies the missing scalars. □

5.3 Iterated Tensor Products and Tensor Spaces

The tensor-product universal property extends from bilinear maps to multilinear maps.
Its iterated form leads naturally to tensor spaces and contractions.

Definition 5.3.1. *Multilinear Maps*
Let $n \in \mathbb{Z}_{>0}$ and let $\mathcal{V}_1, \dots, \mathcal{V}_n, \mathcal{W}$ be $\mathbb{F}$-vector spaces.

(i) Fix $k \in \{1, \dots, n\}$ and all entries except the kth. For $f : \mathcal{V}_1 \times \cdots \times \mathcal{V}_n \to \mathcal{W}$, set $f_k(\mathbf{v}) := f(\mathbf{v}_1, \dots, \mathbf{v}, \dots, \mathbf{v}_n)$.
The map f is *multilinear*, or *n-linear*, if $f_k \in \mathcal{L}(\mathcal{V}_k, \mathcal{W})$ in this setup.
(ii) The set of such maps is $\mathrm{Mult}_\mathbb{F}(\mathcal{V}_1, \dots, \mathcal{V}_n; \mathcal{W})$.
(iii) If $\mathcal{W} = \mathbb{F}$, these maps are *multilinear forms*.

Example 5.3.2. *Basic Multilinear Maps*

(i) Let A be an associative $\mathbb{F}$-algebra and let $n \in \mathbb{Z}_{>0}$. Set $m_n(a_1, \dots, a_n) := a_1 \cdots a_n$.
Distributivity and homogeneity in A prove that $m_n : A^n \to A$ is n-linear.
(ii) Suppose $\dim \mathcal{V} = n \geq 1$ and β is an ordered basis.
The determinant of the β-coordinate columns is n-linear by Theorem 3.8.2(ii). It is alternating by parts (iii)–(iv).

Definition 5.3.3. *Iterated Tensor Product by Universal Property*
Let $n \in \mathbb{Z}_{>0}$ and let $\mathcal{V}_1, \dots, \mathcal{V}_n$ be $\mathbb{F}$-vector spaces.

(i) A pair $(\mathcal{T}, t)$ is an *iterated tensor product* of $\mathcal{V}_1, \dots, \mathcal{V}_n$ if both conditions hold.
  (a) $t \in \mathrm{Mult}_\mathbb{F}(\mathcal{V}_1, \dots, \mathcal{V}_n; \mathcal{T})$.
  (b) Let $\mathcal{Y}$ be an $\mathbb{F}$-vector space. Set $\mathcal{M}_\mathcal{Y} := \mathrm{Mult}_\mathbb{F}(\mathcal{V}_1, \dots, \mathcal{V}_n; \mathcal{Y})$. $(\forall\, f \in \mathcal{M}_\mathcal{Y})(\exists!\, \widetilde{f} \in \mathcal{L}(\mathcal{T}, \mathcal{Y}))\ f = \widetilde{f} \circ t$.
(ii) Write $\mathcal{T} = \mathcal{V}_1 \otimes \cdots \otimes \mathcal{V}_n$. The notation $\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_n$ abbreviates $t(\mathbf{v}_1, \dots, \mathbf{v}_n)$.

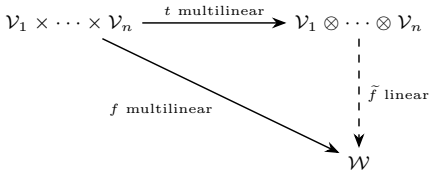

Figure 111: The iterated tensor product is universal for multilinear maps.

Figure 111 depicts the factorization in Definition 5.3.3.
The definition, rather than the diagram, owns the universal property.

Theorem 5.3.4. *Construction and Basic Laws for Iterated Tensor Products*
Let $n \in \mathbb{Z}_{>0}$ and let $\mathcal{V}_1, \dots, \mathcal{V}_n, \mathcal{V}, \mathcal{W}$ be $\mathbb{F}$-vector spaces. For $1 \leq a \leq b \leq n$, set $\mathcal{V}_{a:b}^{\otimes} := \mathcal{V}_a \otimes \cdots \otimes \mathcal{V}_b$.
Write $\mathbf{v}_{a:b}^{\otimes} := \mathbf{v}_a \otimes \cdots \otimes \mathbf{v}_b$. Set $\mathcal{M}_\mathcal{W} := \mathrm{Mult}_\mathbb{F}(\mathcal{V}_1, \dots, \mathcal{V}_n; \mathcal{W})$.

(i) The following construction and uniqueness statements hold.
  (a) Every binary parenthesization of $\mathcal{V}_1 \otimes \cdots \otimes \mathcal{V}_n$ is an iterated tensor product.
  (b) Every iterated tensor product is spanned by its decomposable tensors.
  (c) Any two iterated tensor products are uniquely isomorphic by an isomorphism preserving decomposable tensors.
(ii) Pointwise operations make $\mathcal{M}_\mathcal{W}$ an $\mathbb{F}$-vector space. Map $\Phi : \mathcal{M}_\mathcal{W} \to \mathcal{L}(\mathcal{V}_{1:n}^{\otimes}, \mathcal{W})$ defined by $\Phi(f) := \widetilde{f}$ and is an isomorphism.
(iii) If $1 \leq r < n$, set $\mathcal{A}_r := \mathcal{V}_{1:r}^{\otimes} \otimes \mathcal{V}_{r+1:n}^{\otimes}$. The canonical isomorphism $\alpha_r : \mathcal{A}_r \xrightarrow{\sim} \mathcal{V}_{1:n}^{\otimes}$ satisfies $\alpha_r(\mathbf{v}_{1:r}^{\otimes} \otimes \mathbf{v}_{r+1:n}^{\otimes}) = \mathbf{v}_{1:n}^{\otimes}$.
(iv) If $\pi \in S_n$, set $\mathcal{C}_\pi := \mathcal{V}_{\pi(1)} \otimes \cdots \otimes \mathcal{V}_{\pi(n)}$. The canonical isomorphism $\tau_\pi : \mathcal{V}_{1:n}^{\otimes} \xrightarrow{\sim} \mathcal{C}_\pi$ satisfies $\tau_\pi(\mathbf{v}_{1:n}^{\otimes}) = \mathbf{v}_{\pi(1)} \otimes \cdots \otimes \mathbf{v}_{\pi(n)}$.
(v) The isomorphism $\lambda : \mathbb{F} \otimes \mathcal{V} \xrightarrow{\sim} \mathcal{V}$ is determined by $\lambda(r \otimes \mathbf{v}) = r\mathbf{v}$. The isomorphism $\rho : \mathcal{V} \otimes \mathbb{F} \xrightarrow{\sim} \mathcal{V}$ is determined by $\rho(\mathbf{v} \otimes r) = r\mathbf{v}$.
(vi) If $(\forall\, i \in \{1, \dots, n\})\ \dim \mathcal{V}_i < \infty$, then $\dim(\mathcal{V}_{1:n}^{\otimes}) = \prod_{i=1}^{n} \dim(\mathcal{V}_i)$.

Proof.

(i)

(a) For $n = 1$, take $\mathcal{T} = \mathcal{V}_1$ and $t = I_{\mathcal{V}_1}$. The unique mediator of a linear map $f : \mathcal{V}_1 \to \mathcal{Y}$ is f itself.
Assume the assertion for fewer than n factors and split a binary parenthesization as $\mathcal{A} \otimes \mathcal{B}$.
By induction, $\mathcal{A}$ and $\mathcal{B}$ satisfy the appropriate iterated universal properties.
Let f be a multilinear map from the original factors to $\mathcal{Y}$.
Fixing the factors represented by $\mathcal{B}$ and linearizing the remaining variables produces an element of $\mathcal{L}(\mathcal{A}, \mathcal{Y})$.
This assignment is multilinear in the factors represented by $\mathcal{B}$ because the factorizations through $\mathcal{A}$ are unique.
Linearizing again produces $L : \mathcal{B} \to \mathcal{L}(\mathcal{A}, \mathcal{Y})$. Set $b_f(\mathbf{a}, \mathbf{b}) := L(\mathbf{b})(\mathbf{a})$.
Then map b_f is bilinear, and induces unique map $\mathcal{A} \otimes \mathcal{B} \to \mathcal{Y}$ by Theorem 5.1.6(ii).
Any mediator determines the same two intermediate factorizations and hence the same induced map.
Thus the chosen parenthesization is an iterated tensor product.

(b) Let $(\mathcal{T}, t)$ be an iterated tensor product. Set $\mathcal{S} := \operatorname{span}(t(\mathcal{V}_1 \times \cdots \times \mathcal{V}_n))$.
The quotient map $\pi : \mathcal{T} \to \mathcal{T}/\mathcal{S}$ is linear by Proposition 2.2.8(i).
Both π and the zero map mediate the zero multilinear map because $\pi \circ t = 0$.
Thus $\pi = 0$ by Definition 5.3.3(i). Since π is surjective by Proposition 2.2.8(ii), $\mathcal{T}/\mathcal{S} = 0$ and $\mathcal{S} = \mathcal{T}$.

(c) Let $(\mathcal{T}, t)$ and $(\mathcal{U}, u)$ be iterated tensor products. The universal properties produce a unique $F : \mathcal{T} \to \mathcal{U}$ with $F \circ t = u$.
They produce a unique $G : \mathcal{U} \to \mathcal{T}$ with $G \circ u = t$. Both GF and $I_{\mathcal{T}}$ mediate t, while both FG and $I_{\mathcal{U}}$ mediate u.
Uniqueness implies $GF = I_{\mathcal{T}}$, $FG = I_{\mathcal{U}}$. Any isomorphism preserving decomposable tensors also mediates u, so it equals F.

(ii) The zero map is multilinear, and $af + g$ is multilinear when $a \in \mathbb{F}$ and f, g are multilinear.
The remaining vector-space axioms hold pointwise because they hold in $\mathcal{W}$. Let t be the canonical multilinear map.
Set $\Phi(f) := \widetilde{f}$ by Definition 5.3.3(i). Set $\Psi(T) := T \circ t$. Defining factorisation implies $\Psi\Phi = I$, while uniqueness implies $\Phi\Psi = I$.
The maps $\Phi(af + g)$ and $a\Phi(f) + \Phi(g)$ both mediate $af + g$, so uniqueness proves that Φ is linear. Hence Φ is an isomorphism.

(iii) Set $\mathcal{B} := \mathcal{V}_{1:n}^{\otimes}$. Both $\mathcal{A}_r$ and $\mathcal{B}$ are iterated tensor products by (i)(a).
Their universal properties produce comparison maps $\alpha_r : \mathcal{A}_r \to \mathcal{B}$ and $\beta_r : \mathcal{B} \to \mathcal{A}_r$.
These maps have the displayed actions on decomposable tensors. These maps are inverse isomorphisms by (i)(c).

(iv) The map $p_\pi : \prod_{i=1}^{n} \mathcal{V}_i \to \mathcal{C}_\pi$ satisfies $p_\pi(\mathbf{v}_1, \ldots, \mathbf{v}_n) := \mathbf{v}_{\pi(1)} \otimes \cdots \otimes \mathbf{v}_{\pi(n)}$ and is multilinear.
Its unique mediating map is τ_π by Definition 5.3.3(i). The analogous map for the inverse reordering is inverse to τ_π by (i)(c).

(v) The map $m_L : \mathbb{F} \times \mathcal{V} \to \mathcal{V}$ defined by $m_L(r, \mathbf{v}) := r\mathbf{v}$ is bilinear. The map $m_R : \mathcal{V} \times \mathbb{F} \to \mathcal{V}$ defined by $m_R(\mathbf{v}, r) := r\mathbf{v}$ is bilinear.
Hence λ and ρ exist by Theorem 5.1.6(ii). Define $u_L : \mathcal{V} \to \mathbb{F} \otimes \mathcal{V}$ by $u_L(\mathbf{v}) := 1 \otimes \mathbf{v}$. Define $u_R : \mathcal{V} \to \mathcal{V} \otimes \mathbb{F}$ by $u_R(\mathbf{v}) := \mathbf{v} \otimes 1$.
Both maps are linear by bilinearity of the canonical tensor maps. Direct computation proves $\lambda u_L = I_{\mathcal{V}}$ and $\rho u_R = I_{\mathcal{V}}$.
Maps $u_L\lambda$ and $u_R\rho$ fix decomposable tensors by bilinearity, hence are identity maps by (i)(b). Hence λ and ρ are isomorphisms.

(vi) Choose finite bases B_i of $\mathcal{V}_i$. Set $\mathcal{D} := \{\mathbf{b}_1 \otimes \cdots \otimes \mathbf{b}_n : \mathbf{b}_i \in B_i\}$.

The set $\mathcal{D}$ is a basis by repeated application of Theorem 5.2.3(i). Consequently, $\dim(\mathcal{V}_{1:n}^{\otimes}) = \#\mathcal{D} = \prod_{i=1}^{n} \#B_i = \prod_{i=1}^{n} \dim \mathcal{V}_i$.

Structural Commentary: Induction builds products; quotients prove spanning; uniqueness fixes maps.
Key Insight: Every parenthesization realizes the same multilinear universal property. □

Definition 5.3.5. *Tensor Spaces of Type (p, q)*
Let $\dim \mathcal{V} < \infty$.

(i) Set $\mathcal{V}^{\otimes 0} := \mathbb{F}$. If $k \in \mathbb{Z}_{>0}$, let $\mathcal{V}^{\otimes k}$ denote the iterated tensor product of k copies of $\mathcal{V}$.

(ii) Let $(p, q) \in \mathbb{Z}_{\geq 0}^2 \setminus \{(0, 0)\}$. Set $\mathcal{T}_q^p(\mathcal{V}) := \mathcal{V}^{\otimes p} \otimes (\mathcal{V}')^{\otimes q}$.
Parentheses are suppressed by Theorem 5.3.4(iii). Unit factors are identified by part (v).

(iii) Space $\mathcal{T}_q^p(\mathcal{V})$ is *tensor space of type (p, q)*. Its p factors from $\mathcal{V}$ are contravariant, q factors from $\mathcal{V}'$ are covariant. $\mathcal{T}_0^0(\mathcal{V}) := \mathbb{F}$.

(iv) If $p + q \geq 1$, set $\mathcal{M}_{p,q}(\mathcal{V}) := \operatorname{Mult}_{\mathbb{F}}((\mathcal{V}')^{\times p} \times \mathcal{V}^{\times q}; \mathbb{F})$.
Its elements are multilinear forms on p arguments from $\mathcal{V}'$ followed by q arguments from $\mathcal{V}$.

Proposition 5.3.6. *Tensor Spaces as Multilinear Functionals*
Let $\dim \mathcal{V} = n < \infty$ and $p, q \in \mathbb{Z}_{\geq 0}$. Write $\mathbf{v}^{\otimes} := \mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_p$. Write $\boldsymbol{\varphi}^{\otimes} := \varphi_1 \otimes \cdots \otimes \varphi_q$.
Set $\boldsymbol{\eta} := (\eta_1, \ldots, \eta_p)$ and $\mathbf{x} := (\mathbf{x}_1, \ldots, \mathbf{x}_q)$. In an argument list, $(\boldsymbol{\eta}, \mathbf{x})$ denotes the concatenation of these tuples.
Set $P_{\mathbf{v}}(\boldsymbol{\eta}) := \prod_{a=1}^{p} \eta_a(\mathbf{v}_a)$ and $Q_{\boldsymbol{\varphi}}(\mathbf{x}) := \prod_{b=1}^{q} \varphi_b(\mathbf{x}_b)$. An empty tensor or product below equals 1.

(i) $\dim \mathcal{T}_q^p(\mathcal{V}) = n^{p+q}$.

(ii) If $p + q \geq 1$, a canonical isomorphism $\Theta_{p,q} : \mathcal{T}_q^p(\mathcal{V}) \xrightarrow{\sim} \mathcal{M}_{p,q}(\mathcal{V})$ is determined by $\Theta_{p,q}(\mathbf{v}^{\otimes} \otimes \boldsymbol{\varphi}^{\otimes})(\boldsymbol{\eta}, \mathbf{x}) = P_{\mathbf{v}}(\boldsymbol{\eta}) Q_{\boldsymbol{\varphi}}(\mathbf{x})$.

(iii) Suppose $p, q \geq 1$ and $(i, j) \in \{1, \ldots, p\} \times \{1, \ldots, q\}$. A subscript $\widehat{\imath}$ or $\widehat{\jmath}$ denotes omission from the corresponding tensor.
Set $\mathbf{z}_{ij} := \mathbf{v}_{\widehat{\imath}}^{\otimes} \otimes \boldsymbol{\varphi}_{\widehat{\jmath}}^{\otimes}$. A unique linear map $C_{ij} : \mathcal{T}_q^p(\mathcal{V}) \to \mathcal{T}_{q-1}^{p-1}(\mathcal{V})$ satisfies $C_{ij}(\mathbf{v}^{\otimes} \otimes \boldsymbol{\varphi}^{\otimes}) = \varphi_j(\mathbf{v}_i)\mathbf{z}_{ij}$.

(iv) If $n \geq 1$, an isomorphism $R : \mathcal{V} \otimes \mathcal{V}' \xrightarrow{\sim} \mathcal{L}(\mathcal{V})$ satisfies $R(\mathbf{v} \otimes \varphi)(\mathbf{x}) := \varphi(\mathbf{x})\mathbf{v}$. On $\mathcal{T}_1^1(\mathcal{V})$, $C_{11} = \operatorname{tr} \circ R$.

Proof.

(i) The equality $\dim \mathcal{V}' = n$ holds by Theorem 4.1.4(ii). If $p = q = 0$, then $\mathcal{T}_0^0(\mathcal{V}) = \mathbb{F}$ by Definition 5.3.5(iv).
Hence $\dim \mathcal{T}_0^0(\mathcal{V}) = 1 = n^0$, where $n^0 := 1$. If $p + q \geq 1$, then $\mathcal{T}_q^p(\mathcal{V})$ has p factors of dimension n and q factors of dimension n.
Its dimension is n^{p+q} by Theorem 5.3.4(vi) and Definition 5.3.5(ii).

(ii) Target of $\Theta_{p,q}$ is vector space by Theorem 5.3.4(ii). Displayed formula defines multilinear form in $\eta_1, \ldots, \eta_p, \mathbf{x}_1, \ldots, \mathbf{x}_q$.
Varying $\mathbf{v}_1, \ldots, \mathbf{v}_p, \varphi_1, \ldots, \varphi_q$ defines a multilinear assignment into that target.
Unique linear map $\Theta_{p,q}$ therefore exists by Theorem 5.3.4(ii). Set $\mathcal{X} := (\mathcal{V}')^{\otimes p} \otimes \mathcal{V}^{\otimes q}$.
The codomain is canonically isomorphic to $\mathcal{X}'$ by Theorem 5.3.4(ii). The domain has dimension n^{p+q} by part (i).
The equality $\dim \mathcal{X} = n^{p+q}$ holds by Theorem 5.3.4(vi). The codomain has dimension $\dim \mathcal{X}' = \dim \mathcal{X}$ by Theorem 4.1.4(ii).
If $n = 0$, this dimension is zero because $p + q \geq 1$, so $\Theta_{p,q}$ is an isomorphism.
Suppose $n \geq 1$. Choose a basis $(\mathbf{e}_1, \ldots, \mathbf{e}_n)$ and its dual basis $(\varepsilon_1, \ldots, \varepsilon_n)$.
For $I = (i_1, \ldots, i_p)$, set $\mathbf{e}_I^{\otimes} := \mathbf{e}_{i_1} \otimes \cdots \otimes \mathbf{e}_{i_p}$. For $J = (j_1, \ldots, j_q)$, set $\varepsilon_J^{\otimes} := \varepsilon_{j_1} \otimes \cdots \otimes \varepsilon_{j_q}$. Set $\mathbf{b}_{I,J} := \mathbf{e}_I^{\otimes} \otimes \varepsilon_J^{\otimes}$.
The elements $\mathbf{b}_{I,J}$ form a basis by repeated application of Theorem 5.2.3(i).
For $K = (k_1, \ldots, k_p)$, set $\delta_{K,I} := \prod_{a=1}^{p} \delta_{k_a, i_a}$. For $L = (\ell_1, \ldots, \ell_q)$, set $\delta_{J,L} := \prod_{b=1}^{q} \delta_{j_b, \ell_b}$.

Set $\boldsymbol{\varepsilon}_K := (\varepsilon_{k_1}, \dots, \varepsilon_{k_p})$. Set $\mathbf{e}_L := (\mathbf{e}_{\ell_1}, \dots, \mathbf{e}_{\ell_q})$. The defining formula implies $\Theta_{p,q}(\mathbf{b}_{I,J})(\boldsymbol{\varepsilon}_K, \mathbf{e}_L) = \delta_{K,I}\delta_{J,L}$.
If $z \in \ker \Theta_{p,q}$, evaluation at $(\boldsymbol{\varepsilon}_I, \mathbf{e}_J)$ equals both zero and the coefficient of $\mathbf{b}_{I,J}$ in z.
Thus every coefficient is zero, so $\Theta_{p,q}$ is injective. It is an isomorphism by Corollary 1.7.6(ii).

(iii) Let Γ_{ij} be the rule in part (iii). In the selected variables $\mathbf{v}_i$ and φ_j, linearity follows from bilinearity of evaluation.
In every remaining variable, linearity holds by Theorem 5.3.4(i)(a).
Thus Γ_{ij} is multilinear, and a unique linear map C_{ij} with the required action exists by part (ii) of that theorem.

(iv) The rule $(\mathbf{v}, \varphi) \mapsto (\mathbf{x} \mapsto \varphi(\mathbf{x})\mathbf{v})$ is bilinear. Thus R exists by Theorem 5.1.6(ii).
Choose a basis $(\mathbf{e}_1, \dots, \mathbf{e}_n)$ and its dual basis $(\varepsilon_1, \dots, \varepsilon_n)$. The map R sends $\mathbf{e}_a \otimes \varepsilon_b$ to the operator whose matrix is $E_{a,b}$.
The source elements form a basis by Theorem 5.2.3(i). The matrices $E_{a,b}$ form a basis by Proposition 3.1.5(ii).
Matrix representation identifies this basis with an operator basis by Theorem 3.4.5(i).

Hence R is an isomorphism. Write $\mathbf{v} = \sum_{a=1}^{n} x_a \mathbf{e}_a$. The diagonal entries of $[R(\mathbf{v} \otimes \varphi)]$ are $x_a\varphi(\mathbf{e}_a)$.

The identity $\operatorname{tr}(R(\mathbf{v} \otimes \varphi)) = \sum_{a=1}^{n} x_a\varphi(\mathbf{e}_a)$ holds by Definition 1.1.18(i).

Sum equals $\varphi(\mathbf{v}) = C_{11}(\mathbf{v} \otimes \varphi)$ by linearity and part (iii). Maps $\operatorname{tr} \circ R$ and C_{11} are linear by Proposition 1.1.1 and part (iii).
They agree on the spanning decomposable tensors by Theorem 5.3.4(i)(b), so they are equal.

Structural Commentary: Bases establish dimension and duality; evaluation defines contractions.
Key Insight: Contraction evaluates one vector–covector pair and preserves the remaining slots. □

Definition 5.3.7. *Contraction*
Let $\dim \mathcal{V} < \infty$ and let $p, q \in \mathbb{Z}_{>0}$. The maps C_{ij} in Proposition 5.3.6(iii) are the *contractions* of $\mathcal{T}^p_q(\mathcal{V})$.
The *standard contraction* is $C := C_{11}$.

Example 5.3.8. *Rank-One Operators and Trace*
Let $n := \dim \mathcal{V} \in \mathbb{Z}_{>0}$ and let $(\mathbf{e}_1, \dots, \mathbf{e}_n)$ be a basis. Let $(\varepsilon_1, \dots, \varepsilon_n)$ be the dual basis.
By Proposition 5.3.6(iv), $R(\mathbf{e}_a \otimes \varepsilon_b)$ has matrix $E_{a,b}$ for $a, b \in \{1, \dots, n\}$. Its contraction records the trace: $C(\mathbf{e}_a \otimes \varepsilon_b) = \delta_{a,b} = \operatorname{tr}(E_{a,b})$.

6 Symmetric and Exterior Algebras

6.1 Symmetric and Exterior Powers

Definition 6.1.1. *Symmetric, Skew-Symmetric, and Alternating Maps*
Let $n \in \mathbb{Z}_{>0}$, let $\mathcal{V}, \mathcal{W}$ be $\mathbb{F}$-vector spaces, and set $P_n := \{(i,j) \in \{1, \dots, n\}^2 : i < j\}$. Let $f \in \operatorname{Mult}_{\mathbb{F}}(\mathcal{V}, \dots, \mathcal{V}; \mathcal{W})$, with n copies of $\mathcal{V}$.
For $\sigma \in \mathfrak{S}_n$, set $f^{\sigma}(\mathbf{v}_1, \dots, \mathbf{v}_n) := f(\mathbf{v}_{\sigma(1)}, \dots, \mathbf{v}_{\sigma(n)})$. For $(i,j) \in P_n$, let s_{ij} transpose i and j.

(i) The map f is *symmetric* if $(\forall\,(i,j) \in P_n)\, f^{s_{ij}} = f$.
(ii) The map f is *skew-symmetric* if $(\forall\,(i,j) \in P_n)\, f^{s_{ij}} = -f$.
(iii) The map f is *alternating* if $(\forall\, \mathbf{v} \in \mathcal{V}^{\times n})[(\exists\,(i,j) \in P_n)\, \mathbf{v}_i = \mathbf{v}_j \Rightarrow f(\mathbf{v}) = 0]$.

Proposition 6.1.2. *Alternation, Skew-Symmetry, and Characteristic*
Let $n \in \mathbb{Z}_{>0}$, let $\mathcal{V}, \mathcal{W}$ be $\mathbb{F}$-vector spaces, and set $P_n := \{(i,j) \in \{1, \dots, n\}^2 : i < j\}$. Let $f \in \operatorname{Mult}_{\mathbb{F}}(\mathcal{V}, \dots, \mathcal{V}; \mathcal{W})$, with n copies of $\mathcal{V}$.

(i) If f is alternating, then f is skew-symmetric.
(ii) If $\operatorname{char}(\mathbb{F}) \neq 2$ and f is skew-symmetric, then f is alternating.
(iii) If $\operatorname{char}(\mathbb{F}) = 2$, then the symmetric and skew-symmetric conditions coincide.

Proof.

(i) Fix $(i,j) \in P_n$ and the entries outside slots i, j, and let $g : \mathcal{V}^2 \to \mathcal{W}$ be the resulting bilinear map.
Then $(\forall\, \mathbf{u} \in \mathcal{V})\, g(\mathbf{u}, \mathbf{u}) = 0$ by alternation. For $\mathbf{u}, \mathbf{v} \in \mathcal{V}$, $0 = g(\mathbf{u}+\mathbf{v}, \mathbf{u}+\mathbf{v}) = g(\mathbf{u}, \mathbf{v}) + g(\mathbf{v}, \mathbf{u})$.
Hence $g(\mathbf{v}, \mathbf{u}) = -g(\mathbf{u}, \mathbf{v})$. The fixed data were arbitrary, so $(\forall\,(i,j) \in P_n)\, f^{s_{ij}} = -f$.

(ii) Fix $\mathbf{v} \in \mathcal{V}^{\times n}$ and $(i,j) \in P_n$ with $\mathbf{v}_i = \mathbf{v}_j$. Then $f(\mathbf{v}) = f^{s_{ij}}(\mathbf{v}) = -f(\mathbf{v})$ by skew-symmetry, whence $2f(\mathbf{v}) = 0$.
The scalar 2 is invertible in $\mathbb{F}$ by $\operatorname{char}(\mathbb{F}) \neq 2$, so $f(\mathbf{v}) = 0$.

(iii) The equality $-1 = 1$ holds in $\mathbb{F}$ by $\operatorname{char}(\mathbb{F}) = 2$, so the two conditions coincide.

Structural Commentary: Diagonal polarization establishes skew-symmetry; invertibility of 2 recovers alternation.
Key Insight: Characteristic 2 removes the sign distinction but not diagonal vanishing. □

Definition 6.1.3. *Permutation Action on Tensor Powers*
Let $\mathcal{V}$ be an $\mathbb{F}$-vector space and $p \in \mathbb{Z}_{\geq 0}$. Set $T_0 := \mathbb{F}$, $T_p := \mathcal{V}^{\otimes p}$ for $p > 0$, and $G_p := \mathfrak{S}_p$.
For $p = 0$, let $t_0 : \{()\} \to T_0$ satisfy $t_0(()) = 1$ and set $\lambda_{\mathrm{id}} := I_{T_0}$.
For $p > 0$, let $t_p : \mathcal{V}^{\times p} \to T_p$ be canonical and set $\lambda_\sigma := \tau_{\sigma^{-1}} \in \mathcal{L}(T_p)$ for $\sigma \in G_p$ by Theorem 5.3.4(iv).
Thus $\lambda_\sigma t_p(\mathbf{v}_1, \dots, \mathbf{v}_p) = t_p(\mathbf{v}_{\sigma^{-1}(1)}, \dots, \mathbf{v}_{\sigma^{-1}(p)})$.

Proposition 6.1.4. *Permutation Representation on Tensor Powers*
Let $\mathcal{V}$ be an $\mathbb{F}$-vector space and $p \in \mathbb{Z}_{\geq 0}$. Let T_p, G_p, and $(\lambda_\sigma)_{\sigma \in G_p}$ be as in Definition 6.1.3.

(i) $\lambda_{\mathrm{id}} = I_{T_p}$.
(ii) $(\forall\, \sigma, \tau \in G_p)\, \lambda_\sigma \lambda_\tau = \lambda_{\sigma\tau}$.

Proof. Both claims hold by Definition 6.1.3 when $p = 0$. Assume $p > 0$.

(i) $(\forall\, \mathbf{v} \in \mathcal{V}^{\times p})\, \lambda_{\mathrm{id}} t_p(\mathbf{v}) = t_p(\mathbf{v})$. Hence $\lambda_{\mathrm{id}} = I_{T_p}$ by Theorem 5.3.4(i)(b).

(ii) For $(\sigma, \tau, \mathbf{v}) \in G_p^2 \times \mathcal{V}^{\times p}$, $\lambda_\sigma \lambda_\tau t_p(\mathbf{v}) = t_p(\mathbf{v}_{\tau^{-1}\sigma^{-1}(1)}, \dots, \mathbf{v}_{\tau^{-1}\sigma^{-1}(p)}) = \lambda_{\sigma\tau} t_p(\mathbf{v})$. Thus $(\forall\, \sigma, \tau \in G_p)\, \lambda_\sigma \lambda_\tau = \lambda_{\sigma\tau}$ by Theorem 5.3.4(i)(b).

Structural Commentary: Decomposable evaluation verifies each law; spanning extends it to T_p.
Key Insight: Inverse indexing converts factor permutations into a left action. □

Definition 6.1.5. *Symmetric and Exterior Powers*
Let $\mathcal{V}$ be an $\mathbb{F}$-vector space, let $p \in \mathbb{Z}_{\geq 0}$, and use the notation of Definition 6.1.3.
Set $P_p := \{(i,j) \in \{1, \dots, p\}^2 : i < j\}$ and $\Delta_p(\mathcal{V}) := \{\mathbf{v} \in \mathcal{V}^{\times p} : (\exists\,(i,j) \in P_p)\, \mathbf{v}_i = \mathbf{v}_j\}$.

(i) The *symmetric tensors* are $\mathrm{ST}^p(\mathcal{V}) := \{\mathbf{z} \in T_p : (\forall\, \sigma \in G_p)\, \lambda_\sigma \mathbf{z} = \mathbf{z}\}$.

(ii) The *antisymmetric tensors* are $\mathrm{AT}^p(\mathcal{V}) := \{\mathbf{z} \in T_p : (\forall\, \sigma \in G_p)\, \lambda_\sigma \mathbf{z} = \mathrm{sign}(\sigma)\mathbf{z}\}$.
(iii) Set $R_{\vee,p} := \mathrm{span}\{\lambda_\sigma \mathbf{z} - \mathbf{z} : \sigma \in G_p,\ \mathbf{z} \in T_p\}$.
(iv) Set $R_{\wedge,p} := \mathrm{span}\{t_p(\mathbf{v}) : \mathbf{v} \in \Delta_p(\mathcal{V})\}$.
(v) The *symmetric power* is $\mathrm{Sym}^p(\mathcal{V}) := T_p/R_{\vee,p}$. For the quotient map $q_{\vee,p}$, set $q_{\vee,p}t_p(\mathbf{v}) := \mathbf{v}_1 \vee \cdots \vee \mathbf{v}_p$.
(vi) The *exterior power* is $\bigwedge^p \mathcal{V} := T_p/R_{\wedge,p}$. For the quotient map $q_{\wedge,p}$, set $q_{\wedge,p}t_p(\mathbf{v}) := \mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_p$.

For $p = 0$, each empty product denotes $1 \in \mathbb{F}$.

Theorem 6.1.6. *Universal Properties of Symmetric and Exterior Powers*
Let $\mathcal{V},\mathcal{U}$ be $\mathbb{F}$-vector spaces and $p \in \mathbb{Z}_{>0}$. Set $M := \mathrm{Mult}_{\mathbb{F}}(\mathcal{V},\dots,\mathcal{V};\mathcal{U})$, with p copies of $\mathcal{V}$.
Let $t_p : \mathcal{V}^{\times p} \to T_p$ be canonical. For $f \in M$ and $\sigma \in G_p$, set $f^\sigma(\mathbf{v}_1,\dots,\mathbf{v}_p) := f(\mathbf{v}_{\sigma(1)},\dots,\mathbf{v}_{\sigma(p)})$.
(i) $M_\vee := \{f \in M : (\forall\, \sigma \in G_p)\, f^\sigma = f\}$. Map $\Phi_\vee : \mathcal{L}(\mathrm{Sym}^p(\mathcal{V}),\mathcal{U}) \to M_\vee$ defined by $\Phi_\vee(T) := T \circ q_{\vee,p} \circ t_p$ is linear isomorphism.
(ii) $M_\wedge := \{f \in M : (\forall\, \mathbf{v} \in \Delta_p(\mathcal{V}))\, f(\mathbf{v}) = 0\}$. Map $\Phi_\wedge : \mathcal{L}(\bigwedge^p \mathcal{V},\mathcal{U}) \to M_\wedge$ defined by $\Phi_\wedge(T) := T \circ q_{\wedge,p} \circ t_p$ is linear isomorphism.

Proof.
(i) For $T \in \mathcal{L}(\mathrm{Sym}^p(\mathcal{V}),\mathcal{U})$, $(\forall\, \sigma \in G_p)\, q_{\vee,p}\lambda_\sigma = q_{\vee,p}$ by the definition of $R_{\vee,p}$. Hence $\Phi_\vee(T) \in M_\vee$.
Map $\Phi_\vee$ is linear by pointwise operations, linear composition. For $f \in M_\vee$, $(\exists!\, \widetilde{f} \in \mathcal{L}(T_p,\mathcal{U}))\, f = \widetilde{f} \circ t_p$ by Theorem 5.3.4(ii).
The identity $(\forall\, \sigma \in G_p)\, \widetilde{f}\lambda_\sigma = \widetilde{f}$ holds on decomposable tensors by symmetry and on T_p by Theorem 5.3.4(i)(b).
Hence $R_{\vee,p} \le \ker(\widetilde{f})$. Thus $(\exists!\, \overline{f} \in \mathcal{L}(\mathrm{Sym}^p(\mathcal{V}),\mathcal{U}))\, \widetilde{f} = \overline{f} \circ q_{\vee,p}$ by Theorem 2.2.11(i).
For $T \in \mathcal{L}(\mathrm{Sym}^p(\mathcal{V}),\mathcal{U})$, the construction applied to $\Phi_\vee(T)$ has $\widetilde{\Phi_\vee(T)} = T \circ q_{\vee,p}$. Thus $\overline{\Phi_\vee(T)} = T$ by uniqueness.
For $f \in M_\vee$, $\Phi_\vee(\overline{f}) = \overline{f} \circ q_{\vee,p} \circ t_p = \widetilde{f} \circ t_p = f$. Thus $\Phi_\vee$ is an isomorphism.
(ii) For $T \in \mathcal{L}(\bigwedge^p \mathcal{V},\mathcal{U})$, $\Phi_\wedge(T) \in M_\wedge$ by the definition of $R_{\wedge,p}$. The map $\Phi_\wedge$ is linear by pointwise operations and linear composition.
For $f \in M_\wedge$, $(\exists!\, \widetilde{f} \in \mathcal{L}(T_p,\mathcal{U}))\, f = \widetilde{f} \circ t_p$ by Theorem 5.3.4(ii).
The inclusion $R_{\wedge,p} \le \ker(\widetilde{f})$ holds by alternation. Thus $(\exists!\, \overline{f} \in \mathcal{L}(\bigwedge^p \mathcal{V},\mathcal{U}))\, \widetilde{f} = \overline{f} \circ q_{\wedge,p}$ by Theorem 2.2.11(i).
For $T \in \mathcal{L}(\bigwedge^p \mathcal{V},\mathcal{U})$, the construction applied to $\Phi_\wedge(T)$ has $\widetilde{\Phi_\wedge(T)} = T \circ q_{\wedge,p}$. Thus $\overline{\Phi_\wedge(T)} = T$ by uniqueness.
For $f \in M_\wedge$, $\Phi_\wedge(\overline{f}) = \overline{f} \circ q_{\wedge,p} \circ t_p = \widetilde{f} \circ t_p = f$. Thus $\Phi_\wedge$ is an isomorphism.

Structural Commentary: Tensor universality linearizes each map; quotient descent removes its relation subspace.
Key Insight: Kernel containment is the exact descent criterion for both tensor quotients. □

Theorem 6.1.7. *Dimensions of Symmetric and Exterior Powers*
Let $\dim \mathcal{V} = n \in \mathbb{Z}_{>0}$, let $p \in \mathbb{Z}_{\ge 0}$, and let $E = (\mathbf{e}_1,\dots,\mathbf{e}_n)$ be an ordered basis. If $p = 0$, set $I_\vee = I_\wedge := \{()\}$.
If $p > 0$, set $I_\vee := \{(i_1,\dots,i_p) \in \{1,\dots,n\}^p : i_1 \le \cdots \le i_p\}$ and $I_\wedge := \{(i_1,\dots,i_p) \in \{1,\dots,n\}^p : i_1 < \cdots < i_p\}$.
For $I = (i_1,\dots,i_p)$, set $\mathbf{e}_I^\vee := \mathbf{e}_{i_1} \vee \cdots \vee \mathbf{e}_{i_p}$ and $\mathbf{e}_I^\wedge := \mathbf{e}_{i_1} \wedge \cdots \wedge \mathbf{e}_{i_p}$, with empty products equal to $1 \in \mathbb{F}$.
Set $B_\vee := \{\mathbf{e}_I^\vee : I \in I_\vee\}$ and $B_\wedge := \{\mathbf{e}_I^\wedge : I \in I_\wedge\}$.
(i) The following symmetric-power conclusions hold.
(a) The set $B_\vee$ is a basis of $\mathrm{Sym}^p(\mathcal{V})$.
(b) $\dim \mathrm{Sym}^p(\mathcal{V}) = \#I_\vee = \binom{n+p-1}{p}$.
(ii) The following exterior-power conclusions hold, with $\binom{n}{p} := 0$ for $p > n$.
(a) The set $B_\wedge$ is a basis of $\bigwedge^p \mathcal{V}$.
(b) $\dim \bigwedge^p \mathcal{V} = \#I_\wedge = \binom{n}{p}$.

Proof. For $p > 0$, let $t_p : \mathcal{V}^{\times p} \to T_p$ be canonical and, for finite S, set $\mathcal{P}_p(S) := \{A \subseteq S : \#A = p\}$.
For $p > 0$, the tensor words $\mathbf{e}_{j_1} \otimes \cdots \otimes \mathbf{e}_{j_p}$ form a basis of T_p by repeated applications of Theorem 5.2.3(i).
(i)
(a) If $p = 0$, then $R_{\vee,0} = \{0\}$ and $B_\vee = \{1\}$, so $B_\vee$ is a basis.
Assume $p > 0$. Each tensor word is congruent modulo $R_{\vee,p}$ to its nondecreasing rearrangement; hence $B_\vee$ spans.
For $I \in I_\vee$, define $\chi_I \in T_p'$ on the tensor-word basis by $\chi_I(\mathbf{e}_{j_1} \otimes \cdots \otimes \mathbf{e}_{j_p}) = 1$ when $(j_1,\dots,j_p)$ is a rearrangement of I, and 0 otherwise. The inclusion $R_{\vee,p} \le \ker(\chi_I)$ holds by $(\forall\, \sigma \in G_p)\, \chi_I\lambda_\sigma = \chi_I$.
Thus $(\exists!\, \overline{\chi}_I \in (\mathrm{Sym}^p(\mathcal{V}))')\, \chi_I = \overline{\chi}_I \circ q_{\vee,p}$ by Theorem 2.2.11(i).
For $I, J \in I_\vee$, $\overline{\chi}_I(\mathbf{e}_J^\vee) = \delta_{I,J}$; hence $B_\vee$ is linearly independent and therefore a basis.
(b) If $p = 0$, then $\dim \mathrm{Sym}^0(\mathcal{V}) = \#I_\vee = 1 = \binom{n-1}{0}$ by Proposition 4.3.6(i).
For $p > 0$, the map $(i_1,\dots,i_p) \mapsto \{i_1, i_2+1, \dots, i_p+p-1\}$ is a bijection from $I_\vee$ to $\mathcal{P}_p(\{1,\dots,n+p-1\})$.
Inverse sends $\{a_1 < \cdots < a_p\}$ to $(a_1, a_2-1, \dots, a_p-p+1)$. Thus $\dim \mathrm{Sym}^p(\mathcal{V}) = \#I_\vee = \binom{n+p-1}{p}$ by (a), Proposition 4.3.4.

(ii)
(a) If $p = 0$, then $R_{\wedge,0} = \{0\}$ and $B_\wedge = \{1\}$, so $B_\wedge$ is a basis.
Assume $p > 0$. If $p \ge 2$, fix two slots and all other factors, and write $w(\mathbf{u},\mathbf{v})$ for the resulting tensor word.
Then $w(\mathbf{u},\mathbf{v}) + w(\mathbf{v},\mathbf{u}) = w(\mathbf{u}+\mathbf{v},\mathbf{u}+\mathbf{v}) - w(\mathbf{u},\mathbf{u}) - w(\mathbf{v},\mathbf{v}) \in R_{\wedge,p}$. Thus a transposition changes sign modulo $R_{\wedge,p}$.
Repeated basis words lie in $R_{\wedge,p}$ by definition, and every other basis word is congruent up to sign to an increasing word; hence $B_\wedge$ spans. Let $E' = (\varepsilon_1,\dots,\varepsilon_n)$ be the dual basis. For $I = (i_1,\dots,i_p) \in I_\wedge$, set $a_I(\mathbf{v}_1,\dots,\mathbf{v}_p) := \det[\varepsilon_{i_r}(\mathbf{v}_s)]_{r,s=1}^p$.
The form a_I is alternating by Theorem 3.8.2(ii)–(iv). Thus $(\exists!\, \ell_I \in (\bigwedge^p \mathcal{V})')\, a_I = \ell_I \circ q_{\wedge,p} \circ t_p$ by Theorem 6.1.6(ii).
For $I, J \in I_\wedge$, $\ell_I(\mathbf{e}_J^\wedge) = \delta_{I,J}$; hence $B_\wedge$ is linearly independent and therefore a basis.
(b) If $p = 0$, then $\dim \bigwedge^0 \mathcal{V} = \#I_\wedge = 1 = \binom{n}{0}$ by Proposition 4.3.6(i).
For $0 < p \le n$, the map $(i_1,\dots,i_p) \mapsto \{i_1,\dots,i_p\}$ is a bijection from $I_\wedge$ to $\mathcal{P}_p(\{1,\dots,n\})$.
Thus $\dim \bigwedge^p \mathcal{V} = \#I_\wedge = \binom{n}{p}$ by (a) and Proposition 4.3.4.
If $p > n$, then $I_\wedge = \emptyset$ and $\dim \bigwedge^p \mathcal{V} = 0 = \binom{n}{p}$ by (a) and the stated convention.

Structural Commentary: Orbit-constant functionals separate symmetric words; determinants separate increasing exterior words.
Key Insight: Dual separators turn spanning normal forms into bases. □

Proposition 6.1.8. *Symmetrization and Antisymmetrization in Characteristic Zero*
Let $\mathcal{V}$ be $\mathbb{F}$-vector space, $p \in \mathbb{Z}_{\geq 0}$, $\operatorname{char}(\mathbb{F}) = 0$. The scalar $p!$ is nonzero in $\mathbb{F}$.
Define $S := \frac{1}{p!} \sum_{\sigma \in G_p} \lambda_\sigma \in \mathcal{L}(T_p)$; $A := \frac{1}{p!} \sum_{\sigma \in G_p} \operatorname{sign}(\sigma) \lambda_\sigma \in \mathcal{L}(T_p)$.

(i) $\operatorname{im} S = \mathrm{ST}^p(\mathcal{V})$.
(ii) $S^2 = S$.
(iii) $\operatorname{im} A = \mathrm{AT}^p(\mathcal{V})$.
(iv) $A^2 = A$.

Proof.

(i) For $\tau \in G_p$, $\lambda_\tau S = \frac{1}{p!} \sum_{\sigma \in G_p} \lambda_{\tau\sigma} = \frac{1}{p!} \sum_{\rho \in G_p} \lambda_\rho = S$ by the reindexing $\rho = \tau\sigma$. Hence $\operatorname{im} S \subseteq \mathrm{ST}^p(\mathcal{V})$.
If $\mathbf{z} \in \mathrm{ST}^p(\mathcal{V})$, then $S\mathbf{z} = \frac{1}{p!} \sum_{\sigma \in G_p} \mathbf{z} = \mathbf{z}$ by Proposition 4.3.3(iii). Thus $\mathrm{ST}^p(\mathcal{V}) \subseteq \operatorname{im} S$; $\operatorname{im} S = \mathrm{ST}^p(\mathcal{V})$.

(ii) For $\mathbf{x} \in T_p$, $S\mathbf{x} \in \mathrm{ST}^p(\mathcal{V})$ by (i), so $S^2\mathbf{x} = S\mathbf{x}$ by the defining average and Proposition 4.3.3(iii). Hence $S^2 = S$.

(iii) For $p > 0$, let $(\mathbf{e}_1, \ldots, \mathbf{e}_p)$ be the standard basis of $\mathbb{F}^p$, and let P_σ have columns $\mathbf{e}_{\sigma(1)}, \ldots, \mathbf{e}_{\sigma(p)}$ for $\sigma \in G_p$.
Then $\det P_\sigma = \operatorname{sign}(\sigma)$ by Definition 3.8.1(ii), and $P_\sigma P_\tau = P_{\sigma\tau}$.
Hence $\operatorname{sign}(\sigma\tau) = \operatorname{sign}(\sigma)\operatorname{sign}(\tau)$ by Theorem 3.8.2(vi). The identity also holds for $p = 0$.
For $\tau \in G_p$, $\lambda_\tau A = \frac{1}{p!} \sum_{\sigma \in G_p} \operatorname{sign}(\sigma) \lambda_{\tau\sigma} = \operatorname{sign}(\tau) A$ by the reindexing $\rho = \tau\sigma$. Hence $\operatorname{im} A \subseteq \mathrm{AT}^p(\mathcal{V})$.
If $\mathbf{z} \in \mathrm{AT}^p(\mathcal{V})$, then $A\mathbf{z} = \frac{1}{p!} \sum_{\sigma \in G_p} \operatorname{sign}(\sigma)^2 \mathbf{z} = \mathbf{z}$ by Proposition 4.3.3(iii). Thus $\mathrm{AT}^p(\mathcal{V}) \subseteq \operatorname{im} A$; $\operatorname{im} A = \mathrm{AT}^p(\mathcal{V})$.

(iv) For $\mathbf{x} \in T_p$, $A\mathbf{x} \in \mathrm{AT}^p(\mathcal{V})$ by (iii), so $A^2\mathbf{x} = A\mathbf{x}$ by the defining average and Proposition 4.3.3(iii). Hence $A^2 = A$.

Structural Commentary: Reindexed character averages identify the images; fixed-point identities establish idempotence.
Key Insight: Normalisation by $p!$ turns each character average into a projection. □

Definition 6.1.9. *Tensor, Symmetric, and Exterior Algebras*
Let $\mathcal{V}$ be an $\mathbb{F}$-vector space.

(i) The *tensor algebra* is $\mathcal{T}(\mathcal{V}) := \bigoplus_{p \geq 0} T_p$. Unit is $1 \in T_0 = \mathbb{F}$, homogeneous multiplication is tensor concatenation.

(ii) The *symmetric algebra* is $\mathrm{Sym}(\mathcal{V}) := \bigoplus_{p \geq 0} \mathrm{Sym}^p(\mathcal{V})$. For $\mathbf{x} \in T_p$ and $\mathbf{y} \in T_q$, set $q_{\vee,p}(\mathbf{x}) \vee q_{\vee,q}(\mathbf{y}) := q_{\vee,p+q}(\mathbf{x} \otimes \mathbf{y})$.

(iii) The *exterior algebra* is $\bigwedge \mathcal{V} := \bigoplus_{p \geq 0} \bigwedge^p \mathcal{V}$. For $\mathbf{x} \in T_p$ and $\mathbf{y} \in T_q$, set $q_{\wedge,p}(\mathbf{x}) \wedge q_{\wedge,q}(\mathbf{y}) := q_{\wedge,p+q}(\mathbf{x} \otimes \mathbf{y})$.

Proposition 6.1.10. *Graded Algebra Laws*
Let $\mathcal{V}$ be an $\mathbb{F}$-vector space, with the three graded constructions and products from Definition 6.1.9.

(i) Tensor concatenation makes $\mathcal{T}(\mathcal{V})$ an associative unital graded $\mathbb{F}$-algebra.
(ii) The symmetric product is well-defined and bilinear.
(iii) The symmetric product makes $\mathrm{Sym}(\mathcal{V})$ an associative unital graded $\mathbb{F}$-algebra.
(iv) The exterior product is well-defined and bilinear.
(v) The exterior product makes $\bigwedge \mathcal{V}$ an associative unital graded $\mathbb{F}$-algebra.

Proof.

(i) Tensor concatenation is bilinear and associative under the canonical identifications of iterated tensor products.
Its unit is $1 \in T_0$, and $(\forall\, p, q \in \mathbb{Z}_{\geq 0})\, T_p T_q \subseteq T_{p+q}$ by construction.

(ii) Let $p, q \in \mathbb{Z}_{\geq 0}$. Extend $\sigma \in G_p$ to $\widehat{\sigma} \in G_{p+q}$ by fixing the last q indices.
Extend $\tau \in G_q$ to $\widehat{\tau} \in G_{p+q}$ by fixing the first p indices.
For $\mathbf{x} \in T_p$ and $\mathbf{y} \in T_q$, $(\lambda_\sigma \mathbf{x} - \mathbf{x}) \otimes \mathbf{y} = \lambda_{\widehat{\sigma}}(\mathbf{x} \otimes \mathbf{y}) - \mathbf{x} \otimes \mathbf{y} \in R_{\vee,p+q}$.
Similarly, $\mathbf{x} \otimes (\lambda_\tau \mathbf{y} - \mathbf{y}) = \lambda_{\widehat{\tau}}(\mathbf{x} \otimes \mathbf{y}) - \mathbf{x} \otimes \mathbf{y} \in R_{\vee,p+q}$.
Hence $R_{\vee,p} \otimes T_q + T_p \otimes R_{\vee,q} \subseteq R_{\vee,p+q}$.
The quotient formula is therefore independent of representatives, and bilinearity descends from concatenation.

(iii) Let $p, q, r \in \mathbb{Z}_{\geq 0}$ and $(\mathbf{x}, \mathbf{y}, \mathbf{z}) \in T_p \times T_q \times T_r$. Set $\mathbf{a} := q_{\vee,p}(\mathbf{x})$, $\mathbf{b} := q_{\vee,q}(\mathbf{y})$, and $\mathbf{c} := q_{\vee,r}(\mathbf{z})$.
Then $(\mathbf{a} \vee \mathbf{b}) \vee \mathbf{c} = q_{\vee,p+q+r}((\mathbf{x} \otimes \mathbf{y}) \otimes \mathbf{z}) = q_{\vee,p+q+r}(\mathbf{x} \otimes (\mathbf{y} \otimes \mathbf{z})) = \mathbf{a} \vee (\mathbf{b} \vee \mathbf{c})$.
The identities $1 \vee \mathbf{a} = \mathbf{a} = \mathbf{a} \vee 1$ hold by the tensor unit identifications.
For $\mathbf{a} \in \mathrm{Sym}^p(\mathcal{V})$ and $\mathbf{b} \in \mathrm{Sym}^q(\mathcal{V})$, $\mathbf{a} \vee \mathbf{b} \in \mathrm{Sym}^{p+q}(\mathcal{V})$ by definition.

(iv) Let $p, q \in \mathbb{Z}_{\geq 0}$. For $(\mathbf{v}, \mathbf{w}) \in \mathcal{V}^{\times p} \times \mathcal{V}^{\times q}$, $t_p(\mathbf{v}) \otimes t_q(\mathbf{w}) \in R_{\wedge,p+q}$ if $\mathbf{v} \in \Delta_p(\mathcal{V})$ or $\mathbf{w} \in \Delta_q(\mathcal{V})$. For $k = 0$, T_k is spanned by $t_k(())$.
For $k > 0$, decomposable tensors span T_k by Theorem 5.3.4(i)(b). Hence $R_{\wedge,p} \otimes T_q + T_p \otimes R_{\wedge,q} \subseteq R_{\wedge,p+q}$.
The quotient formula is therefore independent of representatives, and bilinearity descends from concatenation.

(v) Let $p, q, r \in \mathbb{Z}_{\geq 0}$ and $(\mathbf{x}, \mathbf{y}, \mathbf{z}) \in T_p \times T_q \times T_r$ Set $\mathbf{a} := q_{\wedge,p}(\mathbf{x})$, $\mathbf{b} := q_{\wedge,q}(\mathbf{y})$, and $\mathbf{c} := q_{\wedge,r}(\mathbf{z})$.
Then $(\mathbf{a} \wedge \mathbf{b}) \wedge \mathbf{c} = q_{\wedge,p+q+r}((\mathbf{x} \otimes \mathbf{y}) \otimes \mathbf{z}) = q_{\wedge,p+q+r}(\mathbf{x} \otimes (\mathbf{y} \otimes \mathbf{z})) = \mathbf{a} \wedge (\mathbf{b} \wedge \mathbf{c})$.
The identities $1 \wedge \mathbf{a} = \mathbf{a} = \mathbf{a} \wedge 1$ hold by the tensor unit identifications. For $\mathbf{a} \in \bigwedge^p \mathcal{V}$ and $\mathbf{b} \in \bigwedge^q \mathcal{V}$, $\mathbf{a} \wedge \mathbf{b} \in \bigwedge^{p+q} \mathcal{V}$ by definition.

Structural Commentary: Block-relation stability descends concatenation; tensor identities transfer the algebra laws.
Key Insight: Adjoining tensor factors preserves both relation subspaces. □

6.2 Determinants from Exterior Powers

Corollary 6.2.1. *Determinant from the Exterior Universal Property*
Let $\dim \mathcal{V} = n \in \mathbb{Z}_{>0}$, $E = (\mathbf{e}_1, \ldots, \mathbf{e}_n)$ be ordered basis. Set $\Omega_E := \mathbf{e}_1 \wedge \cdots \wedge \mathbf{e}_n$.
Define $A_E : \mathcal{V}^{\times n} \to \mathrm{Mat}(n, n, \mathbb{F})$ by $A_E(\mathbf{v}) := ([\mathbf{v}_j]_i)_{i,j=1}^n$ for $\mathbf{v} = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$.

(i) $(\exists!\, \ell_E \in (\bigwedge^n \mathcal{V})')\, \ell_E(\Omega_E) = 1$.
(ii) Define $d_E : \mathcal{V}^{\times n} \to \mathbb{F}$ by $d_E(\mathbf{v}) := \ell_E(\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_n)$. The map d_E is the unique alternating form satisfying $d_E(E) = 1$.
(iii) $(\forall\, \mathbf{v} \in \mathcal{V}^{\times n})\, d_E(\mathbf{v}) = \sum_{\sigma \in \mathfrak{S}_n} \operatorname{sign}(\sigma) \prod_{j=1}^n [\mathbf{v}_j]_{\sigma(j)} = \det A_E(\mathbf{v})$.

Proof.
(i) Singleton $\{\Omega_E\}$ is basis of $\bigwedge^n \mathcal{V}$ by Theorem 6.1.7(ii)(a). A unique $\ell_E \in (\bigwedge^n \mathcal{V})'$ satisfies $\ell_E(\Omega_E) = 1$ by Proposition 1.5.8.
(ii) The form d_E is alternating by Theorem 6.1.6(ii), $d_E(E) = \ell_E(\Omega_E) = 1$. Let $g : \mathcal{V}^{\times n} \to \mathbb{F}$ be alternating with $g(E) = 1$.
A unique $\ell \in (\bigwedge^n \mathcal{V})'$ satisfies $g(\mathbf{v}) = \ell(\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_n)$ by Theorem 6.1.6(ii).
$\ell(\Omega_E) = g(E) = 1$, so $\ell = \ell_E$ by (i) and $g = d_E$ by the two factorizations.
(iii) Define $g : \mathcal{V}^{\times n} \to \mathbb{F}$ by $g(\mathbf{v}) := \det A_E(\mathbf{v})$. Map g is multilinear and alternating by coordinate linearity and Theorem 3.8.2(ii),(iv).
The identity $g(E) = \det I_n = 1$ holds by Theorem 3.8.2(i). Hence $g = d_E$ by (ii).
The permutation identity in (iii) holds by Definition 3.8.1(ii).

Structural Commentary: Top-degree normalization fixes ℓ_E; exterior universality transfers uniqueness.
Key Insight: One basis value determines a normalized top-degree alternating form. □

Corollary 6.2.2. *Classical Laws for the Exterior Determinant*
Let $n \in \mathbb{Z}_{>0}$ and $A, B \in \mathrm{Mat}(n, n, \mathbb{F})$. For the standard basis E of $\mathbb{F}^n$, define $d : \mathrm{Mat}(n, n, \mathbb{F}) \to \mathbb{F}$ by $d(C) := d_E(C_{\cdot,1}, \ldots, C_{\cdot,n})$.
(i) $d(A^t) = d(A)$.
(ii) $d(AB) = d(A)d(B)$.
(iii) $A \in \mathrm{GL}(n, \mathbb{F}) \iff d(A) \neq 0$.

Proof. The identity $(\forall\, C \in \mathrm{Mat}(n, n, \mathbb{F}))\, d(C) = \det C$ holds by Corollary 6.2.1(iii).
(i) $d(A^t) = \det(A^t) = \det A = d(A)$ by Theorem 3.8.2(ix).
(ii) $d(AB) = \det(AB) = \det(A)\det(B) = d(A)d(B)$ by Theorem 3.8.2(vi).
(iii) $(\Rightarrow)$ $A \in \mathrm{GL}(n, \mathbb{F}) \Rightarrow \det A \neq 0 \Rightarrow d(A) \neq 0$ by Theorem 3.8.2(vii) and $d(A) = \det A$.
(iii) $(\Leftarrow)$ $d(A) \neq 0 \Rightarrow \det A \neq 0 \Rightarrow A \in \mathrm{GL}(n, \mathbb{F})$ by $d(A) = \det A$ and Theorem 3.8.2(vii).

Structural Commentary: The identity $d = \det$ transfers transpose, product, and invertibility laws.
Key Insight: Exterior normalization and the permutation determinant define the same scalar. □

6.3 Multilinear Algebra Revisited

7 Chain Complexes and Homology

7.1 Chain Complexes

Throughout this subsection, R denotes a nonzero commutative ring with identity 1_R.
All modules are R-modules.

Definition 7.1.1. *Chain Complex*
A *chain complex* $C_\bullet = (C_n, d_n^C)_{n\in\mathbb{Z}}$ consists of R-modules C_n. Its *differentials* are homomorphisms $d_n^C : C_n \to C_{n-1}$.
They satisfy $(\forall\, n \in \mathbb{Z})\, d_{n-1}^C \circ d_n^C = 0$.

Proposition 7.1.2. *Successive Differentials*
Let $C_\bullet$ be a chain complex. Then $(\forall\, n \in \mathbb{Z})$ $\operatorname{im} d_{n+1}^C \leq \ker d_n^C$.

Proof. Fix $n \in \mathbb{Z}$ and $y \in \operatorname{im} d_{n+1}^C$. Choose $x \in C_{n+1}$ with $y = d_{n+1}^C(x)$ by definition of the image.
Then $d_n^C(y) = d_n^C d_{n+1}^C(x) = 0$ by Definition 7.1.1, so $y \in \ker d_n^C$.
Structural Commentary: Differential composition sends image representatives into the next kernel.
Key Insight: Consecutive differentials compose to zero. □

Definition 7.1.3. *Chain Maps and Chain Isomorphisms*
Let $C_\bullet, D_\bullet$ be chain complexes.
(i) A degreewise homomorphism $f_\bullet : C_\bullet \to D_\bullet$ is a family $(f_n)_{n\in\mathbb{Z}}$ with $f_n \in \mathrm{Hom}_R(C_n, D_n)$.
It is a *chain map* if $(\forall\, n \in \mathbb{Z})\, d_n^D f_n = f_{n-1} d_n^C$.
(ii) A chain map $g_\bullet : D_\bullet \to C_\bullet$ is an *inverse* of $f_\bullet$ if $g_\bullet f_\bullet = \mathrm{id}_{C_\bullet}$ and $f_\bullet g_\bullet = \mathrm{id}_{D_\bullet}$.
The map $f_\bullet$ is a *chain isomorphism* if it has an inverse.

Proposition 7.1.4. *Composition and Degreewise Inversion*
Let $C_\bullet, D_\bullet, E_\bullet$ be chain complexes.
(i) $(\mathrm{id}_{C_n})_{n\in\mathbb{Z}}$ *is a chain map* $C_\bullet \to C_\bullet$.
(ii) Let $f_\bullet : C_\bullet \to D_\bullet$ and $g_\bullet : D_\bullet \to E_\bullet$ be chain maps. Then $(g_n f_n)_{n\in\mathbb{Z}}$ is a chain map $C_\bullet \to E_\bullet$.
(iii) Let $f_\bullet : C_\bullet \to D_\bullet$ be a chain map.
Then $f_\bullet$ is a chain isomorphism if and only if $(\forall\, n \in \mathbb{Z})$ f_n is an R-module isomorphism.

Proof.
(i) $(\forall\, n \in \mathbb{Z})\, d_n^C \mathrm{id}_{C_n} = \mathrm{id}_{C_{n-1}} d_n^C = d_n^C$. Identity family is chain map by Definition 7.1.3(i).
(ii) For $n \in \mathbb{Z}$, $d_n^E g_n f_n = g_{n-1} d_n^D f_n = g_{n-1} f_{n-1} d_n^C$ by the chain-map identities for $g_\bullet, f_\bullet$; $(g_n f_n)_{n\in\mathbb{Z}}$ is a chain map.
(iii) $(\Rightarrow)$ Let $g_\bullet$ be an inverse of $f_\bullet$. Then $(\forall\, n \in \mathbb{Z})\, g_n f_n = \mathrm{id}_{C_n}$ and $f_n g_n = \mathrm{id}_{D_n}$ by Definition 7.1.3(ii).
Thus each f_n is an R-module isomorphism.
(iii) $(\Leftarrow)$ Assume each f_n is an R-module isomorphism and set $g_n := f_n^{-1}$.
Fix $n \in \mathbb{Z}$, $(a, b) \in R^2$, and $(y, z) \in D_n^2$. For $x = g_n(y)$ and $w = g_n(z)$, $f_n(ax + bw) = ay + bz$.
Hence $g_n(ay + bz) = ax + bw = a g_n(y) + b g_n(z)$ by bijectivity of f_n, so $g_n \in \mathrm{Hom}_R(D_n, C_n)$.
$d_n^C g_n = g_{n-1} f_{n-1} d_n^C g_n = g_{n-1} d_n^D f_n g_n = g_{n-1} d_n^D$ by the chain-map identity for $f_\bullet$.
Thus $g_\bullet$ is a chain map, and $g_\bullet f_\bullet = \mathrm{id}_{C_\bullet}$ and $f_\bullet g_\bullet = \mathrm{id}_{D_\bullet}$ degreewise.

Structural Commentary: Commuting squares persist under composition and componentwise inversion.
Key Insight: Inverting every component reverses the chain-map square. □

Definition 7.1.5. *Subcomplex*
Let $C_\bullet$ be a chain complex. A *subcomplex* $S_\bullet \leq C_\bullet$ consists of submodules $S_n \leq C_n$ indexed by $n \in \mathbb{Z}$.
They satisfy $(\forall\, n \in \mathbb{Z})\, d_n^C(S_n) \subseteq S_{n-1}$, and their differentials are $d_n^S := d_n^C|_{S_n}$.

Proposition 7.1.6. *Kernel and Image Subcomplexes*
Let $f_\bullet : C_\bullet \to D_\bullet$ be a chain map.

(i) $(\ker f_n)_{n\in\mathbb{Z}}$ *is a subcomplex of* $C_\bullet$.
(ii) $(\operatorname{im} f_n)_{n\in\mathbb{Z}}$ *is a subcomplex of* $D_\bullet$.

Proof.

(i) Each $\ker f_n \le C_n$ by Proposition 1.4.2(ii). Fix $x \in \ker f_n$; $f_{n-1}(d_n^C x) = d_n^D f_n(x) = 0$ by Definition 7.1.3(i), so $d_n^C x \in \ker f_{n-1}$.
(ii) Each $\operatorname{im} f_n \le D_n$ by Proposition 1.4.2(iii). Fix $y \in \operatorname{im} f_n$. Choose $x \in C_n$ with $y = f_n(x)$ by the definition of the image. Then $d_n^D(y) = f_{n-1}(d_n^C x) \in \operatorname{im} f_{n-1}$ by Definition 7.1.3(i).

Structural Commentary: Commuting squares restrict to kernels and transport images.
Key Insight: Commuting with differentials preserves both vanishing and representability. □

Proposition 7.1.7. *Quotient Complex*
Let $C_\bullet$ be a chain complex and let $S_\bullet \le C_\bullet$ be a subcomplex. Set $(C/S)_n := C_n/S_n$.
For $n \in \mathbb{Z}$ and $c \in C_n$, set $\overline{d}_n(c + S_n) := d_n^C(c) + S_{n-1}$.

(i) Each $\overline{d}_n : (C/S)_n \to (C/S)_{n-1}$ *is a well-defined R-homomorphism.*
(ii) $C_\bullet/S_\bullet := ((C/S)_n, \overline{d}_n)_{n\in\mathbb{Z}}$ *is a chain complex.*
(iii) The quotient maps $\pi_n : C_n \twoheadrightarrow C_n/S_n$ form a chain map $\pi_\bullet : C_\bullet \to C_\bullet/S_\bullet$.
(iv) $(\forall\, n \in \mathbb{Z})\ \ker \pi_n = S_n$.

Proof.

(i) If $c + S_n = c' + S_n$, then $c - c' \in S_n$ by Proposition 1.5.2(i). Thus $d_n^C(c - c') \in S_{n-1}$ by Definition 7.1.5. Hence $d_n^C(c) + S_{n-1} = d_n^C(c') + S_{n-1}$ by Proposition 1.5.2(i). Hence $\overline{d}_n$ is well-defined. Fix $(a, b, c, c') \in R^2 \times C_n^2$. $\overline{d}_n\big(a(c + S_n) + b(c' + S_n)\big) = a\overline{d}_n(c + S_n) + b\overline{d}_n(c' + S_n)$ by R-linearity of d_n^C. Thus $\overline{d}_n$ is R-linear.
(ii) For $n \in \mathbb{Z}$ and $c \in C_n$, $\overline{d}_{n-1}\overline{d}_n(c + S_n) = d_{n-1}^C d_n^C(c) + S_{n-2} = S_{n-2}$ by Definition 7.1.1. Hence $\overline{d}_{n-1}\overline{d}_n = 0$.
(iii) For $n \in \mathbb{Z}$ and $c \in C_n$, $\overline{d}_n \pi_n(c) = d_n^C(c) + S_{n-1} = \pi_{n-1} d_n^C(c)$. Thus $\pi_\bullet$ is a chain map by Definition 7.1.3(i).
(iv) $(\forall\, n \in \mathbb{Z})\ \ker \pi_n = S_n$ by Proposition 1.5.2(iii).

Structural Commentary: Subcomplex stability descends differentials and preserves projection kernels.
Key Insight: Differential images of equivalent representatives remain equivalent. □

Definition 7.1.8. *Exact Sequences and Exact Complexes*

(i) Homomorphisms $M' \xrightarrow{u} M \xrightarrow{v} M''$ are *exact at M* if $\operatorname{im} u = \ker v$.
(ii) A sequence of modules and homomorphisms is *exact* if it is exact at each module. An exact sequence $0 \to A \xrightarrow{u} B \xrightarrow{v} C \to 0$ is *short exact*.
(iii) A chain complex $C_\bullet$ is *exact* if $(\forall\, n \in \mathbb{Z})\ \operatorname{im} d_{n+1}^C = \ker d_n^C$.
(iv) Let $u_\bullet : A_\bullet \to B_\bullet$ and $v_\bullet : B_\bullet \to C_\bullet$ be chain maps.
The sequence $0 \to A_\bullet \xrightarrow{u_\bullet} B_\bullet \xrightarrow{v_\bullet} C_\bullet \to 0$ is *short exact* if $(\forall\, n \in \mathbb{Z})$, $0 \to A_n \xrightarrow{u_n} B_n \xrightarrow{v_n} C_n \to 0$ is exact.

Proposition 7.1.9. *Short Exact Sequence Criterion*
Let $u \in \operatorname{Hom}_R(A, B)$ and $v \in \operatorname{Hom}_R(B, C)$. The following conditions are equivalent:

(i) The sequence $0 \to A \xrightarrow{u} B \xrightarrow{v} C \to 0$ is exact.
(ii) The map u is a monomorphism, $\operatorname{im} u = \ker v$, and v is an epimorphism.

Proof.

(i) $\Rightarrow$ *(ii)* Assume (i). Exactness at A implies $\ker u = \operatorname{im}(0 \to A) = \{0_A\}$. Thus u is a monomorphism by Proposition 1.4.2(iv). Exactness at B is $\operatorname{im} u = \ker v$. Exactness at C implies $\operatorname{im} v = \ker(C \to 0) = C$, so v is an epimorphism by Definition 1.4.1(iv).
(ii) $\Rightarrow$ *(i)* Assume (ii). Then $\operatorname{im}(0 \to A) = \{0_A\} = \ker u$ by Proposition 1.4.2(iv). Middle equality is an assumption, and $\operatorname{im} v = C = \ker(C \to 0)$ by surjectivity of v; sequence is exact by Definition 7.1.8(i)–(ii).

Structural Commentary: Endpoints test injectivity and surjectivity; the middle compares image and kernel.
Key Insight: Zero endpoints convert exactness into kernel and image tests. □

Corollary 7.1.10. *Degreewise Criterion for Short Exact Complexes*
Let $u_\bullet : A_\bullet \to B_\bullet$ and $v_\bullet : B_\bullet \to C_\bullet$ be chain maps. The following conditions are equivalent:

(i) The sequence $0 \to A_\bullet \xrightarrow{u_\bullet} B_\bullet \xrightarrow{v_\bullet} C_\bullet \to 0$ is short exact.
(ii) $(\forall\, n \in \mathbb{Z})$, u_n is a monomorphism, $\operatorname{im} u_n = \ker v_n$, and v_n is an epimorphism.

Proof.

(i) $\Rightarrow$ *(ii)* Assume (i) and fix $n \in \mathbb{Z}$. The component sequence is exact by Definition 7.1.8(iv). Thus u_n is a monomorphism, $\operatorname{im} u_n = \ker v_n$, and v_n is an epimorphism by Proposition 7.1.9.
(ii) $\Rightarrow$ *(i)* Assume (ii) and fix $n \in \mathbb{Z}$. Then $0 \to A_n \xrightarrow{u_n} B_n \xrightarrow{v_n} C_n \to 0$ is exact by Proposition 7.1.9. Hence the sequence of chain maps is short exact by Definition 7.1.8(iv).

Structural Commentary: The module criterion transfers short exactness degree by degree.
Key Insight: Short exactness of complexes is componentwise. □

Example 7.1.11. *An Exact Integer Complex*
Take $R = \mathbb{Z}$. Let $u : \mathbb{Z} \to \mathbb{Z}$, $u(n) := 2n$, $\pi : \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ be quotient map. Then u is injective, $\operatorname{im} u = 2\mathbb{Z} = \ker \pi$, and π is surjective. Hence $0 \to \mathbb{Z} \xrightarrow{u} \mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \to 0$ is short exact by Proposition 7.1.9. Set $C_2 = C_1 = \mathbb{Z}$, $C_0 = \mathbb{Z}/2\mathbb{Z}$, and $(\forall\, n \in \mathbb{Z} \setminus \{0, 1, 2\})\, C_n = 0$. Set $d_2^C = u$, $d_1^C = \pi$, and all other differentials equal to zero.
Three checks above and the zero terms imply $(\forall\, n \in \mathbb{Z})\ \operatorname{im} d_{n+1}^C = \ker d_n^C$. Hence $C_\bullet$ is an exact chain complex by Definition 7.1.8(iii).

7.2 Homology

Throughout this subsection, R denotes a nonzero commutative ring with identity 1_R. All modules are R-modules.

Definition 7.2.1. *Cycles, Boundaries, and Homology*
Let $C_\bullet$ be a chain complex and let $n \in \mathbb{Z}$.

(i) The *n-cycle module* is $Z_n(C) := \ker d_n^C$.
(ii) The *n-boundary module* is $B_n(C) := \operatorname{im} d_{n+1}^C$.
(iii) $B_n(C) \leq Z_n(C)$ by Proposition 7.1.2. The *nth homology module* is $H_n(C) := Z_n(C)/B_n(C)$. For $z \in Z_n(C)$, $[z]_C := z + B_n(C)$.

Example 7.2.2. *Homology of a Two-Term Complex*
Take $R = \mathbb{Z}$ and $m \in \mathbb{N}$. Set $C_1 = C_0 = \mathbb{Z}$ and $(\forall\, n \in \mathbb{Z} \setminus \{0,1\})\, C_n = 0$. Set $d_1^C(k) := mk$ and all other differentials equal to zero.
Every consecutive composite is zero, so $C_\bullet$ is a chain complex by Definition 7.1.1.
Then $Z_1(C) = B_1(C) = \{0\}$, $Z_0(C) = \mathbb{Z}$, and $B_0(C) = m\mathbb{Z}$. Hence $H_1(C) = \{0\}$, $H_0(C) = \mathbb{Z}/m\mathbb{Z}$, and $(\forall\, n \in \mathbb{Z} \setminus \{0,1\})\, H_n(C) = \{0\}$.

Proposition 7.2.3. *Exactness Is Vanishing Homology*
Let $C_\bullet$ be a chain complex. The following conditions are equivalent:

(i) The complex $C_\bullet$ is exact.
(ii) $(\forall\, n \in \mathbb{Z})\, H_n(C) = \{0\}$.

Proof.

(i) $\Rightarrow$ (ii) Assume (i), $n \in \mathbb{Z}$. Then $B_n(C) = Z_n(C)$ by Definition 7.1.8(iii); $H_n(C) = Z_n(C)/B_n(C) = \{0\}$ by Definition 7.2.1(iii).
(ii) $\Rightarrow$ (i) Assume (ii), $n \in \mathbb{Z}$. For $z \in Z_n(C)$, $[z]_C = 0_{H_n(C)} = B_n(C)$. Thus $z \in B_n(C)$ by Proposition 1.5.2(i), so $Z_n(C) \subseteq B_n(C)$. The reverse inclusion holds by Proposition 7.1.2. Therefore $Z_n(C) = B_n(C)$, and $C_\bullet$ is exact by Definition 7.1.8(iii).

Structural Commentary: Quotient zero turns boundary containment into degreewise equality.
Key Insight: Zero homology is degreewise exactness. □

Proposition 7.2.4. *Functoriality of Homology*
Let $f_\bullet : C_\bullet \to D_\bullet$ be a chain map and let $n \in \mathbb{Z}$.

(i) $f_n(Z_n(C)) \subseteq Z_n(D)$.
(ii) $f_n(B_n(C)) \subseteq B_n(D)$.
(iii) The rule $H_n(f)([z]_C) := [f_n(z)]_D$ defines $H_n(f) \in \operatorname{Hom}_R(H_n(C), H_n(D))$.
(iv) $H_n(\mathrm{id}_{C_\bullet}) = \mathrm{id}_{H_n(C)}$.
(v) For a chain map $g_\bullet : D_\bullet \to E_\bullet$, $H_n(g_\bullet f_\bullet) = H_n(g)H_n(f)$.
(vi) If $f_\bullet$ is a chain isomorphism, then $H_n(f)$ is an R-module isomorphism.

Proof.

(i) Fix $z \in Z_n(C)$, so $d_n^C(z) = 0$. Then $d_n^D f_n(z) = f_{n-1} d_n^C(z) = 0$ by Definition 7.1.3(i), so $f_n(z) \in Z_n(D)$.
(ii) Fix $b \in B_n(C)$, choose $x \in C_{n+1}$ with $b = d_{n+1}^C(x)$ by Definition 7.2.1(ii); $f_n(b) = d_{n+1}^D f_{n+1}(x) \in B_n(D)$ by Definition 7.1.3(i).
(iii) If $[z]_C = [z']_C$, then $z - z' \in B_n(C)$ by Proposition 1.5.2(i). Thus $f_n(z) - f_n(z') \in B_n(D)$ by (ii), so $[f_n(z)]_D = [f_n(z')]_D$. Hence $H_n(f)$ is well-defined. Fix $(a,b) \in R^2$ and $([z]_C, [z']_C) \in H_n(C)^2$.
$H_n(f)(a[z]_C + b[z']_C) = aH_n(f)([z]_C) + bH_n(f)([z']_C)$ by R-linearity of f_n.
(iv) $(\forall\, z \in Z_n(C))\, H_n(\mathrm{id}_{C_\bullet})([z]_C) = [z]_C$ by the defining rule in (iii).
(v) For $z \in Z_n(C)$, $H_n(g_\bullet f_\bullet)([z]_C) = [g_n f_n(z)]_E = H_n(g)H_n(f)([z]_C)$ by (iii).
(vi) Let $g_\bullet : D_\bullet \to C_\bullet$ be an inverse of $f_\bullet$. Then $H_n(g)H_n(f) = \mathrm{id}_{H_n(C)}$ and $H_n(f)H_n(g) = \mathrm{id}_{H_n(D)}$ by (iv)–(v). The map $H_n(f)$ is bijective by these identities. Hence it is an R-module isomorphism by Definition 1.4.1(iv).

Structural Commentary: Differential commutation descends maps and preserves composition on homology.
Key Insight: Cycle and boundary preservation makes homology functorial. □

Theorem 7.2.5. *Long Exact Sequence in Homology*
Let $0 \to A_\bullet \xrightarrow{u_\bullet} E_\bullet \xrightarrow{v_\bullet} C_\bullet \to 0$ be a short exact sequence of chain complexes.
For $n \in \mathbb{Z}$ and $c \in Z_n(C)$, choose $e \in E_n$ with $v_n(e) = c$. Choose $a \in A_{n-1}$ with $u_{n-1}(a) = d_n^E(e)$, and set $\partial_n([c]_C) := [a]_A$.

(i) The required e, a exist, and $a \in Z_{n-1}(A)$.
(ii) The class $\partial_n([c]_C)$ is independent of the representative c and the choices e, a.
(iii) $\partial_n \in \operatorname{Hom}_R(H_n(C), H_{n-1}(A))$.
(iv) $(\forall\, n \in \mathbb{Z})\ \operatorname{im} \partial_{n+1} = \ker H_n(u)$.
(v) $(\forall\, n \in \mathbb{Z})\ \operatorname{im} H_n(u) = \ker H_n(v)$.
(vi) $(\forall\, n \in \mathbb{Z})\ \operatorname{im} H_n(v) = \ker \partial_n$.

Proof.

(i) Fix $n \in \mathbb{Z}$ and $c \in Z_n(C)$, so $d_n^C(c) = 0$. The map v_n is surjective by Corollary 7.1.10 and Definition 1.4.1(iv). Choose $e \in E_n$ with $v_n(e) = c$. Then $v_{n-1} d_n^E(e) = d_n^C v_n(e) = d_n^C(c) = 0$ by the chain-map identity for $v_\bullet$. Thus $d_n^E(e) \in \ker v_{n-1} = \operatorname{im} u_{n-1}$ by Corollary 7.1.10. Choose $a \in A_{n-1}$ with $u_{n-1}(a) = d_n^E(e)$. $u_{n-2} d_{n-1}^A(a) = d_{n-1}^E d_n^E(e) = 0$ by the chain-map and chain-complex identities. The map u_{n-2} is injective by Corollary 7.1.10 and Definition 1.4.1(iv). Hence $d_{n-1}^A(a) = 0$ and $a \in Z_{n-1}(A)$.
(ii) Fix $n \in \mathbb{Z}$ and let $c, c' \in Z_n(C)$ with $[c]_C = [c']_C$. Let (e, a) and (e'', a'') be construction data for c, c', respectively. Then $c' - c \in B_n(C)$ by Proposition 1.5.2(i). Choose $t \in C_{n+1}$ with $c' - c = d_{n+1}^C(t)$ by Definition 7.2.1(ii). The map v_{n+1} is surjective by Corollary 7.1.10 and Definition 1.4.1(iv). Choose $s \in E_{n+1}$ with $v_{n+1}(s) = t$. Set $e' := e + d_{n+1}^E(s)$. Then $v_n(e') = c + d_{n+1}^C(t) = c'$ by the chain-map identity for $v_\bullet$. $d_n^E(e') = d_n^E(e)$ by Definition 7.1.1, so (e', a) is construction data for c'. Now $e'' - e' \in \ker v_n = \operatorname{im} u_n$ by Corollary 7.1.10. Choose $x \in A_n$ with $u_n(x) = e'' - e'$. $u_{n-1}(a'' - a - d_n^A x) = 0$ by construction data, differential commutation, $u_n(x) = e'' - e'$. The map u_{n-1} is injective by Corollary 7.1.10 and Definition 1.4.1(iv). Thus $a'' - a = d_n^A x \in B_{n-1}(A)$ and $[a'']_A = [a]_A$.
(iii) Fix $n \in \mathbb{Z}$, $(r,s) \in R^2$, and $([c]_C, [c']_C) \in H_n(C)^2$. Let (e, a) and (e', a') be construction data for c, c'. By R-linearity, $(re + se', ra + sa')$ is construction data for $rc + sc'$. Hence $\partial_n(r[c]_C + s[c']_C) = r\partial_n([c]_C) + s\partial_n([c']_C)$ by (ii).

(iv) Fix $n \in \mathbb{Z}$ and $[c]_C \in H_{n+1}(C)$ with construction data (e, a). $H_n(u)\partial_{n+1}([c]_C) = [u_n(a)]_E = [d^E_{n+1}(e)]_E = 0_{H_n(E)}$.
Thus $\operatorname{im}\partial_{n+1} \subseteq \ker H_n(u)$. Let $[a]_A \in \ker H_n(u)$ with $a \in Z_n(A)$. Choose $e \in E_{n+1}$ with $u_n(a) = d^E_{n+1}(e)$ by $[u_n(a)]_E = 0_{H_n(E)}$.
Set $c := v_{n+1}(e)$. Then $d^C_{n+1}(c) = v_n d^E_{n+1}(e) = v_n u_n(a) = 0$, so $c \in Z_{n+1}(C)$.
The pair (e, a) is construction data for c, hence $\partial_{n+1}([c]_C) = [a]_A$.

(v) Fix $n \in \mathbb{Z}$ and $[a]_A \in H_n(A)$. $H_n(v)H_n(u)([a]_A) = [v_n u_n(a)]_C = 0_{H_n(C)}$ by exactness at E_n.
Thus $\operatorname{im} H_n(u) \subseteq \ker H_n(v)$. Let $[e]_E \in \ker H_n(v)$ with $e \in Z_n(E)$. Choose $c \in C_{n+1}$ with $d^C_{n+1}(c) = v_n(e)$ by $[v_n(e)]_C = 0_{H_n(C)}$.
The map v_{n+1} is surjective by Corollary 7.1.10 and Definition 1.4.1(iv). Choose $e' \in E_{n+1}$ with $v_{n+1}(e') = c$.
$v_n(e - d^E_{n+1}(e')) = v_n(e) - d^C_{n+1}(c) = 0$ by chain-map identity for $v_\bullet$. Thus $e - d^E_{n+1}(e') \in \ker v_n = \operatorname{im} u_n$ by Corollary 7.1.10.
Choose $a \in A_n$ with $u_n(a) = e - d^E_{n+1}(e')$. Then $u_{n-1}d^A_n(a) = d^E_n u_n(a) = 0$ by $e \in Z_n(E)$, Definition 7.1.1.
Map u_{n-1} is monomorphism by Corollary 7.1.10; injective by Definition 1.4.1(iv), so $a \in Z_n(A)$; $[e]_E = [u_n(a)]_E = H_n(u)([a]_A)$.

(vi) Fix $n \in \mathbb{Z}$ and $[e]_E \in H_n(E)$. The construction of $\partial_n(H_n(v)([e]_E))$ may use $(e, 0_{A_{n-1}})$, so $\partial_n H_n(v)([e]_E) = 0_{H_{n-1}(A)}$.
Thus $\operatorname{im} H_n(v) \subseteq \ker \partial_n$. Let $[c]_C \in \ker \partial_n$ with construction data (e, a).
Choose $x \in A_n$ with $a = d^A_n(x)$ by $[a]_A = 0_{H_{n-1}(A)}$. Set $e_0 := e - u_n(x)$.
Then $d^E_n(e_0) = d^E_n(e) - u_{n-1}d^A_n(x) = 0$, and $v_n(e_0) = v_n(e) = c$ by exactness at E_n. Hence $e_0 \in Z_n(E)$ and $[c]_C = H_n(v)([e_0]_E)$.

Structural Commentary: Lifts define connecting classes; exactness matches three image–kernel pairs.
Key Insight: Failed cycle lifts become boundaries one degree lower. □

7.3 Derived Functors Preview

Throughout this subsection, R denotes a nonzero commutative ring with identity 1_R. All modules are R-modules.

Definition 7.3.1. *Projective and Injective Modules*
Let P and I be R-modules.

(i) The module P is *projective* if each epimorphism $q : E \to N$ and homomorphism $f : P \to N$ admit $\widetilde{f} \in \operatorname{Hom}_R(P, E)$ with $q\widetilde{f} = f$.
The map $\widetilde{f}$ is a *lift* of f through q.

(ii) The module I is *injective* if each monomorphism $j : A \to B$ and homomorphism $f : A \to I$ admit $\widetilde{f} \in \operatorname{Hom}_R(B, I)$ with $\widetilde{f}j = f$.
The map $\widetilde{f}$ is an *extension* of f along j.

Theorem 7.3.2. *Basic Projective Constructions*
Assume the Choice Principle 6.1.2.

(i) Every free R-module is projective.
(ii) Every retract of a projective R-module is projective.
(iii) Every direct summand of a free R-module is projective.

Proof.

(i) Let F be free with basis $\mathcal{B}$, let $q : E \to N$ be an epimorphism, and let $f : F \to N$ be a homomorphism.
Then $(\forall\, b \in \mathcal{B})\, q^{-1}(\{f(b)\}) \neq \emptyset$ by surjectivity of q. Choose $(e_b)_{b\in\mathcal{B}} \in \prod_{b\in\mathcal{B}} q^{-1}(\{f(b)\})$ by the Choice Principle.
The assignment $b \mapsto e_b$ extends uniquely to $\widetilde{f} \in \operatorname{Hom}_R(F, E)$ by Theorem 2.1.4.
Maps $q\widetilde{f}$ and f agree on $\mathcal{B}$, so $q\widetilde{f} = f$ by the uniqueness clause of that theorem; F is projective by Definition 7.3.1(i).

(ii) Let Q be a retract of a projective module P, with $i : Q \to P$, $r : P \to Q$, and $ri = \mathrm{id}_Q$.
Let $q : E \to N$ be an epimorphism and let $f : Q \to N$ be a homomorphism.
Choose $h : P \to E$ with $qh = fr$ by projectivity of P; $q(hi) = f(ri) = f$, so hi lifts f; Q is projective by Definition 7.3.1(i).

(iii) Let Q be a direct summand of a free module F. Then Q is a retract of F by Corollary 1.8.3.
The module F is projective by (i), so Q is projective by (ii).

Structural Commentary: Basis lifts establish freeness, and retractions transfer lifting problems to a projective ambient module.
Key Insight: Projectivity is stable under retracts. □

Proposition 7.3.3. *Injective Submodules Split*
Let I be injective and let $j : I \to E$ be a monomorphism.

(i) The map j has a left inverse $r : E \to I$.
(ii) The submodule $\operatorname{im} j$ is a direct summand of E.

Proof.

(i) Choose $r : E \to I$ with $rj = \mathrm{id}_I$ by injectivity of I, applied to $\mathrm{id}_I : I \to I$.

(ii) We prove $E = \operatorname{im} j \oplus \ker r$. For $e \in E$, $e = j(r(e)) + (e - j(r(e)))$ and $r(e - j(r(e))) = r(e) - (rj)(r(e)) = 0$.
Hence $E = \operatorname{im} j + \ker r$. If $x \in \operatorname{im} j \cap \ker r$, choose $a \in I$ with $x = j(a)$.
Then $a = (rj)(a) = r(x) = 0$, so $x = 0$. Thus the sum is direct.

Structural Commentary: Extending the identity of I produces a retraction, whose kernel is a complementary summand.
Key Insight: Injective modules split every monomorphism out of them. □

Definition 7.3.4. *Cochain Complexes and Cohomology*

(i) A *cochain complex* $K^\bullet = (K^n, \delta^n_K)_{n\in\mathbb{Z}}$ consists of homomorphisms $\delta^n_K : K^n \to K^{n+1}$ satisfying $(\forall\, n \in \mathbb{Z})\, \delta^{n+1}_K \delta^n_K = 0$.

(ii) The associated chain complex $K_\sharp$ is defined by $(K_\sharp)_m := K^{-m}$ and $d^{K_\sharp}_m := \delta^{-m}_K$.

(iii) Set $Z^n(K) := \ker \delta^n_K$ and $B^n(K) := \operatorname{im} \delta^{n-1}_K$. Then $B^n(K) \leq Z^n(K)$ by Proposition 7.1.2 applied to $K_\sharp$.
The *nth cohomology module* is $H^n(K) := Z^n(K)/B^n(K) = H_{-n}(K_\sharp)$.

Definition 7.3.5. *Projective and Injective Resolutions*

(i) A *projective resolution* of M consists of a chain complex $P_\bullet = (P_n, d_n)_{n\in\mathbb{Z}}$ and an epimorphism $\varepsilon : P_0 \to M$.
It satisfies $(\forall\, n < 0)\, P_n = 0$, $\ker\varepsilon = \operatorname{im} d_1$, $(\forall\, n \in \mathbb{N})\ \operatorname{im} d_{n+1} = \ker d_n$, and each P_n for $n \in \mathbb{N}_0$ is projective.

(ii) An *injective resolution* of N consists of a cochain complex $I^\bullet = (I^n, \delta^n_I)_{n\in\mathbb{Z}}$ and a monomorphism $\eta : N \to I^0$.
It satisfies $(\forall\, n < 0)\, I^n = 0$, $\operatorname{im}\eta = \ker\delta^0_I$, $(\forall\, n \in \mathbb{N})\ \operatorname{im}\delta^{n-1}_I = \ker\delta^n_I$, and each I^n for $n \in \mathbb{N}_0$ is injective.

Proposition 7.3.6. *The Hom Cochain Complex*
Let M be an R-module and let $I^\bullet = (I^n, \delta_I^n)_{n\in\mathbb{Z}}$ be a cochain complex. For $n \in \mathbb{Z}$, set $C^n := \mathrm{Hom}_R(M, I^n)$ and $\Delta^n(\varphi) := \delta_I^n \varphi$.

(i) Each $\Delta^n : C^n \to C^{n+1}$ is an R-module homomorphism.
(ii) The family $C^\bullet = (C^n, \Delta^n)_{n\in\mathbb{Z}}$ is a cochain complex.

Proof.

(i) Fix $(a, b) \in R^2$ and $(\varphi, \psi) \in (C^n)^2$. Then $\Delta^n(a\varphi + b\psi) = a\Delta^n(\varphi) + b\Delta^n(\psi)$ by R-linearity of δ_I^n.

(ii) For $\varphi \in C^n$, $\Delta^{n+1}\Delta^n(\varphi) = \delta_I^{n+1}\delta_I^n\varphi = 0$ by Definition 7.3.4(i). Hence $C^\bullet$ is a cochain complex by that definition.

Structural Commentary: The covariant variable of $\mathrm{Hom}_R(M, -)$ preserves the direction of the coboundary maps.
Key Insight: Applying $\mathrm{Hom}_R(M, -)$ to an injective resolution produces a cochain complex. □

Definition 7.3.7. *Chosen-Resolution Model for Ext*
Let M, N be R-modules, and let $(I^\bullet, \eta)$ be an injective resolution of N. For $n \in \mathbb{N}_0$, set $\mathrm{Ext}_R^n(M, N; I^\bullet) := H^n\big(\mathrm{Hom}_R(M, I^\bullet)\big)$.
The resolution remains in the notation because resolution independence is not part of this definition.

Perspective 7.3.8. *Resolution Models for Tor and Ext*
After tensor products of arbitrary R-modules and their induced maps are developed, a projective resolution $P_\bullet \to M$ produces a tensor complex with terms $P_n \otimes_R N$. Its homology is the projective-resolution model for $\mathrm{Tor}_n^R(M, N)$, parallel to Definition 7.3.7.
A comparison theorem is still required to identify the models from different resolutions by canonical isomorphisms.
Until that theorem and the module-level tensor construction are available, the abbreviations $\mathrm{Tor}_n^R(M, N)$ and $\mathrm{Ext}_R^n(M, N)$ are forward notation rather than proof authority.

Part IX
Commutative Algebra

1 Prime Ideals and Spectra

1.1 Prime Ideals

Definition 1.1.1. *Prime Ideals*
Let R be a commutative ring with identity. An ideal $\mathfrak{p} \trianglelefteq R$ is *prime* if $\mathfrak{p} \neq R$ and $(\forall\, a, b \in R)\,[ab \in \mathfrak{p} \Rightarrow (a \in \mathfrak{p} \vee b \in \mathfrak{p})]$.

Theorem 1.1.2. *Prime Ideals and Quotient Domains*
Let R be a commutative ring with identity and $\mathfrak{p} \trianglelefteq R$. Then $\mathfrak{p}$ is prime $\iff$ $R/\mathfrak{p}$ is an integral domain.

Proof.
($\Rightarrow$) Assume $\mathfrak{p}$ is prime. The ring $R/\mathfrak{p}$ is commutative with identity $1_R + \mathfrak{p}$ by Definition 3.4.1.
The relation $1_R \notin \mathfrak{p}$ holds by $\mathfrak{p} \neq R$ and ideal absorption. The relation $1_R + \mathfrak{p} \neq \mathfrak{p}$ holds by additive-coset equality.
Fix $a, b \in R$ and assume $(a+\mathfrak{p})(b+\mathfrak{p}) = \mathfrak{p}$. The relation $ab \in \mathfrak{p}$ holds by quotient multiplication and additive-coset equality.
The relation $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$ holds by Definition 1.1.1. The relation $a+\mathfrak{p} = \mathfrak{p}$ or $b+\mathfrak{p} = \mathfrak{p}$ holds by additive-coset equality.
The ring $R/\mathfrak{p}$ has no zero divisors by this zero-product test. It is an integral domain by Definition 3.5.1.
($\Leftarrow$) Assume $R/\mathfrak{p}$ is an integral domain. The relation $\mathfrak{p} \neq R$ holds by its distinct zero and identity cosets.
Fix $a, b \in R$ and assume $ab \in \mathfrak{p}$. The equality $(a+\mathfrak{p})(b+\mathfrak{p}) = \mathfrak{p}$ holds by quotient multiplication and additive-coset equality.
The relation $a+\mathfrak{p} = \mathfrak{p}$ or $b+\mathfrak{p} = \mathfrak{p}$ holds by absence of zero divisors. Relation $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$ holds by additive-coset equality.
The ideal $\mathfrak{p}$ is prime by Definition 1.1.1.
Structural Commentary: Quotient multiplication transfers the zero-divisor test to product membership in $\mathfrak{p}$.
Key Insight: A zero product of cosets is precisely a product in $\mathfrak{p}$. □

Corollary 1.1.3. *Maximal Ideals Are Prime*
Let R be a commutative ring with identity. Every maximal ideal of R is prime.

Proof. Let $\mathfrak{m} \trianglelefteq R$ be maximal. The quotient $R/\mathfrak{m}$ is a field by Theorem 3.4.4.
Fix $x, y \in R/\mathfrak{m}$ with $xy = 0$ and $x \neq 0$. The equality $y = x^{-1}(xy) = 0$ holds by field inversion.
The quotient $R/\mathfrak{m}$ is an integral domain by Definition 3.5.1. The ideal $\mathfrak{m}$ is prime by Theorem 1.1.2.
Structural Commentary: The quotient-field theorem feeds the quotient-domain criterion.
Key Insight: Invertibility excludes zero divisors in every field. □

Definition 1.1.4. *Radicals and Radical Ideals*
Let R be a commutative ring with identity and $\mathcal{I} \trianglelefteq R$.
The *radical* of $\mathcal{I}$ is $\operatorname{rad}(\mathcal{I}) := \sqrt{\mathcal{I}} := \{r \in R : (\exists\, n \in \mathbb{N})\, r^n \in \mathcal{I}\}$. The ideal $\mathcal{I}$ is *radical* if $\sqrt{\mathcal{I}} = \mathcal{I}$.

Proposition 1.1.5. *Radical Closure*
Let R be a commutative ring with identity and $\mathcal{I} \trianglelefteq R$.
(i) $\sqrt{\mathcal{I}} \trianglelefteq R$.
(ii) $\mathcal{I} \subseteq \sqrt{\mathcal{I}}$.
(iii) The ideal $\sqrt{\mathcal{I}}$ is radical: $\operatorname{rad}(\operatorname{rad}(\mathcal{I})) = \operatorname{rad}(\mathcal{I})$.
(iv) If $\mathcal{J} \trianglelefteq R$ is radical and $\mathcal{I} \subseteq \mathcal{J}$, then $\sqrt{\mathcal{I}} \subseteq \mathcal{J}$.

Proof.
(i) The relation $0_R \in \sqrt{\mathcal{I}}$ holds by $0_R^1 \in \mathcal{I}$. Fix $x, y \in \sqrt{\mathcal{I}}$ and choose $m, n \in \mathbb{N}$ with $x^m, y^n \in \mathcal{I}$.
For $0 \leq k \leq m+n$, either $k \geq m$ or $m+n-k \geq n$; the relation $x^k(-y)^{m+n-k} \in \mathcal{I}$ holds by ideal absorption.
The relation $(x-y)^{m+n} \in \mathcal{I}$ holds by distributivity, ideal absorption, and additive closure; $x - y \in \sqrt{\mathcal{I}}$ by Definition 1.1.4.
For $r \in R$, $(rx)^m = r^m x^m \in \mathcal{I}$ by commutativity and ideal absorption. The relation $rx = xr \in \sqrt{\mathcal{I}}$ holds by Definition 1.1.4.
The conclusion $\sqrt{\mathcal{I}} \trianglelefteq R$ holds by Definition 3.3.1.
(ii) Fix $x \in \mathcal{I}$; $x^1 = x \in \mathcal{I}$. The relation $x \in \sqrt{\mathcal{I}}$ holds by Definition 1.1.4. The inclusion $\mathcal{I} \subseteq \sqrt{\mathcal{I}}$ holds by this element test.
(iii) Fix $x \in \operatorname{rad}(\mathcal{I})$; $x^1 \in \operatorname{rad}(\mathcal{I})$. The relation $x \in \operatorname{rad}(\operatorname{rad}(\mathcal{I}))$ holds by Definition 1.1.4.
Inclusion $\operatorname{rad}(\mathcal{I}) \subseteq \operatorname{rad}(\operatorname{rad}(\mathcal{I}))$ holds by this element test. If $x \in \operatorname{rad}(\operatorname{rad}(\mathcal{I}))$, choose $m \in \mathbb{N}$ with $x^m \in \operatorname{rad}(\mathcal{I})$.
Relation $(\exists\, n \in \mathbb{N})\, x^{mn} = (x^m)^n \in \mathcal{I}$ holds by Definition 1.1.4, exponent laws. Relation $x \in \operatorname{rad}(\mathcal{I})$ holds by Definition 1.1.4.
Equality $\operatorname{rad}(\operatorname{rad}(\mathcal{I})) = \operatorname{rad}(\mathcal{I})$ holds by mutual inclusion. Ideal $\sqrt{\mathcal{I}}$ is radical by Definition 1.1.4.
(iv) Let $\mathcal{J} \trianglelefteq R$ be radical with $\mathcal{I} \subseteq \mathcal{J}$. If $x \in \sqrt{\mathcal{I}}$, choose $n \in \mathbb{N}$ with $x^n \in \mathcal{I} \subseteq \mathcal{J}$.
The relation $x \in \sqrt{\mathcal{J}} = \mathcal{J}$ holds by Definition 1.1.4. The inclusion $\sqrt{\mathcal{I}} \subseteq \mathcal{J}$ holds by this element test.
Structural Commentary: Power witnesses establish ideal closure, idempotence, and minimality under radical containment.
Key Insight: A sufficiently large power absorbs every term in a binomial expansion. □

1.2 Spectra

Definition 1.2.1. *Spectrum, Vanishing Sets, and Principal Complements*
Let R be a commutative ring with identity.
(i) The *prime spectrum* of R is $\operatorname{Spec} R := \{\mathfrak{p} \trianglelefteq R : \mathfrak{p} \text{ is prime}\}$.
(ii) For $\mathcal{I} \trianglelefteq R$, set $V(\mathcal{I}) := \{\mathfrak{p} \in \operatorname{Spec} R : \mathcal{I} \subseteq \mathfrak{p}\}$.
(iii) For $f \in R$, set $D(f) := \operatorname{Spec} R \setminus V(\langle f \rangle)$.

Proposition 1.2.2. *Vanishing-Set Calculus*
Let R be a commutative ring with identity, $\mathcal{I}, \mathcal{J} \trianglelefteq R$. Let $\{\mathcal{I}_\alpha\}_{\alpha \in A}$ be a nonempty family of ideals of R.
(i) $V(\langle 0_R \rangle) = \operatorname{Spec} R$.
(ii) $V(R) = \emptyset$.

(iii) $\bigcap_{\alpha\in A} V(\mathcal{I}_\alpha) = V\left(\left\langle \bigcup_{\alpha\in A} \mathcal{I}_\alpha \right\rangle\right)$.
(iv) $V(\mathcal{I}) \cup V(\mathcal{J}) = V(\mathcal{I}\cap\mathcal{J})$.

Proof.

(i) Fix $\mathfrak{p} \in \operatorname{Spec} R$. The relation $0_R \in \mathfrak{p}$ holds by the ideal property. The inclusion $\langle 0_R\rangle \subseteq \mathfrak{p}$ holds by Proposition 3.3.2.
The equality $V(\langle 0_R\rangle) = \operatorname{Spec} R$ holds by Definition 1.2.1(ii) and set extensionality.
(ii) Fix $\mathfrak{p} \in \operatorname{Spec} R$. The relation $R \nsubseteq \mathfrak{p}$ holds by Definition 1.1.1. The equality $V(R) = \emptyset$ holds by Definition 1.2.1(ii).
(iii) Set $\mathcal{K} := \left\langle \bigcup_{\alpha\in A} \mathcal{I}_\alpha \right\rangle$. Fix $\mathfrak{p} \in \operatorname{Spec} R$. Membership in $\bigcap_{\alpha\in A} V(\mathcal{I}_\alpha)$ is equivalent to $\bigcup_{\alpha\in A} \mathcal{I}_\alpha \subseteq \mathfrak{p}$ by Definition 1.2.1(ii).
The latter inclusion is equivalent to $\mathcal{K} \subseteq \mathfrak{p}$ by Proposition 3.3.2.
The asserted equality holds by Definition 1.2.1(ii) and set extensionality.
(iv) The inclusions $\mathcal{I}\cap\mathcal{J} \subseteq \mathcal{I}$ and $\mathcal{I}\cap\mathcal{J} \subseteq \mathcal{J}$ hold by definition of intersection.
The inclusion $V(\mathcal{I}) \cup V(\mathcal{J}) \subseteq V(\mathcal{I}\cap\mathcal{J})$ holds by Definition 1.2.1(ii). Fix $\mathfrak{p} \in V(\mathcal{I}\cap\mathcal{J})$ and assume $\mathfrak{p} \notin V(\mathcal{I}) \cup V(\mathcal{J})$.
Choose $a \in \mathcal{I} \setminus \mathfrak{p}$ and $b \in \mathcal{J} \setminus \mathfrak{p}$ by the failed containments. The relation $ab \in \mathcal{I}\cap\mathcal{J} \subseteq \mathfrak{p}$ holds by ideal absorption.
This contradicts primeness by Definition 1.1.1. The reverse inclusion holds by contradiction.

Structural Commentary: Generated unions control intersections; primality converts ideal intersections into finite unions.
Key Insight: A product in $\mathcal{I}\cap\mathcal{J}$ detects which ideal a prime contains. □

Proposition 1.2.3. *Principal-Complement Calculus*
Let R be a commutative ring with identity and let $f, g \in R$.

(i) $D(0_R) = \emptyset$.
(ii) $D(1_R) = \operatorname{Spec} R$.
(iii) $D(f) \cap D(g) = D(fg)$.

Proof.

(i) The equality $D(0_R) = \operatorname{Spec} R \setminus V(\langle 0_R\rangle) = \emptyset$ holds by Proposition 1.2.2(i).
(ii) The equality $\langle 1_R\rangle = R$ holds by Definition 3.3.1. The equality $D(1_R) = \operatorname{Spec} R \setminus V(R) = \operatorname{Spec} R$ holds by Proposition 1.2.2(ii).
(iii) The relation $(\forall\,(\mathfrak{p}, h) \in \operatorname{Spec} R \times R)\,[\mathfrak{p} \in D(h) \iff h \notin \mathfrak{p}]$ holds by Definition 1.2.1(iii) and Proposition 3.3.2.
Fix $\mathfrak{p} \in \operatorname{Spec} R$. The equivalence $\mathfrak{p} \in D(f)\cap D(g) \iff (f \notin \mathfrak{p} \wedge g \notin \mathfrak{p})$ holds by the preceding test.
The equivalence $(f \notin \mathfrak{p} \wedge g \notin \mathfrak{p}) \iff fg \notin \mathfrak{p}$ holds by ideal absorption and Definition 1.1.1.
The equivalence $fg \notin \mathfrak{p} \iff \mathfrak{p} \in D(fg)$ holds by the preceding test. The equality $D(f)\cap D(g) = D(fg)$ holds by set extensionality.

Structural Commentary: Complementation transfers boundary values and primality to principal-complement intersections.
Key Insight: The product fg avoids a prime exactly when both factors do. □

2 Localization and Local Rings

2.1 Localization

Definition 2.1.1. *Multiplicative Sets and Ring Localization*
Let R be a commutative ring with identity.

(i) A subset $S \subseteq R$ is *multiplicative* if $1_R \in S$ and $(\forall\, s, t \in S)\, st \in S$.
(ii) On $R \times S$, define $(r, s) \sim (r', s') \iff (\exists\, u \in S)\, u(s'r - sr') = 0_R$.
(iii) The *localization* of R at S is $S^{-1}R := (R \times S)/\!\sim$; write $[(r, s)]_\sim = r/s$.
(iv) For $(r, s), (r', s') \in R \times S$, define $\frac{r}{s} + \frac{r'}{s'} := \frac{s'r + sr'}{ss'}$ and $\frac{r}{s}\frac{r'}{s'} := \frac{rr'}{ss'}$. Set $0_{S^{-1}R} := 0_R/1_R$ and $1_{S^{-1}R} := 1_R/1_R$.

Proposition 2.1.2. *Ring Localization Construction*
Let R be a commutative ring with identity and let $S \subseteq R$ be multiplicative.

(i) The relation $\sim$ on $R \times S$ is an equivalence relation.
(ii) The fraction operations are well defined and make $S^{-1}R$ a commutative ring with identity.
(iii) The map $\lambda_S : R \to S^{-1}R$, $\lambda_S(r) := r/1_R$, is a ring homomorphism.
(iv) $\lambda_S(S) \subseteq (S^{-1}R)^\times$.
(v) $\ker(\lambda_S) = \{r \in R : (\exists\, s \in S)\, sr = 0_R\}$.

Proof.

(i) Fix $(r, s), (r', s') \in R \times S$. Then $(r, s) \sim (r, s)$ with witness $1_R \in S$.
If $(r, s) \sim (r', s')$ with witness $u \in S$, then $u(sr' - s'r) = -u(s'r - sr') = 0_R$, so $(r', s') \sim (r, s)$.
For transitivity, assume $(a, s) \sim (b, t)$ via $u \in S$ and $(b, t) \sim (c, q)$ via $v \in S$.
Then $uvt(qa - sc) = uvq(ta - sb) + uvs(qb - tc) = 0_R$ by the two witness identities. Thus $(a, s) \sim (c, q)$ with witness $uvt \in S$.
(ii) Assume $a/s = a'/s'$ with witness $u \in S$ and $b/t = b'/t'$ with witness $v \in S$.
The cross-multiplied sum difference is $tt'(s'a - sa') + ss'(t'b - tb')$ and vanishes after multiplication by uv.
The cross-multiplied product difference is $t'b(s'a - sa') + sa'(t'b - tb')$ and likewise vanishes after multiplication by uv.
Since $uv \in S$, both operations are well defined by Definition 2.1.1(ii).
Fix $(a, s), (b, t), (c, q) \in R \times S$. Then $(a/s + b/t) + c/q = (tqa + sqb + stc)/(stq) = a/s + (b/t + c/q)$.
$((a/s)(b/t))(c/q) = abc/(stq) = (a/s)((b/t)(c/q))$. Fraction operations are commutative by commutativity of R.
Distributivity holds by $(a/s)(b/t + c/q) = (aqb + atc)/(stq) = ab/(st) + ac/(sq)$.
The classes $0_R/1_R$ and $1_R/1_R$ are the identities, while $-(a/s) = (-a)/s$; hence $S^{-1}R$ is a commutative ring with identity.
(iii) Fix $a, b \in R$. The identities $\lambda_S(a + b) = \lambda_S(a) + \lambda_S(b)$, $\lambda_S(ab) = \lambda_S(a)\lambda_S(b)$, and $\lambda_S(1_R) = 1$ hold by Definition 2.1.1(iv).
(iv) Fix $s \in S$. Then $\lambda_S(s) \in (S^{-1}R)^\times$ by $\lambda_S(s)(1_R/s) = 1$.
(v) For $r \in R$, $\lambda_S(r) = 0 \iff (\exists\, u \in S)\, ur = 0_R$ by Definition 2.1.1(ii).

Structural Commentary: Witness products secure equivalence and operations; representatives verify ring laws.
Key Insight: One denominator witness certifies every equality of localized fractions. □

Theorem 2.1.3. *Universal Property of Ring Localization*
Let R, A be commutative rings with identity, $S \subseteq R$ be multiplicative, $\varphi : R \to A$ ring homomorphism satisfying $\varphi(S) \subseteq A^\times$.

(i) The rule $\widetilde{\varphi} : S^{-1}R \to A$, $r/s \mapsto \varphi(r)\varphi(s)^{-1}$, is a ring homomorphism. It satisfies $\widetilde{\varphi} \circ \lambda_S = \varphi$.
(ii) The homomorphism $\widetilde{\varphi}$ is unique subject to $\widetilde{\varphi} \circ \lambda_S = \varphi$.

Proof.

(i) If $r/s = r'/s'$, choose $u \in S$ with $u(s'r - sr') = 0_R$ by Definition 2.1.1(ii).
Then $\varphi(s')\varphi(r) = \varphi(s)\varphi(r')$ by the homomorphism property and cancellation of the unit $\varphi(u)$.
The equality $\widetilde{\varphi}(r/s) = \widetilde{\varphi}(r'/s')$ holds by multiplication by $\varphi(s)^{-1}\varphi(s')^{-1}$. Thus the rule is well defined. Fix $(r,s),(r',s') \in R \times S$.
$\widetilde{\varphi}(r/s + r'/s') = \varphi(s'r + sr')\varphi(ss')^{-1} = \widetilde{\varphi}(r/s) + \widetilde{\varphi}(r'/s')$; $\widetilde{\varphi}((r/s)(r'/s')) = \varphi(rr')\varphi(ss')^{-1} = \widetilde{\varphi}(r/s)\widetilde{\varphi}(r'/s')$.
The map $\widetilde{\varphi}$ is a ring homomorphism by these identities and $\widetilde{\varphi}(1_R/1_R) = 1_A$. Equality $\widetilde{\varphi} \circ \lambda_S = \varphi$ holds by $\widetilde{\varphi}(r/1_R) = \varphi(r)$.
(ii) Let $\psi : S^{-1}R \to A$ be a ring homomorphism with $\psi \circ \lambda_S = \varphi$. Fix $(r,s) \in R \times S$.
$\psi(r/s) = \psi(\lambda_S(r))\psi(\lambda_S(s))^{-1} = \varphi(r)\varphi(s)^{-1} = \widetilde{\varphi}(r/s)$. Thus $\psi = \widetilde{\varphi}$ by function extensionality.

Structural Commentary: Unit cancellation descends fractions; denominator factorization forces uniqueness.
Key Insight: Images of numerators and inverted denominators determine every localized homomorphism. □

Definition 2.1.4. *Module Localization*
Let R be a commutative ring with identity, let $S \subseteq R$ be multiplicative, and let M be an R-module.

(i) On $M \times S$, define $(m,s) \sim (n,t) \iff (\exists\, u \in S)\, u(tm - sn) = 0_M$.
(ii) Set $S^{-1}M := (M \times S)/\sim$ and write $[(m,s)]_\sim = m/s$.
(iii) For $(m,s),(n,t) \in M \times S$, define $\frac{m}{s} + \frac{n}{t} := \frac{tm+sn}{st}$. For $(r,q) \in R \times S$ and $(m,s) \in M \times S$, define $\frac{r}{q}\frac{m}{s} := \frac{rm}{qs}$.

Proposition 2.1.5. *Module Localization Construction*
Let R be a commutative ring with identity, let $S \subseteq R$ be multiplicative, and let M be an R-module.

(i) The relation $\sim$ on $M \times S$ is an equivalence relation.
(ii) The fraction operations are well defined and make $S^{-1}M$ an $S^{-1}R$-module.
(iii) The map $\eta_S : M \to S^{-1}M$, $m \mapsto m/1_R$, is R-linear via $r \cdot x := \lambda_S(r)x$.
(iv) $\ker(\eta_S) = \{m \in M : (\exists\, s \in S)\, sm = 0_M\}$.

Proof.

(i) Fix $(m,s),(n,t) \in M \times S$. Then $(m,s) \sim (m,s)$ with witness $1_R \in S$.
If $(m,s) \sim (n,t)$ with witness $u \in S$, then $u(sn - tm) = -u(tm - sn) = 0_M$, so $(n,t) \sim (m,s)$.
Assume $(m,s) \sim (n,t)$ via $u \in S$ and $(n,t) \sim (p,q)$ via $v \in S$.
Then $uvt(qm - sp) = uvq(tm - sn) + uvs(qn - tp) = 0_M$ by the two witness identities. Thus $(m,s) \sim (p,q)$ with witness $uvt \in S$.
(ii) Assume $m/s = m'/s'$ with witness $u \in S$ and $n/t = n'/t'$ with witness $v \in S$.
The cross-multiplied sum difference is $tt'(s'm - sm') + ss'(t'n - tn')$ and vanishes after multiplication by uv.
Thus addition is well defined by Definition 2.1.4(i). Assume $a/q = a'/q'$ in $S^{-1}R$ with witness $w \in S$.
The scalar-product difference is $s'm(q'a - qa') + qa'(s'm - sm')$ and vanishes after multiplication by uw.
Thus scalar multiplication is well defined by Definitions 2.1.1(ii) and 2.1.4(i).
For $(m,s),(n,t),(p,u) \in M \times S$, $(m/s + n/t) + p/u = (tum + sun + stp)/(stu) = m/s + (n/t + p/u)$.
Localized addition is commutative by commutativity of M; $0_M/1_R$ and $(-m)/s$ are its identity and inverses.
Fix $a/q, b/t \in S^{-1}R$ and $m/s, n/u \in S^{-1}M$. Then $((a/q)(b/t))(m/s) = abm/(qts) = (a/q)((b/t)(m/s))$,
$((a/q) + (b/t))(m/s) = (tam + qbm)/(qts) = (a/q)(m/s) + (b/t)(m/s)$,
$(a/q)(m/s + n/u) = (aum + asn)/(qsu) = (a/q)(m/s) + (a/q)(n/u)$, and $(1_R/1_R)(m/s) = m/s$; $S^{-1}M$ is an $S^{-1}R$-module.
(iii) Fix $r \in R$ and $m,n \in M$. The identities $\eta_S(m+n) = \eta_S(m) + \eta_S(n)$ and $\eta_S(rm) = \lambda_S(r)\eta_S(m)$ hold by Definition 2.1.4(iii).
(iv) For $m \in M$, $\eta_S(m) = 0 \iff (\exists\, s \in S)\, sm = 0_M$ by Definition 2.1.4(i).

Structural Commentary: Witness products descend addition and scalars; representatives verify module laws.
Key Insight: Local vanishing is equivalent to annihilation by one denominator. □

Theorem 2.1.6. *Universal Property of Module Localization*
Let R be a commutative ring with identity, $S \subseteq R$ be multiplicative, M be an R-module.
Let N be an $S^{-1}R$-module, $\psi : M \to N$ be R-linear for action $r \cdot x := \lambda_S(r)x$.

(i) The rule $\widetilde{\psi} : S^{-1}M \to N$, $m/s \mapsto (1_R/s)\psi(m)$, is $S^{-1}R$-linear. It satisfies $\widetilde{\psi} \circ \eta_S = \psi$.
(ii) The map $\widetilde{\psi}$ is unique subject to $\widetilde{\psi} \circ \eta_S = \psi$.

Proof.

(i) If $m/s = n/t$, choose $u \in S$, $u(tm - sn) = 0_M$ by Definition 2.1.4(i); $\lambda_S(u)[\lambda_S(t)\psi(m) - \lambda_S(s)\psi(n)] = 0_N$ by R-linearity of ψ.
The equality $(1_R/s)\psi(m) = (1_R/t)\psi(n)$ holds by cancelling the unit $\lambda_S(u)$ and scaling by $\lambda_S(s)^{-1}\lambda_S(t)^{-1}$.
Thus the rule is well defined. Fix $(m,s),(n,t) \in M \times S$ and $r/q \in S^{-1}R$.
$\widetilde{\psi}(m/s + n/t) = \frac{1_R}{st}\psi(tm + sn) = \frac{1_R}{s}\psi(m) + \frac{1_R}{t}\psi(n)$; $\widetilde{\psi}((r/q)(m/s)) = \frac{1_R}{qs}\psi(rm) = \frac{r}{q}\frac{1_R}{s}\psi(m) = \frac{r}{q}\widetilde{\psi}(m/s)$.
The map $\widetilde{\psi}$ is $S^{-1}R$-linear by the preceding identities. The equality $\widetilde{\psi} \circ \eta_S = \psi$ holds by $\widetilde{\psi}(m/1_R) = \psi(m)$.
(ii) Let $\theta : S^{-1}M \to N$ be $S^{-1}R$-linear with $\theta \circ \eta_S = \psi$. Fix $(m,s) \in M \times S$.
$\theta(m/s) = (1_R/s)\theta(m/1_R) = (1_R/s)\psi(m) = \widetilde{\psi}(m/s)$. Thus $\theta = \widetilde{\psi}$ by function extensionality.

Structural Commentary: Unit cancellation descends module fractions; factorization forces uniqueness.
Key Insight: Denominator-one values determine every localized module map. □

Definition 2.1.7. *Extension and Contraction under Localization*
Let R be a commutative ring with identity and let $S \subseteq R$ be multiplicative.

(i) The *extension* of $\mathcal{I} \trianglelefteq R$ is $\mathcal{I}^{\mathrm{e}} := S^{-1}\mathcal{I} = \{a/s : a \in \mathcal{I},\, s \in S\}$.
(ii) The *contraction* of $\mathcal{J} \trianglelefteq S^{-1}R$ is $\mathcal{J}^{\mathrm{c}} := \lambda_S^{-1}(\mathcal{J})$.

Proposition 2.1.8. *Localization Extension–Contraction Calculus*
Let R be a commutative ring with identity, $S \subseteq R$ be multiplicative. Let $\mathcal{I} \trianglelefteq R$ and $\mathcal{J} \trianglelefteq S^{-1}R$.

(i) $\mathcal{I}^{\mathrm{e}} \trianglelefteq S^{-1}R$.
(ii) $(\forall\,(r,s) \in R \times S)\,[r/s \in \mathcal{I}^{\mathrm{e}} \iff (\exists\,u \in S)\,ur \in \mathcal{I}]$.
(iii) $\mathcal{J}^{\mathrm{c}} \trianglelefteq R$.
(iv) $\mathcal{I}^{\mathrm{e}} = S^{-1}R \iff \mathcal{I} \cap S \neq \emptyset$.

Proof.

(i) $0_R/1_R \in \mathcal{I}^{\mathrm{e}}$ holds by $0_R \in \mathcal{I}$. Fix $(a,s),(b,t) \in \mathcal{I} \times S$ and $r/q \in S^{-1}R$; then $(a/s) - (b/t) = (ta - sb)/(st) \in \mathcal{I}^{\mathrm{e}}$ by $ta - sb \in \mathcal{I}$. The membership $(r/q)(a/s) = ra/(qs) \in \mathcal{I}^{\mathrm{e}}$ holds by ideal absorption. Thus $\mathcal{I}^{\mathrm{e}} \trianglelefteq S^{-1}R$ by the ideal axioms.
(ii) ($\Rightarrow$) Assume $r/s \in \mathcal{I}^{\mathrm{e}}$, $(a,t) \in \mathcal{I} \times S$ with $r/s = a/t$. Choose $u \in S$ satisfying $u(tr - sa) = 0_R$ by Definition 2.1.1(ii). Then $(ut)r = u(sa) \in \mathcal{I}$ by ideal absorption, and $ut \in S$ by multiplicativity.
(ii) ($\Leftarrow$) Choose $u \in S$ satisfying $ur \in \mathcal{I}$. Then $r/s = (ur)/(us) \in \mathcal{I}^{\mathrm{e}}$ by Definitions 2.1.1(ii) and 2.1.7(i).
(iii) The relation $0_R \in \mathcal{J}^{\mathrm{c}}$ holds by $\lambda_S(0_R) = 0 \in \mathcal{J}$. Fix $a,b \in \mathcal{J}^{\mathrm{c}}$ and $r \in R$. $\lambda_S(a-b) = \lambda_S(a) - \lambda_S(b) \in \mathcal{J}$ and $\lambda_S(ra) = \lambda_S(r)\lambda_S(a) \in \mathcal{J}$ by ideal closure; $\mathcal{J}^{\mathrm{c}} \trianglelefteq R$ by Definition 2.1.7(ii) and ideal axioms.
(iv) ($\Rightarrow$) Assume $\mathcal{I}^{\mathrm{e}} = S^{-1}R$. Choose $u \in S \cap \mathcal{I}$ by $1_R/1_R \in \mathcal{I}^{\mathrm{e}}$ and (ii).
(iv) ($\Leftarrow$) Choose $u \in \mathcal{I} \cap S$. Then $1_R/1_R \in \mathcal{I}^{\mathrm{e}}$ by (ii), so $\mathcal{I}^{\mathrm{e}} = S^{-1}R$ by ideal absorption.

Structural Commentary: Ideal closure handles both transfers; numerator membership detects the unit ideal.
Key Insight: Extension membership depends only on a denominator multiple of the numerator. □

Theorem 2.1.9. *Prime Ideals under Localization*
Let R be a commutative ring with identity and let $S \subseteq R$ be multiplicative. Set $\mathcal{X}_S := \{\mathfrak{p} \in \operatorname{Spec} R : \mathfrak{p} \cap S = \emptyset\}$. The assignment $\mathfrak{q} \mapsto \mathfrak{q}^{\mathrm{c}}$ is a bijection $\operatorname{Spec}(S^{-1}R) \to \mathcal{X}_S$; its inverse is $\mathfrak{p} \mapsto \mathfrak{p}^{\mathrm{e}}$.

Proof.

(i) *Contraction*: Fix $\mathfrak{q} \in \operatorname{Spec}(S^{-1}R)$. Then $\mathfrak{q}^{\mathrm{c}} \trianglelefteq R$ by Proposition 2.1.8(iii). The ideal $\mathfrak{q}^{\mathrm{c}}$ is proper by $\lambda_S(1_R) = 1 \notin \mathfrak{q}$. If $ab \in \mathfrak{q}^{\mathrm{c}}$, then $\lambda_S(a)\lambda_S(b) = \lambda_S(ab) \in \mathfrak{q}$. Hence $a \in \mathfrak{q}^{\mathrm{c}}$ or $b \in \mathfrak{q}^{\mathrm{c}}$ by primeness of $\mathfrak{q}$; $\mathfrak{q}^{\mathrm{c}} \in \operatorname{Spec} R$ by Definition 1.1.1. Fix $s \in S$. The element $\lambda_S(s)$ is a unit by Proposition 2.1.2(iv). The relation $\lambda_S(s) \notin \mathfrak{q}$ holds by properness and ideal absorption. Therefore $\mathfrak{q}^{\mathrm{c}} \cap S = \emptyset$ by Definition 2.1.7(ii).
(ii) *Extension*: Fix $\mathfrak{p} \in \mathcal{X}_S$. Then $\mathfrak{p}^{\mathrm{e}} \trianglelefteq S^{-1}R$ by Proposition 2.1.8(i). The ideal $\mathfrak{p}^{\mathrm{e}}$ is proper by Proposition 2.1.8(iv). Fix $(a,s),(b,t) \in R \times S$ and suppose $(a/s)(b/t) \in \mathfrak{p}^{\mathrm{e}}$. Choose $u \in S$ with $uab \in \mathfrak{p}$ by Proposition 2.1.8(ii). The relation $ab \in \mathfrak{p}$ holds by $u \notin \mathfrak{p}$ and primeness; hence $a \in \mathfrak{p}$ or $b \in \mathfrak{p}$ by primeness. Thus $a/s \in \mathfrak{p}^{\mathrm{e}}$ or $b/t \in \mathfrak{p}^{\mathrm{e}}$ by Definition 2.1.7(i). Therefore $\mathfrak{p}^{\mathrm{e}} \in \operatorname{Spec}(S^{-1}R)$ by Definition 1.1.1.
(iii) *Contracting an Extension*: Fix $\mathfrak{p} \in \mathcal{X}_S$ and $r \in R$. The equivalence $r \in (\mathfrak{p}^{\mathrm{e}})^{\mathrm{c}} \iff r/1_R \in \mathfrak{p}^{\mathrm{e}}$ holds by Definition 2.1.7(ii). The latter condition is equivalent to $(\exists\,u \in S)\,ur \in \mathfrak{p}$ by Proposition 2.1.8(ii). If $ur \in \mathfrak{p}$ for $u \in S$, then $u \notin \mathfrak{p}$ and $r \in \mathfrak{p}$ by primeness. Converse holds with $u = 1_R$. Hence $(\mathfrak{p}^{\mathrm{e}})^{\mathrm{c}} = \mathfrak{p}$ by set extensionality.
(iv) *Extending a Contraction*: Fix $\mathfrak{q} \in \operatorname{Spec}(S^{-1}R)$. If $r \in \mathfrak{q}^{\mathrm{c}}$ and $s \in S$, then $r/s = (r/1_R)(1_R/s) \in \mathfrak{q}$; $(\mathfrak{q}^{\mathrm{c}})^{\mathrm{e}} \subseteq \mathfrak{q}$. Conversely, fix $(r,s) \in R \times S$ with $r/s \in \mathfrak{q}$. Then $r/1_R = (s/1_R)(r/s) \in \mathfrak{q}$, so $r \in \mathfrak{q}^{\mathrm{c}}$ by Definition 2.1.7(ii). Thus $r/s \in (\mathfrak{q}^{\mathrm{c}})^{\mathrm{e}}$ by Definition 2.1.7(i); $(\mathfrak{q}^{\mathrm{c}})^{\mathrm{e}} = \mathfrak{q}$ by mutual inclusion. Asserted bijection follows by (i)–(iv).

Structural Commentary: Primality survives both transfers; numerator tests prove mutual inversion.
Key Insight: A localized prime records exactly which original elements avoid all denominators. □

Definition 2.1.10. *Principal Denominator Set*
Let R be a commutative ring with identity and let $f \in R$. Define $S_f := \{f^n : n \in \mathbb{N}_0\}$.

Proposition 2.1.11. *Canonical Denominator Sets*
Let R be a commutative ring with identity, let $f \in R$, and let $\mathfrak{p} \in \operatorname{Spec} R$.

(i) The set S_f is multiplicative.
(ii) The set $R \setminus \mathfrak{p}$ is multiplicative.

Proof.

(i) Multiplicativity holds by $1_R = f^0 \in S_f$ and $(\forall\,m,n \in \mathbb{N}_0)\,f^m f^n = f^{m+n} \in S_f$.
(ii) The relation $1_R \notin \mathfrak{p}$ holds by properness of $\mathfrak{p}$. If $a,b \notin \mathfrak{p}$, then $ab \notin \mathfrak{p}$ by the contrapositive of primeness.

Structural Commentary: Powers and prime complements form the two denominator systems.
Key Insight: Primeness is precisely what makes a complement closed under multiplication. □

Definition 2.1.12. *Principal and Prime Localizations*
Let R be a commutative ring with identity and let M be an R-module. Fix $f \in R$ and $\mathfrak{p} \in \operatorname{Spec} R$.

(i) The *principal localizations* are $R_f := S_f^{-1}R$ and $M_f := S_f^{-1}M$.
(ii) The *localizations at* $\mathfrak{p}$ are $R_{\mathfrak{p}} := (R \setminus \mathfrak{p})^{-1}R$ and $M_{\mathfrak{p}} := (R \setminus \mathfrak{p})^{-1}M$.

Proposition 2.1.13. *Canonical Localization Consequences*
Let R be a commutative ring with identity and let M be an R-module.

(i) $(\forall\,f \in R)$*, contraction induces a bijection* $\operatorname{Spec}(R_f) \to D(f)$.
(ii) $(\forall\,(\mathfrak{p},m) \in \operatorname{Spec} R \times M)\,[m/1_R = 0_{M_{\mathfrak{p}}} \iff (\exists\,s \in R \setminus \mathfrak{p})\,sm = 0_M]$.
(iii) $(\forall\,m \in M)\,[m = 0_M \iff (\forall\,\mathfrak{p} \in \operatorname{Spec} R)\,m/1_R = 0_{M_{\mathfrak{p}}}]$.
(iv) If R is an integral domain with field of quotients K, then $(R \setminus \{0_R\})^{-1}R \cong K$ canonically.

Proof.

(i) Fix $f \in R$ and $\mathfrak{p} \in \operatorname{Spec} R$. The equivalence $\mathfrak{p} \cap S_f = \emptyset \iff f \notin \mathfrak{p}$ holds by primeness and induction. Equivalence $f \notin \mathfrak{p} \iff \mathfrak{p} \in D(f)$ holds by Proposition 1.2.3(iii). Asserted bijection follows by Theorem 2.1.9.
(ii) ($\Rightarrow$) Fix $(\mathfrak{p},m) \in \operatorname{Spec} R \times M$ and assume $m/1_R = 0_{M_{\mathfrak{p}}}$. The set $R \setminus \mathfrak{p}$ is multiplicative by Proposition 2.1.11(ii). Choose $s \in R \setminus \mathfrak{p}$ satisfying $sm = 0_M$ by Proposition 2.1.5(iv).
(ii) ($\Leftarrow$) Fix $(\mathfrak{p},m) \in \operatorname{Spec} R \times M$, $s \in R \setminus \mathfrak{p}$ satisfying $sm = 0_M$. Equality $m/1_R = 0_{M_{\mathfrak{p}}}$ holds by Proposition 2.1.5(iv).

(*iii*) ($\Rightarrow$) Fix $m \in M$, $m = 0_M$. Relation $(\forall \mathfrak{p} \in \operatorname{Spec} R)\, m/1_R = 0_{M_\mathfrak{p}}$ holds by (ii) with $s = 1_R$.
(*iii*) ($\Leftarrow$) Fix $m \in M$. For contrapositive, suppose $m \neq 0_M$, $\mathcal{A} := \operatorname{Ann}_R(m)$. The set $\mathcal{A}$ is an ideal by Proposition 1.6.5(i).
It is proper by $m \neq 0_M$, $1_R m = m$, and Definition 1.6.4(i). Set $\mathcal{P} := \{\mathcal{I} \trianglelefteq R : \mathcal{A} \subseteq \mathcal{I},\ \mathcal{I} \neq R\}$, ordered by inclusion.
Then $\mathcal{A} \in \mathcal{P}$, and $\mathcal{P}$ is a nonempty poset by Proposition 6.1.5. The ideal $\mathcal{A}$ is an upper bound for the empty chain.
Fix a nonempty chain $\mathcal{C} \subseteq \mathcal{P}$, $\mathcal{U} := \bigcup_{\mathcal{I} \in \mathcal{C}} \mathcal{I}$; $\mathcal{U} \trianglelefteq R$ by Proposition 3.3.3. Inclusion $\mathcal{A} \subseteq \mathcal{U}$ holds by $\mathcal{C} \neq \emptyset$, $(\forall \mathcal{I} \in \mathcal{C})\, \mathcal{A} \subseteq \mathcal{I}$.
Relation $1_R \notin \mathcal{U}$ holds by $(\forall \mathcal{I} \in \mathcal{C})\, 1_R \notin \mathcal{I}$; $\mathcal{U} \in \mathcal{P}$ is upper bound for $\mathcal{C}$; chain-upper-bound hypothesis of Principle 6.1.3 holds.
Choose a maximal $\mathfrak{m} \in \mathcal{P}$ by Principle 6.1.3. If $\mathfrak{m} \subseteq \mathcal{J} \trianglelefteq R$ and $\mathcal{J} \neq R$, then $\mathcal{J} \in \mathcal{P}$; $\mathfrak{m}$ is maximal in R by Definition 3.4.3.
Ideal $\mathfrak{m}$ prime by Corollary 1.1.3. If $m/1_R = 0_{M_\mathfrak{m}}$, choose $s \in R \setminus \mathfrak{m}$ with $sm = 0_M$ by (ii); contradicts $s \in \operatorname{Ann}_R(m) = \mathcal{A} \subseteq \mathfrak{m}$.
The inequality $m/1_R \neq 0_{M_\mathfrak{m}}$ holds by contradiction; the contrapositive follows by this prime $\mathfrak{m}$.
(*iv*) The set $R \setminus \{0_R\}$ is multiplicative by the integral-domain axioms Fix $r, r' \in R$ and $s, s' \in R \setminus \{0_R\}$.
The relation $(r, s) \sim (r', s')$ is equivalent to $s'r = sr'$ by cancellation.
Thus the localization and field-of-quotients equivalence relations and fraction operations agree by Definition 3.5.3.
The identity on $R \times (R \setminus \{0_R\})$ therefore descends to the canonical ring isomorphism.

Structural Commentary: Prime correspondence handles denominators; maximal annihilators detect nonvanishing.
Key Insight: Vanishing in all prime localizations detects the zero element. □

2.2 Local Rings

Definition 2.2.1. *Local Rings*
A commutative ring R with identity is *local* if it has a unique maximal ideal $\mathfrak{m}$. This unique ideal is the *maximal ideal* of R.

Definition 2.2.2. *Localized Prime Ideal*
Let R be a commutative ring with identity and let $\mathfrak{p} \in \operatorname{Spec} R$. The *localized prime ideal* is $\mathfrak{p}R_\mathfrak{p} := (R \setminus \mathfrak{p})^{-1}\mathfrak{p}$.

Proposition 2.2.3. *Elements of a Prime Localization*
Let R be a commutative ring with identity, $\mathfrak{p} \in \operatorname{Spec} R$. Let $(a, s) \in R \times (R \setminus \mathfrak{p})$.

(i) $a/s \in \mathfrak{p}R_\mathfrak{p} \iff a \in \mathfrak{p}$.
(ii) $a/s \notin \mathfrak{p}R_\mathfrak{p} \implies a \in R \setminus \mathfrak{p}$.
(iii) If $a \in R \setminus \mathfrak{p}$, then s/a is a multiplicative inverse of a/s in $R_\mathfrak{p}$.

Proof.

(*i*) ($\Rightarrow$) Assume $a/s \in \mathfrak{p}R_\mathfrak{p}$. Choose $u \in R \setminus \mathfrak{p}$ with $ua \in \mathfrak{p}$ by Proposition 2.1.8(ii); $a \in \mathfrak{p}$ by $u \notin \mathfrak{p}$ and primeness.
(*i*) ($\Leftarrow$) Assume $a \in \mathfrak{p}$. Then $a/s \in \mathfrak{p}R_\mathfrak{p}$ by Definition 2.2.2.
(*ii*) The implication holds by the contrapositive of (i).
(*iii*) The membership $s/a \in R_\mathfrak{p}$ holds by $a \in R \setminus \mathfrak{p}$. The identity $(a/s)(s/a) = 1_{R_\mathfrak{p}}$ holds by Definition 2.1.1(ii),(iv).

Structural Commentary: Extension tests numerators; swapping fractions constructs inverses.
Key Insight: Numerators outside $\mathfrak{p}$ become denominators for explicit inverses. □

Theorem 2.2.4. *Prime Localizations Are Local*
Let R be a commutative ring with identity and let $\mathfrak{p} \in \operatorname{Spec} R$.

(i) The ideal $\mathfrak{p}R_\mathfrak{p}$ is the unique maximal ideal of $R_\mathfrak{p}$.
(ii) The ring $R_\mathfrak{p}$ is local.
(iii) The quotient ring $R_\mathfrak{p}/\mathfrak{p}R_\mathfrak{p}$ is a field.

Proof.

(i) The relation $\mathfrak{p}R_\mathfrak{p} \trianglelefteq R_\mathfrak{p}$ holds by Proposition 2.1.8(i). The ideal is proper by $\mathfrak{p} \cap (R \setminus \mathfrak{p}) = \emptyset$ and Proposition 2.1.8(iv).
Fix a proper ideal $\mathcal{J} \trianglelefteq R_\mathfrak{p}$ and assume $\mathcal{J} \not\subseteq \mathfrak{p}R_\mathfrak{p}$. Choose $x \in \mathcal{J} \setminus \mathfrak{p}R_\mathfrak{p}$ by the failed inclusion.
Choose $(a, s) \in R \times (R \setminus \mathfrak{p})$ with $x = a/s$ by Definition 2.1.1(iii); $a \in R \setminus \mathfrak{p}$ and $(a/s)(s/a) = 1_{R_\mathfrak{p}}$ by Proposition 2.2.3(ii),(iii).
The membership $1_{R_\mathfrak{p}} = x(s/a) \in \mathcal{J}$ contradicts properness by ideal absorption. Thus $\mathcal{J} \subseteq \mathfrak{p}R_\mathfrak{p}$.
Fix $\mathcal{K} \trianglelefteq R_\mathfrak{p}$ with $\mathfrak{p}R_\mathfrak{p} \subseteq \mathcal{K}$ and $\mathcal{K} \neq R_\mathfrak{p}$. Then $\mathcal{K} \subseteq \mathfrak{p}R_\mathfrak{p}$ by the proper-ideal containment.
Hence $\mathcal{K} = \mathfrak{p}R_\mathfrak{p}$, so $\mathfrak{p}R_\mathfrak{p}$ is maximal by Definition 3.4.3. If $\mathfrak{m} \trianglelefteq R_\mathfrak{p}$ is maximal, then $\mathfrak{m} \subseteq \mathfrak{p}R_\mathfrak{p}$ by the proper-ideal containment.
Therefore $\mathfrak{m} = \mathfrak{p}R_\mathfrak{p}$ by maximality of $\mathfrak{m}$ and properness of $\mathfrak{p}R_\mathfrak{p}$.
(ii) The ring $R_\mathfrak{p}$ is local by (i) and Definition 2.2.1.
(iii) The quotient is a field by (i) and Theorem 3.4.4.

Structural Commentary: Explicit inverses force proper ideals into $\mathfrak{p}R_\mathfrak{p}$; quotient theory finishes.
Key Insight: Fractions outside $\mathfrak{p}R_\mathfrak{p}$ invert by swapping numerator and denominator. □

Definition 2.2.5. *Residue Fields*
Let R be a commutative ring with identity.

(i) If R is local with maximal ideal $\mathfrak{m}$, its *residue field* is $R/\mathfrak{m}$.
(ii) For $\mathfrak{p} \in \operatorname{Spec} R$, the *residue field at $\mathfrak{p}$* is $k(\mathfrak{p}) := R_\mathfrak{p}/\mathfrak{p}R_\mathfrak{p}$.

3 Noetherian Rings and Modules

3.1 Noetherian Rings

Theorem 3.1.1. *Hilbert Basis Theorem*
Let A be a nonzero commutative ring with identity. If A is Noetherian, then $A[x]$ is Noetherian.

Proof.

(i) *Reduction*: By Theorem 2.4.2(ii), to prove $(\forall \mathcal{J} \trianglelefteq A[x])\, \mathcal{J}$ is f.g. Fix $\mathcal{J} \trianglelefteq A[x]$. If $\mathcal{J} = 0$, then $\mathcal{J} = \langle 0 \rangle$; assume $\mathcal{J} \neq 0$.
For $g = \sum_{j=0}^{n} b_j x^j \in A[x]$ with $n \in \mathbb{N}_0$ and $b_n \neq 0$, set $\deg g := n$ and $\operatorname{lc}(g) := b_n$.

(ii) *Leading-Coefficient Generators*: Set $L := \langle \mathrm{lc}(g) : g \in \mathcal{J} \setminus \{0\} \rangle \trianglelefteq A$.
The ideal L is f.g. by Noetherianity of A and Theorem 2.4.2(ii). Choose generators $\ell_1, \dots, \ell_s$ of L by finite generation of L.
Each ℓ_j is a finite A-linear combination of displayed leading coefficients by Definition 3.3.1(ii).
Write the collected coefficients as $\mathrm{lc}(f_1), \dots, \mathrm{lc}(f_m)$ with $(f_1, \dots, f_m) \in (\mathcal{J} \setminus \{0\})^m$.
$L = \langle \mathrm{lc}(f_i) : 1 \le i \le m \rangle$ by the generator expansions and the definition of L.
Set $d := \max\limits_{1 \le i \le m} \deg f_i$ and replace each f_i with $x^{d - \deg f_i} f_i$.
$(\forall\, i \in \{1, \dots, m\})\, [f_i \in \mathcal{J} \wedge \deg f_i = d]$ by ideal absorption and the definition of d.
$L = \langle \mathrm{lc}(f_i) : 1 \le i \le m \rangle$ by invariance of leading coefficients under these monomial shifts.

(iii) *Low-Degree Generators*: For $0 \le k < d$, set $L_k := \langle \mathrm{lc}(g) : g \in \mathcal{J},\ \deg g = k \rangle$. Each L_k is f.g. by Theorem 2.4.2(ii).
Choose finite generators of L_k by its finite generation.
Each generator is a finite A-linear combination of those coefficients by Definition 3.3.1(ii).
Let $P_k \subseteq \{p \in \mathcal{J} : \deg p = k\}$ be the corresponding finite polynomial set.
Then $L_k = \langle \mathrm{lc}(p) : p \in P_k \rangle$ by the generator expansions and the definition of L_k.
Set $G := \{f_1, \dots, f_m\} \cup \bigcup\limits_{0 \le k < d} P_k$ and $\mathcal{I} := \langle G \rangle \trianglelefteq A[x]$.
The set G is finite by finiteness of the index range and each constituent. $\mathcal{I} \subseteq \mathcal{J}$ by Proposition 3.3.2.

(iv) *Degree Descent*: Suppose $\mathcal{I} \neq \mathcal{J}$. Set $D := \{\deg u + 1 : u \in \mathcal{J} \setminus \mathcal{I}\} \subseteq \mathbb{N}$. $D \neq \emptyset$ by $\mathcal{I} \neq \mathcal{J}$.
Choose $g \in \mathcal{J} \setminus \mathcal{I}$ with $\deg g + 1 = \min D$ by Assumption 2.6.1. Set $r := \deg g$. If $r < d$, then $\mathrm{lc}(g) \in L_r$ by the definition of L_r.
Choose $(c_p)_{p \in P_r} \in A^{P_r}$ by generation of L_r by the leading coefficients indexed by P_r.
$\mathrm{lc}(g) = \sum\limits_{p \in P_r} c_p \,\mathrm{lc}(p)$ by the choice of $(c_p)_{p \in P_r}$. In this case, set $h := \sum\limits_{p \in P_r} c_p p$. If $r \ge d$, then $\mathrm{lc}(g) \in L$ by the definition of L.
Choose $c_1, \dots, c_m \in A$ by $L = \langle \mathrm{lc}(f_i) : 1 \le i \le m \rangle$. $\mathrm{lc}(g) = \sum\limits_{i=1}^{m} c_i \,\mathrm{lc}(f_i)$ by the choice of $c_1, \dots, c_m$.
In this case, set $h := \sum\limits_{i=1}^{m} c_i x^{r-d} f_i$. In both cases, $h \in \mathcal{I}$, $\deg h = r$, and $\mathrm{lc}(h) = \mathrm{lc}(g)$ by construction.
If $g - h \in \mathcal{I}$, then $g = (g - h) + h \in \mathcal{I}$, a contradiction. Hence $g - h \in \mathcal{J} \setminus \mathcal{I}$ by $g, h \in \mathcal{J}$ and the contradiction above.
$\deg(g - h) < r$ by cancellation of the degree-r coefficient.
$\deg(g - h) + 1 \in D$ by $g - h \in \mathcal{J} \setminus \mathcal{I}$, while $\deg(g - h) + 1 < \min D$ by the preceding inequality, a contradiction.
$\mathcal{J} = \mathcal{I} = \langle G \rangle$ by contradiction; hence $\mathcal{J}$ is f.g. $A[x]$ is Noetherian by arbitrariness of $\mathcal{J}$ and Theorem 2.4.2(ii).

Structural Commentary: Finite leading-coefficient data span $\mathcal{J}$ by degree descent.
Key Insight: Matching the leading coefficient cancels the highest-degree term. □

3.2 Noetherian Modules

Theorem 3.2.1. *Finitely Generated Modules over Noetherian Rings*
Let A be a nonzero commutative ring with identity. Then A is Noetherian $\iff$ $(\forall\, M)\, [M$ is an f.g. A-module $\Rightarrow M$ is Noetherian$]$.

Proof.

($\Rightarrow$) Assume A is Noetherian.

(a) *Finite Free Modules*: For $n \in \mathbb{N}$, set $Q(n) := (\forall\, S \le A^n)\, S$ is f.g.; $Q(1)$ holds by Definition 2.4.1(ii), Theorem 2.4.2(i).
Fix $n \in \mathbb{N}$, $Q(n)$, $S \le A^{n+1}$. Let $\pi \in \mathrm{Hom}_A(S, A)$ be last-coordinate projection. Set $K := \{v \in A^n : (v, 0_A) \in S\} \subseteq A^n$.
$0_{A^n} \in K$ by $(0_{A^n}, 0_A) = 0_{A^{n+1}} \in S$. $(\forall\, (a, b, v, w) \in A^2 \times K^2)\, av + bw \in K$ by $(av + bw, 0_A) = a(v, 0_A) + b(w, 0_A) \in S$.
$K \le A^n$ by Theorem 1.1.5. $\ker \pi \le S$ by Proposition 1.4.2(ii). Map $v \mapsto (v, 0_A)$ identifies K with $\ker \pi$ by definition of π.
Thus K is f.g. by $Q(n)$. The image $\pi(S) \le {}_A A$ by Proposition 1.4.2(iii). The module $\pi(S)$ is f.g. by $Q(1)$.
Choose $p \in \mathbb{N}$ and $(k_1, \dots, k_p) \in K^p$ by finite generation of K. $K = \langle\!\langle k_1, \dots, k_p \rangle\!\rangle_A$ by the choice of $(k_1, \dots, k_p)$.
Choose $q \in \mathbb{N}$ and $(t_1, \dots, t_q) \in \pi(S)^q$ by finite generation of $\pi(S)$. $\pi(S) = \langle\!\langle t_1, \dots, t_q \rangle\!\rangle_A$ by the choice of $(t_1, \dots, t_q)$.
Choose $(s_1, \dots, s_q) \in S^q$ satisfying $(\forall\, j \in \{1, \dots, q\})\, \pi(s_j) = t_j$ by the definition of $\pi(S)$.
Fix $s \in S$. Choose $(a_1, \dots, a_q) \in A^q$ satisfying $\pi(s) = \sum\limits_{j=1}^{q} a_j t_j$ by generation of $\pi(S)$.
Set $u := s - \sum\limits_{j=1}^{q} a_j s_j \in \ker \pi$ by A-linearity of π and the preceding equality. Write $u = (k, 0_A)$ with $k \in K$.
Choose $(b_1, \dots, b_p) \in A^p$ satisfying $k = \sum\limits_{i=1}^{p} b_i k_i$ by generation of K.
$s = \sum\limits_{j=1}^{q} a_j s_j + \sum\limits_{i=1}^{p} b_i (k_i, 0_A)$ by the defining equations for u, k, and $(b_i)_{i=1}^{p}$.
Thus S is f.g. by arbitrariness of s, closure of S, and Definition 1.2.3(ii).
$Q(n+1)$ holds by arbitrariness of S; $(\forall\, n \in \mathbb{N})\, Q(n)$ by Theorem 2.6.2; $(\forall\, n \in \mathbb{N})\, [A^n$ is Noetherian$]$ by Theorem 2.4.2(i).

(b) *Finite Free Cover*: Fix an f.g. A-module M. Choose $n \in \mathbb{N}$ and $(v_1, \dots, v_n) \in M^n$ by finite generation of M.
$M = \langle\!\langle v_1, \dots, v_n \rangle\!\rangle_A$ by choice of $(v_1, \dots, v_n)$. Define $\varphi : A^n \to M$ by $\varphi(r_1, \dots, r_n) := \sum\limits_{i=1}^{n} r_i v_i$.
The map φ is A-linear by the module laws and surjective by generation of M.

(c) *Submodule Preimages*: Fix $N \le M$ and set $P := \varphi^{-1}(N) \subseteq A^n$. $0_{A^n} \in P$ by $\varphi(0_{A^n}) = 0_M \in N$.
$(\forall\, (a, b, x, y) \in A^2 \times P^2)\, ax + by \in P$ by A-linearity of φ and closure of N. $P \le A^n$ by Theorem 1.1.5.
Module P is f.g. by Noetherianity of A^n, Theorem 2.4.2(i). Choose $m \in \mathbb{N}$ and $(p_1, \dots, p_m) \in P^m$ by finite generation of P.
$P = \langle\!\langle p_1, \dots, p_m \rangle\!\rangle_A$ by the choice of $(p_1, \dots, p_m)$. $N = \varphi(P)$ by surjectivity of φ and the definition of P.
$N = \langle\!\langle \varphi(p_1), \dots, \varphi(p_m) \rangle\!\rangle_A$ by A-linearity of φ and generation of P. Hence M is Noetherian by Theorem 2.4.2(i).
The forward implication holds by arbitrariness of M.

($\Leftarrow$) Assume $(\forall\, M)\, [M$ is an f.g. A-module $\Rightarrow M$ is Noetherian$]$. Regular module ${}_A A = \langle\!\langle 1_A \rangle\!\rangle_A$ is f.g. by Definition 1.2.3(ii).
It is Noetherian by the hypothesis. Hence A is Noetherian by Definition 2.4.1(ii).

Structural Commentary: Induction handles A^n; free covers transfer Noetherianity to quotients.
Key Insight: Generators of $\varphi^{-1}(N)$ map to generators of N. □

4 Integral Dependence and Dimension

4.1 Integral Dependence

4.2 Dimension Theory

5 Regularity and Singularities

5.1 Regularity

Definition 5.1.1. *Ideal Multiples and the Local Cotangent Module*
Let R be a commutative ring with identity, let $\mathcal{I} \trianglelefteq R$, and let M be an R-module.

(i) The *ideal multiple* of M is $\mathcal{I}M := \langle\!\langle ax : (a,x) \in \mathcal{I} \times M \rangle\!\rangle_R$.
(ii) If R is local with maximal ideal $\mathfrak{m}$, set $\mathfrak{m}^2 := \mathfrak{m}\mathfrak{m}$. The quotient R-module $\mathfrak{m}/\mathfrak{m}^2$ is the *local cotangent module* of R.

Proposition 5.1.2. *Units in a Local Ring*
Let R be nonzero commutative local ring with identity and maximal ideal $\mathfrak{m}$. Then $(\forall\, a \in R)\,[a \notin \mathfrak{m} \iff (\exists\, b \in R)\, ab = 1_R]$.

Proof.
($\Rightarrow$) Fix $a \notin \mathfrak{m}$ and suppose $(\forall\, b \in R)\, ab \neq 1_R$. Then $\mathcal{I} := \langle a \rangle$ is proper. The quotient $S := R/\mathcal{I}$ is nonzero.
Choose a maximal ideal $\mathfrak{n} \trianglelefteq S$ by Theorem 3.4.5. Let $q : R \twoheadrightarrow S$ be the quotient map and set $\mathfrak{p} := q^{-1}(\mathfrak{n})$.
The set $\mathfrak{p}$ is a proper ideal by closure of $\mathfrak{n}$ and $1_S \notin \mathfrak{n}$. Let $\mathfrak{p} \subseteq \mathcal{J} \trianglelefteq R$. The image $q(\mathcal{J}) \trianglelefteq S$ by surjectivity of q and ideal closure.
Equality $q(\mathfrak{p}) = \mathfrak{n}$ holds by surjectivity of q, so $\mathfrak{n} \subseteq q(\mathcal{J})$. Thus $q(\mathcal{J}) = \mathfrak{n}$ or $q(\mathcal{J}) = S$ by maximality.
In first case, $\mathcal{J} = \mathfrak{p}$ by $\ker q = \mathcal{I} \subseteq \mathfrak{p}$. In second case, choose $j \in \mathcal{J}$ with $q(j) = 1_S$; then $1_R - j \in \mathcal{I} \subseteq \mathcal{J}$, so $\mathcal{J} = R$.
Hence $\mathfrak{p}$ is maximal by Definition 3.4.3, and $\mathfrak{p} = \mathfrak{m}$ by locality. But $a \in \mathcal{I} \subseteq \mathfrak{p} = \mathfrak{m}$, a contradiction.
($\Leftarrow$) If $ab = 1_R$ and $a \in \mathfrak{m}$, then $1_R = ab \in \mathfrak{m}$ by ideal absorption, contradicting properness of $\mathfrak{m}$.
Structural Commentary: Maximal ideals above a nonunit principal ideal reduce invertibility to membership in $\mathfrak{m}$.
Key Insight: Every nonunit lies in the unique maximal ideal. □

Theorem 5.1.3. *Nakayama's Lemma*
Let R be a nonzero commutative local ring with identity and maximal ideal $\mathfrak{m}$.
If M is a finitely generated R-module and $\mathfrak{m}M = M$, then $M = \{0_M\}$.

Proof.
(i) *Minimal Generators*: Suppose $M \neq \{0_M\}$.
Choose a generating tuple $(x_i)_{i=1}^n$ of minimal positive length by finite generation and Assumption 2.6.1.
(ii) *Coefficient Relation*: The tuple $(x_i)_{i=1}^n$ generates M.
Thus $(\forall\, y \in \mathfrak{m}M)(\exists\, (a_i)_{i=1}^n \in \mathfrak{m}^n)\, y = \sum_{i=1}^n a_i x_i$ by distributivity and ideal absorption.
Choose such $a_1, \ldots, a_n$ for $y = x_n$ by $x_n \in M = \mathfrak{m}M$. Then $(1_R - a_n)x_n = \sum_{i=1}^{n-1} a_i x_i$.
(iii) *Unit Reduction*: The relation $1_R - a_n \notin \mathfrak{m}$ holds because $\mathfrak{m}$ is proper and $a_n \in \mathfrak{m}$.
Choose $b \in R$ with $b(1_R - a_n) = 1_R$ by Proposition 5.1.2. Multiplication by b places x_n in $\langle\!\langle x_1, \ldots, x_{n-1} \rangle\!\rangle_R$.
(iv) *Contradiction*: Thus $M = \langle\!\langle x_1, \ldots, x_{n-1} \rangle\!\rangle_R$, contrary to minimality of n. Hence $M = \{0_M\}$.
Structural Commentary: Minimal generators convert $\mathfrak{m}M = M$ into a removable last generator.
Key Insight: A coefficient congruent to 1_R modulo $\mathfrak{m}$ is invertible. □

Proposition 5.1.4. *Residue-Field Structure on the Local Cotangent Module*
Let R be a nonzero commutative local ring with identity, maximal ideal $\mathfrak{m}$, and residue field $k := R/\mathfrak{m}$.
The formula $(a + \mathfrak{m})(x + \mathfrak{m}^2) := ax + \mathfrak{m}^2$ makes $\mathfrak{m}/\mathfrak{m}^2$ a k-vector space.

Proof. The inclusion $\mathfrak{m}^2 \subseteq \mathfrak{m}$ holds by ideal absorption and Definition 5.1.1. The ring k is a field by Theorem 3.4.4.
If $a' - a \in \mathfrak{m}$ and $x' - x \in \mathfrak{m}^2$, then $a'x' - ax = a'(x' - x) + (a' - a)x \in \mathfrak{m}^2$.
Thus the scalar action is well defined. The vector-space axioms hold by the R-module axioms and quotient operations.
Structural Commentary: Ideal absorption makes scalar representatives modulo $\mathfrak{m}$ act consistently modulo $\mathfrak{m}^2$.
Key Insight: Products of two maximal-ideal elements vanish in the cotangent quotient. □

Definition 5.1.5. *Embedding Dimension*
Let R be a nonzero commutative local ring with maximal ideal $\mathfrak{m}$ and residue field $k = R/\mathfrak{m}$.
The *embedding dimension* of R is $\operatorname{edim}(R) := \dim_k(\mathfrak{m}/\mathfrak{m}^2)$.

Proposition 5.1.6. *Embedding Dimension Counts Minimal Generators*
Let R be a nonzero Noetherian commutative local ring with identity and maximal ideal $\mathfrak{m}$.

(i) $\operatorname{edim}(R) \in \mathbb{N}_0$.
(ii) $\operatorname{edim}(R) = \min\{n \in \mathbb{N}_0 : (\exists\, (x_i)_{i=1}^n \in \mathfrak{m}^n)\, \mathfrak{m} = \langle x_1, \ldots, x_n \rangle\}$.

Proof. The ideal $\mathfrak{m}$ is finitely generated by Theorem 2.4.2(ii). Choose $r \in \mathbb{N}_0$ and $x_1, \ldots, x_r \in \mathfrak{m}$ with $\mathfrak{m} = \langle x_1, \ldots, x_r \rangle$.
(i) Cotangent space is finite-dimensional by Definition 1.3.1(iii) with spanning list $(x_i + \mathfrak{m}^2)_{i=1}^r$; $\operatorname{edim}(R) \in \mathbb{N}_0$ by Definition 1.4.2.
(ii) Set $d := \operatorname{edim}(R)$. If $\mathfrak{m} = \langle z_1, \ldots, z_s \rangle$, then $d \leq s$ by Theorem 1.3.11 with spanning list $(z_i + \mathfrak{m}^2)_{i=1}^s$.
Choose a k-basis $(y_i + \mathfrak{m}^2)_{i=1}^d$ with $y_i \in \mathfrak{m}$, $N := \langle y_1, \ldots, y_d \rangle$. Then $\mathfrak{m} = N + \mathfrak{m}^2$ by spanning property. Set $Q := \mathfrak{m}/N$.
The module Q is finitely generated by the images of $x_1, \ldots, x_r$. The equality $\mathfrak{m}Q = (\mathfrak{m}^2 + N)/N = Q$ holds by $\mathfrak{m} = N + \mathfrak{m}^2$.
Thus $Q = \{0_Q\}$ by Theorem 5.1.3. Hence $\mathfrak{m} = N$, so d generators attain the displayed minimum.
Structural Commentary: Cotangent spanning yields a quotient vanishing by Nakayama; arbitrary generators descend to spanning lists.
Key Insight: Modulo $\mathfrak{m}^2$, precisely the irredundant generator directions remain. □

Definition 5.1.7. *Krull Dimension and Regular Local Rings*
Let R be a nonzero commutative local ring with identity.

(i) Let $\mathscr{C}(R)$ be the set of finite strictly increasing chains in $\operatorname{Spec} R$. For $\mathcal{P} = (\mathfrak{p}_0 \subsetneq \cdots \subsetneq \mathfrak{p}_n) \in \mathscr{C}(R)$, set $\ell(\mathcal{P}) := n$. The *Krull dimension* is $\dim R := \sup_{\mathcal{P} \in \mathscr{C}(R)} \ell(\mathcal{P})$. Its value is ∞ if these lengths are unbounded.

(ii) The ring R is *regular local* if it is Noetherian and $\dim R = \operatorname{edim}(R)$.

5.2 Singularities Preview

Definition 5.2.1. *Singular Local Rings and Embedding-Dimension Excess*
Let R be a nonzero Noetherian commutative local ring with identity.

(i) The ring R is *singular* if it is not regular. Equivalently, $\dim R \neq \operatorname{edim}(R)$ by Definition 5.1.7(ii).

(ii) Assume $\dim R \in \mathbb{N}_0$ and $\dim R \leq \operatorname{edim}(R)$. The *embedding-dimension excess* is $\operatorname{exc}(R) := \operatorname{edim}(R) - \dim R$.

Proposition 5.2.2. *Positive Embedding-Dimension Excess Detects Singularity*
Let R be a nonzero Noetherian commutative local ring with identity.
If $\dim R \in \mathbb{N}_0$ and $\dim R \leq \operatorname{edim}(R)$, then R is singular $\iff \operatorname{exc}(R) > 0$.

Proof.

($\Rightarrow$) If R is singular, then $\dim R \neq \operatorname{edim}(R)$ by Definition 5.2.1(i). Thus $\dim R < \operatorname{edim}(R)$ by the dimension-order hypothesis. The inequality $\operatorname{exc}(R) > 0$ holds by Definition 5.2.1(ii).

($\Leftarrow$) If $\operatorname{exc}(R) > 0$, then $\dim R < \operatorname{edim}(R)$ by Definition 5.2.1(ii). Hence R is singular by Definition 5.2.1(i).

Structural Commentary: The dimension order converts failure of regularity equality into positivity of the excess.
Key Insight: The excess vanishes exactly when Krull and embedding dimensions coincide. □

Example 5.2.3. *A Square-Zero Singular Local Ring*
Let k be a field and set $R := k[x,y]/\langle x^2, xy, y^2\rangle$. Write $\bar{x}, \bar{y} \in R$ for the residue classes of x, y, and set $\mathfrak{m} := \langle \bar{x}, \bar{y}\rangle$.
Relation $(\forall\, r \in R)(\exists!\, (a,b,c) \in k^3)\, r = a + b\bar{x} + c\bar{y}$ holds by polynomial reduction. Equality $\mathfrak{m}^2 = \{0_R\}$ holds by quotient relations.
For $(a,u) \in (k \setminus \{0_k\}) \times \mathfrak{m}$, $(a+u)(a^{-1} - a^{-2}u) = 1_R$. Thus $(\forall\, r \in R \setminus \mathfrak{m})(\exists\, s \in R)\, rs = 1_R$.
The quotient $R/\mathfrak{m} \cong k$ is a field, so $\mathfrak{m}$ is maximal by Theorem 3.4.4.
The implication $(\forall\, \mathcal{J} \trianglelefteq R)\, [\mathcal{J} \neq R \Rightarrow \mathcal{J} \subseteq \mathfrak{m}]$ holds because a proper ideal contains no invertible element.
Hence R is local with maximal ideal $\mathfrak{m}$. The equality $\dim_k R = 3$ holds by the unique normal form. Fix $\mathcal{J} \trianglelefteq R$.
Since $\mathcal{J}$ is a k-subspace of R, choose a finite k-basis by Corollary 1.3.14(i)–(ii). This basis generates $\mathcal{J}$ as an R-module.
Hence R is Noetherian by Theorem 2.4.2(ii), because $\mathcal{J}$ was arbitrary.
The inclusion $(\forall\, \mathfrak{p} \in \operatorname{Spec} R)\, \{\bar{x}, \bar{y}\} \subseteq \mathfrak{p}$ holds by $\bar{x}^2 = \bar{y}^2 = 0_R$ and primeness. Thus $\operatorname{Spec} R = \{\mathfrak{m}\}$.
The equality $\dim R = 0$ holds by Definition 5.1.7(i). The tuple $(\bar{x} + \mathfrak{m}^2, \bar{y} + \mathfrak{m}^2)$ is a k-basis of $\mathfrak{m}/\mathfrak{m}^2$.
Thus $\operatorname{edim}(R) = 2$ by Definition 5.1.5. Therefore $\operatorname{exc}(R) = 2 > 0$, and R is singular by Proposition 5.2.2.

Part XI
Real and Topological Analysis

1 Number Systems and Completeness

1.1 Ordered Fields, Suprema, and Real Structure

$\mathbb{Q}$ has gaps that completeness repairs in $\mathbb{R}$, while $\mathbb{C}$ retains field algebra without a compatible order.

Definition 1.1.1. *Ordered Fields*
Let F be a field equipped with a total order $<$. Then F is an *ordered field* iff

(i) $(\forall x, y, z \in F)\,[y < z \Rightarrow x + y < x + z]$;
(ii) $(\forall x, y \in F)\,[(0 < x \wedge 0 < y) \Rightarrow 0 < xy]$.

Proposition 1.1.2. *Basic Consequences of the Field Axioms*
Let F be a field. Then $(\forall a, b, c, x, y \in F)$:

(i) $a + c = b + c \Rightarrow a = b$, *and* $c \neq 0 \Rightarrow (ac = bc \Rightarrow a = b)$.
(ii) *The identities* $0, 1$ *and the inverses* $-a$, a^{-1} *for* $a \neq 0$ *are unique.*
(iii) $0x = 0$.
(iv) $xy = 0 \Rightarrow (x = 0 \vee y = 0)$.
(v) $(-x)y = -(xy) = x(-y)$ *and* $(-x)(-y) = xy$.

Proof.

(i) $a = b$ by adding $-c$ to $a + c = b + c$. If $c \neq 0$, then $a = b$ by multiplying $ac = bc$ by c^{-1}.
(ii) In a group $(G, *, e)$, any identity e' satisfies $e = e * e' = e'$.
If $u * a = e = a * v$, then $u = u * e = u * (a * v) = (u * a) * v = v$. These calculations apply to $(F, +, 0)$ and $(F \setminus \{0\}, \cdot, 1)$.
(iii) $0x = 0$ by cancellation from $0x + 0x = (0 + 0)x = 0x$.
(iv) If $x = 0$, then $x = 0 \vee y = 0$. If $xy = 0$ and $x \neq 0$, then $y = 0$ by multiplication by x^{-1}.
(v) $(-x)y = -(xy)$ by $xy + (-x)y = (x + (-x))y = 0$, and $x(-y) = -(xy)$ by the same calculation.
The identity $(-x)(-y) = -(x(-y)) = xy$ follows by the first equality.

Structural Commentary: Group cancellation fixes identities and inverses; distributivity then controls zero and signs.
Key Insight: Uniqueness turns zero-sum identities into sign laws. □

Proposition 1.1.3. *Basic Inequality Rules in Ordered Fields*
Let F be an ordered field. Then $(\forall c, x, y \in F)$:

(i) $x > 0 \iff -x < 0$.
(ii) $(c > 0 \wedge x < y) \Rightarrow cx < cy$.
(iii) $(c < 0 \wedge x < y) \Rightarrow cy < cx$.
(iv) $x \neq 0 \Rightarrow x^2 > 0$; *in particular,* $1 > 0$.
(v) $0 < x < y \Rightarrow 0 < y^{-1} < x^{-1}$.

Proof.

(i) ($\Rightarrow$) $-x < 0$ by adding $-x$ to $0 < x$.
(i) ($\Leftarrow$) $0 < x$ by adding x to $-x < 0$.
(ii) The relations $0 < y - x$ and $0 < c(y - x) = cy - cx$ hold by additive order invariance and Definition 1.1.1(ii), respectively.
The inequality $cx < cy$ follows by adding cx to $0 < cy - cx$.
(iii) $-c > 0$ by (i), and $(-c)x < (-c)y$ by (ii). The inequality $cy < cx$ follows by adding $cx + cy$ to $-cx < -cy$.
(iv) If $x > 0$, then $x^2 > 0$ by Definition 1.1.1(ii). If $x < 0$, then $-x > 0$ by (i), so $x^2 = (-x)^2 > 0$.
One case holds by $x \neq 0$ and totality. For $x = 1$, $1 = 1^2 > 0$.
(v) $x^{-1} = x(x^{-1})^2 > 0$ and $y^{-1} = y(y^{-1})^2 > 0$ by (iv) and Definition 1.1.1(ii).
$x^{-1}y^{-1} > 0$ by Definition 1.1.1(ii), and $y^{-1} < x^{-1}$ by (ii) with multiplier $x^{-1}y^{-1}$.

Structural Commentary: Additive order invariance reduces every inequality rule to multiplication by a positive element.
Key Insight: A negative multiplier is the negative of a positive one. □

Motivation 1.1.4. *Completeness Becomes a Theorem*
Dedekind cuts encode a real number by its rational lower side.
The construction turns rational arithmetic into cut arithmetic and bounded suprema into unions.

Definition 1.1.5. *Dedekind Cuts and Their Order*
A *cut* is a set $\alpha \subseteq \mathbb{Q}$ such that

(i) $\emptyset \neq \alpha \neq \mathbb{Q}$;
(ii) $(\forall p \in \alpha)(\forall q \in \mathbb{Q})\,[q < p \Rightarrow q \in \alpha]$;
(iii) $(\forall p \in \alpha)(\exists r \in \alpha)\, p < r$.

Let $\mathscr{D}$ be the set of cuts. For $\alpha, \beta \in \mathscr{D}$, define $\alpha \leq \beta \iff \alpha \subseteq \beta$ and $\alpha < \beta \iff \alpha \subsetneq \beta$.
Within the construction, $p, q, r, \ldots \in \mathbb{Q}$ and $\alpha, \beta, \gamma, \ldots \in \mathscr{D}$. A cut is a proper rational initial segment without a largest element.

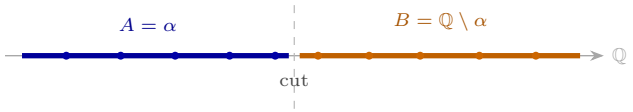

Figure 112: A Dedekind cut splits $\mathbb{Q}$ into α and $\mathbb{Q} \setminus \alpha$, with no last rational in α.

Figure 112 depicts the two sides determined by Definition 1.1.5.

Remark 1.1.6. *Left Cuts Versus Two-Sided Cuts*
Two-sided notation writes $A \mid B$ with $A = \alpha$ and $B = \mathbb{Q} \setminus \alpha$.
Definition 1.1.5 retains A; its lack of a largest element prevents duplicate boundary representations.

Definition 1.1.7. *Arithmetic of Cuts*
For $\alpha, \beta \in \mathscr{D}$, define $\alpha + \beta := \{r + s : r \in \alpha,\ s \in \beta\}$ and $0^* := \{q \in \mathbb{Q} : q < 0\}$.
Define $-\alpha := \{p \in \mathbb{Q} : (\exists r \in \mathbb{Q})\,[r > 0 \wedge -p - r \notin \alpha]\}$ and $\mathscr{D}^+ := \{\alpha \in \mathscr{D} : 0^* < \alpha\}$.
For $\alpha, \beta \in \mathscr{D}^+$, define $\alpha\beta := \{p \in \mathbb{Q} : (\exists r \in \alpha)(\exists s \in \beta)\,[r > 0 \wedge s > 0 \wedge p \le rs]\}$. Set $1^* := \{q \in \mathbb{Q} : q < 1\}$.
For $\alpha \in \mathscr{D}^+$, define $\alpha^{-1} := \{p \in \mathbb{Q} : p \le 0 \vee [p > 0 \wedge (\exists q \in \mathbb{Q} \setminus \alpha)\,(q > 0 \wedge p < q^{-1})]\}$.
Extend multiplication to zero factors by $\alpha 0^* = 0^*\alpha = 0^*$.

$$\alpha\beta := \begin{cases} (-\alpha)(-\beta), & \alpha < 0^*,\ \beta < 0^*, \\ -\big((-\alpha)\beta\big), & \alpha < 0^*,\ \beta > 0^*, \\ -\big(\alpha(-\beta)\big), & \alpha > 0^*,\ \beta < 0^*. \end{cases}$$

Positive rational representatives multiply without reversing order.
The sign rules reduce every remaining product to the positive case.

Definition 1.1.8. *Rational Cuts*
For $r \in \mathbb{Q}$, define the *rational cut* $r^* := \{p \in \mathbb{Q} : p < r\}$. Define $\iota : \mathbb{Q} \to \mathscr{D}$ by $\iota(r) := r^*$.

Theorem 1.1.9. *Existence of the Real Field*
The Dedekind-cut construction satisfies the following claims.

(i) $(\mathscr{D}, +, \cdot, <)$ is an ordered field with the least-upper-bound property.
(ii) The map $\iota : \mathbb{Q} \to \mathscr{D}$, $r \mapsto r^*$, is an order-preserving field embedding.

Proof.

(i) *Field and completeness*:

(a) *Order and suprema*: Inclusion is reflexive, antisymmetric, and transitive. If $\alpha \not\subseteq \beta$, choose $p \in \alpha \setminus \beta$.
The relation $(\forall q \in \beta)\, q < p$ holds by downward closure of β, and $\beta \subseteq \alpha$ by downward closure of α. Hence inclusion is total.
Let $\emptyset \neq A \subseteq \mathscr{D}$ have upper bound β, and set $\gamma := \bigcup_{\alpha \in A} \alpha$. The set γ is nonempty, and $\gamma \subseteq \beta \neq \mathbb{Q}$.
Downward closure and the absence of a largest element pass from the member of A containing a chosen $p \in \gamma$; hence $\gamma \in \mathscr{D}$.
Every $\alpha \in A$ satisfies $\alpha \subseteq \gamma$, while any upper bound δ of A contains every $\alpha \in A$ and hence contains γ.
These bound relations prove $\gamma = \sup A$.

(b) *Addition*: Set $\alpha + \beta$ is nonempty. Choose $r' \notin \alpha$, $s' \notin \beta$. Relation $r + s < r' + s'$ holds for $r \in \alpha$, $s \in \beta$, so $r' + s' \notin \alpha + \beta$.
Downward closure follows from $q < r + s \Rightarrow q = r + (s + q - r - s)$ because the final summand lies in β.
If $p = r + s$, choose $r_1 \in \alpha$ with $r < r_1$; then $p < r_1 + s \in \alpha + \beta$. These properties prove $\alpha + \beta \in \mathscr{D}$.
Commutativity and associativity follow from the rational identities. Inclusion $\alpha + 0^* \subseteq \alpha$ holds by downward closure.
The reverse inclusion follows from $p = r + (p - r)$ with $p < r \in \alpha$, so $\alpha + 0^* = \alpha$.
The set $-\alpha$ is nonempty by any $q \notin \alpha$ and the witness $p = -q - 1$. It is proper because $-a \notin -\alpha$ for $a \in \alpha$.
Downward closure follows from upward closure of $\mathbb{Q} \setminus \alpha$, and $p \in -\alpha$ with witness $r > 0$ satisfies $p < p + \frac{r}{2} \in -\alpha$.
Thus $-\alpha$ is a cut. For $s \in -\alpha$, relation $-s \notin \alpha$ follows by its witness, so $(\forall r \in \alpha)\, r + s < 0$ and $\alpha + (-\alpha) \subseteq 0^*$.
For the reverse inclusion, let $v < 0$ and set $w := -\frac{v}{2} > 0$. Rational multiples of w are unbounded in both directions.
Indeed, if $w = \frac{A}{B}$ and $q = \frac{C}{D}$ with $A, B, D \in \mathbb{N}$, then $n = B(|C| + 1)$ satisfies $nw > q$.
The same calculation for $-q$ supplies a negative multiple below q.
Choose $a \in \alpha$ and $b \notin \alpha$. Select $j < k$ in $\mathbb{Z}$ with $jw < a$ and $kw > b$ by this unboundedness.
The finite set $\{\ell \in \mathbb{Z} : j \le \ell \le k,\ \ell w \in \alpha\}$ has a largest element n, with $(n + 1)w \notin \alpha$.
The relations $nw \in \alpha$, $-(n + 2)w \in -\alpha$ with witness w, and $v = nw - (n + 2)w$ prove $v \in \alpha + (-\alpha)$. Hence $\alpha + (-\alpha) = 0^*$.

(c) *Positive multiplication*: For $\alpha, \beta > 0^*$, the product $\alpha\beta$ is nonempty because both cuts contain positive rationals.
Positive $r' \notin \alpha$ and $s' \notin \beta$ satisfy $\alpha\beta \subseteq \{p : p < r's'\}$, so the product is proper.
Downward closure follows from the defining inequality. If $p \le rs$ is a defining witness, choose $p < q < rs$ when $p < rs$.
If $p = rs$, choose $r < r_1 \in \alpha$ and then $p < q < r_1 s$. Hence $\alpha\beta$ has no largest element.
Commutativity follows from $rs = sr$. If $p \in (\alpha\beta)\gamma$, then $p \le ut \le rst$ for positive $u \in \alpha\beta$, $r \in \alpha$, $s \in \beta$, and $t \in \gamma$.
Since $st \in \beta\gamma$, $p \in \alpha(\beta\gamma)$. The reverse inclusion is symmetric, so multiplication is associative.
If $p \in \alpha(\beta + \gamma)$, choose positive $r \in \alpha$, $u = s_0 + t_0 \in \beta + \gamma$ with $p \le ru$, and then positive $s \in \beta$, $t \in \gamma$ with $s > s_0$, $t > t_0$.
The membership $p \in \alpha\beta + \alpha\gamma$ follows from $p < r(s + t) = rs + rt$.
Conversely, if $p = u + v$ with $u \in \alpha\beta$ and $v \in \alpha\gamma$, choose positive witnesses $u \le r_1 s$, $v \le r_2 t$, and $r \in \alpha$ with $r > \max\{r_1, r_2\}$.
Then $p < r(s + t)$ with $s + t \in \beta + \gamma$, so $p \in \alpha(\beta + \gamma)$. Thus positive multiplication distributes over addition.
If $p \le rs$ with $r \in \alpha$, $0 < s < 1$, then $p < r$ and $p \in \alpha$. Conversely, for $p \in \alpha$, choose $p < r \in \alpha$ and $0 < s < 1$ with $p \le rs$.
Such an s exists when $p > 0$, while any $s > 0$ works when $p \le 0$. Hence $\alpha 1^* = \alpha$, and $\alpha, \beta > 0^* \Rightarrow \alpha\beta > 0^*$.

(d) *Positive reciprocals*: For $\alpha > 0^*$, the set α^{-1} contains every nonpositive rational and is nonempty.
It is proper because $r^{-1} \notin \alpha^{-1}$ for any positive $r \in \alpha$.
Downward closure is immediate. A larger member follows from a positive defining witness by taking a midpoint.
A nonpositive member is smaller than $\frac{1}{2q} \in \alpha^{-1}$ for any positive $q \notin \alpha$. These properties prove $\alpha^{-1} \in \mathscr{D}^+$.
If $p \in \alpha\alpha^{-1}$, then $p \le rs$ for positive $r \in \alpha$ and $s < q^{-1}$ with positive $q \notin \alpha$. Since $r < q$, $p < \frac{r}{q} < 1$, so $\alpha\alpha^{-1} \subseteq 1^*$.
For the reverse inclusion, fix $0 < c < 1$ and positive $r_0 \in \alpha$, $q_0 \notin \alpha$.
Repeated bisection produces $r_k \in \alpha$, $q_k \notin \alpha$ with $0 < r_0 \le r_k < q_k$ and $q_k - r_k = 2^{-k}(q_0 - r_0)$.
Choose k with $q_k - r_k < \frac{(1-c)r_0}{c}$; such a k exists because $2^k \ge k + 1$ and positive rational multiples are unbounded.
Then $cq_k < r_k$. Choose $s \in \mathbb{Q}$ with $\frac{c}{r_k} < s < \frac{1}{q_k}$. The relations $s \in \alpha^{-1}$ and $c < r_k s$ prove $c \in \alpha\alpha^{-1}$.
Every $c \le 0$ belongs to the product by any positive pair of witnesses. Therefore $\alpha\alpha^{-1} = 1^*$.

(e) *Signs and order compatibility*: Addition by a fixed cut preserves inclusion.
If $\beta < \gamma$, then $\alpha + \beta \subseteq \alpha + \gamma$; equality would imply $\beta = \gamma$ by adding $-\alpha$. Hence $\alpha + \beta < \alpha + \gamma$ and $\alpha > 0^* \iff -\alpha < 0^*$.
Every nonzero cut has the form εa with $a > 0^*$ and $\varepsilon \in \{1, -1\}$.
The signed definition makes products commutative and associative and sets $(-a)^{-1} = -a^{-1}$.
For distributivity, $a(b - c) = ab - ac$ when $a, b, c > 0^*$.
If $b > c$, then $a(b - c) + ac = ab$ by positive distributivity and additive cancellation.

The cases $b = c$ and $b < c$ follow by zero and sign reversal, so this identity covers all sign patterns.
Since $0^* \neq 1^*$, all field axioms hold. Strict addition compatibility and $\alpha, \beta > 0^* \Rightarrow \alpha\beta > 0^*$ make the field ordered.

(ii) *Rational embedding*: Each r^* is a cut. For $r, s \in \mathbb{Q}$, one inclusion in $r^* + s^* = (r+s)^*$ follows from $u < r$ and $v < s$.
For $p < r + s$, set $t := \frac{r+s-p}{2} > 0$. Then $r - t \in r^*$, $s - t \in s^*$, and $p = (r - t) + (s - t)$, so $p \in r^* + s^*$.
For $r, s > 0$, the forward inclusion in $r^*s^* = (rs)^*$ follows from $0 < u < r$, $0 < v < s \Rightarrow uv < rs$.
Conversely, if $0 < p < rs$, choose $0 < \delta < \min\{r, s, \frac{rs-p}{r+s}\}$. Then $p < (r - \delta)(s - \delta)$, so $p \in r^*s^*$.
Nonpositive p belongs by any positive witnesses, and the signed cases follow from the definitions.
Finally, $r < s \iff r^* < s^*$. The forward implication follows from $r \in s^* \setminus r^*$.
The reverse implication follows because $r^* < s^*$ supplies $p \in s^* \setminus r^*$ with $r \leq p < s$.
Hence ι is injective and preserves $0, 1, +, \cdot$, and order.

Structural Commentary: Cut inclusion supplies suprema; rational witnesses transfer field operations and reciprocals.
Key Insight: Bounded unions and boundary approximation create completeness and inverses. □

Write $\mathbb{R} := \mathscr{D}$ and identify $\mathbb{Q}$, together with its subsets $\mathbb{Z}$ and $\mathbb{N}$, with its image under ι.

Definition 1.1.10. *Irrational and Dense Subsets*
A real number x is *irrational* iff $x \in \mathbb{R} \setminus \mathbb{Q}$. A set $D \subseteq \mathbb{R}$ is *dense in* $\mathbb{R}$ iff $(\forall a, b \in \mathbb{R})\,[a < b \Rightarrow (\exists d \in D)\, a < d < b]$.

Theorem 1.1.11. *Existence and Uniqueness of Positive nth Roots*
Let $x \in \mathbb{R}$ with $x > 0$, and let $n \in \mathbb{N}$.
(i) $(\exists y \in \mathbb{R})\,[y > 0 \wedge y^n = x]$.
(ii) $(\forall y, z \in \mathbb{R})\,[(y > 0 \wedge z > 0 \wedge y^n = x \wedge z^n = x) \Rightarrow y = z]$.
Denote this unique root by $x^{1/n}$.

Proof.
(i) *Existence*:
(a) *Supremum candidate*: Set $E := \{t \in \mathbb{R} : t > 0,\ t^n < x\}$. For $t_0 := \frac{x}{1+x}$, $0 < t_0 < 1$ and $t_0^n \leq t_0 < x$, so $E \neq \emptyset$.
Every $t \in E$ satisfies $t \leq 1 + x$ because $t > 1 + x$ would imply $t^n \geq t > x$.
Hence $y := \sup E$ exists by Theorem 1.1.9, and $y \geq t_0 > 0$.
(b) *Lower perturbation*: For $0 < a < b$, the factorization satisfies $0 < b^n - a^n \leq n(b - a)b^{n-1}$.
Suppose $y^n < x$ and choose $0 < h < \min\{1, \frac{x-y^n}{n(y+1)^{n-1}}\}$.
The bound $(y + h)^n - y^n \leq hn(y + h)^{n-1} < x - y^n$ places $y + h$ in E, contradicting that y is an upper bound.
(c) *Upper perturbation*: Suppose $y^n > x$ and set $k := \frac{y^n - x}{ny^{n-1}}$. Then $0 < k < \frac{y}{n} \leq y$, and $y^n - (y - k)^n \leq kny^{n-1} = y^n - x$.
The inequality $(y - k)^n \geq x$ makes $y - k$ an upper bound of E by monotonicity of positive integer powers.
This contradicts $y = \sup E$. Hence $y^n = x$ by trichotomy.
(ii) *Uniqueness*: If $0 < y < z$, then $z^n - y^n = (z - y)(z^{n-1} + z^{n-2}y + \cdots + y^{n-1}) > 0$.
Equal positive nth powers therefore have equal bases by trichotomy.

Structural Commentary: Completeness selects a supremum; two perturbations exclude powers below and above x.
Key Insight: The supremum cannot survive either strict power inequality. □

Corollary 1.1.12. *Product Rule for Positive Roots*
For $a, b \in \mathbb{R}$ with $a, b > 0$ and $n \in \mathbb{N}$, $(ab)^{1/n} = a^{1/n}b^{1/n}$.

Proof. Set $\alpha := a^{1/n}$ and $\beta := b^{1/n}$. Then $(\alpha\beta)^n = \alpha^n\beta^n = ab$ by commutativity; $(ab)^{1/n} = \alpha\beta$ holds by Theorem 1.1.11(ii).
Structural Commentary: Multiplicativity of nth powers transfers the product to the uniqueness claim.
Key Insight: Equal positive nth powers have equal bases. □

Proposition 1.1.13. *The Rational Gap at $\sqrt{2}$*
Let $A := \{p \in \mathbb{Q} : p > 0,\ p^2 < 2\}$ and $B := \{p \in \mathbb{Q} : p > 0,\ p^2 > 2\}$.
(i) $(\nexists p \in \mathbb{Q})\, p^2 = 2$.
(ii) The set A has no largest element, and B has no smallest element.
(iii) The nonempty set A is bounded above in $\mathbb{Q}$ but has no supremum in $\mathbb{Q}$.

Proof.
(i) Suppose $p = \frac{m}{n} \in \mathbb{Q}$ satisfies $p^2 = 2$, where $m, n \in \mathbb{Z}$ and $n \neq 0$. Then $m^2 = 2n^2$, with $m, n \neq 0$.
The conflicting parity of the exponent of 2 contradicts unique factorization in $\mathbb{Z}$ by Theorems 3.10.2 and 3.10.7.
(ii) For $p > 0$, set $q := p - \frac{p^2-2}{p+2} = \frac{2p+2}{p+2}$. Then $q - p = -\frac{p^2-2}{p+2}$ and $q^2 - 2 = \frac{2(p^2-2)}{(p+2)^2}$.
Thus $p \in A \Rightarrow q \in A$ with $q > p$, while $p \in B \Rightarrow q \in B$ with $0 < q < p$.
(iii) Relations $1 \in A$ and $(\forall p \in A)\, p < 2$ make A nonempty, bounded above. Suppose $s = \sup_{\mathbb{Q}} A$. Then $s \geq 1$, and $s^2 \neq 2$ by (i).
If $s^2 < 2$, the element constructed in (ii) belongs to A and exceeds s.
If $s^2 > 2$, the element q from (ii) satisfies $0 < q < s$ and is an upper bound of A.
Any $a \in A$ with $a \geq q$ would satisfy $a^2 \geq q^2 > 2$. Both cases contradict $s = \sup_{\mathbb{Q}} A$.

Structural Commentary: Unique factorization excludes the boundary; a rational correction moves toward it from either side.
Key Insight: Every rational candidate can be improved without crossing the gap. □

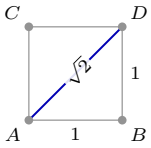

Figure 113: The diagonal of a unit square has length $\sqrt{2}$, so the rational gap is geometric as well as algebraic.

Figure 113 illustrates Proposition 1.1.13 geometrically.

Remark 1.1.14. *Density Does Not Mean Completeness*
Both $\mathbb{Q}$ and $\mathbb{R}$ are ordered fields. For $r, s \in \mathbb{Q}$ with $r < s$, the midpoint $\frac{r+s}{2}$ proves that $\mathbb{Q}$ is order-dense in itself.
$\mathbb{Q}$ nevertheless lacks the least-upper-bound property by Proposition 1.1.13(iii). The field $\mathbb{R}$ has this property by Theorem 1.1.9(i).

Corollary 1.1.15. *Infimum by Reflection*
Let $\emptyset \neq B \subseteq \mathbb{R}$ be bounded below and set $-B := \{-b : b \in B\}$. Then $-B$ is bounded above and $\inf B = -\sup(-B)$.

Proof. If m is a lower bound of B, then $-m$ is an upper bound of $-B$. Hence $s := \sup(-B)$ exists by Theorem 1.1.9.
The element $-s$ is a lower bound of B by $(\forall b \in B)\,(-b \leq s \Rightarrow -s \leq b)$.
If t is a lower bound of B, then $-t$ is an upper bound of $-B$, so $s \leq -t$ and $t \leq -s$. Thus $-s = \inf B$ by the definition of an infimum.
Structural Commentary: Order reversal converts lower bounds of B into upper bounds of $-B$.
Key Insight: Negating the least upper bound makes the greatest lower bound. □

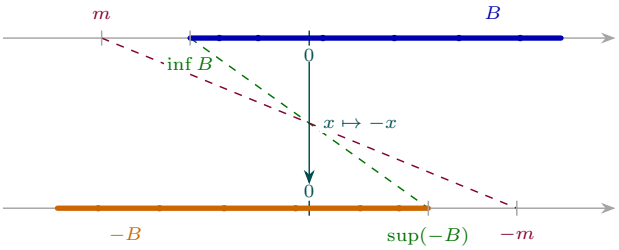

Figure 114: Reflecting B through 0 turns lower bounds of B into upper bounds of $-B$, so $\inf B = -\sup(-B)$.

Figure 114 illustrates the order reversal used in the proof.

Definition 1.1.16. *Real Absolute Value and Distance*
For $x \in \mathbb{R}$, define $|x| := \max\{x, -x\}$. For $a, b \in \mathbb{R}$, define their real-line distance by $d(a, b) := |a - b|$.

Proposition 1.1.17. *Real Absolute-Value Laws*
For $x, y, a, b, c \in \mathbb{R}$:

(i) $|x| \geq 0$, $|x| = 0 \iff x = 0$, *and* $-|x| \leq x \leq |x|$;
(ii) $|xy| = |x|\,|y|$;
(iii) $|x + y| \leq |x| + |y|$;
(iv) $|a - b| \leq |a - c| + |c - b|$.

Proof.

(*i*) ($\Rightarrow$) At least one of x and $-x$ is nonnegative by totality, so $|x| = \max\{x, -x\} \geq 0$.
Both $x \leq |x|$ and $-x \leq |x|$ hold by the definition of a maximum, and the second inequality is equivalent to $-|x| \leq x$.
If $|x| = 0$, then $x = 0$ in each of the cases $x \geq 0$ and $x < 0$ by Definition 1.1.16.
(*i*) ($\Leftarrow$) $|0| = 0$ by Definition 1.1.16.
(*ii*) If $xy > 0$, then $|xy| = xy = |x|\,|y|$ when $x, y > 0$ or $x, y < 0$. If $xy < 0$, then $|xy| = -xy = |x|\,|y|$; the case $xy = 0$ follows directly.
(*iii*) The inequalities $x + y \leq |x| + |y|$ and $-(x + y) \leq |x| + |y|$ follow by (i). Their maximum is $|x + y|$, and therefore $|x + y| \leq |x| + |y|$.
(*iv*) $|a - b| = |(a - c) + (c - b)| \leq |a - c| + |c - b|$ by (iii).
Structural Commentary: The maximum representation supplies two-sided bounds; addition then transfers them to sums and distances.
Key Insight: Bounding a number and its negative bounds its absolute value. □

Perspective 1.1.18. *Number Systems from Representatives*
The constructions of $\mathbb{Z}$ and $\mathbb{Q}$ by equivalence classes require operations and order to descend from representatives.
Thus $x \sim x'$ and $y \sim y'$ must imply $x \star y \sim x' \star y'$, with analogous compatibility for order.
Dedekind cuts use subsets rather than equivalence classes, so closure of cut operations replaces representative independence.
Key Insight: Each construction must transfer algebra from its underlying data.

Theorem 1.1.19. *Archimedean Property and Density of $\mathbb{Q}$*

(i) $(\forall x, y \in \mathbb{R})\,[x > 0 \Rightarrow (\exists n \in \mathbb{N})\, nx > y]$.
(ii) $(\forall x, y \in \mathbb{R})\,[x < y \Rightarrow (\exists p \in \mathbb{Q})\, x < p < y]$.

Proof.

(i) Fix $x > 0$ and set $A := \{nx : n \in \mathbb{N}\}$. If A were bounded above, then $\alpha := \sup A$ would exist by Theorem 1.1.9.
Since $\alpha - x < \alpha$, element $\alpha - x$ is not upper bound of A. Choose $m \in \mathbb{N}$ with $\alpha - x < mx$; $\alpha < (m + 1)x \in A$, contradiction.
(ii) Fix $x < y$. Choose $n \in \mathbb{N}$ with $n(y - x) > 1$ by (i), and choose $N \in \mathbb{N}$ with $N > |nx| + 1$ by (i) with unit step.
The finite set $S := \{k \in \mathbb{Z} : -N \leq k \leq N,\ k \leq nx\}$ is nonempty; let $m := \max S$.
Since $nx < N$, inequalities $m \leq nx < m + 1$ hold by maximality; $nx < m + 1 \leq nx + 1 < ny$, so $x < \frac{m+1}{n} < y$ with $\frac{m+1}{n} \in \mathbb{Q}$.

Structural Commentary: Completeness forbids finite supremum for integer multiples; finite integer grid then locates rational point.
Key Insight: A mesh smaller than $y - x$ must cross the interval. □

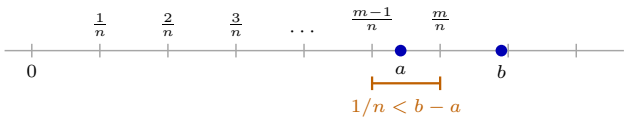

Figure 115: Choose n so the spacing $\frac{1}{n}$ is smaller than $b - a$; then one grid point $\frac{m}{n}$ falls inside (a, b).

Figure 115 illustrates the grid step used in Theorem 1.1.19(ii).

Corollary 1.1.20. *Density of Rational and Irrational Points*
For $x, y \in \mathbb{R}$ with $x < y$, $(\exists r \in \mathbb{Q})(\exists s \in \mathbb{R} \setminus \mathbb{Q})\,[x < r < y \wedge x < s < y]$.

Proof. Choose $r \in \mathbb{Q} \cap (x, y)$ by Theorem 1.1.19(ii). The number $\eta := 2^{1/2} > 0$ exists by Theorem 1.1.11(i) with $x = n = 2$.
It satisfies $\eta \notin \mathbb{Q}$ by Proposition 1.1.13(i). Choose $n \in \mathbb{N}$ with $n(y - x) > \eta$ by Theorem 1.1.19(i), $q \in \mathbb{Q} \cap (x - \frac{\eta}{n}, y - \frac{\eta}{n})$ by part (ii).
Then $s := q + \frac{\eta}{n}$ lies in (x, y), and $s \notin \mathbb{Q}$ because $s \in \mathbb{Q}$ would imply $\eta = n(s - q) \in \mathbb{Q}$.
Structural Commentary: Rational density is applied before and after translating the interval by a small irrational.
Key Insight: A rational translate of a nonzero irrational remains irrational. □

Definition 1.1.21. *Extended Real Number System*
The *extended real line* is $\overline{\mathbb{R}} := \mathbb{R} \cup \{-\infty, +\infty\}$. It retains the usual order on $\mathbb{R}$ and satisfies $(\forall x \in \mathbb{R})\ -\infty < x < +\infty$.
For $E \subseteq \mathbb{R}$, extend the extrema as follows.

(i) $E = \emptyset \Rightarrow \sup E = -\infty$; if E is unbounded above, $\sup E := +\infty$; otherwise retain the real supremum.
(ii) $E = \emptyset \Rightarrow \inf E = +\infty$; if E is unbounded below, $\inf E := -\infty$; otherwise retain the real infimum.

Definition 1.1.22. *Extended Arithmetic Conventions*
For $x \in \mathbb{R}$, define the following non-indeterminate operations:

(i) $(+\infty) + (+\infty) = +\infty$ and $(-\infty) + (-\infty) = -\infty$.
(ii) $x + (+\infty) = (+\infty) + x = +\infty$ and $x + (-\infty) = (-\infty) + x = -\infty$.
(iii) $x > 0 \Rightarrow [x(+\infty) = (+\infty)x = +\infty \wedge x(-\infty) = (-\infty)x = -\infty]$.
(iv) $x < 0 \Rightarrow [x(+\infty) = (+\infty)x = -\infty \wedge x(-\infty) = (-\infty)x = +\infty]$.

The forms $(+\infty) + (-\infty)$ and $0(\pm\infty)$ are undefined, so $\overline{\mathbb{R}}$ is not a field.

Definition 1.1.23. *Unbounded Real Intervals*
For $a, b \in \mathbb{R}$:

(i) $(a, +\infty) := \{x \in \mathbb{R} : a < x\}$ and $[a, +\infty) := \{x \in \mathbb{R} : a \leq x\}$.
(ii) $(-\infty, b) := \{x \in \mathbb{R} : x < b\}$ and $(-\infty, b] := \{x \in \mathbb{R} : x \leq b\}$.

Define $(-\infty, +\infty) := \mathbb{R}$.

1.2 Complex Numbers and Absolute Value

Definition 1.2.1. *Complex Numbers*
Let $\mathbb{C} := \mathbb{R}^2$. For $x = (a, b)$ and $y = (c, d)$ in $\mathbb{C}$:

(i) $x = y \iff (a = c \wedge b = d)$.
(ii) $x + y := (a + c, b + d)$.
(iii) $xy := (ac - bd, ad + bc)$.

Elements of $\mathbb{C}$ are *complex numbers*, and $i := (0, 1) \in \mathbb{C}$ is the *complex unit*.

Theorem 1.2.2. *The Complex Numbers Form a Field*
Let $\mathbb{C} = \mathbb{R}^2$ with $(a, b) + (c, d) = (a + c, b + d)$ and $(a, b)(c, d) = (ac - bd, ad + bc)$.

(i) The additive and multiplicative identities are $(0, 0)$ and $(1, 0)$.
(ii) Every $x = (a, b) \neq (0, 0)$ has inverse $x^{-1} = \left(\frac{a}{a^2+b^2}, -\frac{b}{a^2+b^2}\right)$.
(iii) With these operations, $\mathbb{C}$ is a field.

Proof.

(i) For $x = (a, b)$, $x + (0, 0) = (0, 0) + x = x$ and $x(1, 0) = (1, 0)x = x$ by direct calculation.
(ii) At least one of a, b is nonzero, so $a^2 + b^2 > 0$ by Proposition 1.1.3(iv).
Set $q := \left(\frac{a}{a^2+b^2}, -\frac{b}{a^2+b^2}\right)$. Direct multiplication verifies $xq = qx = \left(\frac{a^2+b^2}{a^2+b^2}, 0\right) = (1, 0)$.
(iii) Write $x = (a, b)$, $y = (c, d)$, and $u = (e, f)$. The coordinate formulas lie in $\mathbb{R}^2$, so both operations are closed.
Additive associativity is $(x + y) + u = (a + c + e, b + d + f) = x + (y + u)$.
Additive commutativity is $x + y = (c + a, d + b) = y + x$.
Together with (i) and $-(a, b) = (-a, -b)$, these identities make $(\mathbb{C}, +)$ an abelian group.
Multiplicative commutativity is $xy = (ac - bd, ad + bc) = (ca - db, cb + da) = yx$.
Multiplicative associativity is $(xy)u = (ace - adf - bcf - bde, acf + ade + bce - bdf) = x(yu)$.
The identity $x(y + u) = (a(c + e) - b(d + f), a(d + f) + b(c + e)) = xy + xu$ proves left distributivity.
Right distributivity holds by commutativity. Parts (i)–(ii) and $(0, 0) \neq (1, 0)$ complete the field axioms.

Structural Commentary: Coordinate identities verify the ring laws; $a^2 + b^2 > 0$ constructs each inverse.
Key Insight: The relation $a^2 + b^2 > 0$ makes conjugate-over-norm division possible. □

Proposition 1.2.3. *Real Numbers Inside Complex Numbers*
Let $\iota : \mathbb{R} \to \mathbb{C}$ *be* $\iota(a) := (a, 0)$.
(i) $(\forall a, b \in \mathbb{R})\,[\iota(a+b) = \iota(a) + \iota(b) \wedge \iota(ab) = \iota(a)\iota(b)]$.
(ii) ι *is injective,* $\iota(0) = (0,0)$, *and* $\iota(1) = (1,0)$.

Proof.
(i) $\iota(a) + \iota(b) = (a,0) + (b,0) = (a+b,0) = \iota(a+b)$, and $\iota(a)\iota(b) = (a,0)(b,0) = (ab,0) = \iota(ab)$.
(ii) If $\iota(a) = \iota(b)$, then $(a,0) = (b,0)$, so $a = b$. The identities $\iota(0) = (0,0)$ and $\iota(1) = (1,0)$ hold directly.
Structural Commentary: Zero second coordinates are stable under both operations; pair equality proves injectivity.
Key Insight: The map $a \mapsto (a,0)$ realizes real arithmetic on the first coordinate. □

Convention 1.2.4. *Real Scalars Inside* $\mathbb{C}$
Henceforth identify $a \in \mathbb{R}$ with its image $\iota(a) = (a,0) \in \mathbb{C}$.

Proposition 1.2.5. *Coordinate Form and* i^2
For $i = (0,1) \in \mathbb{C}$*:*
(i) $i^2 = -1$.
(ii) $(\forall a, b \in \mathbb{R})\,[(a,b) = a + bi]$.

Proof.
(i) $i^2 = (0,1)(0,1) = (-1,0) = -1$.
(ii) $a + bi = (a,0) + (b,0)(0,1) = (a,0) + (0,b) = (a,b)$.
Structural Commentary: The products $(0,1)^2 = (-1,0)$ and $(b,0)(0,1) = (0,b)$ convert pair coordinates into $a + bi$.
Key Insight: Multiplication by $i = (0,1)$ transfers a real scalar to the second coordinate. □

Definition 1.2.6. *Conjugate, Real Part, and Imaginary Part*
Let $z = a + bi$ with $a, b \in \mathbb{R}$.
(i) The *complex conjugate* of z is $\overline{z} := a - bi$.
(ii) The *real part* and *imaginary part* of z are $\mathrm{Re}(z) := a$ and $\mathrm{Im}(z) := b$.

Proposition 1.2.7. *Basic Conjugation Identities*
If $z, w \in \mathbb{C}$, *then*
(i) $\overline{z+w} = \overline{z} + \overline{w}$;
(ii) $\overline{zw} = \overline{z}\,\overline{w}$;
(iii) $z + \overline{z} = 2\,\mathrm{Re}(z)$ *and* $z - \overline{z} = 2i\,\mathrm{Im}(z)$;
(iv) $z\overline{z} \in [0,\infty)$; $z \neq 0 \Rightarrow z\overline{z} > 0$, *and* $z = 0 \Rightarrow z\overline{z} = 0$.

Proof. Write $z = a + bi$ and $w = c + di$.
(i) $\overline{z+w} = (a+c) - (b+d)i = \overline{z} + \overline{w}$.
(ii) $\overline{zw} = (ac - bd) - (ad + bc)i = (a - bi)(c - di) = \overline{z}\,\overline{w}$.
(iii) $z + \overline{z} = 2a = 2\,\mathrm{Re}(z)$ and $z - \overline{z} = 2bi = 2i\,\mathrm{Im}(z)$.
(iv) $z\overline{z} = a^2 + b^2 \in [0,\infty)$. For $z \neq 0$, $a^2 + b^2 > 0$ by Proposition 1.1.3(iv), as at least one coordinate nonzero. For $z = 0$, $z\overline{z} = 0\overline{0} = 0$.
Structural Commentary: Coordinate sign reversal preserves both operations and turns $z\overline{z}$ into a sum of squares.
Key Insight: $z\overline{z} = a^2 + b^2 \geq 0$. □

Definition 1.2.8. *Absolute Value of a Complex Number*
For $z = a + bi \in \mathbb{C}$, define $|z| := \sqrt{z\overline{z}} = \sqrt{a^2 + b^2}$ as the unique $r \in [0,\infty)$ with $r^2 = a^2 + b^2$.
For $z \neq 0$, existence and uniqueness hold by Proposition 1.2.7(iv) and Theorem 1.1.11 with $n = 2$.
For $z = 0$, the unique nonnegative solution is $r = 0$ by Proposition 1.1.3(iv).

Theorem 1.2.9. *Absolute Value Identities*
For $z, w \in \mathbb{C}$,
(i) $|z| \geq 0$; $z = 0 \Rightarrow |z| = 0$, *and* $z \neq 0 \Rightarrow |z| > 0$;
(ii) $|\overline{z}| = |z|$;
(iii) $|zw| = |z|\,|w|$;
(iv) $|\mathrm{Re}(z)| \leq |z|$;
(v) $|z + w| \leq |z| + |w|$.

Proof. For $r, s \in [0,\infty)$, $r^2 \leq s^2 \Rightarrow r \leq s$, since $s < r$ would imply $0 < (r-s)(r+s) = r^2 - s^2$.
For $t \in \mathbb{R}$ with $t \geq 0$, $t = |t|$ by equality of their nonnegative squares. For $t < 0$, $t < 0 \leq |t|$; thus $(\forall t \in \mathbb{R})\, t \leq |t|$.
(i) The relations $|z| \geq 0$ and $|0| = 0$ hold by Definition 1.2.8. For $z \neq 0$, $|z|^2 = z\overline{z} > 0$ by Proposition 1.2.7(iv).
The inequality $|z| > 0$ holds by $|z|^2 > 0$ and nonnegativity.
(ii) Since $\overline{\overline{z}} = z$ by definition, $|\overline{z}|^2 = \overline{z}z = z\overline{z} = |z|^2$. Then $|\overline{z}| = |z|$ holds by preliminary square comparison in both directions.
(iii) $|zw|^2 = (zw)\overline{zw} = (z\overline{z})(w\overline{w})$ by Proposition 1.2.7(ii) and commutativity. $|zw|^2 = |z|^2\,|w|^2 = (|z|\,|w|)^2$.
Then $|zw| = |z|\,|w|$ holds by the preliminary square comparison and nonnegativity.
(iv) For $z = a + bi$, $|\mathrm{Re}(z)|^2 = a^2 \leq a^2 + b^2 = |z|^2$. Then $|\mathrm{Re}(z)| \leq |z|$ holds by preliminary square comparison and nonnegativity.
(v) Set $q := z\overline{w}$. The identity $\overline{q} = \overline{z}w$ holds by Proposition 1.2.7(ii) and the definition of conjugation.
The bound $\mathrm{Re}(q) \leq |\mathrm{Re}(q)| \leq |q|$ holds by the real estimate and (iv). The identity $|q| = |z|\,|w|$ holds by (iii).
By Proposition 1.2.7(i), $|z+w|^2 = (z+w)(\overline{z} + \overline{w})$. By distributivity, $(z+w)(\overline{z} + \overline{w}) = |z|^2 + q + \overline{q} + |w|^2$.
Identity $q + \overline{q} = 2\,\mathrm{Re}(q)$ holds by Proposition 1.2.7(iii). $|z+w|^2 \leq |z|^2 + 2\,|z|\,|w| + |w|^2 = (|z| + |w|)^2$ by preceding bounds.
$|z + w| \leq |z| + |w|$ by the preliminary square comparison and nonnegativity.
Structural Commentary: Squared moduli prove (ii)–(iv); the expansion in (v) reduces its cross term to (iii)–(iv).
Key Insight: The identity $z\overline{z} = a^2 + b^2$ converts complex algebra into ordered real estimates. □

2 Real Sequences and Completeness Methods

2.1 Sequences, Cauchy Criteria, and Completeness

Sequences test how limits interact with algebra, order, and completeness. This subsection develops limit algebra and subsequences. It then derives monotone convergence, Bolzano–Weierstrass, and the Cauchy criterion.
Divergence and upper and lower limits appear in the next subsection.

Definition 2.1.1. *Convergent Real and Complex Sequences*
Let $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, let (s_n) be a sequence in $\mathbb{K}$, and let $s \in \mathbb{K}$.

(i) (s_n) *converges* to s iff $(\forall \varepsilon > 0)(\exists N \in \mathbb{N})(\forall n \geq N)\ |s_n - s| < \varepsilon$.
(ii) Write $s_n \to s$ or $\lim_{n\to\infty} s_n = s$. The sequence *diverges* iff no $s \in \mathbb{K}$ satisfies (i).

For $\mathbb{K} = \mathbb{R}$, $|\cdot|$ is from Definition 1.1.16. For $\mathbb{K} = \mathbb{C}$, it is from Definition 1.2.8.

Figure 116: For a real sequence, the tail $\{s_n : n \geq N\}$ stays inside $(s - \varepsilon, s + \varepsilon)$.

For real sequences, Figure 116 illustrates the tail condition in the definition.

Definition 2.1.2. *Range and Boundedness of a Real Sequence*
Let (s_n) be a real sequence.

(i) The *range* of (s_n) is $\text{range}(s_n) := \{s_n : n \in \mathbb{N}\}$.
(ii) (s_n) is *bounded* iff $(\exists m, M \in \mathbb{R})(\forall n \in \mathbb{N})\ m \leq s_n \leq M$.

Convention 2.1.3. *Eventual Properties*
For statements $P(n)$ indexed by $n \in \mathbb{N}$, $P(n)$ holds *eventually* iff $(\exists N \in \mathbb{N})(\forall n \geq N)\ P(n)$.

Proposition 2.1.4. *Basic Consequences of Sequence Convergence*
Let $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, and let (s_n) and (t_n) be sequences in $\mathbb{K}$.

(i) If $s_n \to s$ and $s_n \to t$, then $s = t$.
(ii) If $s_n \to s$, then $\{|s_n| : n \in \mathbb{N}\}$ is bounded.
(iii) If $\mathbb{K} = \mathbb{R}$, $s_n \leq t_n$ eventually, $s_n \to s$, and $t_n \to t$, then $s \leq t$.
If $\mathbb{K} = \mathbb{R}$ and $c \in \mathbb{R}$, then $s_n \leq c$ eventually and $s_n \to s$ imply $s \leq c$.

Proof. For $\mathbb{K} = \mathbb{R}$, positivity, triangle inequality hold by Proposition 1.1.17(i),(iii). For $\mathbb{K} = \mathbb{C}$, these hold by Theorem 1.2.9(i),(v).

(i) Suppose $s \neq t$ and set $d := |s - t| > 0$. For $\varepsilon := \frac{d}{3}$, choose N such that $|s_n - s| < \varepsilon$ and $|s_n - t| < \varepsilon$ for $n \geq N$.
Then $d \leq |s - s_n| + |s_n - t| < 2\varepsilon = \frac{2d}{3}$, a contradiction.
(ii) Choose $N \geq 2$ such that $|s_n - s| < 1$ for $n \geq N$, and set $M := \max\{|s_1|, \ldots, |s_{N-1}|, |s| + 1\}$.
For $n \geq N$, $|s_n| \leq |s_n - s| + |s| < |s| + 1 \leq M$. The set $\{|s_n| : n \in \mathbb{N}\}$ is bounded by $(\forall n \in \mathbb{N})\ 0 \leq |s_n| \leq M$.
(iii) Suppose $s > t$ and set $\varepsilon := \frac{s-t}{3}$. Choose N such that $n \geq N$ implies $s_n \leq t_n$, $|s_n - s| < \varepsilon$, and $|t_n - t| < \varepsilon$.
Then $s_n > s - \varepsilon > t + \varepsilon > t_n$, contradicting $s_n \leq t_n$. Final claim is preceding result with constant sequence $t_n = t = c$.

Structural Commentary: The triangle inequality separates limits, bounds tails, and transfers eventual order.
Key Insight: A common late index turns simultaneous estimates into one contradiction or bound. □

Theorem 2.1.5. *Limit Algebra for Real and Complex Sequences*
Let $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, and let (s_n) and (t_n) be sequences in $\mathbb{K}$. Assume $s_n \to s$ and $t_n \to t$, and let $c \in \mathbb{K}$.

(i) $s_n + t_n \to s + t$;
(ii) $cs_n \to cs$ and $c + s_n \to c + s$;
(iii) $s_n t_n \to st$;
(iv) if $s \neq 0$ and $(\forall n \in \mathbb{N})\ s_n \neq 0$, then $\frac{1}{s_n} \to \frac{1}{s}$.

Proof. For $\mathbb{K} = \mathbb{R}$, required modulus laws hold by Proposition 1.1.17(i)–(iii). For $\mathbb{K} = \mathbb{C}$, these hold by Theorem 1.2.9(i),(iii),(v).

(i) Given $\varepsilon > 0$, choose N with $(\forall n \geq N)\ [|s_n - s| < \frac{\varepsilon}{2} \wedge |t_n - t| < \frac{\varepsilon}{2}]$.
Then $|(s_n + t_n) - (s + t)| \leq |s_n - s| + |t_n - t| < \varepsilon$ by triangle inequality.
(ii) If $c = 0$, then $(\forall n \in \mathbb{N})\ cs_n = 0 = cs$. If $c \neq 0$, then for $\varepsilon > 0$ choose N such that $|s_n - s| < \frac{\varepsilon}{|c|}$ for $n \geq N$.
The inequality $|cs_n - cs| = |c|\,|s_n - s| < \varepsilon$ holds by multiplicativity.
$c + s_n \to c + s$ by (i) and convergence of the constant sequence with value c.
(iii) Choose $M > 0$ with $(\forall n \in \mathbb{N})\ |s_n| \leq M$ by Proposition 2.1.4(ii).
Given $\varepsilon > 0$, choose N with $(\forall n \geq N)\ [|t_n - t| < \frac{\varepsilon}{2M} \wedge |s_n - s| < \frac{\varepsilon}{2(|t|+1)}]$. The identity $s_n t_n - st = s_n(t_n - t) + t(s_n - s)$ holds.
The bound $|s_n t_n - st| \leq M\,|t_n - t| + |t|\,|s_n - s| < \varepsilon$ holds by multiplicativity and the triangle inequality.
(iv) The inequality $|s| > 0$ holds by the relevant positivity law. Choose N_0 such that $|s_n - s| < \frac{|s|}{2}$ for $n \geq N_0$.
The inequality $|s| \leq |s - s_n| + |s_n|$ holds by triangle inequality. For $n \geq N_0$, $|s_n| > \frac{|s|}{2}$ by this inequality, choice of N_0.
Given $\varepsilon > 0$, choose N_1 such that $|s_n - s| < \frac{\varepsilon |s|^2}{2}$ for $n \geq N_1$.
