For $u \in \mathbb{K} \setminus \{0\}$, $\left|u^{-1}\right| = \frac{1}{|u|}$ because $1 = |1| = |u|\left|u^{-1}\right|$ by multiplicativity. Hence $\left|\frac{1}{s_n} - \frac{1}{s}\right| = \frac{|s_n - s|}{|s_n||s|}$.
For $n \geq \max\{N_0, N_1\}$, this quotient is less than $\frac{2}{|s|^2}\,|s_n - s| < \varepsilon$.

Structural Commentary: Uniform bounds control products; reverse triangle bounds control reciprocals.
Key Insight: Every algebraic limit law reduces to an error identity and a late uniform bound. □

Definition 2.1.6. *Subsequences and Subsequential Limits*
Let $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$ and let $p : \mathbb{N} \to \mathbb{K}$, $n \mapsto p_n$, be a sequence.

(i) If $\sigma : \mathbb{N} \to \mathbb{N}$ is strictly increasing, then $p \circ \sigma : k \mapsto p_{\sigma(k)}$ is a *subsequence* of (p_n).

(ii) $q \in \mathbb{K}$ is a *subsequential limit* iff $(\exists\, \sigma : \mathbb{N} \to \mathbb{N})\,[(\forall k \in \mathbb{N})\, \sigma(k+1) > \sigma(k) \wedge p_{\sigma(k)} \to q]$.

Proposition 2.1.7. *Subsequences of Convergent Sequences*
Let $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, (p_n) be a sequence in $\mathbb{K}$, $p \in \mathbb{K}$. Let $\sigma : \mathbb{N} \to \mathbb{N}$ be strictly increasing.

(i) $p_n \to p \Rightarrow p_{\sigma(k)} \to p$.
(ii) If each subsequence of (p_n) converges to p, then $p_n \to p$.

Proof.

(i) Strict increase implies $\sigma(1) \geq 1$ and $\sigma(k+1) \geq \sigma(k) + 1$. The bound $(\forall k \in \mathbb{N})\, \sigma(k) \geq k$ holds by Theorem 2.6.2.
Given $\varepsilon > 0$, choose N such that $|p_n - p| < \varepsilon$ for $n \geq N$. If $k \geq N$, then $\sigma(k) \geq k \geq N$, so $|p_{\sigma(k)} - p| < \varepsilon$.
(ii) Apply the hypothesis to the identity selection map $\sigma(k) = k$.

Structural Commentary: Increasing selection maps place late subsequence indices in the original tail.
Key Insight: The bound $\sigma(k) \geq k$ transfers every convergence threshold. □

Definition 2.1.8. *Monotone Real Sequence*
Let (s_n) be a real sequence.

(i) (s_n) is *monotonically increasing* iff $(\forall n \in \mathbb{N})\, s_n \leq s_{n+1}$.
(ii) (s_n) is *monotonically decreasing* iff $(\forall n \in \mathbb{N})\, s_n \geq s_{n+1}$.

The sequence is *monotonic* iff it is increasing or decreasing.

Definition 2.1.9. *Dominant Index*
For a real sequence (s_n), an index $n \in \mathbb{N}$ is *dominant* iff $(\forall m > n)\, s_n \geq s_m$.

Theorem 2.1.10. *Monotone Subsequence Theorem*
Every real sequence has a monotone subsequence.

Proof.

(i) *Dominant set*: Let $D := \{n \in \mathbb{N} : (\forall m > n)\, s_n \geq s_m\}$.
(ii) *Infinite case*: If D is infinite, set $n_1 := \min D$ by Assumption 2.6.1.
The set $\{n \in D : n > n_k\}$ is nonempty at each stage because D is infinite.
Recursively set $n_{k+1} := \min\{n \in D : n > n_k\}$ by the same assumption.
The subsequence (s_{n_k}) is decreasing by $n_1 < n_2 < \cdots$ and $s_{n_1} \geq s_{n_2} \geq \cdots$.
(iii) *Finite case*: If D is finite, choose N such that no $n \geq N$ belongs to D, and set $n_1 := N$.
Given $n_k \geq N$, choose $n_{k+1} > n_k$ with $s_{n_{k+1}} > s_{n_k}$ by the nondominance of n_k.
The subsequence (s_{n_k}) is increasing by $n_1 < n_2 < \cdots$ and $s_{n_1} < s_{n_2} < \cdots$.

Structural Commentary: Dominant indices decrease; recursive nondominance beyond them increases.
Key Insight: Dominance splits the index set into the two constructions needed for monotonicity. □

Theorem 2.1.11. *Monotone Convergence Theorem for Sequences*
A monotonic real sequence converges iff it is bounded.

Proof.

(⇒) The sequence is bounded by Proposition 2.1.4(ii).
(⇐) Let $E := \{s_n : n \in \mathbb{N}\}$. If (s_n) is increasing, then E is bounded above and $s := \sup E$ exists by Theorem 1.1.9.
Given $\varepsilon > 0$, $s - \varepsilon$ is not an upper bound of E, so choose N with $s - \varepsilon < s_N \leq s$.
For $n \geq N$, $0 \leq s - s_n \leq s - s_N < \varepsilon$, so $|s_n - s| < \varepsilon$ by Definition 1.1.16.
If (s_n) is decreasing, then E is bounded below and $s := \inf E$ exists by Corollary 1.1.15.
Given $\varepsilon > 0$, $s + \varepsilon$ is not a lower bound of E, so choose N with $s \leq s_N < s + \varepsilon$.
For $n \geq N$, $0 \leq s_n - s \leq s_N - s < \varepsilon$, so $|s_n - s| < \varepsilon$ by Definition 1.1.16.

Structural Commentary: Boundedness supplies extrema; monotonicity traps each tail against one term.
Key Insight: An extremum becomes the limit because no ε-shift remains a bound. □

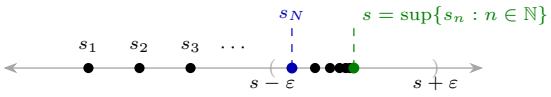

Figure 117: For an increasing bounded sequence, $s = \sup_{n \in \mathbb{N}} s_n$ is the limit.

Figure 117 illustrates the supremum mechanism in the increasing case.

Theorem 2.1.12. *Bolzano–Weierstrass for Real Sequences*
Every bounded real sequence has a convergent subsequence.

Proof. Choose a monotone subsequence (s_{n_k}) by Theorem 2.1.10.
Subsequence (s_{n_k}) is bounded because its range is contained in the bounded range of (s_n). Subsequence converges by Theorem 2.1.11.
Structural Commentary: Monotone subsequences inherit boundedness and therefore converge.
Key Insight: Boundedness survives passage to the monotone subsequence. □

Definition 2.1.13. *Cauchy Real Sequence*
A real sequence (s_n) is *Cauchy* iff $(\forall \varepsilon > 0)(\exists N \in \mathbb{N})(\forall m, n \geq N)\ |s_n - s_m| < \varepsilon$.

Lemma 2.1.14. *Cauchy Plus One Convergent Subsequence*
If a real Cauchy sequence has a subsequence converging to $s \in \mathbb{R}$, then the whole sequence converges to s.

Proof.

(i) *Index growth*: The inequalities $n_1 \geq 1$ and $n_{j+1} \geq n_j + 1$ hold. The bound $(\forall j \in \mathbb{N})\, n_j \geq j$ holds by Theorem 2.6.2.
(ii) *Tail thresholds*: Given $\varepsilon > 0$, choose N_0 such that $m, n \geq N_0 \Rightarrow |s_m - s_n| < \frac{\varepsilon}{2}$. Choose J such that $j \geq J \Rightarrow \left|s_{n_j} - s\right| < \frac{\varepsilon}{2}$.
(iii) *Common anchor*: Fix $j \geq \max\{J, N_0\}$. Then $n_j \geq j \geq N_0$.
(iv) *Final estimate*: The required triangle inequality holds by Proposition 1.1.17(iv). For $n \geq N_0$, $|s_n - s| \leq \left|s_n - s_{n_j}\right| + \left|s_{n_j} - s\right| < \varepsilon$.

Structural Commentary: A term common to both tails anchors every later original term.
Key Insight: A single shared late index joins the two $\frac{\varepsilon}{2}$ estimates. □

Theorem 2.1.15. *Real Cauchy Criterion*
A real sequence converges in $\mathbb{R}$ iff it is Cauchy.

Proof.

(⇒) Given $\varepsilon > 0$, choose N such that $|s_n - s| < \frac{\varepsilon}{2}$ for $n \geq N$.
For $m, n \geq N$, $|s_n - s_m| \leq |s_n - s| + |s - s_m| < \varepsilon$ by Proposition 1.1.17(iv).
(⇐) Choose $N \geq 2$ such that $m, n \geq N \Rightarrow |s_m - s_n| < 1$.
The sequence is bounded because its tail lies in $(s_N - 1, s_N + 1)$ and its finite initial set is bounded.
Choose a subsequence converging to some $s \in \mathbb{R}$ by Theorem 2.1.12. The whole sequence converges by Lemma 2.1.14.

Structural Commentary: Convergence controls late pairs; Cauchy boundedness supplies an anchoring limit.
Key Insight: Bolzano–Weierstrass locates a candidate limit, and the Cauchy lemma propagates it. □

2.2 Divergence, Upper and Lower Limits, and Sequence Estimates

Definition 2.2.1. *Divergence to $\pm\infty$*
Let (s_n) be a real sequence.

(i) $s_n \to +\infty \iff (\forall M \in \mathbb{R})(\exists N \in \mathbb{N})(\forall n \geq N)\, s_n \geq M$.
(ii) $s_n \to -\infty \iff (\forall M \in \mathbb{R})(\exists N \in \mathbb{N})(\forall n \geq N)\, s_n \leq M$.

Proposition 2.2.2. *Monotone Sequences Have Extended Limits*
Let (s_n) be a real sequence.

(i) If (s_n) is increasing, then $s_n \to \sup\{s_n : n \in \mathbb{N}\}$ in $\overline{\mathbb{R}}$.
(ii) If (s_n) is decreasing, then $s_n \to \inf\{s_n : n \in \mathbb{N}\}$ in $\overline{\mathbb{R}}$.
(iii) In either case, the extended limit lies in $\mathbb{R}$ iff (s_n) is bounded.

Proof.

(*i*) Set $a := \sup\{s_n : n \in \mathbb{N}\} \in \overline{\mathbb{R}}$. Since the range is nonempty, $a \neq -\infty$.
If $a \in \mathbb{R}$, fix $\varepsilon > 0$ and choose $N \in \mathbb{N}$ with $a - \varepsilon < s_N \leq a$ by the defining property of a.
Then $(\forall n \geq N)\, a - \varepsilon < s_n \leq a$ by monotonicity, so $s_n \to a$.
If $a = +\infty$, fix $M \in \mathbb{R}$ and choose $N \in \mathbb{N}$ with $s_N \geq M$ by the defining property of a.
Then $(\forall n \geq N)\, s_n \geq M$ by monotonicity, so $s_n \to +\infty$.
(*ii*) Set $b := \inf\{s_n : n \in \mathbb{N}\} \in \overline{\mathbb{R}}$. Since the range is nonempty, $b \neq +\infty$.
If $b \in \mathbb{R}$, fix $\varepsilon > 0$ and choose $N \in \mathbb{N}$ with $b \leq s_N < b + \varepsilon$ by the defining property of b.
Then $(\forall n \geq N)\, b \leq s_n < b + \varepsilon$ by monotonicity, so $s_n \to b$.
If $b = -\infty$, fix $M \in \mathbb{R}$ and choose $N \in \mathbb{N}$ with $s_N \leq M$ by the defining property of b.
Then $(\forall n \geq N)\, s_n \leq M$ by monotonicity, so $s_n \to -\infty$.
(*iii*) (⇒) In the increasing case, a finite limit a bounds the range above, while s_1 bounds it below.
In the decreasing case, a finite limit b bounds the range below, while s_1 bounds it above. Thus the range is bounded.
(*iii*) (⇐) If the range is bounded, its supremum in (i) or infimum in (ii) is real by the extended-extremum definitions.

Structural Commentary: Extended extrema split the finite ε-trap and infinite threshold cases.
Key Insight: Monotonicity propagates one extremal witness through the entire tail. □

Proposition 2.2.3. *Unbounded Real Sequences Have Infinite Subsequences*
A real sequence is unbounded iff some subsequence tends to $+\infty$ or $-\infty$.

Proof.

(⇒) An unbounded real sequence is unbounded above or below. If it is unbounded above, every tail is unbounded above.
Set $n_0 := 0$ and recursively choose $n_k > n_{k-1}$ with $s_{n_k} \geq k$. For $M \in \mathbb{R}$, choose $K \in \mathbb{N}$ with $K \geq M$ by Theorem 1.1.19(i).
Then $(\forall k \geq K)\, s_{n_k} \geq k \geq M$, so $s_{n_k} \to +\infty$. If (s_n) is unbounded below, same construction with $s_{n_k} \leq -k$ satisfies $s_{n_k} \to -\infty$.
(⇐) If $s_{n_k} \to +\infty$, then $(\forall M \in \mathbb{R})(\exists k \in \mathbb{N})\, s_{n_k} \geq M$, so (s_n) is unbounded above.
If $s_{n_k} \to -\infty$, then $(\forall M \in \mathbb{R})(\exists k \in \mathbb{N})\, s_{n_k} \leq M$, so (s_n) is unbounded below.

Structural Commentary: Tail unboundedness supports a recursive threshold subsequence with levels $\pm k$.
Key Insight: Increasing indices convert unbounded tails into extended divergence. □

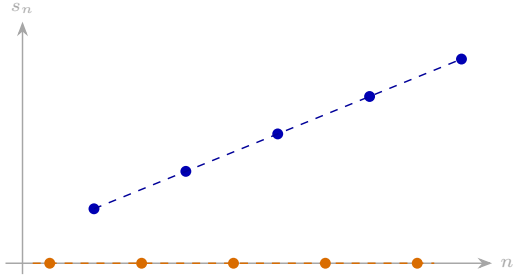

Figure 118: For $s_n = [(-1)^n + 1]n$, odd terms (orange) equal 0, while even terms (blue) equal $2n$ and tend to $+\infty$.

Figure 118 exhibits finite and infinite subsequential limits in one sequence.

Definition 2.2.4. *Upper and Lower Limits*
Let (s_n) be a real sequence and set $E := E(s) := \{x \in \overline{\mathbb{R}} : (\exists\, n_1 < n_2 < \cdots)\ s_{n_k} \to x\}$.

(i) The *upper limit* is $\limsup_{n\to\infty} s_n := s^* := \sup_{\overline{\mathbb{R}}} E$.

(ii) The *lower limit* is $\liminf_{n\to\infty} s_n := s_* := \inf_{\overline{\mathbb{R}}} E$.

Theorem 2.2.5. *Characterization of Upper and Lower Limits*
Let (s_n) be a real sequence and set $E := \{x \in \overline{\mathbb{R}} : (\exists\, n_1 < n_2 < \cdots)\ s_{n_k} \to x\}$. Set $s^* := \sup_{\overline{\mathbb{R}}} E$ and $s_* := \inf_{\overline{\mathbb{R}}} E$.

For $y \in \overline{\mathbb{R}}$, set $U(y) := (\forall x \in \mathbb{R})[x > y \Rightarrow (\exists N \in \mathbb{N})(\forall n \geq N)\, s_n < x]$. Set $L(y) := (\forall x \in \mathbb{R})[x < y \Rightarrow (\exists N \in \mathbb{N})(\forall n \geq N)\, s_n > x]$.

(i) $s^* \in E$.
(ii) $U(s^*)$.
(iii) $\{y \in E : U(y)\} = \{s^*\}$.
(iv) $s_* \in E$.
(v) $L(s_*)$.
(vi) $\{y \in E : L(y)\} = \{s_*\}$.

Proof.

(i) Set $n_0 := 0$ and distinguish the value of s^*.
  (a) If $s^* = +\infty$, choose $y_k \in E$ with $y_k > k$. Choose $n_k > n_{k-1}$ with $s_{n_k} > k$; this is possible by $y_k \in E$ and $y_k > k$.
  For $M \in \mathbb{R}$, choose $K \in \mathbb{N}$ with $K > M$ by Theorem 1.1.19(i). Then $(\forall k \geq K)\, s_{n_k} > k > M$, so $s_{n_k} \to +\infty$ and $+\infty \in E$.
  (b) If $s^* \in \mathbb{R}$, choose $y_k \in E \cap (s^* - k^{-1}, s^*]$ and then $n_k > n_{k-1}$ with $|s_{n_k} - y_k| < k^{-1}$.
  The bound $|s_{n_k} - s^*| < 2k^{-1}$ holds by Proposition 1.1.17(iv). For $\varepsilon > 0$, choose $K > 2\varepsilon^{-1}$ by Theorem 1.1.19(i).
  Then $(\forall k \geq K)\ |s_{n_k} - s^*| < \varepsilon$, so $s_{n_k} \to s^*$ and $s^* \in E$.
  (c) Suppose $s^* = -\infty$ and $-\infty \notin E$. Some tail is bounded below.
  Otherwise the recursive construction with $s_{n_k} \leq -k$ would place $-\infty$ in E.
  If this tail is bounded above, it has a finite subsequential limit by Theorem 2.1.12.
  If it is unbounded above, it has an infinite subsequential limit by Proposition 2.2.3.
  The infinite limit is $+\infty$ because the tail is bounded below.
  Either case places an element greater than $-\infty$ in E, contradicting $s^* = \sup_{\overline{\mathbb{R}}} E = -\infty$.

(ii) Fix $x \in \mathbb{R}$ with $x > s^*$. If $s_n \geq x$ infinitely often, choose a subsequence with $(\forall k \in \mathbb{N})\, s_{n_k} \geq x$.
If subsequence bounded, a further subsequence converges by Theorem 2.1.12. Its limit y satisfies $y \geq x$ by Proposition 2.1.4(iii).
If the subsequence is unbounded, it is bounded below by x. A further subsequence tends to $+\infty$ by Proposition 2.2.3.
Thus $E \cap [x, +\infty] \neq \emptyset$, contradicting $x > s^* = \sup_{\overline{\mathbb{R}}} E$. Therefore $s_n < x$ eventually.

(iii) Let $A := \{y \in E : U(y)\}$. Then $s^* \in A$ by (i)–(ii). If $p, q \in A$ with $p < q$, choose $x \in \mathbb{R}$ with $p < x < q$.
Then $s_n < x$ eventually by $U(p)$. Since $q \in E$, $q > x$, a subsequence is eventually greater than x, contradiction. Thus $A = \{s^*\}$.

(iv) For $r_n := -s_n$, its subsequential-limit set is $-E$, upper limit is $-s_*$.
Relation $-s_* \in -E$ holds by (i) for (r_n); equivalently, $s_* \in E$.

(v) Fix $x \in \mathbb{R}$ with $x < s_*$. Then $-x > -s_*$, so $-s_n < -x$ eventually by (ii) for (r_n). Equivalently, $s_n > x$ eventually.

(vi) The set $\{y \in E : L(y)\}$ is the negative of the upper-characterizing set for (r_n), so it equals $\{s_*\}$ by (iii).

Structural Commentary: Diagonal subsequences attain each extremum; sign reversal transfers the upper characterization downward.
Key Insight: Failure of an eventual bound creates a competing subsequential limit. □

Proposition 2.2.6. *Tail-Envelope Formulae*
For a real sequence (s_n) and $N \in \mathbb{N}$, set $T_N := \{s_n : n \geq N\}$. Set $u_N := \sup_{\overline{\mathbb{R}}} T_N$ and $\ell_N := \inf_{\overline{\mathbb{R}}} T_N$.

(i) $(\forall N \in \mathbb{N})\, [u_{N+1} \leq u_N \wedge \ell_{N+1} \geq \ell_N]$.
(ii) $\limsup_{n\to\infty} s_n = \inf_{N\in\mathbb{N}} u_N$ *and* $\liminf_{n\to\infty} s_n = \sup_{N\in\mathbb{N}} \ell_N$.

Proof.

(i) The inclusion $T_{N+1} \subseteq T_N$ implies $u_{N+1} \leq u_N$ and $\ell_{N+1} \geq \ell_N$.

(ii) Set $s^* := \limsup s_n$ and $u := \inf_{N\in\mathbb{N}} u_N$. If $x \in \mathbb{R}$ and $x > s^*$, then $u \leq x$ by Theorem 2.2.5(ii) and the definition of u.
If $y \in \mathbb{R}$ and $y < s^*$, each tail contains a term greater than y by Theorem 2.2.5(i). Thus $(\forall N \in \mathbb{N})\, u_N \geq y$ and $u \geq y$.
If $s^* = -\infty$, then $(\forall x \in \mathbb{R})\, u \leq x$, so $u = -\infty$. If $s^* = +\infty$, then $(\forall y \in \mathbb{R})\, u \geq y$, so $u = +\infty$.
If $s^* \in \mathbb{R}$, then $(\forall \varepsilon > 0)\, s^* - \varepsilon \leq u \leq s^* + \varepsilon$, so $u = s^*$. For $r_n := -s_n$, its upper tail extrema are $-\ell_N$ and $\limsup r_n = -s_*$.
Thus $-s_* = \inf_{N\in\mathbb{N}} (-\ell_N) = -\sup_{N\in\mathbb{N}} \ell_N$, so $\sup_{N\in\mathbb{N}} \ell_N = s_*$.

Structural Commentary: Nested tails make extrema monotone; subsequential thresholds identify their terminal bounds.
Key Insight: Every extremal subsequence returns arbitrarily far into each tail. □

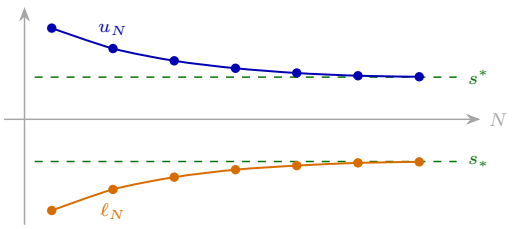

Figure 119: The upper tail extrema u_N decrease to $s^* = \limsup s_n$, while the lower extrema ℓ_N increase to $s_* = \liminf s_n$.

Figure 119 visualizes the two monotone envelopes in Proposition 2.2.6.

Theorem 2.2.7. *Convergence and Equal Upper/Lower Limits*
For a real sequence (s_n) and $s \in \mathbb{R}$, $s_n \to s \iff \limsup_{n\to\infty} s_n = \liminf_{n\to\infty} s_n = s$.

Proof.
($\Rightarrow$) Suppose $s_n \to s$ and set $E := E(s)$. Every subsequence converges to s by Proposition 2.1.7(i).
Choose $M > 0$, $(\forall n \in \mathbb{N})\ |s_n| \le M$ by Proposition 2.1.4(ii). Then $(\forall n \in \mathbb{N})\ -M \le s_n \le M$, no subsequence tends to $\pm\infty$.
Thus $E = \{s\}$ and $\limsup s_n = \liminf s_n = s$.
($\Leftarrow$) Suppose $\limsup s_n = \liminf s_n = s$, $\varepsilon > 0$. Inequalities $s_n < s + \varepsilon$ and $s_n > s - \varepsilon$ hold eventually by Theorem 2.2.5(ii),(v).
Therefore $|s_n - s| < \varepsilon$ eventually, so $s_n \to s$.
Structural Commentary: Subsequence inheritance proves necessity; the two eventual extremal bounds prove sufficiency.
Key Insight: Limsup supplies an eventual ceiling; liminf supplies an eventual floor. □

Theorem 2.2.8. *Order Comparison for Upper and Lower Limits*
Let (s_n) and (t_n) be real sequences with $s_n \le t_n$ eventually.
(i) $\limsup_{n\to\infty} s_n \le \limsup_{n\to\infty} t_n$.
(ii) $\liminf_{n\to\infty} s_n \le \liminf_{n\to\infty} t_n$.

Proof. Choose $N \in \mathbb{N}$ such that $(\forall n \ge N)\ s_n \le t_n$ by the definition of eventual order.
(i) $(\forall k \ge N)\ \sup_{n\ge k} s_n \le \sup_{n\ge k} t_n$. Then $\limsup s_n = \inf_{k\ge N} \sup_{n\ge k} s_n \le \inf_{k\ge N} \sup_{n\ge k} t_n = \limsup t_n$ by Proposition 2.2.6(i)–(ii).
(ii) $(\forall k \ge N)\ \inf_{n\ge k} s_n \le \inf_{n\ge k} t_n$. Then $\liminf s_n = \sup_{k\ge N} \inf_{n\ge k} s_n \le \sup_{k\ge N} \inf_{n\ge k} t_n = \liminf t_n$ by Proposition 2.2.6(i)–(ii).
Structural Commentary: Tailwise extrema transfer eventual pointwise order to both envelope limits.
Key Insight: Deleting finitely many tail extrema preserves their terminal infimum and supremum. □

Theorem 2.2.9. *Pinching Theorem for Real Sequences*
Let (a_n), (s_n), and (b_n) be real sequences, and let $s \in \mathbb{R}$. If $a_n \le s_n \le b_n$ eventually and $a_n, b_n \to s$, then $s_n \to s$.

Proof. Fix $\varepsilon > 0$ and choose N_0 such that $(\forall n \ge N_0)\ a_n \le s_n \le b_n$. Choose N_1, N_2 such that $(\forall n \ge N_1)\ s - \varepsilon < a_n$ and $(\forall n \ge N_2)\ b_n < s + \varepsilon$.
Set $N := \max\{N_0, N_1, N_2\}$. Then $(\forall n \ge N)\ s - \varepsilon < s_n < s + \varepsilon$, so $s_n \to s$.
Structural Commentary: Three eventual thresholds combine at their maximum to trap the middle sequence.
Key Insight: $N = \max\{N_0, N_1, N_2\}$ synchronizes both convergent bounds. □

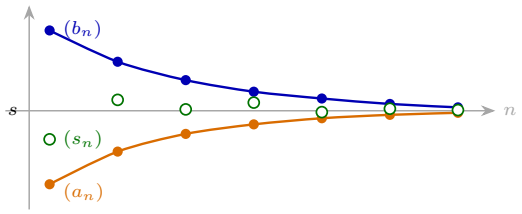

Figure 120: With $a_n \le s_n \le b_n$ and $a_n, b_n \to s$, the middle sequence also tends to s.

Figure 120 shows the middle sequence trapped between the two convergent bounds.

Theorem 2.2.10. *Special Sequence Limits*
(i) If $p > 0$, then $\lim_{n\to\infty} n^{-p} = 0$.
(ii) If $p > 0$, then $\lim_{n\to\infty} \sqrt[n]{p} = 1$.
(iii) $\lim_{n\to\infty} \sqrt[n]{n} = 1$.
(iv) If $p > 0$ and $\alpha \in \mathbb{R}$, then $\lim_{n\to\infty} \frac{n^\alpha}{(1+p)^n} = 0$.
(v) If $|x| < 1$, then $\lim_{n\to\infty} x^n = 0$.

Proof. All positive roots below exist uniquely by Theorem 1.1.11.
(i) Fix $\varepsilon > 0$ and choose $N > \varepsilon^{-p^{-1}}$ by Theorem 1.1.19(i). Then $(\forall n \ge N)\ 0 < n^{-p} < \varepsilon$.
(ii) Suppose $p > 1$ and set $x_n := \sqrt[n]{p} - 1$. Then $x_n > 0$ and $1 + nx_n \le (1 + x_n)^n = p$ by Proposition 4.3.7(i), so $0 < x_n \le (p-1)n^{-1}$.
Upper bound tends to 0 by (i) and Theorem 2.1.5(ii). Thus $x_n \to 0$ by Theorem 2.2.9; $\sqrt[n]{p} = 1 + x_n \to 1$ by Theorem 2.1.5(ii).
If $p = 1$, then $(\forall n \in \mathbb{N})\ \sqrt[n]{p} = 1$. If $0 < p < 1$, set $q := p^{-1} > 1$. Then $\sqrt[n]{q} \to 1$ by the preceding case.
The identity $\sqrt[n]{p} = (\sqrt[n]{q})^{-1}$ holds by Corollary 1.1.12. Therefore $\sqrt[n]{p} \to 1$ by Theorem 2.1.5(iv).
(iii) Set $x_n := \sqrt[n]{n} - 1 \ge 0$. For $n \ge 2$, $n = (1 + x_n)^n \ge \binom{n}{2} x_n^2 = \frac{n(n-1)}{2} x_n^2$ by Proposition 4.3.7(i). Thus $0 \le x_n^2 \le \frac{2}{n-1}$.
Fix $\varepsilon > 0$. Choose $N > 1 + 2\varepsilon^{-2}$ by Theorem 1.1.19(i). For $n \ge \max\{2, N\}$, $0 \le x_n < \varepsilon$. Hence $x_n \to 0$ and $\sqrt[n]{n} = 1 + x_n \to 1$.
(iv) Choose $k \in \mathbb{N}$ with $k > \alpha$ by Theorem 1.1.19(i). If $n > 2k$, then $(\forall j \in \{0, \dots, k-1\})\ n - j > \frac{n}{2}$.
Thus $(1 + p)^n \ge \binom{n}{k} p^k > \frac{n^k p^k}{2^k k!}$ by Proposition 4.3.7(i); $0 < \frac{n^\alpha}{(1+p)^n} < \frac{2^k k!}{p^k} n^{-(k-\alpha)}$.
Upper bound tends to 0 by (i), Theorem 2.1.5(ii). Quotient tends to 0 by Theorem 2.2.9.
(v) If $x \ne 0$, set $p := |x|^{-1} - 1 > 0$. Then $|x| = (1 + p)^{-1}$ and $|x|^n \to 0$ by (iv) with $\alpha = 0$.
The bounds $-|x|^n \le x^n \le |x|^n$ imply $x^n \to 0$ by Theorem 2.2.9. The case $x = 0$ is immediate.

Structural Commentary: Reciprocal powers and binomial lower bounds reduce roots and exponential quotients to pinching.
Key Insight: A fixed binomial term dominates every lower polynomial power. □

Proposition 2.2.11. *Decimal Truncations Squeeze a Real*
Let $x \geq 0$ and set $S_n := \{k \in \mathbb{Z}_{\geq 0} : k10^{-n} \leq x\}$ for $n \in \mathbb{N}_0$.

(i) The maximum $s_n := \max S_n$ exists and satisfies $s_n 10^{-n} \leq x < (s_n+1)10^{-n}$ for $n \in \mathbb{N}_0$.
(ii) $(\forall n \in \mathbb{N}_0)\, 0 \leq x - s_n 10^{-n} < 10^{-n}$, and $s_n 10^{-n} \to x$.
(iii) $(\forall n \in \mathbb{N}_0)(\exists! a_{n+1} \in \{0, \ldots, 9\})\, s_{n+1} = 10s_n + a_{n+1}$.

Proof.

(i) Fix $n \in \mathbb{N}_0$ and set $A_n := \{j \in \mathbb{N} : j10^{-n} > x\}$. The set A_n is nonempty by Theorem 1.1.19(i).
Let m_n be its least element by the standing well-ordering assumption.
Since $x \geq 0$, $m_n \geq 1$, and minimality implies $m_n - 1 \in S_n$. Every $k \in S_n$ satisfies $k < m_n$, so $s_n = m_n - 1 = \max S_n$.
The inequalities $s_n 10^{-n} \leq x < (s_n+1)10^{-n}$ follow from $s_n \in S_n$ and $s_n + 1 = m_n \in A_n$.
(ii) The inequalities in (i) imply $(\forall n \in \mathbb{N}_0)\, 0 \leq x - s_n 10^{-n} < 10^{-n}$. The limit $10^{-n} \to 0$ holds by Theorem 2.2.10(v) with $x = 10^{-1}$.
Thus $x - 10^{-n} \to x$ by Theorem 2.1.5(ii). The bounds $x - 10^{-n} \leq s_n 10^{-n} \leq x$ imply $s_n 10^{-n} \to x$ by Theorem 2.2.9.
(iii) The relations $10s_n \in S_{n+1}$ and $10s_n + 10 \in A_{n+1}$ imply $10s_n \leq s_{n+1} < 10s_n + 10$.
Thus $a_{n+1} := s_{n+1} - 10s_n \in \{0, \ldots, 9\}$, and this formula makes a_{n+1} unique.

Structural Commentary: Archimedean grids define each truncation; nested mesh bounds then support the squeeze.
Key Insight: Refinement by a factor of 10 leaves one digit as the integer remainder. □

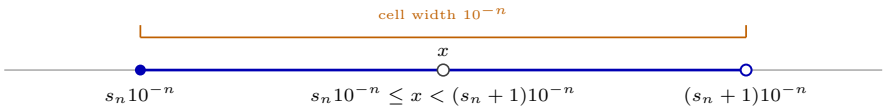

Figure 121: At precision 10^{-n}, x lies in the half-open cell $[s_n 10^{-n}, (s_n+1)10^{-n})$ of width 10^{-n}.

Figure 121 illustrates the shrinking interval in Proposition 2.2.11(i).

Proof Method 2.2.12. *Real-Sequence Proof Patterns*

(i) *Convergence*: Fix $\varepsilon > 0$ and construct N such that $(\forall n \geq N)\, |s_n - s| < \varepsilon$.
(ii) *Uniqueness*: Synchronize two $\frac{\varepsilon}{2}$ tail bounds and compare the proposed limits by the triangle inequality.
(iii) *Subsequences*: Recursively choose $n_k > n_{k-1}$ so the kth term meets a threshold or an error bound of k^{-1}.
(iv) *Cauchy transfer*: Anchor an arbitrary late term to a sufficiently late convergent subsequence term.
(v) *Monotone convergence*: Choose the relevant supremum or infimum and propagate one extremal witness through its tail.

Key Insight: Synchronized tail indices reduce global limit claims to one controlling estimate.

3 Metric Spaces and Euclidean Topology

3.1 Metrics, Open Sets, and Euclidean Topology

Metric topology studies sets through balls: openness, closure, and limit points come from distance.
Euclidean estimates rely on norms, Cauchy–Schwarz, and the triangle inequality.

Definition 3.1.1. *Metric Space*
A *metric space* is a pair (X, d), where X is a set and $d : X \times X \to [0, \infty)$. For all $p, q, r \in X$, the following conditions hold:

i. $d(p,q) = 0 \iff p = q$;
ii. $d(p,q) = d(q,p)$;
iii. $d(p,q) \leq d(p,r) + d(r,q)$.

The function d is called a *distance function* or *metric*.

Definition 3.1.2. *Metric Topology Terminology*
Let (X, d) be a metric space. All points and sets below are understood to be elements and subsets of X, respectively.

(i) For $p \in X$ and $r > 0$, the *open ball* centered at p with radius r is $B_r(p) := \{q \in X : d(p,q) < r\}$.
The corresponding *closed ball* is $\overline{B}_r(p) := \{q \in X : d(p,q) \leq r\}$. The *sphere* of radius r about p is $\{q \in X : d(p,q) = r\}$.
(ii) A point p is an *interior point* of E iff $(\exists\, r > 0)\, B_r(p) \subseteq E$.
(iii) A set E is *open* if every point of E is an interior point of E.
(iv) A *neighborhood* of p is an open set $U \subseteq X$ with $p \in U$.
(v) A point p is a *limit point* of E iff $(\forall\, r > 0)\, B_r(p) \cap (E \setminus \{p\}) \neq \emptyset$.
(vi) If $p \in E$ and p is not a limit point of E, then p is an *isolated point* of E.
(vii) A set E is *closed* iff every limit point of E belongs to E.
(viii) The *complement* of E is $E^c := X \setminus E$.
(ix) A set E is *dense* in X iff every point of X belongs to E, is a limit point of E, or both.

The *metric topology* induced by d is the collection τ_d of all open subsets of X.
For $X = \mathbb{R}$, $B_\varepsilon(a) = (a - \varepsilon, a + \varepsilon)$. Open balls supply the local tests for the metric topology.
Neighborhoods are the open sets containing the point.

Theorem 3.1.3. *Every Open Ball Is Open*
Every open ball in a metric space is an open set.

Proof. Let $E = B_r(p)$, and choose $q \in E$. Put $h := r - d(p,q) > 0$. If $s \in B_h(q)$, then $d(p,s) \leq d(p,q) + d(q,s) < d(p,q) + h = r$.
Thus $B_h(q) \subseteq E$, so q is an interior point of E. Since q was arbitrary, E is open.
Structural Commentary: For $q \in B_r(p)$, positive slack $h = r - d(p,q)$ defines smaller ball. Triangle inequality keeps $B_h(q)$ inside $B_r(p)$.
Key Insight: The triangle inequality turns radius slack into openness. □

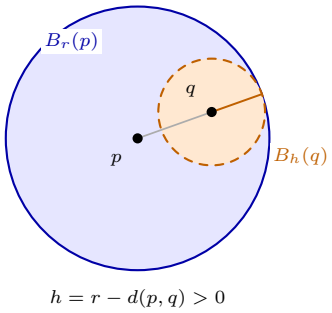

Figure 122: Every point inside a metric ball has a smaller ball still contained in the original ball.

Figure 122 illustrates the smaller-ball construction in the proof.

Perspective 3.1.4. *ε-Closeness Becomes Metric Language*
For the usual metric $d(x,y) := |x-y|$ on $\mathbb{R}$, $|x-y| < \varepsilon \iff y \in B_\varepsilon(x)$.
Metric balls extend this notion of ε-closeness to arbitrary metric spaces.
Key Insight: Absolute value is distance on $\mathbb{R}$.

Example 3.1.5. *Euclidean Metric and Subspaces*
For $\mathbf{x}, \mathbf{y} \in \mathbb{R}^k$, define $d(\mathbf{x},\mathbf{y}) := \|\mathbf{x}-\mathbf{y}\|_2$. Nonnegativity and definiteness hold by Proposition 1.1.12(i)–(ii).
Symmetry holds by Proposition 1.1.12(iii) with scalar -1. Write $\mathbf{x}-\mathbf{z} = (\mathbf{x}-\mathbf{y}) + (\mathbf{y}-\mathbf{z})$.
The metric triangle inequality holds by Theorem 1.1.14(i). Thus the Euclidean space $\mathbb{R}^k$ is a metric space.
If $Y \subseteq X$ for a metric space (X,d), then $d|_{Y\times Y}$ is a metric on Y.

Example 3.1.6. *Discrete Metric*
On any set X, define $d(x,y) := 0$ when $x = y$ and $d(x,y) := 1$ when $x \neq y$. Definiteness and symmetry are immediate.
If $x \neq z$, then at least one of $x \neq y$ or $y \neq z$ holds, so $d(x,z) = 1 \leq d(x,y) + d(y,z)$.
Thus d is the *discrete metric*: distinct points are all distance 1 apart.

Example 3.1.7. *Hamming Distance*
For $x, y \in \{0,1\}^n$, define $h(x,y) := |\{i \in \{1,\dots,n\} : x_i \neq y_i\}|$. Then h is a metric.

Proof. Value $h(x,y)$ nonnegative, satisfies $h(x,y) = h(y,x)$. Moreover, $h(x,y) = 0$ iff $(\forall\, i \in \{1,\dots,n\})\, x_i = y_i$, equivalently $x = y$.
Put $D(u,v) := \{i \in \{1,\dots,n\} : u_i \neq v_i\}$. Then $D(x,y) \subseteq D(x,z) \cup D(z,y)$; $h(x,y) \leq h(x,z) + h(z,y)$ by cardinality of finite unions.
Structural Commentary: Definiteness uses $D(x,y) = \emptyset$; inclusion proves the triangle inequality.
Key Insight: Each disagreement between x and y must be paid for through z in at least one leg. □

Definition 3.1.8. *Euclidean Intervals, Cells, Balls, and Convexity*
(i) In $\mathbb{R}$, $(a,b) := \{x : a < x < b\}$, $[a,b] := \{x : a \leq x \leq b\}$, with $[a,b)$ and $(a,b]$ defined by mixed inequalities.
(ii) A set $J \subseteq \mathbb{R}$ is an *interval* iff $(\forall\, x, y \in J)\, [x < y \Rightarrow [x,y] \subseteq J]$.
(iii) For $a_i < b_i$ with $1 \leq i \leq k$, a *k-cell* is $\prod_{i=1}^{k} [a_i, b_i]$.
(iv) For $\mathbf{x} \in \mathbb{R}^k$ and $r > 0$, $B_r(\mathbf{x}) := \{\mathbf{y} : \|\mathbf{y}-\mathbf{x}\|_2 < r\}$. The corresponding closed ball is $\overline{B}_r(\mathbf{x}) := \{\mathbf{y} : \|\mathbf{y}-\mathbf{x}\|_2 \leq r\}$.
(v) For $\mathbf{x}, \mathbf{y} \in \mathbb{R}^k$, the points $\lambda\mathbf{x} + (1-\lambda)\mathbf{y}$ with $\lambda \in [0,1]$ are the two-point convex combinations.
They form the *line segment* $[\mathbf{x},\mathbf{y}] := \{\lambda\mathbf{x} + (1-\lambda)\mathbf{y} : \lambda \in [0,1]\}$.
(vi) A set $C \subseteq \mathbb{R}^k$ is *convex* iff $(\forall\, \mathbf{x}, \mathbf{y} \in C)\, [\mathbf{x},\mathbf{y}] \subseteq C$.
(vii) The *integer lattice* is $\mathbb{Z}^k$, and the *first orthant* is $\{\mathbf{x} \in \mathbb{R}^k : (\forall\, i \in \{1,\dots,k\})\, x_i \geq 0\}$.
(viii) The *unit ball* is $B^k := \{\mathbf{x} \in \mathbb{R}^k : \|\mathbf{x}\|_2 \leq 1\}$, and the *unit sphere* is $S^{k-1} := \{\mathbf{x} \in \mathbb{R}^k : \|\mathbf{x}\|_2 = 1\}$.

Proposition 3.1.9. *Balls and Cells Are Convex*
(i) Every open or closed ball in $\mathbb{R}^k$ is convex.
(ii) Every k-cell in $\mathbb{R}^k$ is convex.

Proof.
(i) Let $\mathbf{y}, \mathbf{z} \in B_r(\mathbf{x})$, let $\lambda \in [0,1]$, and put $\mathbf{w} := \lambda\mathbf{y} + (1-\lambda)\mathbf{z}$.
Then $\|\mathbf{w}-\mathbf{x}\|_2 \leq \lambda\|\mathbf{y}-\mathbf{x}\|_2 + (1-\lambda)\|\mathbf{z}-\mathbf{x}\|_2 < r$ by norm homogeneity and the triangle inequality.
Hence $B_r(\mathbf{x})$ is convex. For $\mathbf{y}, \mathbf{z} \in \overline{B}_r(\mathbf{x})$ and $\lambda \in [0,1]$, define $\mathbf{w}$ as above. Same estimate ends with $\leq r$, so $\overline{B}_r(\mathbf{x})$ is convex.
(ii) Let $\mathbf{y}, \mathbf{z} \in \prod_{i=1}^{k} [a_i, b_i]$ and $\lambda \in [0,1]$. For every $1 \leq i \leq k$, $a_i \leq \lambda y_i + (1-\lambda) z_i \leq b_i$ by $a_i \leq y_i, z_i \leq b_i$.
Thus $\lambda\mathbf{y} + (1-\lambda)\mathbf{z}$ belongs to the cell.
Structural Commentary: Norm bounds preserve balls; coordinate bounds preserve cells.
Key Insight: Norm subadditivity preserves balls, while order intervals preserve each coordinate. □

Proposition 3.1.10. *Bounded Compression of a Metric*
Let (X,d) be a metric space and set $\rho(x,y) := \frac{d(x,y)}{1+d(x,y)}$.
(i) The function ρ is a bounded metric on X.
(ii) The induced topologies satisfy $\tau_\rho = \tau_d$.

Proof.

(i) Put $f(t) := \frac{t}{1+t}$ for $t \geq 0$. Then $0 \leq f(t) < 1$, so ρ is bounded; definiteness and symmetry follow from d.
For $a, b \geq 0$, $\frac{a}{1+a} + \frac{b}{1+b} - \frac{a+b}{1+a+b} = \frac{ab(a+b+2)}{(1+a)(1+b)(1+a+b)} \geq 0$.
For $0 \leq u \leq v$, $\frac{v}{1+v} - \frac{u}{1+u} = \frac{v-u}{(1+u)(1+v)} \geq 0$. Hence f is nondecreasing and subadditive.
Consequently, $\rho(x,z) = f(d(x,z)) \leq f(d(x,y) + d(y,z)) \leq \rho(x,y) + \rho(y,z)$ by the triangle inequality for d.

(ii) Write $B_s^d(x)$ and $B_s^\rho(x)$ for the balls associated with the indicated metrics.
Since f is strictly increasing, $B_\eta^\rho(x) = B^d_{\frac{\eta}{1-\eta}}(x)$ for $0 < \eta < 1$. Similarly, $B^\rho_{\frac{r}{1+r}}(x) = B_r^d(x)$ for $r > 0$.
A local radius may be reduced below 1, so the two ball identities imply $\tau_\rho = \tau_d$.

Structural Commentary: Scalar monotonicity, subadditivity prove metric claim. Inverse radius formulas prove topology claim.
Key Insight: Compression changes distances but exactly reparametrizes small balls. □

Definition 3.1.11. *Isometries and Pseudometrics*
Let (X, ρ) and (Y, σ) be metric spaces, and let $F : X \to Y$.

(i) The map F is an *isometry* iff $(\forall\, x, y \in X)\, \sigma(Fx, Fy) = \rho(x, y)$.
(ii) The spaces (X, ρ) and (Y, σ) are *isometric*, written $(X, \rho) \cong (Y, \sigma)$, iff a bijective isometry $F : X \to Y$ exists.

For a set Z, a *pseudometric* on Z is a map $d : Z \times Z \to [0, \infty)$.
For all $x, y, z \in Z$, it satisfies $d(x, x) = 0$, $d(x, y) = d(y, x)$, and $d(x, z) \leq d(x, y) + d(y, z)$.
Unlike a metric, a pseudometric may satisfy $d(x, y) = 0$ for distinct points $x, y \in Z$.
Isometries preserve distance; pseudometrics permit zero-distance identification.

Proposition 3.1.12. *Metric Quotient of a Pseudometric*
Let X be set, ρ be pseudometric on X. Define $x \sim_\rho y$ iff $\rho(x, y) = 0$, and $\widetilde{\rho} : X/\!\sim_\rho \times X/\!\sim_\rho \to [0, \infty)$ by $\widetilde{\rho}([x], [y]) := \rho(x, y)$.

(i) $\sim_\rho$ is an equivalence relation on X.
(ii) $\widetilde{\rho}$ is a well-defined metric on $X/\!\sim_\rho$.

Proof.

(i) Reflexivity and symmetry of $\sim_\rho$ follow from $\rho(x, x) = 0$ and symmetry of ρ.
If $x \sim_\rho y$ and $y \sim_\rho z$, then $0 \leq \rho(x, z) \leq \rho(x, y) + \rho(y, z) = 0$ by the pseudometric triangle inequality.
Hence $x \sim_\rho z$, so $\sim_\rho$ is an equivalence relation.

(ii) Suppose $x \sim_\rho x'$ and $y \sim_\rho y'$. Then $\rho(x, y) \leq \rho(x', y')$ by two triangle inequalities and the zero-distance hypotheses.
Interchanging the primed and unprimed representatives proves the reverse inequality.
Thus $\widetilde{\rho}$ is well-defined. For $[x], [y], [z] \in X/\!\sim_\rho$, nonnegativity and symmetry follow from ρ.
Moreover, $\widetilde{\rho}([x], [z]) \leq \widetilde{\rho}([x], [y]) + \widetilde{\rho}([y], [z])$ by the pseudometric triangle inequality.
Finally, $\widetilde{\rho}([x], [y]) = 0$ iff $\rho(x, y) = 0$ iff $[x] = [y]$, so $\widetilde{\rho}$ is definite and therefore a metric.

Structural Commentary: The triangle inequality makes zero distance transitive.
It also makes quotient distance independent of representatives.
Key Insight: Collapsing zero-distance classes restores definiteness and preserves the other axioms. □

Example 3.1.13. *Open, Closed, Both, or Neither*
In $\mathbb{R}$, both $\emptyset$ and $\mathbb{R}$ are open and closed. If $a < b$, then $[a, b)$ is not open because a is not an interior point.
It is not closed because b is a limit point not in the set. If d is discrete on X, then $B_{\frac{1}{2}}(x) = \{x\}$ for every $x \in X$.
Thus every $E \subseteq X$ and its complement are open, so every subset of X is also closed.

Theorem 3.1.14. *Limit Points Force Infinitely Many Nearby Points*
Let (X, d) be metric space, $E \subseteq X$, $p \in X$. If p is limit point of E, then $N \cap E$ is infinite for every neighborhood N of p.

Proof. Let N be a neighborhood of p and suppose $N \cap E$ is finite. Since N is open and $p \in N$, choose $\eta > 0$ with $B_\eta(p) \subseteq N$.
Put $F := (N \cap E) \setminus \{p\}$. If $F = \emptyset$, then $B_\eta(p) \cap (E \setminus \{p\}) = \emptyset$, contrary to the limit-point hypothesis.
Suppose $F \neq \emptyset$, and set $\delta := \min(\{\eta\} \cup \{d(p, q) : q \in F\}) > 0$. If $q \in B_\delta(p) \cap (E \setminus \{p\})$, then $q \in F$ and $d(p, q) < \delta \leq d(p, q)$, impossible.
Thus $B_\delta(p) \cap (E \setminus \{p\}) = \emptyset$, again contrary to the limit-point hypothesis.
Structural Commentary: A finite list of nearby exceptions has a smallest positive distance from p.
Key Insight: Limit points cannot be witnessed by only finitely many neighboring points. □

Corollary 3.1.15. *Finite Point Sets Have No Limit Points*
A finite point set in a metric space has no limit points.

Proof. Let $E \subseteq X$ be finite, and suppose p is a limit point of E.
Every neighborhood of p then contains infinitely many distinct points of E by Theorem 3.1.14.
This contradicts finiteness of E, so E has no limit points.
Structural Commentary: One limit point would force infinitely many members of finite E.
Key Insight: A limit point requires infinitely many nearby witnesses. □

Theorem 3.1.16. *Open Sets and Closed Complements*
Let (X, d) be a metric space and $E \subseteq X$. Then E is open if and only if its complement E^c is closed.

Proof.

(⇒) Suppose E is open. If $x \in E$, then $B_r(x) \subseteq E$ for some $r > 0$, so x is not a limit point of E^c.
Every limit point of E^c therefore belongs to E^c, and E^c is closed.

(⇐) Suppose E^c is closed, and fix $x \in E$. Then $x \notin E^c$ and x is not a limit point of E^c.
Some $r > 0$ therefore satisfies $B_r(x) \cap (E^c \setminus \{x\}) = \emptyset$.
Since $x \notin E^c$, this reduces to $B_r(x) \cap E^c = \emptyset$, so $B_r(x) \subseteq E$. Thus E is open.

Structural Commentary: Ball in E excludes accumulation from E^c. Failure of accumulation supplies the reverse ball.
Key Insight: The same local separation test expresses openness of E and closedness of E^c. □

Corollary 3.1.17. *Closed Sets and Open Complements*
Let (X, d) be a metric space and $F \subseteq X$. Then F is closed if and only if F^c is open.

Proof.
($\Rightarrow$) If F is closed, then $(F^c)^c = F$ is closed; by Theorem 3.1.16 with $E = F^c$, F^c is open.
($\Leftarrow$) If F^c is open, then $(F^c)^c$ is closed by Theorem 3.1.16; since $(F^c)^c = F$, F is closed.
Structural Commentary: Applying the open-complement theorem to F^c exchanges set and complement.
Key Insight: Complement involution turns the open-set criterion into the closed-set criterion. □

Corollary 3.1.18. *Closed Balls Are Closed*
Let (X, d) be a metric space. For every $p \in X$ and $r > 0$, the closed ball $\overline{B}_r(p)$ is closed.

Proof. Let $q \notin \overline{B}_r(p)$ and put $h := d(p, q) - r > 0$. If $s \in B_h(q)$, then $d(p, s) \geq d(p, q) - d(q, s) > r$ by the triangle inequality. Thus $B_h(q) \subseteq (\overline{B}_r(p))^c$, so the complement of $\overline{B}_r(p)$ is open. The closed ball $\overline{B}_r(p)$ is therefore closed by Corollary 3.1.17.
Structural Commentary: At an exterior point, the excess $d(p, q) - r$ defines a ball outside $\overline{B}_r(p)$.
Key Insight: The triangle inequality converts positive boundary separation into an open complement. □

Theorem 3.1.19. *Basic Topological Calculus*
In a metric space:
(i) any union of open sets is open;
(ii) any intersection of closed sets is closed;
(iii) any finite intersection of open sets is open;
(iv) any finite union of closed sets is closed.

Proof.
(i) Let $G := \bigcup_{\alpha \in A} G_\alpha$ for open sets G_α. If $x \in G$, then $x \in G_\alpha$ for some $\alpha \in A$.
Since G_α is open, $B_r(x) \subseteq G_\alpha \subseteq G$ for some $r > 0$. Hence G is open.
(ii) Let $F := \bigcap_{\alpha \in A} F_\alpha$. By Theorem 1.5.2, $F^c = \bigcup_{\alpha \in A} F_\alpha^c$.
Each F_α^c is open by Corollary 3.1.17, so F^c is open by (i). Hence F is closed by Corollary 3.1.17.
(iii) The empty intersection is X, which is open. For $n \geq 1$, let $H := \bigcap_{i=1}^{n} G_i$.
If $x \in H$, choose $r_i > 0$ with $B_{r_i}(x) \subseteq G_i$ for $1 \leq i \leq n$, and set $r := \min_{1 \leq i \leq n} r_i$. Then $B_r(x) \subseteq H$, so H is open.
(iv) The empty union is $\emptyset$, which is closed. For $n \geq 1$, let $F := \bigcup_{i=1}^{n} F_i$. By Theorem 1.5.2, $F^c = \bigcap_{i=1}^{n} F_i^c$.
Each F_i^c is open by Corollary 3.1.17, so F^c is open by (iii). Hence F is closed by Corollary 3.1.17.
Structural Commentary: Open unions retain one ball; finite intersections use a minimum radius.
Complement duality transfers both arguments to closed sets.
Key Insight: Radius minima explain why only finite intersections preserve openness. □

Theorem 3.1.20. *Open Sets on the Real Line Split into Intervals*
Let $\emptyset \neq G \subseteq \mathbb{R}$ be open.
(i) $G = \bigsqcup_{\alpha \in A} I_\alpha$ for a family of pairwise disjoint open intervals $I_\alpha \subseteq \mathbb{R}$, possibly unbounded.
(ii) The index set A is at most countable.

Proof.
(i) For $a, b \in \mathbb{R}$, set $I(a, b) := [\min\{a, b\}, \max\{a, b\}]$.
For $x, y \in G$, set $x \sim y$ iff $I(x, y) \subseteq G$, and let $C_x := [x]_\sim$. Reflexivity and symmetry are immediate.
If $x \sim y$ and $y \sim z$, then $I(x, z) \subseteq I(x, y) \cup I(y, z) \subseteq G$, so $x \sim z$. Thus $\sim$ is an equivalence relation.
If $y \in C_x$ and $z \in I(x, y)$, then $I(x, z) \subseteq I(x, y) \subseteq G$, so $z \in C_x$; hence C_x is an interval.
If $y \in C_x$, choose $r > 0$ with $(y - r, y + r) \subseteq G$. Every $z \in (y - r, y + r)$ satisfies $I(x, z) \subseteq I(x, y) \cup (y - r, y + r) \subseteq G$, so $z \in C_x$.
Thus each C_x is open, and the equivalence classes form a disjoint union of G.
(ii) Let $\mathcal{C} := G/\sim$. Choose a bijection $j \mapsto q_j$ from $\mathbb{N}$ onto $\mathbb{Q}$ by Corollary 6.2.19.
Each $C \in \mathcal{C}$ contains a bounded nonempty open interval, so $C \cap \mathbb{Q} \neq \emptyset$ by Theorem 1.1.19(ii).
By well-ordering, the nonempty set $\{j \in \mathbb{N} : q_j \in C\}$ has a least element; define $\phi(C) := q_{\min\{j : q_j \in C\}}$.
The map $\phi : \mathcal{C} \to \mathbb{Q}$ is injective by disjointness, so $\mathcal{C}$ is at most countable.
Structural Commentary: Segment containment partitions G into open intervals; their least-indexed rationals embed partition into $\mathbb{Q}$.
Key Insight: One rational witness per disjoint component turns interval geometry into countability. □

Definition 3.1.21. *Closure*
Let (X, d) be a metric space and $E \subseteq X$, and E^{acc} denote set of all limit points of E in X. The *closure* of E is $\overline{E} := E \cup E^{\text{acc}}$.

Theorem 3.1.22. *Closure Is the Smallest Closed Superset*
If X is a metric space and $E \subseteq X$, then:
(i) $\overline{E}$ is closed;
(ii) $\overline{E} = E$ if and only if E is closed;
(iii) $\overline{E} \subseteq F$ for every closed set $F \subseteq X$ such that $E \subseteq F$. Consequently, $\overline{E}$ is the smallest closed subset of X containing E.

Proof.
(i) Let $p \notin \overline{E}$. Then $p \notin E$ and p is not a limit point of E, so $B_r(p) \cap E = \emptyset$ for some $r > 0$.
If $q \in B_r(p)$, then $q \notin E$ and $B_{r - d(p,q)}(q) \subseteq B_r(p)$, so $q \notin E^{\text{acc}}$. Hence $B_r(p) \subseteq (\overline{E})^c$, and $\overline{E}$ is closed by Corollary 3.1.17.
(ii) ($\Rightarrow$) If $\overline{E} = E$, then E is closed by (i).
(ii) ($\Leftarrow$) If E is closed, then $E^{\text{acc}} \subseteq E$, so $\overline{E} = E \cup E^{\text{acc}} = E$.

(*iii*) Let F be closed with $E \subseteq F$. Then $E^{\mathrm{acc}} \subseteq F^{\mathrm{acc}} \subseteq F$ by $E \subseteq F$ and closedness of F. Thus $\overline{E} = E \cup E^{\mathrm{acc}} \subseteq F$.
Together with $E \subseteq \overline{E}$ and (i), this proves the asserted minimality.

Structural Commentary: Exterior balls avoid E and its limit points; limit-point monotonicity puts $\overline{E}$ in every closed superset.
Key Insight: The closure is closed, and every closed superset must contain its added limit points. □

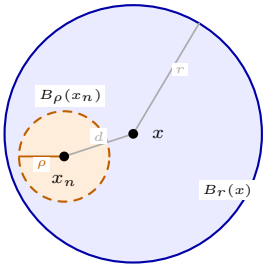

Figure 123: If $d = d(x, x_n) < r$ and $0 < \rho < r - d$, then $B_\rho(x_n) \subseteq B_r(x)$.

Figure 123 depicts the inner-ball containment used in part (i), with $x = p$ and $x_n = q$.

Definition 3.1.23. *Adherent Points*
Let (X, d) be a metric space and $E \subseteq X$. A point $p \in X$ is *adherent* to E iff $(\forall\, r > 0)\, B_r(p) \cap E \neq \emptyset$.
Equivalently, p is adherent to E iff $p \in \overline{E}$. Ball condition is automatic for $p \in E$ and is limit-point condition for $p \notin E$.

Figure 124: Adherent endpoints need not lie in E; isolated points are adherent but not limit points.

Figure 124 distinguishes adherent endpoints and isolated points from limit points.

Definition 3.1.24. *Interior, Exterior, and Boundary*
Let (X, d) be a metric space and $E \subseteq X$.

(i) $E^\circ := \{p \in E : (\exists\, r > 0)\, B_r(p) \subseteq E\}$ is the *interior*.
(ii) $\mathrm{ext}(E) := (E^c)^\circ = \{p \in X : (\exists\, r > 0)\, B_r(p) \cap E = \emptyset\}$ is the *exterior*.
(iii) $\mathrm{bd}(E) := \overline{E} \setminus E^\circ = \{p \in X : (\forall\, r > 0)\, [B_r(p) \cap E \neq \emptyset \wedge B_r(p) \cap E^c \neq \emptyset]\}$ is the *boundary*.

The boundary ball test follows by Definition 3.1.23 applied to E and E^c.

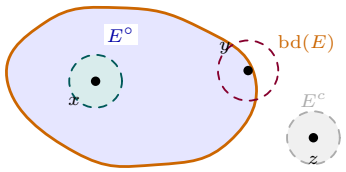

Figure 125: Interior, exterior, and boundary points are distinguished by how small balls meet E and E^c.

Figure 125 compares the ball tests for interior, exterior, and boundary points.

Definition 3.1.25. *Point-Set and Set-Set Distance*
Let (X, d) be a metric space and let $E, F \subseteq X$ be nonempty.

(i) For $p \in X$, the *point-set distance* is $\mathrm{dist}(p, E) := \inf_{q \in E} d(p, q)$.
(ii) The *set-set distance* is $\mathrm{dist}(E, F) := \inf_{(x,y) \in E \times F} d(x, y)$.

Both infima exist in $\mathbb{R}$ by Corollary 1.1.15. The corresponding families of distances are nonempty and bounded below by 0.

Proposition 3.1.26. *Distance-to-Set Closure Criterion*
Let (X, d) be a metric space and $\emptyset \neq E \subseteq X$. For $p \in X$, $p \in \overline{E} \iff \mathrm{dist}(p, E) = 0$.

Proof.

($\Rightarrow$) Suppose $p \in \overline{E}$. If $p \in E$, then $0 \leq \mathrm{dist}(p, E) \leq d(p, p) = 0$.
If $p \notin E$, then p is a limit point of E, so for every $\varepsilon > 0$ there exists $q_\varepsilon \in E$ with $d(p, q_\varepsilon) < \varepsilon$.
Thus $0 \leq \mathrm{dist}(p, E) \leq \varepsilon$ for every $\varepsilon > 0$, and $\mathrm{dist}(p, E) = 0$.
($\Leftarrow$) Suppose $\mathrm{dist}(p, E) = 0$. If $p \notin \overline{E}$, then some $r > 0$ satisfies $B_r(p) \cap E = \emptyset$.
Then $d(p, q) \geq r$ for every $q \in E$, so r is a positive lower bound for $\{d(p, q) : q \in E\}$. Contradicts infimum 0, so $p \in \overline{E}$.

Structural Commentary: Adherence supplies points at every positive scale. Failed adherence supplies a positive lower bound.
Key Insight: Zero distance and intersection with every centered ball both characterize closure. □

Remark 3.1.27. *Set Distance Is Not a Metric on Subsets*
The function $\mathrm{dist}(E, F)$ is useful, but it is not a metric on nonempty subsets.
In $\mathbb{R}$, for example, $\mathrm{dist}((0, 1), (1, 2)) = 0$ although the sets are distinct and disjoint.

3.2 Relative Topology

Definition 3.2.1. *Relative Openness*
Let (X,d) be a metric space and $E \subseteq Y \subseteq X$. The set E is *open relative to Y* iff $(\forall\, p \in E)(\exists\, r>0)\, B_r(p) \cap Y \subseteq E$.

Definition 3.2.2. *Relative Closedness*
Let (X,d) be a metric space and $F \subseteq Y \subseteq X$. The set F is *closed relative to Y* iff $Y \setminus F$ is open relative to Y.

Theorem 3.2.3. *Relative Opens Are Intersections*
Let (X,d) be a metric space, $Y \subseteq X$, $E \subseteq Y$. Then E is open relative to Y iff $(\exists\, G \in \tau_d)\, E = Y \cap G$.

Proof.
($\Rightarrow$) Suppose E is open relative to Y. Let $\mathcal{B} := \{B_r(p) : p \in E,\ r>0,\ B_r(p) \cap Y \subseteq E\}$.
Set $G := \bigcup_{B \in \mathcal{B}} B$. Every $B \in \mathcal{B}$ is open by Theorem 3.1.3, so $G \in \tau_d$ by Theorem 3.1.19(i).
For every $p \in E$, relative openness supplies $B_r(p) \in \mathcal{B}$ containing p, so $E \subseteq G \cap Y$.
If $q \in G \cap Y$, then $q \in B_r(p) \cap Y \subseteq E$ for some $B_r(p) \in \mathcal{B}$. Thus $E = G \cap Y$.
($\Leftarrow$) Suppose $E = G \cap Y$ for some $G \in \tau_d$. For $p \in E$, choose $r>0$ with $B_r(p) \subseteq G$.
Then $B_r(p) \cap Y \subseteq G \cap Y = E$, so E is open relative to Y.
Structural Commentary: Witnessing ambient balls form G; intersecting G with Y recovers E.
Key Insight: Relative openness is exactly ambient openness restricted to Y. □

Corollary 3.2.4. *Relative Closed Sets Are Intersections*
Let (X,d) be a metric space, $Y \subseteq X$, $F \subseteq Y$. Then F is closed relative to Y iff $F = Y \cap C$ for some closed set $C \subseteq X$.

Proof.
($\Rightarrow$) Suppose F is closed relative to Y. Then $Y \setminus F$ is open relative to Y. By Theorem 3.2.3, $Y \setminus F = Y \cap G$ for some $G \in \tau_d$.
Put $C := X \setminus G$. The set C is closed in X by Corollary 3.1.17, and $F = Y \setminus (Y \cap G) = Y \cap C$.
($\Leftarrow$) Suppose $F = Y \cap C$ for a closed set $C \subseteq X$. Then $X \setminus C$ is open by Corollary 3.1.17.
The set $Y \setminus F = Y \cap (X \setminus C)$ is open relative to Y by Theorem 3.2.3. Thus F is closed relative to Y.
Structural Commentary: Complementing $Y \cap G$ in Y replaces open G by closed $X \setminus G$.
Key Insight: Relative closedness is the complement-dual of relative openness. □

Example 3.2.5. *Relative Topology Depends on the Ambient Space*
Let $X := \{(x,0) : x \in \mathbb{R}\} \subseteq \mathbb{R}^2$ with the inherited Euclidean metric, and set $E := \{(x,0) : -1 < x < 1\}$.
No ball in $\mathbb{R}^2$ centered at a point of E lies in the x-axis, so E is not open in $\mathbb{R}^2$.
However, $E = X \cap \big((-1,1) \times (-1,1)\big)$, so E is open relative to X. Set $[0,1)$ is not closed in $\mathbb{R}$ because 1 is a limit point not in the set.
Yet $[0,1) = (-1,1) \cap [0,\infty)$, and $[0,\infty)$ is closed in $\mathbb{R}$. Hence $[0,1)$ is closed relative to $(-1,1)$ by Corollary 3.2.4.

3.3 Density, Separability, and Closure Tests

Proposition 3.3.1. *Density and Closure*
Let (X,d) be a metric space and $E \subseteq X$. Then E is dense in X iff $\overline{E} = X$.

Proof.
($\Rightarrow$) Suppose E dense in X. Every $p \in X$ belongs to E or is limit point of E, so $p \in E \cup E^{\text{acc}} = \overline{E}$. Thus $X \subseteq \overline{E} \subseteq X$, $\overline{E} = X$.
($\Leftarrow$) Suppose $\overline{E} = X$. Then every $p \in X$ belongs to $E \cup E^{\text{acc}}$. Hence p belongs to E or is a limit point of E, so E is dense in X.
Structural Commentary: The density alternative is membership in $E \cup E^{\text{acc}}$.
Key Insight: Closure packages the points of E together with all its limit points. □

Proposition 3.3.2. *Real-Line Density Interval Test*
Let $E \subseteq \mathbb{R}$. Then E is dense in $\mathbb{R}$ iff every nonempty open interval (a,b) satisfies $(a,b) \cap E \neq \emptyset$.

Proof.
($\Rightarrow$) Suppose E is dense in $\mathbb{R}$. Let $(a,b) \neq \emptyset$, choose $p \in (a,b)$, and set $r := \min\{p-a, b-p\} > 0$.
If $p \in E$, then $p \in (a,b) \cap E$. If $p \notin E$, then p is a limit point of E, so choose $q \in B_r(p) \cap (E \setminus \{p\})$.
Since $B_r(p) \subseteq (a,b)$, the point q belongs to $(a,b) \cap E$.
($\Leftarrow$) Suppose every nonempty open interval meets E, and fix $p \in \mathbb{R} \setminus E$.
For every $\varepsilon > 0$, choose $q \in (p-\varepsilon, p+\varepsilon) \cap E$. Then $q \neq p$ and $q \in B_\varepsilon(p) \cap (E \setminus \{p\})$.
Thus every $p \in \mathbb{R} \setminus E$ is a limit point of E, so E is dense in $\mathbb{R}$.
Structural Commentary: On $\mathbb{R}$, balls and open intervals test the same local condition.
Key Insight: Density means no interval can avoid the set. □

Definition 3.3.3. *Separable Metric Space*
A metric space (X,d) is *separable* iff it contains an at most countable dense subset.

Example 3.3.4. *Separable and Nonseparable Metric Spaces*
(i) Let $k \in \mathbb{Z}_{>0}$. The set $\mathbb{Q}^k$ is countable by Theorem 6.2.18 and Corollary 6.2.19.
For $\mathbf{x} \in \mathbb{R}^k$ and $\varepsilon > 0$, choose $\mathbf{q} \in \mathbb{Q}^k$ satisfying $(\forall\, j \in \{1,\dots,k\})\ |x_j - q_j| < \frac{\varepsilon}{\sqrt{k}}$ by Theorem 1.1.19(ii).
Then $\|\mathbf{x}-\mathbf{q}\|_2 = \sqrt{\sum_{j=1}^{k} |x_j - q_j|^2} < \varepsilon$, so $\mathbb{Q}^k$ is dense in $\mathbb{R}^k$. Hence $\mathbb{R}^k$ is separable; in particular, $\mathbb{R}$ is separable.
The standard isometry $\mathbb{C}^k \cong \mathbb{R}^{2k}$ identifies $(\mathbb{Q}+i\mathbb{Q})^k$ with $\mathbb{Q}^{2k}$, so $\mathbb{C}^k$ is separable.
(ii) If discrete X is at most countable, then X itself is a dense witness to separability.
Conversely, let $D \subseteq X$ be an at most countable dense subset. For every $x \in X$, the ball $B_{\frac{1}{2}}(x) = \{x\}$ meets D, so $x \in D$.
Thus $D = X$, and X is at most countable. Therefore X is separable iff X is at most countable.

Structural Commentary: Rational coordinate grids are dense in Euclidean spaces. Singleton balls force $D = X$ in discrete spaces.
Key Insight: Separability depends on whether countable data can meet every open ball.

Theorem 3.3.5. *Suprema Belong to Closures*
Let $\emptyset \neq E \subseteq \mathbb{R}$ be bounded above and let $y := \sup E$.

(i) $y \in \overline{E}$.
(ii) If E is closed, then $y \in E$.

Proof.

(i) If $y \in E$, then $y \in \overline{E}$. Suppose instead that $y \notin E$.
Fix $h > 0$. If $y - h$ were an upper bound for E, then minimality of $y = \sup E$ would imply $y \leq y - h$.
This contradicts $h > 0$, so $y - h$ is not an upper bound for E.
Choose $x_h \in E$ with $y - h < x_h \leq y$. Then $x_h \neq y$, $|x_h - y| < h$, and $B_h(y) \cap (E \setminus \{y\}) \neq \emptyset$. Hence $y \in E^{\text{acc}} \subseteq \overline{E}$.
(ii) If E is closed, then $y \in \overline{E}$ by (i) and $\overline{E} = E$ by Theorem 3.1.22(ii). Hence $y \in E$.

Structural Commentary: Minimality of $y = \sup E$ produces points of E arbitrarily close below y.
Key Insight: A supremum is either attained or approached. □

3.4 Bounded Sets and Metric Sequences

Definition 3.4.1. *Bounded and Perfect Metric Sets*
Let (X, d) be a metric space and let $E \subseteq X$.

(i) The set E is *bounded* iff $(\exists q \in X)(\exists M > 0)\, E \subseteq B_M(q)$.
(ii) The set E is *perfect* iff E is closed and $(\forall p \in E)\, p \in E^{\text{acc}}$.

Definition 3.4.2. *Metric Convergence*
Let (p_n) be a sequence in a metric space (X, d). It *converges* to $p \in X$ iff $(\forall \varepsilon > 0)(\exists N \in \mathbb{N})(\forall n \geq N)\, d(p_n, p) < \varepsilon$.
Write $p_n \to p$ or $\lim_{n\to\infty} p_n = p$. The sequence *diverges* iff $(\nexists p \in X)\, p_n \to p$.

Definition 3.4.3. *Metric Sequence Terminology*
Let $p : \mathbb{N} \to X$, $n \mapsto p_n$, be a sequence in a metric space (X, d).

(i) The *range* of (p_n) is $\text{ran}(p_n) := \{p_n : n \in \mathbb{N}\}$.
(ii) The sequence (p_n) is *bounded* iff $\text{ran}(p_n)$ is bounded.
(iii) If $\sigma : \mathbb{N} \to \mathbb{N}$ satisfies $(\forall k \in \mathbb{N})\, \sigma(k+1) > \sigma(k)$, then $(p_{\sigma(k)})_{k\in\mathbb{N}}$ is a *subsequence* of (p_n).
(iv) A point $q \in X$ is a *subsequential limit* of (p_n) iff $(\exists\, \sigma : \mathbb{N} \to \mathbb{N})\, [(\forall k \in \mathbb{N})\, \sigma(k+1) > \sigma(k) \wedge p_{\sigma(k)} \to q]$.

Definition 3.4.4. *Eventual and Frequent Membership*
Let X be a set, let (p_n) be a sequence in X, and let $E \subseteq X$.

(i) The sequence (p_n) is *eventually in E* iff $(\exists N \in \mathbb{N})(\forall n \geq N)\, p_n \in E$.
(ii) The sequence (p_n) is *frequently in E* iff $(\forall N \in \mathbb{N})(\exists n \geq N)\, p_n \in E$.

Perspective 3.4.5. *Sequences as Metric Tests*
Definitions 3.4.2 and 3.4.4 separate tail control from arbitrarily late recurrence.
In metric spaces, sequences convert local ball conditions into countable tests; this viewpoint does not replace the ball definitions.

Theorem 3.4.6. *Basic Properties of Metric Convergence*
Let (p_n) be a sequence in a metric space X, let $E \subseteq X$, and let $p, p' \in X$.

(i) $p_n \to p \iff (\forall r > 0)(\exists N \in \mathbb{N})(\forall n \geq N)\, p_n \in B_r(p)$.
(ii) $p_n \to p \wedge p_n \to p' \implies p = p'$.
(iii) $p \in E^{\text{acc}} \implies (\exists q : \mathbb{N} \to E \setminus \{p\})\, q_n \to p$.

Proof.

(i) ($\Rightarrow$) Let $r > 0$. Some $N \in \mathbb{N}$ satisfies $(\forall n \geq N)\, p_n \in B_r(p)$ by Definition 3.4.2 with $\varepsilon = r$.
(i) ($\Leftarrow$) Let $\varepsilon > 0$. Choose $N \in \mathbb{N}$ with $(\forall n \geq N)\, d(p_n, p) < \varepsilon$ by the ball condition at $r = \varepsilon$. Then $p_n \to p$ by Definition 3.4.2.
(ii) Suppose $p_n \to p$, $p_n \to p'$, and $p \neq p'$. Set $\delta := d(p, p') > 0$.
Choose $N, N' \in \mathbb{N}$ with $(\forall n \geq N)\, d(p_n, p) < \frac{\delta}{2}$ and $(\forall n \geq N')\, d(p_n, p') < \frac{\delta}{2}$.
For $n \geq \max\{N, N'\}$, $\delta \leq d(p, p_n) + d(p_n, p') < \delta$ by the triangle inequality, a contradiction.
(iii) Suppose $p \in E^{\text{acc}}$. Choose (q_n) with $(\forall n \in \mathbb{N})\, q_n \in (E \setminus \{p\}) \cap B_{\frac{1}{n}}(p)$.
Given $\varepsilon > 0$, choose $N \in \mathbb{N}$, $N\varepsilon > 1$ by Theorem 1.1.19(i). Then $(\forall n \geq N)\, d(q_n, p) < \frac{1}{n} \leq \frac{1}{N} < \varepsilon$, so $q_n \to p$ by Definition 3.4.2.

Structural Commentary: Ball membership restates the metric bound; shrinking punctured balls construct the approximating sequence.
Key Insight: The triangle inequality forbids two distinct limits. □

Corollary 3.4.7. *Subsequences Preserve Metric Limits*
Let (p_{n_k}) be a subsequence of (p_n) in a metric space. If $p_n \to p$, then $p_{n_k} \to p$.

Proof. The bound $(\forall k \in \mathbb{N})\, n_k \geq k$ holds by induction from strict increase. Given $\varepsilon > 0$, choose $N \in \mathbb{N}$ with $(\forall n \geq N)\, d(p_n, p) < \varepsilon$.
Then $(\forall k \geq N)\, n_k \geq k \geq N$, so $d(p_{n_k}, p) < \varepsilon$ and $p_{n_k} \to p$ by Definition 3.4.2.
Structural Commentary: Strictly increasing indices place every subsequence tail inside the corresponding original tail.
Key Insight: Deleting terms preserves every eventual metric bound. □

Proposition 3.4.8. *Subsequential Limit Criterion*
Let (p_n) be a sequence in a metric space X and let $p \in X$. The following are equivalent:

(i) $(\forall r > 0)(\forall N \in \mathbb{N})(\exists n \geq N)\, p_n \in B_r(p)$.
(ii) $(\exists\, \sigma : \mathbb{N} \to \mathbb{N})\, [(\forall k \in \mathbb{N})\, \sigma(k+1) > \sigma(k) \wedge p_{\sigma(k)} \to p]$.

Proof.

(*i*) $\Rightarrow$ (*ii*) Set $n_0 := 0$. Given n_{k-1}, let $I_k := \{n \geq n_{k-1}+1 : p_n \in B_{\frac{1}{k}}(p)\}$.
The set I_k is nonempty by (i); define $n_k := \min I_k$ by well-ordering. Thus $n_k > n_{k-1}$ and $d(p_{n_k}, p) < \frac{1}{k}$.
Given $\varepsilon > 0$, choose $K \in \mathbb{N}$, $K\varepsilon > 1$ by Theorem 1.1.19(i). Then $(\forall k \geq K)\, d(p_{n_k}, p) < \frac{1}{k} \leq \frac{1}{K} < \varepsilon$, so $p_{n_k} \to p$ by Definition 3.4.2.

(*ii*) $\Rightarrow$ (*i*) Write $n_k := \sigma(k)$. The bound $(\forall k \in \mathbb{N})\, n_k \geq k$ holds by induction from strict increase.
Given $r > 0$ and $N \in \mathbb{N}$, choose $K \in \mathbb{N}$ with $(\forall k \geq K)\, d(p_{n_k}, p) < r$. For $k \geq \max\{K, N\}$, $n_k \geq k \geq N$ and $p_{n_k} \in B_r(p)$.

Structural Commentary: Repeated late ball visits support increasing indices with errors bounded by k^{-1}.
Key Insight: Increasing indices turn recurrence at every scale into subsequential convergence. □

Proposition 3.4.9. *Discrete-Metric Convergence*
Let X carry the discrete metric, let (p_n) be a sequence in X, and let $p \in X$. Then $p_n \to p \iff (\exists N \in \mathbb{N})(\forall n \geq N)\, p_n = p$.

Proof.

($\Rightarrow$) Suppose $p_n \to p$. With $\varepsilon = \frac{1}{2}$, choose $N \in \mathbb{N}$ such that $(\forall n \geq N)\, d(p_n, p) < \frac{1}{2}$.
Since $d(X \times X) \subseteq \{0, 1\}$, $(\forall n \geq N)\, d(p_n, p) = 0$, so $(\forall n \geq N)\, p_n = p$.

($\Leftarrow$) Choose $N \in \mathbb{N}$ with $(\forall n \geq N)\, p_n = p$. Then $(\forall \varepsilon > 0)(\forall n \geq N)\, d(p_n, p) = 0 < \varepsilon$, so $p_n \to p$ by Definition 3.4.2.

Structural Commentary: The threshold $\frac{1}{2}$ converts the convergence tail into a zero-distance tail.
Key Insight: In the discrete metric, $d(x, y) < 1 \iff x = y$. □

Definition 3.4.10. *Equivalent Metrics*
Let X be a set and let $\rho, \sigma : X \times X \to [0, \infty)$ be metrics.
They are *equivalent*, written $\rho \sim \sigma$, iff $(\exists c_1, c_2 > 0)(\forall x, y \in X)\, c_1\sigma(x, y) \leq \rho(x, y) \leq c_2\sigma(x, y)$.

Proposition 3.4.11. *Equivalent Metrics Preserve Topological Tests*
Let X be a set, $\rho \sim \sigma$ be metrics on X, τ_ρ, τ_σ be their induced topologies. Let $E \subseteq X$, and (x_n) be a sequence in X with $x \in X$.

(*i*) $\tau_\rho = \tau_\sigma$.
(*ii*) *E is ρ-closed iff E is σ-closed.*
(*iii*) $\rho(x_n, x) \to 0$ *iff* $\sigma(x_n, x) \to 0$.

Proof. Choose $c_1, c_2 > 0$ with $(\forall u, v \in X)\, c_1\sigma(u, v) \leq \rho(u, v) \leq c_2\sigma(u, v)$. Then $(\forall z \in X)(\forall r > 0)\, B^\sigma_{\frac{r}{c_2}}(z) \subseteq B^\rho_r(z) \subseteq B^\sigma_{\frac{r}{c_1}}(z)$.

(*i*) If $U \in \tau_\rho$ and $z \in U$, choose $r > 0$ with $B^\rho_r(z) \subseteq U$. Then $B^\sigma_{\frac{r}{c_2}}(z) \subseteq U$, so $U \in \tau_\sigma$.
If $U \in \tau_\sigma$ and $z \in U$, choose $s > 0$ with $B^\sigma_s(z) \subseteq U$. Since $B^\rho_{c_1 s}(z) \subseteq B^\sigma_s(z)$, $U \in \tau_\rho$.

(*ii*) ($\Rightarrow$) If E is ρ-closed, then $E^c \in \tau_\rho = \tau_\sigma$ by (i). Thus E is σ-closed by Corollary 3.1.17.
(*ii*) ($\Leftarrow$) If E is σ-closed, then $E^c \in \tau_\sigma = \tau_\rho$ by (i). Thus E is ρ-closed by Corollary 3.1.17.

(*iii*) ($\Rightarrow$) Suppose $\rho(x_n, x) \to 0$. Given $\varepsilon > 0$, choose $N \in \mathbb{N}$ with $(\forall n \geq N)\, \rho(x_n, x) < c_1\varepsilon$.
Then $(\forall n \geq N)\, \sigma(x_n, x) \leq \frac{\rho(x_n, x)}{c_1} < \varepsilon$, so $\sigma(x_n, x) \to 0$.

(*iii*) ($\Leftarrow$) Suppose $\sigma(x_n, x) \to 0$. Given $\varepsilon > 0$, choose $N \in \mathbb{N}$ with $(\forall n \geq N)\, \sigma(x_n, x) < \frac{\varepsilon}{c_2}$.
Then $(\forall n \geq N)\, \rho(x_n, x) \leq c_2\sigma(x_n, x) < \varepsilon$, so $\rho(x_n, x) \to 0$.

Structural Commentary: Two-sided comparison nests metric balls, then transfers closedness, convergence through same constants.
Key Insight: Each metric ball contains a scaled ball for the other metric. □

Example 3.4.12. *Coordinate Norm Metrics on $\mathbb{R}^k$*
Let $k \in \mathbb{N}$ and set $d_j(\mathbf{x}, \mathbf{y}) := \|\mathbf{x} - \mathbf{y}\|_j$ for $j \in \{1, 2, \infty\}$. Each $\|\cdot\|_j$ is a norm by Proposition 1.1.21.
Its norm axioms imply nonnegativity, definiteness, symmetry, and the triangle inequality for d_j; hence d_1, d_2, d_∞ are metrics on $\mathbb{R}^k$.
For $\mathbf{v} \in \mathbb{R}^k$, $\|\mathbf{v}\|_\infty \leq \|\mathbf{v}\|_2 \leq \|\mathbf{v}\|_1$. The bound $\|\mathbf{v}\|_1 \leq \sqrt{k}\,\|\mathbf{v}\|_2$ follows by Theorem 1.1.13(i), applied to $(|v_i|)_{i=1}^k$ and $(1)_{i=1}^k$.
Since $\|\mathbf{v}\|_2^2 \leq k\,\|\mathbf{v}\|_\infty^2$, $\|\mathbf{v}\|_2 \leq \sqrt{k}\,\|\mathbf{v}\|_\infty$. Thus d_1, d_2, d_∞ are pairwise equivalent by Definition 3.4.10.
Their convergent sequences coincide by Proposition 3.4.11(iii).

Theorem 3.4.13. *Coordinatewise Convergence in $\mathbb{R}^k$*
Let $k \in \mathbb{N}$, and let $\mathbf{x}_n = (\alpha_{j,n})_{j=1}^k$ and $\mathbf{y}_n = (\gamma_{j,n})_{j=1}^k$ be sequences in $\mathbb{R}^k$.
Let $\mathbf{x} = (\alpha_j)_{j=1}^k$ and $\mathbf{y} = (\gamma_j)_{j=1}^k$ lie in $\mathbb{R}^k$. Let (β_n) be a sequence in $\mathbb{R}$ and let $\beta \in \mathbb{R}$.

(*i*) $\mathbf{x}_n \to \mathbf{x} \iff (\forall j \in \{1, \ldots, k\})\, \alpha_{j,n} \to \alpha_j$.
(*ii*) $\mathbf{x}_n \to \mathbf{x} \wedge \mathbf{y}_n \to \mathbf{y} \Longrightarrow \mathbf{x}_n + \mathbf{y}_n \to \mathbf{x} + \mathbf{y}$.
(*iii*) $\mathbf{x}_n \to \mathbf{x} \wedge \mathbf{y}_n \to \mathbf{y} \Longrightarrow \mathbf{x}_n \cdot \mathbf{y}_n \to \mathbf{x} \cdot \mathbf{y}$.
(*iv*) $\beta_n \to \beta \wedge \mathbf{x}_n \to \mathbf{x} \Longrightarrow \beta_n\mathbf{x}_n \to \beta\mathbf{x}$.

Proof.

(*i*) ($\Rightarrow$) Fix $j \in \{1, \ldots, k\}$ and let $\varepsilon > 0$. Choose $N \in \mathbb{N}$ with $(\forall n \geq N)\, \|\mathbf{x}_n - \mathbf{x}\|_2 < \varepsilon$.
Then $(\forall n \geq N)\, |\alpha_{j,n} - \alpha_j| \leq \|\mathbf{x}_n - \mathbf{x}\|_2 < \varepsilon$, so $\alpha_{j,n} \to \alpha_j$ by Definition 3.4.2.

(*i*) ($\Leftarrow$) Given $\varepsilon > 0$, choose $N_j \in \mathbb{N}$ with $(\forall n \geq N_j)\, |\alpha_{j,n} - \alpha_j| < \frac{\varepsilon}{\sqrt{k}}$ for $j \in \{1, \ldots, k\}$.
For $N := \max_{1 \leq j \leq k} N_j$ and $n \geq N$, $\|\mathbf{x}_n - \mathbf{x}\|_2^2 < \sum_{j=1}^k \frac{\varepsilon^2}{k} = \varepsilon^2$, so $\mathbf{x}_n \to \mathbf{x}$.

(*ii*) The coordinate limits $(\forall j \in \{1, \ldots, k\})\, \alpha_{j,n} + \gamma_{j,n} \to \alpha_j + \gamma_j$ hold by Theorem 2.1.5(i). The vector convergence follows by (i).

(*iii*) The product limits $(\forall j \in \{1, \ldots, k\})\, \alpha_{j,n}\gamma_{j,n} \to \alpha_j\gamma_j$ hold by Theorem 2.1.5(iii).
The convergence $\sum_{j=1}^k \alpha_{j,n}\gamma_{j,n} \to \sum_{j=1}^k \alpha_j\gamma_j$ follows by repeated application of Theorem 2.1.5(i).

(*iv*) The coordinate limits $(\forall j \in \{1, \ldots, k\})\, \beta_n\alpha_{j,n} \to \beta\alpha_j$ hold by Theorem 2.1.5(iii). The vector convergence follows by (i).

Structural Commentary: Coordinate bounds prove (i); scalar limit algebra transfers sums, products, and scalar multiples.
Key Insight: A finite maximum synchronizes all coordinate tails. □

Definition 3.4.14. *Product Distance Functions*
Let (X, d_X) and (Y, d_Y) be metric spaces. For $p = (x, y)$ and $p' = (x', y')$ in $X \times Y$, define:

(i) $d_E(p, p') := \sqrt{d_X(x, x')^2 + d_Y(y, y')^2}$;
(ii) $d_{\max}(p, p') := \max\{d_X(x, x'), d_Y(y, y')\}$;
(iii) $d_{\text{sum}}(p, p') := d_X(x, x') + d_Y(y, y')$.

These are the Euclidean, maximum, and sum product distance functions.

Figure 126 contrasts the maximum and sum product distance functions on $\mathbb{R}^2$.

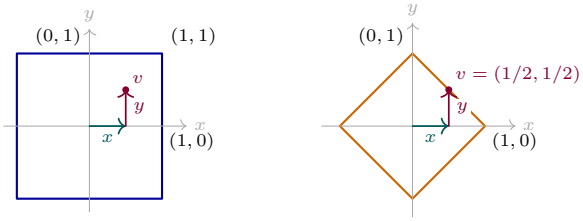

Figure 126: The maximum-metric unit ball is square; the sum-metric unit ball is diamond-shaped.

Proposition 3.4.15. *Product Metrics and Comparisons*
Let (X, d_X) and (Y, d_Y) be metric spaces. The product distance functions $d_E, d_{\max}, d_{\text{sum}}$ satisfy:

(i) $d_E, d_{\max}, d_{\text{sum}}$ are metrics on $X \times Y$;
(ii) $d_{\max} \le d_E \le d_{\text{sum}} \le 2d_{\max}$;
(iii) they are pairwise equivalent and have the same convergent sequences.

Proof.

(i) Let $p = (x, y)$, $p' = (x', y')$, and $p'' = (x'', y'')$, and set $(a, b, c, e) := (d_X(x, x'), d_Y(y, y'), d_X(x', x''), d_Y(y', y''))$.
All three functions are nonnegative and symmetric, and each vanishes iff $a = b = 0$, equivalently $p = p'$.
By the component triangle inequalities, $d_{\text{sum}}(p, p'') \le a + b + c + e = d_{\text{sum}}(p, p') + d_{\text{sum}}(p', p'')$.
Likewise, $d_{\max}(p, p'') \le \max\{a + c, b + e\} \le \max\{a, b\} + \max\{c, e\}$ by the component triangle inequalities.
By Theorem 1.1.14(i), $d_E(p, p'') \le \sqrt{(a + c)^2 + (b + e)^2} \le \sqrt{a^2 + b^2} + \sqrt{c^2 + e^2}$.
(ii) For $p = (x, y)$ and $p' = (x', y')$, set $a := d_X(x, x')$ and $b := d_Y(y, y')$. Then $\max\{a, b\} \le \sqrt{a^2 + b^2} \le a + b \le 2\max\{a, b\}$.
(iii) The metrics are pairwise equivalent by (ii) and Definition 3.4.10. Their convergent sequences coincide by Proposition 3.4.11(iii).

Structural Commentary: Component triangle inequalities prove the metric axioms; uniform comparison transfers convergence.
Key Insight: Maximum and sum bounds trap the Euclidean product distance. □

Proposition 3.4.16. *Sequential Closure Criterion*
Let X be a metric space, let $E \subseteq X$, and let $p \in X$. Then $p \in \overline{E} \iff (\exists u : \mathbb{N} \to E)\, u_n \to p$.

Proof.

($\Rightarrow$) Suppose $p \in \overline{E}$. By Definition 3.1.23, $(\forall n \in \mathbb{N})\, E \cap B_{\frac{1}{n}}(p) \neq \emptyset$. Choose (p_n) with $(\forall n \in \mathbb{N})\, p_n \in E \cap B_{\frac{1}{n}}(p)$.
Given $\varepsilon > 0$, choose $N \in \mathbb{N}$, $N\varepsilon > 1$ by Theorem 1.1.19(i). Then $(\forall n \ge N)\, d(p_n, p) < \frac{1}{n} \le \frac{1}{N} < \varepsilon$, so $p_n \to p$ by Definition 3.4.2.
($\Leftarrow$) Suppose $(\forall n \in \mathbb{N})\, p_n \in E$ and $p_n \to p$. Given $r > 0$, choose $N \in \mathbb{N}$ with $d(p_N, p) < r$.
Then $p_N \in E \cap B_r(p)$, so $p \in \overline{E}$ by Definition 3.1.23.

Structural Commentary: Adherence selects points from shrinking balls; convergence returns a witness to each ball.
Key Insight: The radii n^{-1} encode all positive metric scales. □

Theorem 3.4.17. *Closed Sets and Limit Points via Sequences*
Let X be a metric space and $E \subseteq X$.

(i) $(\forall p \in X)\,[p \in E^{\text{acc}} \iff (\exists u : \mathbb{N} \to E \setminus \{p\})\, u_n \to p]$.
(ii) E is closed iff $(\forall p \in X)(\forall u : \mathbb{N} \to E)\,[u_n \to p \implies p \in E]$.

Proof.

(i) ($\Rightarrow$) Fix $p \in E^{\text{acc}}$. A sequence (p_n) in $E \setminus \{p\}$ with $p_n \to p$ exists by Theorem 3.4.6(iii).
(i) ($\Leftarrow$) Fix $p \in X$ and suppose $(\forall n \in \mathbb{N})\, p_n \in E \setminus \{p\}$ with $p_n \to p$.
Given $r > 0$, choose $N \in \mathbb{N}$ with $p_N \in B_r(p)$. Then $p_N \in B_r(p) \cap (E \setminus \{p\})$, so $p \in E^{\text{acc}}$.
(ii) ($\Rightarrow$) Suppose E closed, $(\forall n \in \mathbb{N})\, p_n \in E$, $p_n \to p \in X$; $p \in \overline{E}$ by Proposition 3.4.16. Since $\overline{E} = E$ by Theorem 3.1.22(ii), $p \in E$.
(ii) ($\Leftarrow$) Assume the sequential limit condition, and fix $p \in \overline{E}$.
By Proposition 3.4.16, some sequence (p_n) in E converges to p, so $p \in E$ by the assumed condition.
Thus $\overline{E} \subseteq E$, while $E \subseteq \overline{E}$ by Definition 3.1.21. Therefore $E = \overline{E}$, and E is closed by Theorem 3.1.22(ii).

Structural Commentary: Punctured-ball sequences characterize accumulation; ordinary ball sequences characterize closure.
Key Insight: Closedness is exactly retention of limits of internal sequences. □

Theorem 3.4.18. *Subsequential Limits Form a Closed Set*
For a sequence (p_n) in a metric space X, the set of all subsequential limits is closed.

Proof.

(i) *Approximation*: Let E^* be set of subsequential limits, $q \in (E^*)^{\text{acc}}$. Choose (x_i) with $(\forall i \in \mathbb{N})\, x_i \in (E^* \setminus \{q\}) \cap B_{\frac{1}{2i}}(q)$.
(ii) *Diagonal selection*: Each x_i satisfies condition (i) by Proposition 3.4.8, direction $(ii) \Rightarrow (i)$.
Set $n_0 := 0$ and recursively choose $n_i > n_{i-1}$ with $d(p_{n_i}, x_i) < \frac{1}{2i}$ by condition (i).

(iii) *Closure*: By the triangle inequality, $(\forall i \in \mathbb{N})\, d(p_{n_i}, q) < \frac{1}{i}$. Given $\varepsilon > 0$, choose $I \in \mathbb{N}$ with $I\varepsilon > 1$ by Theorem 1.1.19(i).
Then $(\forall i \geq I)\, d(p_{n_i}, q) < \frac{1}{i} \leq \frac{1}{I} < \varepsilon$, so $p_{n_i} \to q$ by Definition 3.4.2. Thus $q \in E^*$; $(E^*)^{\mathrm{acc}} \subseteq E^*$, E^* closed by Definition 3.1.2.

Structural Commentary: Shrinking approximants and increasing original indices combine into one diagonal subsequence.
Key Insight: Each diagonal term is simultaneously later and closer to q. □

Proof Method 3.4.19. *Metric Proof Patterns*

(i) To prove openness of G, fix $x \in G$ and construct $r > 0$ with $B_r(x) \subseteq G$; then G is open by Definition 3.1.2.
(ii) To prove closedness of F, establish $F^{\mathrm{acc}} \subseteq F$ and conclude by Definition 3.1.2.
Alternatively, prove F^c open and conclude by Corollary 3.1.17.
(iii) To identify $C = \overline{E}$, verify $E \subseteq C$, $C^{\mathrm{acc}} \subseteq C$, and $(\forall F \subseteq X)\,[(E \subseteq F \wedge F^{\mathrm{acc}} \subseteq F) \Longrightarrow C \subseteq F]$; $C = \overline{E}$ by Theorem 3.1.22.
(iv) For $\emptyset \neq E \subseteq X$, prove $\operatorname{dist}(p, E) = 0$ and conclude $p \in \overline{E}$ by Proposition 3.1.26.
Alternatively, construct (p_n) in E with $p_n \to p$ and conclude by Proposition 3.4.16.

4 Compactness and Completeness

4.1 Compactness, Completeness, and Total Boundedness

Compactness extracts finite or convergent structure from infinite behavior;
completeness asks whether Cauchy approximations converge internally.

Definition 4.1.1. *Open Covers and Compact Sets*
Let (X, d) be a metric space.

(i) A family $(G_\alpha)_{\alpha \in A}$ of open subsets of X is an *open cover* of $E \subseteq X$ iff $E \subseteq \bigcup_{\alpha \in A} G_\alpha$.

(ii) A set $K \subseteq X$ is *compact* iff every open cover of K contains a finite subcover.

Definition 4.1.2. *Finite Intersection Property*
Let X be set, $\mathcal{F} \subseteq \mathcal{P}(X)$. Family $\mathcal{F}$ has *finite intersection property (FIP)* iff $(\forall\, \mathcal{F}_0 \subseteq \mathcal{F})\,[0 < |\mathcal{F}_0| < \infty \Rightarrow \bigcap_{F \in \mathcal{F}_0} F \neq \emptyset]$.

Proposition 4.1.3. *Closed-Set Compactness Test*
A metric space (X, d) is compact iff every nonempty family $\mathcal{F}$ of closed subsets of X with FIP satisfies $\bigcap_{F \in \mathcal{F}} F \neq \emptyset$.

Proof.

($\Rightarrow$) Assume X is compact, and let $\emptyset \neq \mathcal{F} \subseteq \mathcal{P}(X)$ be a family of closed subsets with the finite intersection property.
If $X = \emptyset$, then $\mathcal{F} = \{\emptyset\}$, contrary to its finite intersection property. Suppose $X \neq \emptyset$ and $\bigcap_{F \in \mathcal{F}} F = \emptyset$.
The family $\{X \setminus F : F \in \mathcal{F}\}$ is an open cover of X.
By compactness, choose $n \in \mathbb{N}$ and $F_1, \ldots, F_n \in \mathcal{F}$ such that $X = \bigcup_{j=1}^{n} (X \setminus F_j)$.
Since $X \neq \emptyset$, $n \geq 1$, whereas $\bigcap_{j=1}^{n} F_j = \emptyset$. This contradicts the finite intersection property.

($\Leftarrow$) Assume the closed-family condition, and let $(G_\alpha)_{\alpha \in A}$ be an open cover of X.
If $X = \emptyset$, the empty subfamily covers X. Suppose $X \neq \emptyset$ and no finite subcover exists.
Then $A \neq \emptyset$, and $\mathcal{F} := \{X \setminus G_\alpha : \alpha \in A\}$ is a nonempty family of closed subsets. Let $\emptyset \neq \mathcal{F}_0 \subseteq \mathcal{F}$ be finite.
For $C \in \mathcal{F}_0$, choose $\alpha_C \in A$ with $C = X \setminus G_{\alpha_C}$. Set $A_0 := \{\alpha_C : C \in \mathcal{F}_0\}$.
The finite set A_0 does not index a cover of X, so $\bigcap_{C \in \mathcal{F}_0} C \neq \emptyset$. Thus $\mathcal{F}$ has the finite intersection property.
By the closed-family condition, $\bigcap_{\alpha \in A} (X \setminus G_\alpha) \neq \emptyset$, contrary to $X \subseteq \bigcup_{\alpha \in A} G_\alpha$.

Structural Commentary: Taking complements exchanges finite subcovers with finite intersections.
Key Insight: An empty total intersection is already witnessed finitely. □

Figure 127 depicts the finite extraction required by compactness.

Figure 127: An arbitrary dashed cover of K (left) is reduced to a finite solid subcover (right).

Counterexample 4.1.4. *An Open Cover Without a Finite Subcover*
For $x \in (0, 1)$, set $O_x := (\frac{x}{2}, 1)$. The family $(O_x)_{x \in (0,1)}$ covers $(0, 1)$ because $(\forall\, y \in (0, 1))\, y \in O_y$.
The empty subfamily does not cover $(0, 1)$. Given $x_1, \ldots, x_n \in (0, 1)$ with $n \geq 1$, put $x' := \min_{1 \leq i \leq n} x_i$.
Then $(\forall\, i \in \{1, \ldots, n\})\, O_{x_i} \subseteq O_{x'}$, while $(0, \frac{x'}{2}] \cap O_{x'} = \emptyset$. Hence no finite subfamily covers $(0, 1)$.

Figure 128 shows why the preceding cover of $(0, 1)$ has no finite subcover.

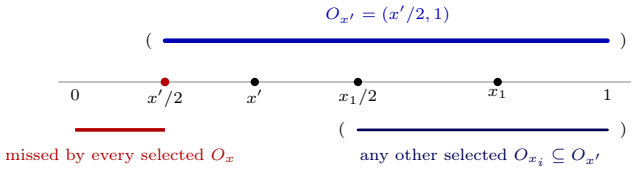

Figure 128: For $x' = \min_i x_i$, $(\forall\, i \in \{1, \dots, n\})\, O_{x_i} \subseteq O_{x'}$, while $(0, \frac{x'}{2}]$ remains uncovered.

Theorem 4.1.5. *Compactness Is Independent of the Ambient Space*
Let (X, d) be a metric space, and suppose $K \subseteq Y \subseteq X$. Then K is compact in X iff it is compact in the subspace $(Y, d|_{Y\times Y})$.

Proof.
($\Rightarrow$) Let $(V_\alpha)_{\alpha\in A}$ be a subspace-open cover of K in Y. Set $\mathcal{G} := \{G \in \tau_d : (\exists\, \alpha \in A)\, Y \cap G = V_\alpha\}$.
The family $\mathcal{G}$ covers K by Theorem 3.2.3. By compactness in X, choose a finite $\mathcal{G}_0 \subseteq \mathcal{G}$ that covers K.
For $G \in \mathcal{G}_0$, choose $\alpha(G) \in A$ with $Y \cap G = V_{\alpha(G)}$. Since $K \subseteq Y$, the finite family $(V_{\alpha(G)})_{G\in\mathcal{G}_0}$ covers K.
($\Leftarrow$) Let $(G_\alpha)_{\alpha\in A}$ be an open cover of K in X. The family $(Y \cap G_\alpha)_{\alpha\in A}$ is a subspace-open cover of K by Theorem 3.2.3.
By compactness in Y, some finite $F \subseteq A$ satisfies $K \subseteq \bigcup_{\alpha\in F} (Y \cap G_\alpha) \subseteq \bigcup_{\alpha\in F} G_\alpha$.

Structural Commentary: Intersecting ambient opens with Y transfers covers in both directions.
Key Insight: Finite subcovers survive restriction to the subspace. □

Theorem 4.1.6. *Compact Sets Are Closed*
Let (X, d) be a metric space. Every compact set $K \subseteq X$ is closed in X.

Proof.
(i) *Pointwise separation*: The claim holds for $K = \emptyset$ by Theorem 3.1.19(iv). Suppose $K \neq \emptyset$, and fix $p \in X \setminus K$.
For $q \in K$, set $r_q := \frac{1}{2}d(p, q) > 0$, $V_q := B_{r_q}(p)$, and $W_q := B_{r_q}(q)$.
If $x \in V_q \cap W_q$, then $d(p, q) \leq d(p, x) + d(x, q) < 2r_q = d(p, q)$, a contradiction. Thus $V_q \cap W_q = \emptyset$.
(ii) *Finite consolidation*: The family $(W_q)_{q\in K}$ covers K.
By compactness, choose $n \in \mathbb{N}$ and $q_1, \dots, q_n \in K$ such that $K \subseteq \bigcup_{i=1}^{n} W_{q_i}$.
The set $V := \bigcap_{i=1}^{n} V_{q_i}$ is open by Theorem 3.1.19(iii), contains p, and is disjoint from K.
(iii) *Complement*: Thus $(\forall\, p \in X \setminus K)(\exists\, V \in \tau_d)\, p \in V \subseteq X \setminus K$. Hence $X \setminus K$ is open, so K is closed.
Structural Commentary: A finite cover converts pointwise disjoint balls into one complement neighborhood.
Key Insight: Half-distance balls around p and q cannot intersect. □

Theorem 4.1.7. *Closed Subsets of Compact Sets Are Compact*
Let (X, d) be a metric space, and suppose $F \subseteq K \subseteq X$. If F is closed in X and K is compact, then F is compact.

Proof. Let $(V_\alpha)_{\alpha\in A}$ be an open cover of F. Since $X \setminus F$ is open, $(V_\alpha)_{\alpha\in A} \cup \{X \setminus F\}$ covers K.
By compactness of K, some finite $F_0 \subseteq A$ satisfies $K \subseteq (X \setminus F) \cup \bigcup_{\alpha\in F_0} V_\alpha$. Therefore $F \subseteq \bigcup_{\alpha\in F_0} V_\alpha$.
Structural Commentary: The open complement extends a cover of F to one of K.
Key Insight: Discarding the complement leaves a finite cover of F. □

Corollary 4.1.8. *Closed Intersections with Compact Sets*
Let (X, d) be a metric space. If $F \subseteq X$ is closed and $K \subseteq X$ is compact, then $F \cap K$ is compact.

Proof. The set K is closed by Theorem 4.1.6. Thus $F \cap K$ is closed by Theorem 3.1.19(ii).
The set $F \cap K$ is compact by Theorem 4.1.7 with $F \cap K \subseteq K$.
Structural Commentary: Closed-set calculus makes $F \cap K$ closed; the closed-subset theorem transfers compactness.
Key Insight: The intersection remains a closed subset of compact K. □

Theorem 4.1.9. *Finite Intersection Property for Compact Sets*
Let (X, d) be a metric space, $(K_\alpha)_{\alpha\in A}$ be compact subsets of X, $A \neq \emptyset$. If $(\forall\, F \subseteq A)\, [0 < |F| < \infty \Rightarrow \bigcap_{\alpha\in F} K_\alpha \neq \emptyset]$, then $\bigcap_{\alpha\in A} K_\alpha \neq \emptyset$.

Proof. Choose $\alpha_0 \in A$ and suppose $\bigcap_{\alpha\in A} K_\alpha = \emptyset$. Then $K_{\alpha_0} \subseteq \bigcup_{\alpha\in A} K_\alpha^c$. Each K_α^c is open by Theorem 4.1.6.
By compactness of K_{α_0}, some finite $F \subseteq A$ satisfies $K_{\alpha_0} \subseteq \bigcup_{\alpha\in F} K_\alpha^c$. Hence $\bigcap_{\alpha\in F\cup\{\alpha_0\}} K_\alpha = \emptyset$, a contradiction.
Structural Commentary: Complements turn failure into a finite cover.
Key Insight: For compact sets, failure of intersection is already witnessed finitely. □

Corollary 4.1.10. *Nested Nonempty Compact Sets Intersect*
Let (X, d) be a metric space. If $K_1 \supseteq K_2 \supseteq \cdots$ are nonempty compact subsets of X, then $\bigcap_{n=1}^{\infty} K_n \neq \emptyset$.

Proof. Let $\emptyset \neq F \subseteq \mathbb{N}$ be finite, and put $m := \max_{n\in F} n$. Then $\bigcap_{n\in F} K_n = K_m \neq \emptyset$ by nestedness.
Thus $(K_n)_{n\in\mathbb{N}}$ has the finite intersection property. Hence $\bigcap_{n=1}^{\infty} K_n \neq \emptyset$ by Theorem 4.1.9.
Structural Commentary: Nestedness reduces finite intersections to one term.
Key Insight: A nested compact sequence has the finite intersection property. □

Theorem 4.1.11. *Infinite Subsets of Compact Sets Have Limit Points*
Let (X,d) be a metric space, let $K \subseteq X$ be compact, and let $E \subseteq K$ be infinite. Then $E^{\mathrm{acc}} \cap K \neq \emptyset$.

Proof. Suppose $E^{\mathrm{acc}} \cap K = \emptyset$, and set $\mathcal{U} := \{B_r(q) : q \in K,\ r > 0,\ B_r(q) \cap (E \setminus \{q\}) = \emptyset\}$.
The family $\mathcal{U}$ covers K because no $q \in K$ is an accumulation point of E.
By compactness, choose $n \in \mathbb{N}$ and $B_{r_i}(q_i) \in \mathcal{U}$, $1 \le i \le n$, such that $K \subseteq \bigcup_{i=1}^{n} B_{r_i}(q_i)$.
Each selected ball meets E in at most one point, so $|E| \le n$, contrary to the infinitude of E.
Structural Commentary: Compactness reduces locally isolated intersections with E to finitely many balls.
Key Insight: Finitely many one-point intersections cannot cover infinite E. □

Definition 4.1.12. *Sequential Compactness*
A metric space (X,d) is *sequentially compact* iff every sequence in X has a subsequence converging in X.

Theorem 4.1.13. *Compactness Produces Convergent Subsequences*
If (p_n) is a sequence in a compact metric space (X,d), then some subsequence (p_{n_i}) converges to a point $p \in X$.

Proof. Let $E := \{p_n : n \in \mathbb{N}\}$. If E is finite and $(\forall\, q \in E)\,|\{n \in \mathbb{N} : p_n = q\}| < \infty$, then $\mathbb{N}$ is finite, a contradiction.
Thus some $p \in E$ occurs infinitely often when E is finite, and $(\forall\, r > 0)(\forall\, N \in \mathbb{N})(\exists\, n \ge N)\, p_n \in B_r(p)$.
Suppose E is infinite. Some $p \in E^{\mathrm{acc}} \cap X$ exists by Theorem 4.1.11 with $K = X$.
Fix $r > 0$ and $N \in \mathbb{N}$. The set $B_r(p) \cap E$ is infinite by Theorem 3.1.14, whereas $\{p_1, \dots, p_{N-1}\}$ is finite.
Therefore $(\exists\, n \ge N)\, p_n \in B_r(p)$. In either case, a subsequence converges to p by Proposition 3.4.8, $(i) \Rightarrow (ii)$.
Structural Commentary: Finite ranges repeat; infinite compact ranges contain an accumulation point.
Key Insight: Repetition and accumulation both create a convergent subsequence. □

Definition 4.1.14. *Cauchy Sequence*
A sequence (p_n) in a metric space (X,d) is *Cauchy* if $(\forall\, \varepsilon > 0)(\exists\, N \in \mathbb{N})(\forall\, m,n \ge N)\, d(p_m,p_n) < \varepsilon$.

Definition 4.1.15. *Diameter*
Let (X,d) be a metric space and $\emptyset \neq E \subseteq X$. The *diameter* of E is $\operatorname{diam} E := \sup_{\overline{\mathbb{R}}}\{d(p,q) : p,q \in E\} \in [0,+\infty]$.

Proposition 4.1.16. *Basic Diameter Properties*
Let (X,d) be a metric space and let $\emptyset \neq E, F \subseteq X$.
(i) E is bounded iff $\operatorname{diam} E < \infty$.
(ii) $\operatorname{diam} E = 0 \iff |E| = 1$.
(iii) $E \subseteq F \implies \operatorname{diam} E \le \operatorname{diam} F$.
(iv) E, F bounded $\implies E \cup F$ bounded.

Proof.
(i) ($\Rightarrow$) If E is bounded, choose $q \in X$ and $M > 0$ such that $E \subseteq B_M(q)$.
Then $(\forall\, x,y \in E)\, d(x,y) < 2M$ by the triangle inequality, so $\operatorname{diam} E \le 2M < \infty$.

(i) ($\Leftarrow$) If $\operatorname{diam} E < \infty$ and $q \in E$, then $E \subseteq B_{\operatorname{diam} E+1}(q)$, so E is bounded.
(ii) ($\Rightarrow$) If $\operatorname{diam} E = 0$, then $(\forall\, x,y \in E)\, d(x,y) = 0$. Thus all points of the nonempty set E are equal, and $|E| = 1$.

(ii) ($\Leftarrow$) If $|E| = 1$, then $(\forall\, x,y \in E)\, d(x,y) = 0$, so $\operatorname{diam} E = 0$.
(iii) Since $\{d(x,y) : x,y \in E\} \subseteq \{d(x,y) : x,y \in F\}$, $\operatorname{diam} E \le \operatorname{diam} F$ by monotonicity of the supremum.
(iv) Choose $e \in E$, $f \in F$, and set $D := \operatorname{diam} E + d(e,f) + \operatorname{diam} F < \infty$.
If x,y lie in the same one of E, F, then $d(x,y) \le D$. Otherwise, after swapping x,y, assume $x \in E$ and $y \in F$.
Then $d(x,y) \le d(x,e) + d(e,f) + d(f,y) \le D$. Thus $\operatorname{diam}(E \cup F) \le D < \infty$, so $E \cup F$ is bounded by (i).
Structural Commentary: Ball bounds control diameters; bridge points control cross-distances in unions.
Key Insight: One bridge distance joins two bounded sets. □

Proposition 4.1.17. *Cauchy Sequences and Tail Diameters*
For (p_n) in a metric space X, set $E_N := \{p_j : j \ge N\}$. Then (p_n) is Cauchy if and only if $\operatorname{diam} E_N \to 0$.

Proof.
($\Rightarrow$) Given $\varepsilon > 0$, choose N_0 so that $m,n \ge N_0$ implies $d(p_m,p_n) < \frac{\varepsilon}{2}$.
If $N \ge N_0$, then $(\forall\, m,n \ge N)\, d(p_m,p_n) < \frac{\varepsilon}{2}$, so $\operatorname{diam} E_N \le \frac{\varepsilon}{2} < \varepsilon$.
($\Leftarrow$) Given $\varepsilon > 0$, choose N_0 with $\operatorname{diam} E_{N_0} < \varepsilon$. If $m,n \ge N_0$, then $p_m, p_n \in E_{N_0}$, hence $d(p_m,p_n) \le \operatorname{diam} E_{N_0} < \varepsilon$.
Structural Commentary: The Cauchy quantifiers match convergence of the decreasing tail diameters.
Key Insight: Tail diameter measures mutual closeness without naming a limit. □

Definition 4.1.18. *Contracting Sequence of Sets*
Let (X,d) be a metric space and let $(F_n)_{n\ge1}$ satisfy $\emptyset \neq F_n \subseteq X$.
(i) The sequence (F_n) is *descending* iff $(\forall\, n \ge 1)\, F_{n+1} \subseteq F_n$.
(ii) The sequence (F_n) is *contracting* iff it is descending and $\operatorname{diam} F_n \to 0$.

Figure 129 visualizes the tail-diameter criterion for Cauchy sequences.

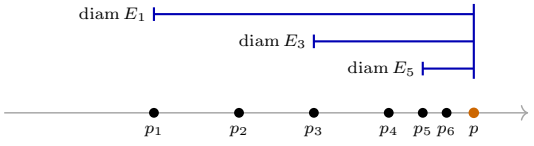

Figure 129: Tail diameters $\operatorname{diam} E_N$ shrink toward 0.

Theorem 4.1.19. *Nested Compact Sets with Shrinking Diameter*
Let (X,d) be a metric space.

(i) If $\emptyset \neq E \subseteq X$, then $\operatorname{diam} \overline{E} = \operatorname{diam} E$.

(ii) If $K_1 \supseteq K_2 \supseteq \cdots$ are nonempty compact subsets of X and $\operatorname{diam} K_n \to 0$, then $\left|\bigcap_{n=1}^{\infty} K_n\right| = 1$.

Proof.

(i) Since $E \subseteq \overline{E}$, $\operatorname{diam} E \leq \operatorname{diam} \overline{E}$ by Proposition 4.1.16(iii). If $\operatorname{diam} E = +\infty$, equality follows.
Suppose $\operatorname{diam} E < \infty$. For $p, q \in \overline{E}$ and $\varepsilon > 0$, choose $p', q' \in E$ with $d(p,p'), d(q,q') < \frac{\varepsilon}{2}$.
Then $d(p,q) < \operatorname{diam} E + \varepsilon$. Since $\varepsilon > 0$ is arbitrary, $d(p,q) \leq \operatorname{diam} E$; hence $\operatorname{diam} \overline{E} \leq \operatorname{diam} E$.

(ii) Set $I := \bigcap_{n=1}^{\infty} K_n$. Then $I \neq \emptyset$ by Corollary 4.1.10.
For $x, y \in I$, $(\forall\, n \in \mathbb{N})\, d(x,y) \leq \operatorname{diam} K_n$, so $d(x,y) = 0$ by $\operatorname{diam} K_n \to 0$. Thus $x = y$, and $|I| = 1$.

Structural Commentary: Closure preserves diameter; nested compactness and shrinking diameters split existence from uniqueness.
Key Insight: Every two intersection points have distance zero. □

Theorem 4.1.20. *Cauchy Criterion and Completeness Results*

(i) Every convergent sequence in a metric space is Cauchy.

(ii) Every Cauchy sequence in a compact metric space X converges in X.

Proof.

(i) If $p_n \to p$, then for $\varepsilon > 0$ choose N with $d(p_n, p) < \frac{\varepsilon}{2}$ for $n \geq N$. For $m, n \geq N$, $d(p_m, p_n) \leq d(p_m, p) + d(p, p_n) < \varepsilon$.

(ii) Let (p_n) be Cauchy in compact X, and set $E_N := \{p_j : j \geq N\}$ and $F_N := \overline{E_N}$. Each F_N is nonempty.
Since $E_{N+1} \subseteq E_N \subseteq F_N$, one has $F_{N+1} \subseteq F_N$ by Theorem 3.1.22(iii).
Each F_N is closed by Theorem 3.1.22(i), hence compact by Theorem 4.1.7.
The convergence $\operatorname{diam} F_N = \operatorname{diam} E_N \to 0$ holds by Proposition 4.1.17 and Theorem 4.1.19(i).
The relation $(\exists\, p \in X) \bigcap_{N=1}^{\infty} F_N = \{p\}$ holds by Theorem 4.1.19(ii).
Given $\varepsilon > 0$, choose N with $\operatorname{diam} F_N < \varepsilon$. For $n \geq N$, both $p_n, p \in F_N$, so $d(p_n, p) < \varepsilon$.

Structural Commentary: Cauchy tails create a contracting nest whose compact intersection supplies the limit.
Key Insight: Shrinking closed tails trap every late term near one point. □

Lemma 4.1.21. *A Cauchy Sequence with a Convergent Subsequence Converges*
Let (p_n) be a Cauchy sequence in a metric space X. If some subsequence (p_{n_j}) converges to $p \in X$, then $p_n \to p$.

Proof. Given $\varepsilon > 0$, choose N_0 so that $m, n \geq N_0$ implies $d(p_m, p_n) < \frac{\varepsilon}{2}$.
Choose $j \geq N_0$ with $d(p_{n_j}, p) < \frac{\varepsilon}{2}$; then $n_j \geq j \geq N_0$. For $n \geq N_0$, $d(p_n, p) \leq d(p_n, p_{n_j}) + d(p_{n_j}, p) < \varepsilon$.
Structural Commentary: A late subsequence term links the Cauchy tail to the subsequential limit.
Key Insight: One convergent thread fixes the destination of the entire tail. □

Proposition 4.1.22. *Boundedness and Distances of Cauchy Sequences*
Let (X,d) be a metric space.

(i) If (p_n) is Cauchy, then $\operatorname{ran}(p_n)$ is bounded.

(ii) If (p_n) and (q_n) are Cauchy, then $(d(p_n, q_n))$ converges in $\mathbb{R}$.

(iii) A bounded real sequence need not be Cauchy.

Proof.

(i) Choose $N \in \mathbb{N}$ with $m, n \geq N \Longrightarrow d(p_m, p_n) < 1$, and set $R := 1 + \max_{1 \leq j \leq N} d(p_j, p_N)$.
If $n \leq N$, then $d(p_n, p_N) < R$; if $n \geq N$, then $d(p_n, p_N) < 1 \leq R$. Hence $\operatorname{ran}(p_n) \subseteq B_R(p_N)$.

(ii) Let (p_n), (q_n) be Cauchy. For $m, n \in \mathbb{N}$, triangle inequality in both directions establishes $|d(p_n, q_n) - d(p_m, q_m)| \leq d(p_n, p_m) + d(q_n, q_m)$.
Given $\varepsilon > 0$, both terms on the right are less than $\frac{\varepsilon}{2}$ for sufficiently large m, n.
Hence $(d(p_n, q_n))$ is Cauchy in $\mathbb{R}$ and converges by Theorem 2.1.15.

(iii) Let $a_n := (-1)^n$. Then $(\forall\, n \in \mathbb{N})\, |a_n| \leq 1$, so (a_n) is bounded.
For $N \in \mathbb{N}$, choose even $m \geq N$ and odd $n \geq N$; then $|a_m - a_n| = 2$. Thus (a_n) is not Cauchy.

Structural Commentary: A bounded tail controls the range; the four-point estimate controls pairwise distances.
Key Insight: Cauchy control persists under the metric map. □

Definition 4.1.23. *Complete Metric Space*
A metric space (X,d) is *complete* iff every Cauchy sequence in X converges in X.

Corollary 4.1.24. *Compact Metric Spaces Are Complete*
Every compact metric space is complete.

Proof. Every Cauchy sequence converges to a point of the space by Theorem 4.1.20(ii); hence the space is complete.
Structural Commentary: The compact Cauchy criterion discharges the defining convergence requirement.
Key Insight: Compactness keeps every Cauchy limit inside the space. □

Remark 4.1.25. *Intrinsic and Ambient Metric Properties*
For $E \subseteq X$ in a metric space (X,d), boundedness, compactness, and completeness are intrinsic to $d|_{E \times E}$.
In contrast, openness, closedness, and perfection depend on the ambient metric space.

Proposition 4.1.26. *Completeness and Closed Subspaces*
Let (X,d) be a metric space, let $E \subseteq X$, and set $d_E := d|_{E \times E}$.

(i) If (E, d_E) is complete, then E is closed in X, equivalently $E = \overline{E}^{\,X}$.

(ii) If (X,d) is complete, then (E,d_E) is complete if and only if E is closed in X, equivalently $E=\overline{E}^{\,X}$.

Proof.

(i) Assume (E,d_E) is complete, and let (p_n) be a sequence in E with $p_n\to p\in X$.
The sequence is Cauchy in X by Theorem 4.1.20(i), hence it is Cauchy in (E,d_E).
Choose $q\in E$ with $p_n\to q$ in (E,d_E) by completeness. The same convergence holds in X because $d_E=d|_{E\times E}$.
Equality $p=q$ holds by Theorem 3.4.6(ii); E is closed by Theorem 3.4.17(ii). Equality $E=\overline{E}^{\,X}$ holds by Theorem 3.1.22(ii).

(ii) ($\Rightarrow$) Assume (X,d) and (E,d_E) are complete. Then $E=\overline{E}^{\,X}$ by (i).

(ii) ($\Leftarrow$) Assume (X,d) is complete and $E=\overline{E}^{\,X}$. Then E is closed by Theorem 3.1.22(ii).
If (p_n) is Cauchy in (E,d_E), then it is Cauchy in X, and $p_n\to p\in X$ by completeness.
The membership $p\in E$ holds by Theorem 3.4.17(ii). Thus every Cauchy sequence in (E,d_E) converges in (E,d_E).

Structural Commentary: Subspace completeness forces closure; ambient completeness plus closure returns subspace limits.
Key Insight: Closedness is exactly the limit-retention condition. □

Theorem 4.1.27. *Cantor Intersection Theorem*
Let (X,d) be a metric space. Then X is complete iff every contracting sequence $(F_n)_{n\geq 1}$ of closed subsets of X satisfies $\left|\bigcap_{n=1}^{\infty}F_n\right|=1$.

Proof.

($\Rightarrow$) Assume X is complete, and let (F_n) satisfy the stated hypotheses. Choose (x_n) with $(\forall\, n\in\mathbb{N})\,x_n\in F_n$.
Given $\varepsilon>0$, choose N with $\operatorname{diam}F_N<\varepsilon$. For $m,n\geq N$, descendingness places x_m,x_n in F_N, so $d(x_m,x_n)<\varepsilon$.
The sequence (x_n) is Cauchy, and $x_n\to x\in X$ by completeness.
For $N\in\mathbb{N}$, the tail $(x_n)_{n\geq N}$ lies in closed F_N, so $x\in F_N$ by Theorem 3.4.17(ii).
Hence $x\in\bigcap_{N=1}^{\infty}F_N$. If $y\in\bigcap_{N=1}^{\infty}F_N$, then $(\forall\, N\in\mathbb{N})\,d(x,y)\leq\operatorname{diam}F_N$, so $x=y$ by $\operatorname{diam}F_N\to 0$.

($\Leftarrow$) Assume the intersection property, and let (x_n) be Cauchy. Set $E_N:=\{x_n : n\geq N\}$ and $F_N:=\overline{E_N}$ for $N\in\mathbb{N}$.
Each F_N is nonempty and closed by Theorem 3.1.22(i).
The inclusions $E_{N+1}\subseteq E_N\subseteq F_N$ imply $F_{N+1}\subseteq F_N$ by Theorem 3.1.22(iii).
The convergence $\operatorname{diam}F_N=\operatorname{diam}E_N\to 0$ holds by Proposition 4.1.17 and Theorem 4.1.19(i).
Choose $x\in X$ with $\bigcap_{N=1}^{\infty}F_N=\{x\}$ by the intersection property.
Given $\varepsilon>0$, choose N with $\operatorname{diam}F_N<\varepsilon$. If $n\geq N$, then $x_n,x\in F_N$, so $d(x_n,x)<\varepsilon$. Thus $x_n\to x$, and X is complete.

Structural Commentary: Complete limits intersect closed nests; closed Cauchy tails reconstruct limits.
Key Insight: Contracting tails encode both Cauchy control and a unique destination. □

We now turn from contracting closed families to the finite-resolution side of compact metric spaces.

Definition 4.1.28. *Total Boundedness*
Let (X,d) be a metric space and let $E\subseteq X$.

(i) For $\varepsilon>0$, a finite set $F\subseteq X$ is an *ε-net* for E iff $E\subseteq\bigcup_{x\in F}B_\varepsilon(x)$.

(ii) The set E is *totally bounded* iff $(\forall\,\varepsilon>0)(\exists\, F\subseteq X)\,[|F|<\infty\wedge E\subseteq\bigcup_{x\in F}B_\varepsilon(x)]$.

(iii) The metric space (X,d) is *totally bounded* iff condition (ii) holds with $E=X$.

Proposition 4.1.29. *Centers of Finite Nets*
Let (X,d) be a metric space and let $\emptyset\neq E\subseteq X$.
Then E is totally bounded iff every $\varepsilon>0$ admits a finite ε-net $F\subseteq E$.

Proof.

($\Rightarrow$) Suppose E is totally bounded, $\varepsilon>0$. Choose finite $\frac{\varepsilon}{2}$-net $A\subseteq X$ for E, $A':=\{a\in A : E\cap B_{\frac{\varepsilon}{2}}(a)\neq\emptyset\}$.
For $a\in A'$, choose $x_a\in E\cap B_{\frac{\varepsilon}{2}}(a)$, and set $F:=\{x_a : a\in A'\}\subseteq E$. The set F is finite.
Given $y\in E$, some $a\in A'$ satisfies $y\in B_{\frac{\varepsilon}{2}}(a)$. Then $d(y,x_a)<\varepsilon$ by the triangle inequality, so F is an ε-net for E.

($\Leftarrow$) Fix $\varepsilon>0$, and choose a finite ε-net $F\subseteq E$ by stated condition. Since $F\subseteq X$, the defining condition for total boundedness holds.

Structural Commentary: Half-radius nets move ambient centers into E without losing coverage.
Key Insight: Two points in one half-radius ball are ε-close. □

Figure 130 compares finite nets at two resolutions.

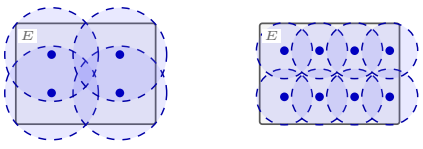

Figure 130: Dots mark a finite ε-net (left) and finer δ-net (right); their balls cover E, with $0<\delta<\varepsilon$.

Theorem 4.1.30. *Total Boundedness Implies Boundedness*
Let (X,d) be a metric space. If X is totally bounded, then X is bounded.

Proof. If $X=\emptyset$, it is bounded. Suppose $X\neq\emptyset$, choose finite 1-net $F\subseteq X$. Then $F\neq\emptyset$; fix $x_0\in F$ and put $R:=1+\max_{a\in F}d(a,x_0)$.
For $x\in X$, some $a\in F$ satisfies $d(x,a)<1$, so $d(x,x_0)\leq d(x,a)+d(a,x_0)<R$. Hence $X\subseteq B_R(x_0)$.
Structural Commentary: A finite unit-ball cover converts finitely many center distances into one radius.
Key Insight: One fixed scale already supplies a global bound. □

Counterexample 4.1.31. *Bounded Need Not Mean Totally Bounded*
In $\ell^2(\mathbb{F})$, let $B := \{\mathbf{x} \in \ell^2(\mathbb{F}) : \|\mathbf{x}\|_2 \le 1\}$. Then $B \subseteq B_2(0)$, so B is bounded.
For the standard unit vectors (e_n), $(\forall\, n \in \mathbb{N})\, e_n \in B$ and $(\forall\, m \ne n)\ \|e_n - e_m\|_2 = \sqrt{2}$.
Any $\frac{1}{2}$-ball contains at most one e_n, because two points in such a ball have distance less than 1.
Thus B has no finite $\frac{1}{2}$-net, so B is not totally bounded.

Definition 4.1.32. *Lebesgue Number*
Let (X, d) be a metric space, $\mathcal{U}$ be an open cover of X. A number $\delta > 0$ is a *Lebesgue number* for $\mathcal{U}$ iff $(\forall\, x \in X)(\exists\, U \in \mathcal{U})\, B_\delta(x) \subseteq U$.

Lemma 4.1.33. *Lebesgue Covering Lemma*
Let (X, d) be a metric space.

(i) If X is sequentially compact, then every open cover of X has a Lebesgue number.
(ii) If X is compact, then every open cover of X has a Lebesgue number.

Proof.

(i) Let $\mathcal{U} = (U_\alpha)_{\alpha \in A}$ be an open cover of sequentially compact X.
If $\mathcal{U}$ has no Lebesgue number, choose (x_n) in X satisfying $(\forall\, n \in \mathbb{N})(\forall\, \alpha \in A)\, B_{\frac{1}{n}}(x_n) \not\subseteq U_\alpha$.
Choose a subsequence $x_{n_k} \to x \in X$. Since $\mathcal{U}$ covers X, choose $\alpha_0 \in A$ and $r > 0$ such that $x \in U_{\alpha_0}$ and $B_r(x) \subseteq U_{\alpha_0}$.
For sufficiently large k, both $d(x_{n_k}, x) < \frac{r}{2}$ and $\frac{1}{n_k} < \frac{r}{2}$. If $y \in B_{\frac{1}{n_k}}(x_{n_k})$, then $d(y, x) < r$, so $B_{\frac{1}{n_k}}(x_{n_k}) \subseteq U_{\alpha_0}$, a contradiction.

(ii) If X is compact, then it is sequentially compact by Theorem 4.1.13. Hence every open cover of X has a Lebesgue number by (i).

Structural Commentary: Bad-radius sequences contradict subsequential convergence; compactness supplies sequential compactness.
Key Insight: Near the limit, one cover set absorbs every small ball. □

Theorem 4.1.34. *Compactness as Complete Finite Resolution*
Let (X, d) be a metric space. The following are equivalent:

(i) X is compact;
(ii) X is complete and totally bounded;
(iii) X is sequentially compact.

Proof.

$(i) \Rightarrow (ii)$ Every Cauchy sequence in X converges by Theorem 4.1.20(ii), so X is complete. Fix $\varepsilon > 0$.
Family $\{B_\varepsilon(x) : x \in X\}$ is open cover of X. By compactness, it has finite subcover, whose centers form a finite ε-net. QED.

$(ii) \Rightarrow (iii)$ Let (x_n) be a sequence in X, and put $I_0 := \mathbb{N}$ and $n_0 := 0$.
Recursively, suppose I_{j-1} is infinite and choose a finite $\frac{1}{j}$-net $A_j \subseteq X$.
If each ball centered in A_j contained x_n for only finitely many $n \in I_{j-1}$, then I_{j-1} would be finite.
Hence some $B_{\frac{1}{j}}(a_j)$ contains x_n for infinitely many $n \in I_{j-1}$. Set $I_j := \{n \in I_{j-1} : x_n \in B_{\frac{1}{j}}(a_j)\}$, which is infinite.
Choose $n_j \in I_j$ with $n_j > n_{j-1}$. If $k, \ell \ge j$, then $x_{n_k}, x_{n_\ell} \in B_{\frac{1}{j}}(a_j)$, so $d(x_{n_k}, x_{n_\ell}) < \frac{2}{j}$.
Given $\varepsilon > 0$, choose J with $\frac{2}{J} < \varepsilon$. If $k, \ell \ge J$, then $d(x_{n_k}, x_{n_\ell}) < \varepsilon$ by the preceding bound.
Thus (x_{n_j}) is Cauchy and converges in X by completeness.

$(iii) \Rightarrow (i)$ Suppose X is not totally bounded, so some $\varepsilon > 0$ admits no finite ε-net.
Then $X \ne \emptyset$ as $\emptyset$ is an ε-net for itself. Choose $x_1 \in X$, and recursively choose $x_{n+1} \notin \bigcup_{j=1}^{n} B_\varepsilon(x_j)$.
Then $(\forall\, j < n)\, d(x_n, x_j) \ge \varepsilon$, so no subsequence is Cauchy.
No subsequence converges by Theorem 4.1.20(i), contrary to sequential compactness. Thus X is totally bounded.
Let $(U_\alpha)_{\alpha \in A}$ be an open cover of X. Choose a Lebesgue number $\delta > 0$ by Lemma 4.1.33(i).
Choose a finite $\frac{\delta}{2}$-net $F \subseteq X$. For $z \in F$, choose $\alpha(z) \in A$ with $B_\delta(z) \subseteq U_{\alpha(z)}$.
If $x \in X$, then $(\exists\, z \in F)\, x \in B_{\frac{\delta}{2}}(z) \subseteq U_{\alpha(z)}$. Hence the finite family $(U_{\alpha(z)})_{z \in F}$ covers X, so X is compact.

Structural Commentary: Finite nets create Cauchy subsequences; Lebesgue numbers convert nets into finite subcovers.
Key Insight: Completeness turns finite-resolution control into actual convergence. □

Figure 131 summarizes the three equivalent compactness tests.

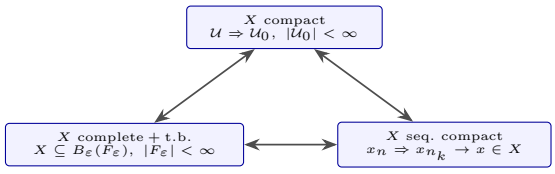

Figure 131: The proof cycle connects finite subcovers, completeness with finite ε-nets, and convergent subsequences.

Proposition 4.1.35. *Compact Metric Spaces Are Separable*
Let (X, d) be a compact metric space. Then X contains an at most countable set D such that $\overline{D}^X = X$.

Proof. The space X is totally bounded by Theorem 4.1.34, direction $(i) \Rightarrow (ii)$.
Choose finite $\frac{1}{n}$-nets $F_n \subseteq X$ for $n \in \mathbb{N}$. Set $D := \bigcup_{n=1}^{\infty} F_n$. The set D is at most countable by Corollary 6.2.16.
Let $x \in X$ and $r > 0$, and choose $n \in \mathbb{N}$ with $\frac{1}{n} < r$. Some $a \in F_n$ satisfies $d(x, a) < \frac{1}{n} < r$, so $a \in B_r(x) \cap D$.
Thus every open ball centered at x meets D, so $x \in \overline{D}^X$. Therefore $\overline{D}^X = X$, and X is separable.
Structural Commentary: Finite nets at reciprocal scales form an at most countable dense union.
Key Insight: One sufficiently fine net meets every prescribed ball. □

4.2 Heine–Borel and Euclidean Compactness

Theorem 4.2.1. *Nested Closed Intervals Intersect*

Let $(I_n)_{n\in\mathbb{N}}$ be nonempty closed intervals in $\mathbb{R}$, where $I_n = [a_n, b_n]$. If $(\forall n \in \mathbb{N})\, I_{n+1} \subseteq I_n$, then $\bigcap_{n=1}^{\infty} I_n \neq \emptyset$.

Proof. Set $A := \{a_n : n \in \mathbb{N}\}$, and fix $m \in \mathbb{N}$. If $n \geq m$, then $a_n \in I_n \subseteq I_m$, so $a_n \leq b_m$.
If $n < m$, then $b_m \in I_m \subseteq I_n$, so $a_n \leq b_m$. Thus b_m is an upper bound for A.
Since $A \neq \emptyset$ and A is bounded above, $x := \sup A$ exists by Theorem 1.1.9(i).

Inequalities $a_m \leq x \leq b_m$ follow from $a_m \in A$ and the upper-bound property of b_m. Therefore $(\forall m \in \mathbb{N})\, x \in I_m$, so $x \in \bigcap_{n=1}^{\infty} I_n$.

Structural Commentary: Nestedness makes each right endpoint bound all left endpoints; real completeness supplies their supremum.
Key Insight: Every interval contains $\sup\{a_n : n \in \mathbb{N}\}$. □

Figure 132 depicts the common point selected by the supremum construction.

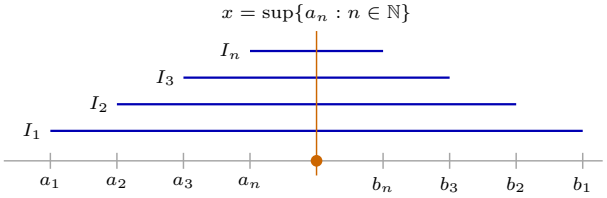

Figure 132: The nested segments represent $I_n = [a_n, b_n]$; the marked point $x = \sup\{a_n : n \in \mathbb{N}\}$ lies between every endpoint pair.

Theorem 4.2.2. *Nested k-Cells Intersect*

Let $k \in \mathbb{N}$, $(I_n)_{n\in\mathbb{N}}$ be sequence of nonempty k-cells, where $I_n = \prod_{j=1}^{k} [a_{n,j}, b_{n,j}] \subseteq \mathbb{R}^k$. If $(\forall n \in \mathbb{N})\, I_{n+1} \subseteq I_n$, then $\bigcap_{n=1}^{\infty} I_n \neq \emptyset$.

Proof. For $n \in \mathbb{N}$ and $1 \leq j \leq k$, coordinate projection of $I_{n+1} \subseteq I_n$ establishes $[a_{n+1,j}, b_{n+1,j}] \subseteq [a_{n,j}, b_{n,j}]$.
Choose $x_j^* \in \bigcap_{n=1}^{\infty} [a_{n,j}, b_{n,j}]$ for $1 \leq j \leq k$ by Theorem 4.2.1. Then $\mathbf{x}^* := (x_1^*, \ldots, x_k^*)$ satisfies $(\forall n \in \mathbb{N})\, \mathbf{x}^* \in I_n$, so $\mathbf{x}^* \in \bigcap_{n=1}^{\infty} I_n$.
Structural Commentary: Coordinate projection reduces a nested cell sequence to k nested interval sequences.
Key Insight: One persistent point in each coordinate defines a persistent vector. □

Figure 133 illustrates the product structure of the first three cell dimensions.

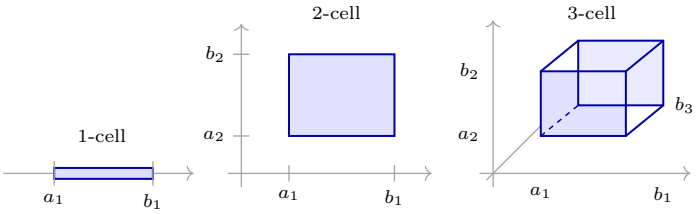

Figure 133: One-, two-, and three-factor cells are an interval, rectangle, and box; dashes mark a hidden edge.

Theorem 4.2.3. *k-Cells Are Compact*

Let $k \in \mathbb{N}$, and let $I = \prod_{j=1}^{k} [a_j, b_j] \subseteq \mathbb{R}^k$ be a nonempty k-cell. Then I is compact.

Proof.

(i) *Contradictory cover*: Put $\delta := \|(b_1 - a_1, \ldots, b_k - a_k)\|_2$. Suppose an open cover $\mathcal{G} = (G_\alpha)_{\alpha\in A}$ of I has no finite subcover.

(ii) *Nested construction*: Set $I_0 := I$. Bisecting every coordinate interval covers I_n by 2^k nonempty subcells.
If each subcell had a finite $\mathcal{G}$-subcover, their finite union would cover I_n. Thus some subcell has no finite subcover.
Choose I_{n+1} as the lexicographically first such subcell. This recursion defines $I_0 \supseteq I_1 \supseteq \cdots$.

(iii) *Diameter control*: The jth side of I_n has length $2^{-n}(b_j - a_j)$. Hence $(\forall\, \mathbf{p}, \mathbf{q} \in I_n)\ \|\mathbf{p} - \mathbf{q}\|_2 \leq 2^{-n}\delta$, so $\operatorname{diam} I_n \leq 2^{-n}\delta$.

(iv) *Contradiction*: Choose $\mathbf{x}^* \in \bigcap_{n=1}^{\infty} I_n$ by Theorem 4.2.2. Choose $\alpha \in A$ with $\mathbf{x}^* \in G_\alpha$, and $r > 0$ with $B_r(\mathbf{x}^*) \subseteq G_\alpha$.
The bound $(\forall n \in \mathbb{N})\, 2^n \geq n + 1$ holds by induction: $2^1 = 2$, and $2^n \geq n + 1$ implies $2^{n+1} \geq 2(n + 1) \geq n + 2$.
Choose $n \in \mathbb{N}$ with $n + 1 > \frac{\delta}{r}$ by Theorem 1.1.19(i). Then $2^{-n}\delta < r$.
Because $\mathbf{x}^* \in I_n$, the diameter bound implies $I_n \subseteq B_r(\mathbf{x}^*) \subseteq G_\alpha$. This one-member subcover contradicts the construction of I_n.

Structural Commentary: Recursive bisection combines nested-cell intersection with geometric diameter decay.
Key Insight: An open neighborhood of the trapped point eventually contains an entire bad cell. □

Figure 134 depicts the nested subcells and the terminal neighborhood contradiction.

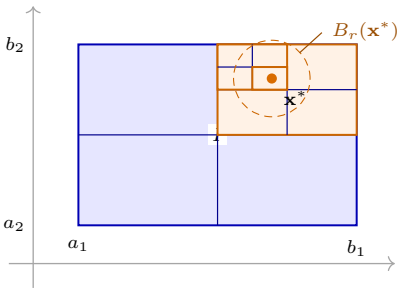

Figure 134: Successive outlined subcells form a nested chain; the dashed ball about $\mathbf{x}^*$ eventually contains a selected subcell.

Lemma 4.2.4. *Bounded Euclidean Sets Fit in k-Cells*
Let $k \in \mathbb{N}$ and let $E \subseteq \mathbb{R}^k$ be bounded. Then E is contained in a k-cell.

Proof. If $E = \emptyset$, then $E \subseteq \prod_{j=1}^{k} [-1, 1]$. Suppose $E \neq \emptyset$, and choose $\mathbf{q} = (q_1, \ldots, q_k) \in \mathbb{R}^k$ and $M > 0$ with $E \subseteq B_M(\mathbf{q})$.

Set $I := \prod_{j=1}^{k} [q_j - M, q_j + M]$. If $\mathbf{p} = (p_1, \ldots, p_k) \in E$, then $(\forall j \in \{1, \ldots, k\})\ |p_j - q_j| \leq \|\mathbf{p} - \mathbf{q}\|_2 < M$. Hence $\mathbf{p} \in I$, $E \subseteq I$.
Structural Commentary: A containing Euclidean ball transfers its radius bound to every coordinate interval.
Key Insight: Euclidean distance dominates each coordinate difference. □

Theorem 4.2.5. *Heine–Borel in $\mathbb{R}^k$*
Let $k \in \mathbb{N}$ and let $E \subseteq \mathbb{R}^k$. The following are equivalent:

(i) E is closed and bounded;
(ii) E is compact;
(iii) $(\forall\, S \subseteq E)\,[S$ infinite $\implies S^{\mathrm{acc}} \cap E \neq \emptyset]$.

Proof.

(i) ⇒ *(ii)* Choose a k-cell I with $E \subseteq I$ by Lemma 4.2.4. The set I is compact by Theorem 4.2.3.
Since E is closed in $\mathbb{R}^k$, it is compact by Theorem 4.1.7 with $E \subseteq I$.

(ii) ⇒ *(iii)* If $S \subseteq E$ is infinite, then $S^{\mathrm{acc}} \cap E \neq \emptyset$ by Theorem 4.1.11.

(iii) ⇒ *(i)*

(a) *Boundedness*: Suppose E is unbounded. Choose $(\mathbf{x}_n) \subseteq E$ with $(\forall n \in \mathbb{N})\ \|\mathbf{x}_n\|_2 > n$, $S := \{\mathbf{x}_n : n \in \mathbb{N}\}$.
The set S is infinite because a finite subset of $\mathbb{R}^k$ has bounded norms. If $\mathbf{x}_n \in B_1(\mathbf{y})$, then $n < \|\mathbf{x}_n\|_2 < \|\mathbf{y}\|_2 + 1$.
Thus $(\forall\, \mathbf{y} \in \mathbb{R}^k)\,[S \cap B_1(\mathbf{y})$ is finite$]$. Hence $S^{\mathrm{acc}} = \emptyset$ by contrapositive of Theorem 3.1.14.
This contradicts (iii), and hence E is bounded.

(b) *Closedness*: Suppose E is not closed, and choose $\mathbf{x}_0 \in \overline{E} \setminus E$. Then $\mathbf{x}_0 \in E^{\mathrm{acc}}$ by Definition 3.1.21.
Choose $(\mathbf{x}_n) \subseteq E \setminus \{\mathbf{x}_0\}$ with $\mathbf{x}_n \to \mathbf{x}_0$ by Theorem 3.4.17(i).
Set $S := \{\mathbf{x}_n : n \in \mathbb{N}\}$. If S were finite, then $\rho := \min_{\mathbf{x} \in S} \|\mathbf{x} - \mathbf{x}_0\|_2 > 0$.
Since $(\forall n \in \mathbb{N})\ \mathbf{x}_n \in S$, this contradicts $\mathbf{x}_n \to \mathbf{x}_0$; hence S is infinite. Fix $\mathbf{y} \neq \mathbf{x}_0$, and put $r := \frac{1}{3}\|\mathbf{y} - \mathbf{x}_0\|_2$.
The balls $B_r(\mathbf{y})$ and $B_r(\mathbf{x}_0)$ are disjoint, while all but finitely many $\mathbf{x}_n$ lie in $B_r(\mathbf{x}_0)$.
Hence $B_r(\mathbf{y}) \cap S$ is finite, so $\mathbf{y} \notin S^{\mathrm{acc}}$ by the contrapositive of Theorem 3.1.14.
Therefore $S^{\mathrm{acc}} \subseteq \{\mathbf{x}_0\}$ and $S^{\mathrm{acc}} \cap E = \emptyset$, contradicting (iii); hence E is closed.

Structural Commentary: Compact cells prove sufficiency; escaping and boundary-convergent sequences prove necessity.
Key Insight: Failure of either bound or closure creates an infinite set without internal accumulation. □

Theorem 4.2.6. *Weierstrass Limit-Point Theorem*
Let $k \in \mathbb{N}$ and let $E \subseteq \mathbb{R}^k$ be bounded and infinite. Then $E^{\mathrm{acc}} \neq \emptyset$.

Proof. Choose a k-cell I with $E \subseteq I$ by Lemma 4.2.4. Set I is compact by Theorem 4.2.3, so $E^{\mathrm{acc}} \cap I \neq \emptyset$ by Theorem 4.1.11.
Structural Commentary: Cell containment transfers the abstract compact accumulation theorem to bounded Euclidean sets.
Key Insight: A bounded infinite set is an infinite subset of one compact cell. □

Corollary 4.2.7. *Bounded Euclidean Sequences Have Convergent Subsequences*
Let $k \in \mathbb{N}$ and let $(\mathbf{x}_n)$ be a bounded sequence in $\mathbb{R}^k$. Then $(\mathbf{x}_n)$ has a convergent subsequence.

Proof. Set $R := \{\mathbf{x}_n : n \in \mathbb{N}\}$. Choose a k-cell I with $R \subseteq I$ by Lemma 4.2.4.
The set I is compact by Theorem 4.2.3; hence $(\mathbf{x}_n)$ has a convergent subsequence by Theorem 4.1.13.
Structural Commentary: Range containment moves the sequence into a compact cell before subsequence extraction.
Key Insight: One compact cell contains every term. □

Corollary 4.2.8. *Euclidean Cauchy Convergence*
Let $k \in \mathbb{N}$ and let $(\mathbf{x}_n)$ be a Cauchy sequence in $\mathbb{R}^k$. Then $(\mathbf{x}_n)$ converges.

Proof. The range of $(\mathbf{x}_n)$ is bounded by Proposition 4.1.22(i). Thus $(\mathbf{x}_n)$ has a convergent subsequence by Corollary 4.2.7.
Therefore $(\mathbf{x}_n)$ converges by Lemma 4.1.21.
Structural Commentary: Cauchy boundedness supplies a convergent subsequence, whose limit controls the full sequence.
Key Insight: A Cauchy sequence cannot diverge from a convergent subsequence. □

Corollary 4.2.9. *Euclidean Compactness Tests*
Let $k \in \mathbb{N}$ and let $E \subseteq \mathbb{R}^k$, with the subspace metric. The following are equivalent:

(i) *E is closed and bounded;*
(ii) *E is compact;*
(iii) $(\forall\, (\mathbf{x}_n) \subseteq E)(\exists\, n_1 < n_2 < \cdots)(\exists\, \mathbf{x} \in E)\, \mathbf{x}_{n_j} \to \mathbf{x}$.

Proof.

(i) $\Rightarrow$ *(ii)* The set E is compact by Theorem 4.2.5, direction $(i) \Rightarrow (ii)$.
(ii) $\Rightarrow$ *(iii)* Condition (iii) holds by Theorem 4.1.13.
(iii) $\Rightarrow$ *(i)* The metric space E is sequentially compact by (iii). Hence E is compact by Theorem 4.1.34, direction $(iii) \Rightarrow (i)$. Therefore E is closed and bounded by Theorem 4.2.5, direction $(ii) \Rightarrow (i)$.

Structural Commentary: Heine–Borel and metric sequential compactness connect geometric, cover, and subsequence criteria.
Key Insight: In Euclidean space, closed bounded geometry is exactly sequential compactness. □

Corollary 4.2.10. *Heine–Borel on the Real Line*
Let $E \subseteq \mathbb{R}$, with the usual metric. The following are equivalent:

(i) *E is closed and bounded;*
(ii) *E is compact;*
(iii) $(\forall\, (x_n) \subseteq E)(\exists\, n_1 < n_2 < \cdots)(\exists\, x \in E)\, x_{n_j} \to x$.

Proof.

(i) $\Rightarrow$ *(ii)* The set E is compact by Corollary 4.2.9, direction $(i) \Rightarrow (ii)$, with $k = 1$.
(ii) $\Rightarrow$ *(iii)* Condition (iii) holds by Corollary 4.2.9, direction $(ii) \Rightarrow (iii)$, with $k = 1$.
(iii) $\Rightarrow$ *(i)* The set E is closed and bounded by Corollary 4.2.9, direction $(iii) \Rightarrow (i)$, with $k = 1$.

Structural Commentary: Specializing the Euclidean compactness cycle to $k = 1$ transfers all three implications.
Key Insight: Real-line compactness is the one-dimensional Euclidean case. □

Corollary 4.2.11. *Nested Closed Bounded Real Sets Intersect*
Let $(F_n)_{n\in\mathbb{N}}$ be nonempty closed subsets of $\mathbb{R}$ with $(\forall n \in \mathbb{N})\, F_{n+1} \subseteq F_n$. If F_1 is bounded, then $\bigcap_{n=1}^{\infty} F_n \neq \emptyset$.

Proof. The set F_1 is compact by Corollary 4.2.10, direction $(i) \Rightarrow (ii)$.

For $n \in \mathbb{N}$, $F_n \subseteq F_1$ by nestedness, so F_n is compact by Theorem 4.1.7. Hence $\bigcap_{n=1}^{\infty} F_n \neq \emptyset$ by Corollary 4.1.10.

Structural Commentary: Heine–Borel makes F_1 compact; closed-subset compactness transfers this to the nested tail.
Key Insight: Nested nonempty compact sets have the finite intersection property. □

4.3 Baire Category

Definition 4.3.1. *F_σ, G_δ, and Nowhere-Dense Sets*
Let (X, d) be a metric space.

(i) A set $A \subseteq X$ is an *F_σ set* iff $A = \bigcup_{n=1}^{\infty} F_n$ for a sequence (F_n) of closed subsets of X.
(ii) A set $B \subseteq X$ is a *G_δ set* iff $B = \bigcap_{n=1}^{\infty} G_n$ for a sequence (G_n) of open subsets of X.
(iii) A set $E \subseteq X$ is *nowhere dense* iff $(\overline{E})^\circ = \emptyset$; equivalently, no nonempty open set is contained in $\overline{E}$.

For $X = \mathbb{R}$, this says exactly that $\overline{E}$ contains no nonempty open interval.

Proposition 4.3.2. *Open Real Sets Are F_σ*
Let $G, A \subseteq \mathbb{R}$.

(i) *If G is open, then G is F_σ.*
(ii) *If A is closed, then A is G_δ.*

Proof.

(i)

(a) *Whole-line case*: If $G = \mathbb{R}$, then $G = \bigcup_{m=1}^{\infty} [-m, m]$ by Theorem 1.1.19(i). Each interval closed by Corollary 3.1.18.
(b) *Distance control*: Suppose $G \neq \mathbb{R}$, and set $C := \mathbb{R} \setminus G \neq \emptyset$.
For $m \in \mathbb{N}$, define $D_m := \{x \in \mathbb{R} : \operatorname{dist}(x, C) \geq \frac{1}{m}\}$ and $F_m := [-m, m] \cap D_m$.
For $x, y \in \mathbb{R}$ and $c \in C$, $|x - c| \leq |x - y| + |y - c|$ by the triangle inequality.
Taking the infimum over $c \in C$, $\operatorname{dist}(x, C) \leq |x - y| + \operatorname{dist}(y, C)$ by Definition 3.1.25(i).
After interchanging x and y, $|\operatorname{dist}(x, C) - \operatorname{dist}(y, C)| \leq |x - y|$.
(c) *Closed approximants*: If $x \notin D_m$, put $\eta := \frac{1}{m} - \operatorname{dist}(x, C) > 0$. Then $y \in B_\eta(x)$ implies $\operatorname{dist}(y, C) < \frac{1}{m}$, so $B_\eta(x) \subseteq D_m^c$.
Thus D_m is closed by Corollary 3.1.17. The interval $[-m, m]$ is closed, so F_m is closed by Theorem 3.1.19(ii).
(d) *Exhaustion*: If $x \in C$, then $\operatorname{dist}(x, C) = 0$; hence $F_m \cap C = \emptyset$ and $F_m \subseteq G$. Fix $x \in G$, $r > 0$ with $(x - r, x + r) \subseteq G$.
Then $(\forall c \in C)\ |x - c| \geq r$, so $\operatorname{dist}(x, C) \geq r$. Choose $m \in \mathbb{N}$, $m \geq |x|$, $\frac{1}{m} \leq r$ by Theorem 1.1.19(i); $x \in F_m$, so $G = \bigcup_{m=1}^{\infty} F_m$.

(ii) If A is closed, then $A^c = \bigcup_{m=1}^{\infty} F_m$ for a sequence (F_m) of closed sets by (i). Therefore $A = \bigcap_{m=1}^{\infty} F_m^c$ is G_δ.

Structural Commentary: Distance from the complement constructs a closed exhaustion; complementation transfers it to closed sets.
Key Insight: Positive distance converts local openness into closed approximants. □

Definition 4.3.3. *First Category*

Let (X,d) be metric space, $E \subseteq X$. Set E is *meager* in X iff $E \subseteq \bigcup_{n=1}^{\infty} N_n$ for sequence (N_n) of nowhere-dense subsets of X.

The terms *of first category* and *thin* are synonymous. The ambient space X is part of the property.

Theorem 4.3.4. *Dense Open Intersections in $\mathbb{R}$*

Let $(G_n)_{n\in\mathbb{N}}$ be dense open subsets of $\mathbb{R}$. Then $\bigcap_{n=1}^{\infty} G_n \neq \emptyset$.

Proof.

(i) *Initialization*: Choose $x_1 \in G_1 \cap (0,1)$ by Proposition 3.3.2. By openness, choose $s_1 > 0$ with $B_{s_1}(x_1) \subseteq G_1 \cap (0,1)$.
Set $\rho_1 := \min\{\frac{s_1}{2}, \frac{1}{4}\}$ and $I_1 := [x_1 - \rho_1, x_1 + \rho_1]$. Then $I_1 \subseteq G_1 \cap (0,1)$ and $I_1^\circ \neq \emptyset$.

(ii) *Recursion*: Suppose $I_n = [a_n, b_n] \subseteq G_n$ and $a_n < b_n$. Choose $x_{n+1} \in G_{n+1} \cap (a_n, b_n)$ by Proposition 3.3.2.
By openness, choose $s_{n+1} > 0$ with $B_{s_{n+1}}(x_{n+1}) \subseteq G_{n+1} \cap (a_n, b_n)$.
Put $\rho_{n+1} := \frac{s_{n+1}}{2}$ and $I_{n+1} := [x_{n+1} - \rho_{n+1}, x_{n+1} + \rho_{n+1}]$. Then $I_{n+1} \subseteq I_n \cap G_{n+1}$ and $I_{n+1}^\circ \neq \emptyset$.

(iii) *Intersection*: Choose $x \in \bigcap_{n=1}^{\infty} I_n$ by Theorem 4.2.1. Since $(\forall n \in \mathbb{N})\, I_n \subseteq G_n$, one has $x \in \bigcap_{n=1}^{\infty} G_n$.

Structural Commentary: Dense openness constructs nested intervals; real completeness supplies their common point.
Key Insight: Each interval can be trapped inside the next dense open set. □

Theorem 4.3.5. *Dense Open Intersections in Complete Metric Spaces*
Let (X,d) be complete, and let $(O_n)_{n\in\mathbb{N}}$ be dense open subsets of X.

(i) If $\emptyset \neq U \subseteq X$ is open, then $U \cap \bigcap_{n=1}^{\infty} O_n \neq \emptyset$.

(ii) The set $\bigcap_{n=1}^{\infty} O_n$ is dense in X.

Proof.

(i)

(a) *Initialization*: Fix a nonempty open set $U \subseteq X$. Choose $x_1 \in U \cap O_1$ by density of O_1.
By openness, choose $s_1 > 0$, $B_{s_1}(x_1) \subseteq U \cap O_1$. Set $r_1 := \min\{\frac{s_1}{2}, \frac{1}{4}\}$, $C_1 := \overline{B}_{r_1}(x_1)$; $C_1 \subseteq U \cap O_1$ and $0 < r_1 \leq \frac{1}{2}$.

(b) *Recursion*: Suppose $C_n = \overline{B}_{r_n}(x_n) \subseteq U \cap \bigcap_{j=1}^{n} O_j$, $0 < r_n \leq \frac{1}{2n}$. Since O_{n+1} is dense, choose $x_{n+1} \in B_{r_n}(x_n) \cap O_{n+1}$.
By openness, choose $s_{n+1} > 0$ with $B_{s_{n+1}}(x_{n+1}) \subseteq B_{r_n}(x_n) \cap O_{n+1}$.
Set $r_{n+1} := \min\{\frac{s_{n+1}}{2}, \frac{1}{2(n+1)}\}$ and $C_{n+1} := \overline{B}_{r_{n+1}}(x_{n+1})$. Then $C_{n+1} \subseteq C_n \cap O_{n+1}$ and $0 < r_{n+1} \leq \frac{1}{2(n+1)}$.

(c) *Diameter decay*: Each C_n is nonempty and closed by Corollary 3.1.18. For $p, q \in C_n$, $d(p,q) \leq 2r_n \leq \frac{1}{n}$, so $\operatorname{diam} C_n \leq \frac{1}{n}$.
Given $\varepsilon > 0$, choose $N \in \mathbb{N}$ with $N > \frac{1}{\varepsilon}$ by Theorem 1.1.19(i). Then $(\forall n \geq N)\, \operatorname{diam} C_n \leq \frac{1}{n} < \varepsilon$, so $\operatorname{diam} C_n \to 0$.

(d) *Intersection*: Choose $x \in X$ with $\bigcap_{n=1}^{\infty} C_n = \{x\}$ by Theorem 4.1.27, direction ($\Rightarrow$). As $C_n \subseteq U \cap O_n$, $x \in U \cap \bigcap_{n=1}^{\infty} O_n$.

(ii) Set $D := \bigcap_{n=1}^{\infty} O_n$. If $p \in X \setminus D$ and $r > 0$, then the nonempty open ball $B_r(p)$ meets D by (i).
Hence $B_r(p) \cap (D \setminus \{p\}) \neq \emptyset$, so $p \in D^{\mathrm{acc}}$. Thus $X = D \cup D^{\mathrm{acc}} = \overline{D}$, and D is dense by Proposition 3.3.1.

Structural Commentary: Dense openness builds contracting closed balls; Cantor intersection supplies the common point.
Key Insight: Completeness prevents a nested sequence of shrinking admissible balls from vanishing. □

Figure 135 illustrates the nested-ball construction in the complete-metric proof.

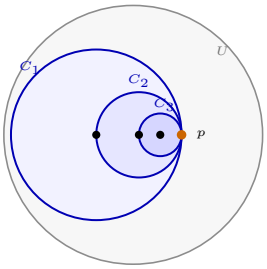

Figure 135: Nested closed balls $C_1 \supseteq C_2 \supseteq C_3$ lie in U; filled dots are their centers, and p is their common point.

Definition 4.3.6. *Residual, Thick, and Generic Sets*
Let (X,d) be a metric space.

(i) A set $G \subseteq X$ is *residual* in X iff it contains a countable intersection of dense open subsets of X. Term *thick* is synonymous.
(ii) A property P is *generic* in X iff $\{x \in X : P(x)\}$ is residual in X.

Thus meager sets are topologically small, whereas residual sets contain a countable dense-open core.

Corollary 4.3.7. *Residual Subsets of Complete Metric Spaces Are Dense*
Let (X,d) be complete, and let $G \subseteq X$ be residual. Then G is dense in X.

Proof. Choose dense open sets (O_n) in X with $\bigcap_{n=1}^{\infty} O_n \subseteq G$ by Definition 4.3.6(i).

Set $D := \bigcap_{n=1}^{\infty} O_n$. The set D is dense by Theorem 4.3.5(ii), so $\overline{D} = X$ by Proposition 3.3.1.

Since $D \subseteq G$, one has $X = \overline{D} \subseteq \overline{G} \subseteq X$; hence G is dense by Proposition 3.3.1.
Structural Commentary: Baire makes the dense-open core dense; closure monotonicity transfers density to its residual superset.
Key Insight: Every superset of a dense set is dense. □

Theorem 4.3.8. *Baire Category Theorem for Complete Metric Spaces*

Let (X, d) be a nonempty complete metric space, and let $(E_n)_{n\in\mathbb{N}}$ be nowhere-dense subsets of X. Then $X \neq \bigcup_{n=1}^{\infty} E_n$.

Proof. Suppose $X = \bigcup_{n=1}^{\infty} E_n$, $O_n := X \setminus \overline{E_n}$. Then (O_n) is sequence of open subsets of X by Theorem 3.1.22(i), Corollary 3.1.17.
Fix $n \in \mathbb{N}$, $p \in X \setminus O_n$, $r > 0$. Since $(\overline{E_n})^\circ = \emptyset$, ball $B_r(p)$ is not contained in $\overline{E_n}$. Hence $B_r(p) \cap O_n \neq \emptyset$, so $p \in O_n^{\mathrm{acc}}$.
Thus (O_n) is a sequence of dense open subsets of X by Definition 3.1.2.
Choose $x \in \bigcap_{n=1}^{\infty} O_n$ by Theorem 4.3.5(i) with $U = X$. Then $(\forall n \in \mathbb{N})\, x \notin E_n$, contradicting $X = \bigcup_{n=1}^{\infty} E_n$.
Structural Commentary: Nowhere-dense closures have dense open complements; their Baire intersection avoids the proposed cover.
Key Insight: One point can simultaneously escape every nowhere-dense layer. □

Theorem 4.3.9. *Baire's Theorem for $\mathbb{R}$*

If $(E_n)_{n\in\mathbb{N}}$ are nowhere-dense subsets of $\mathbb{R}$, then $\mathbb{R} \neq \bigcup_{n=1}^{\infty} E_n$.

Proof. Suppose $\mathbb{R} = \bigcup_{n=1}^{\infty} E_n$, $U_n := \mathbb{R} \setminus \overline{E_n}$. Then (U_n) is a sequence of open subsets of $\mathbb{R}$ by Theorem 3.1.22(i), Corollary 3.1.17.
Fix $n \in \mathbb{N}$ and a nonempty open interval I. The set I meets U_n because $I \not\subseteq \overline{E_n}$.
Hence (U_n) is a sequence of dense open subsets of $\mathbb{R}$ by Proposition 3.3.2.
Choose $x \in \bigcap_{n=1}^{\infty} U_n$ by Theorem 4.3.4. Then $(\forall n \in \mathbb{N})\, x \notin E_n$, contradicting $\mathbb{R} = \bigcup_{n=1}^{\infty} E_n$.
Structural Commentary: Real-line interval tests turn nowhere-dense complements into the dense-open intersection theorem.
Key Insight: Countably many thin sets leave a common point uncovered. □

Corollary 4.3.10. *Rationals and Irrationals by Category*

(i) The set $\mathbb{Q}$ is F_σ.
(ii) The set $\mathbb{R} \setminus \mathbb{Q}$ is G_δ.
(iii) The set $\mathbb{Q}$ is not G_δ.
(iv) The set $\mathbb{R} \setminus \mathbb{Q}$ is not F_σ.

Proof.

(i) Choose an enumeration $\mathbb{Q} = \{q_1, q_2, \ldots\}$ by Corollary 6.2.19.
For $n \in \mathbb{N}$, the singleton $\{q_n\}$ is closed by Corollary 3.1.15 and Definition 3.1.2. Hence $\mathbb{Q} = \bigcup_{n=1}^{\infty} \{q_n\}$ is F_σ.

(ii) Taking complements in (i), $\mathbb{R} \setminus \mathbb{Q} = \bigcap_{n=1}^{\infty} (\mathbb{R} \setminus \{q_n\})$ is G_δ.

(iii)

(a) *Dense layers*: Suppose $\mathbb{Q} = \bigcap_{n=1}^{\infty} G_n$, where (G_n) is a sequence of open subsets of $\mathbb{R}$. Fix $n \in \mathbb{N}$.
The set G_n is dense by $\mathbb{Q} \subseteq G_n$, Theorem 1.1.19(ii), and Proposition 3.3.2.

(b) *Punctured layers*: For $n \in \mathbb{N}$, set $H_n := G_n \setminus \{q_n\}$.
Each H_n is open by Corollary 3.1.17 and Theorem 3.1.19(iii). Fix $n \in \mathbb{N}$ and a nonempty open interval (a, b).
Choose $y \in (a, b) \cap G_n$ by density of G_n. By openness, choose $\varepsilon > 0$ with $(y - \varepsilon, y + \varepsilon) \subseteq (a, b) \cap G_n$.
At least one of $y - \frac{\varepsilon}{2}$ and $y + \frac{\varepsilon}{2}$ differs from q_n, so $(a, b) \cap H_n \neq \emptyset$. Thus H_n is dense by Proposition 3.3.2.

(c) *Baire contradiction*: Therefore (H_n) is a sequence of dense open subsets of $\mathbb{R}$.
Choose $x \in \bigcap_{n=1}^{\infty} H_n$ by Theorem 4.3.4. Since $(\forall n \in \mathbb{N})\, H_n \subseteq G_n$, one has $x \in \bigcap_{n=1}^{\infty} G_n = \mathbb{Q}$.
Choose $k \in \mathbb{N}$, $x = q_k$ by $\mathbb{Q} = \{q_1, q_2, \ldots\}$. Then $x \notin H_k$, whereas $x \in H_k$ by choice of x, contradiction.

(iv) If $\mathbb{R} \setminus \mathbb{Q}$ were F_σ, then its complement $\mathbb{Q}$ would be G_δ, contrary to (iii).

Structural Commentary: Singleton decompositions establish the positive classes; Baire excludes the reversed classifications.
Key Insight: Removing the enumerated rational from each dense open layer forces an impossible intersection. □

Corollary 4.3.11. *Closed Cover Interior Test*

Let X be a complete metric space and let $(F_n)_{n\in\mathbb{N}}$ be closed subsets of X.

(i) If $\emptyset \neq U \subseteq X$ is open and $U \subseteq \bigcup_{n=1}^{\infty} F_n$, then $(\exists N \in \mathbb{N})\, F_N^\circ \neq \emptyset$.

(ii) If $X \neq \emptyset$ and $(\forall n \in \mathbb{N})\, F_n^\circ = \emptyset$, then $X \neq \bigcup_{n=1}^{\infty} F_n$.

Proof.

(i) Suppose conclusion fails, and $O_n := X \setminus F_n$. Then (O_n) is sequence of open subsets of X by Corollary 3.1.17.
Fix $n \in \mathbb{N}$, $p \in F_n$, and $r > 0$. Then $B_r(p) \not\subseteq F_n$ because $F_n^\circ = \emptyset$. Thus $B_r(p) \cap O_n \neq \emptyset$, so $p \in O_n^{\mathrm{acc}}$.
Hence (O_n) is a sequence of dense open subsets of X by Definition 3.1.2.
Choose $x \in U \cap \bigcap_{n=1}^{\infty} O_n$ by Theorem 4.3.5(i). Then $x \in U \subseteq \bigcup_{n=1}^{\infty} F_n$ while $(\forall n \in \mathbb{N})\, x \notin F_n$, a contradiction.

(ii) If $X = \bigcup_{n=1}^{\infty} F_n$, then (i) with $U = X$ implies $(\exists N \in \mathbb{N})\, F_N^\circ \neq \emptyset$, contrary to the hypothesis.

Structural Commentary: Empty interiors create dense open complements; their Baire intersection contradicts the closed cover.
Key Insight: A complete space cannot be covered locally by closed sets with empty interior. □

Perspective 4.3.12. *Category in Function Spaces*
Theorems 4.3.5 and 4.3.8 depend on metric completeness rather than the order structure of $\mathbb{R}$.
They therefore transfer to later function spaces after completeness of the chosen function-space metric has been established.

Proof Method 4.3.13. *Baire-Category Proof Patterns*

(i) *Dense-open target*: to prove $\bigcap_{n=1}^{\infty} O_n$ dense, fix a nonempty open set U. Construct a witness in $U \cap \bigcap_{n=1}^{\infty} O_n$.
(ii) *Complete-metric construction*: choose nonempty closed balls $C_{n+1} \subseteq C_n \cap O_{n+1}$ with $\operatorname{diam} C_n \to 0$.
The common point exists by Theorem 4.1.27.
(iii) *Nowhere-dense input*: replace exceptional sets E_n by the dense open complements $X \setminus \overline{E_n}$.
(iv) *Meager exceptional set*: find nowhere-dense (E_n) with $E \subseteq \bigcup_{n=1}^{\infty} E_n$.
Then choose a point in the complementary dense-open intersection.
(v) *Residual property*: exhibit dense open sets (O_n) with $\bigcap_{n=1}^{\infty} O_n$ contained in the truth set.
(vi) *F_σ/G_δ duality*: complement a countable union of closed sets by De Morgan's laws.

4.4 Perfect Sets and the Cantor Set

Theorem 4.4.1. *Euclidean Perfect Sets Are Uncountable*
Let $k \in \mathbb{N}$, and let $\emptyset \neq P \subseteq \mathbb{R}^k$ be perfect. Then P is uncountable.

Proof.

(i) *Enumeration*: Suppose P is at most countable.
By Proposition 6.2.13, choose $(\mathbf{x}_n)$ satisfying $P = \{\mathbf{x}_n : n \in \mathbb{N}\}$. Set $\mathbf{c}_1 := \mathbf{x}_1$ and $r_1 := 1$.
(ii) *Recursive construction*: Suppose $\mathbf{c}_n \in P$ and $r_n > 0$ have been defined.
The point $\mathbf{c}_n$ belongs to P^{acc} by Definition 3.4.1(ii). The ball $B_{r_n}(\mathbf{c}_n)$ is a neighborhood of $\mathbf{c}_n$ by Theorem 3.1.3.
Hence $P \cap B_{r_n}(\mathbf{c}_n)$ is infinite by Theorem 3.1.14. Set $A_n := \{j \in \mathbb{N} : \mathbf{x}_j \in B_{r_n}(\mathbf{c}_n),\ \mathbf{x}_j \neq \mathbf{x}_n\} \neq \emptyset$.
The minimum $m_n := \min A_n$ exists by Assumption 2.6.1. Put $\mathbf{y}_n := \mathbf{x}_{m_n}$ and $\mathbf{c}_{n+1} := \mathbf{y}_n$.
Set $\delta_n := \min\{r_n - \|\mathbf{y}_n - \mathbf{c}_n\|_2, \|\mathbf{y}_n - \mathbf{x}_n\|_2\}$ and $r_{n+1} := \frac{\delta_n}{2}$.
The relations $\|\mathbf{y}_n - \mathbf{c}_n\|_2 < r_n$ and $\|\mathbf{y}_n - \mathbf{x}_n\|_2 > 0$ imply $\delta_n > 0$ and $r_{n+1} > 0$.
(iii) *Containment and avoidance*: Fix $\mathbf{u} \in \overline{B}_{r_{n+1}}(\mathbf{c}_{n+1})$.
Then $\|\mathbf{u} - \mathbf{c}_n\|_2 \leq r_{n+1} + \|\mathbf{y}_n - \mathbf{c}_n\|_2 \leq \frac{r_n + \|\mathbf{y}_n - \mathbf{c}_n\|_2}{2} < r_n$ by the triangle inequality.
Thus $\overline{B}_{r_{n+1}}(\mathbf{c}_{n+1}) \subseteq B_{r_n}(\mathbf{c}_n)$. Hence $\|\mathbf{x}_n - \mathbf{c}_{n+1}\|_2 = \|\mathbf{x}_n - \mathbf{y}_n\|_2 \geq \delta_n = 2r_{n+1} > r_{n+1}$, so $\mathbf{x}_n \notin \overline{B}_{r_{n+1}}(\mathbf{c}_{n+1})$.
(iv) *Compact intersection*: Put $K_n := \overline{B}_{r_n}(\mathbf{c}_n) \cap P$; then $\mathbf{c}_n \in K_n$.
The set P is closed by Definition 3.4.1(ii). The ball $\overline{B}_{r_n}(\mathbf{c}_n)$ is closed by Corollary 3.1.18.
Set K_n is closed by Theorem 3.1.19(ii) and bounded. Hence K_n is compact by Theorem 4.2.5, direction $(i) \Rightarrow (ii)$.
The inclusion $K_{n+1} \subseteq K_n$ holds by stage (iii). Choose $\mathbf{z} \in \bigcap_{n=1}^{\infty} K_n$ by Corollary 4.1.10.
Then $\mathbf{z} \in K_1 \subseteq P$ and $(\forall n \in \mathbb{N})\,[\mathbf{z} \in K_{n+1} \wedge \mathbf{x}_n \notin K_{n+1}]$, so $(\forall n \in \mathbb{N})\,\mathbf{z} \neq \mathbf{x}_n$.
This contradicts $P = \{\mathbf{x}_n : n \in \mathbb{N}\}$. Hence P is uncountable by Definition 6.2.4(iv)–(v).

Structural Commentary: The enumeration determines nested compact balls whose nth refinement excludes $\mathbf{x}_n$.
Key Insight: Perfectness selects centers; compactness preserves one point through every exclusion. □

Figure 136 depicts stage (iii) on the real line.

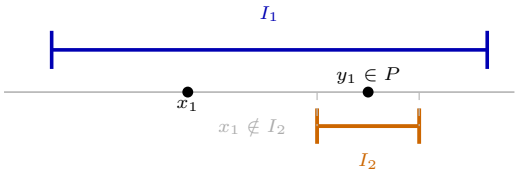

Figure 136: A closed interval $I_2 \subseteq I_1$ centered at $y_1 \in P$ avoids x_1.

Corollary 4.4.2. *Nondegenerate Intervals and the Real Line Are Uncountable*
Let $J \subseteq \mathbb{R}$ be an interval.

(i) If J contains two distinct points, then J is uncountable.
(ii) $\mathbb{R}$ is uncountable.

Proof.

(i) Choose $u < v$ in J, $I := [u, v] \subseteq J$ by Definition 3.1.8(ii). Set I is nonempty 1-cell, hence compact by Theorem 4.2.3.
It is closed by Theorem 4.1.6. Fix $x \in I$ and $\varepsilon > 0$. If $x < v$, put $y := x + \frac{1}{2}\min\{\varepsilon, v - x\}$.
If $x = v$, put $y := v - \frac{1}{2}\min\{\varepsilon, v - u\}$. In either case, $y \in I \cap (B_\varepsilon(x) \setminus \{x\})$. Thus I is perfect by Definition 3.4.1(ii).
The set I is uncountable by Theorem 4.4.1 with $k = 1$.
At-most-countability of J imply that of $I \subseteq J$ by Proposition 6.2.12(i), contradiction; J uncountable by Definition 6.2.4(iv)–(v).
(ii) Since $\mathbb{R}$ is an interval and contains the distinct points 0 and 1, it is uncountable by (i).

Structural Commentary: A closed subinterval transfers Euclidean perfect-set uncountability to its ambient interval.
Key Insight: Each endpoint is approached from within the closed interval. □

Definition 4.4.3. *Cantor Set*
Set $\mathcal{I}_0 := \{[0,1]\}$. For $n \in \mathbb{N}_0$, define $\mathcal{I}_{n+1} := \bigcup_{[a,b]\in\mathcal{I}_n} \left\{\left[a, \frac{2a+b}{3}\right], \left[\frac{a+2b}{3}, b\right]\right\}$. Put $E_n := \bigcup_{I\in\mathcal{I}_n} I$. The *Cantor set* is $P := \bigcap_{n=0}^{\infty} E_n$.

Figure 137 displays the first four stages in Definition 4.4.3.

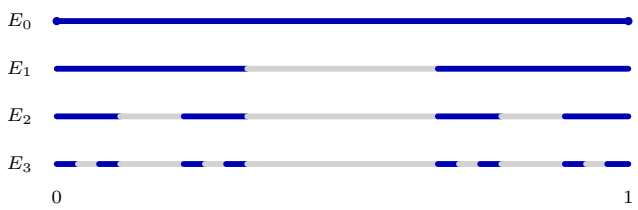

Figure 137: The retained intervals shrink from E_0 through E_3, while the middle-third gaps persist.

Proposition 4.4.4. *Basic Topological Properties of the Cantor Set*
Let $(\mathcal{I}_n)_{n\in\mathbb{N}_0}$, $(E_n)_{n\in\mathbb{N}_0}$, and P be as in Definition 4.4.3.
(i) $(\forall n \in \mathbb{N}_0)$, *the family $\mathcal{I}_n$ consists of 2^n pairwise disjoint compact intervals of length 3^{-n}.*
(ii) $(\forall n \in \mathbb{N}_0)\, E_{n+1} \subseteq E_n$.
(iii) The set P is nonempty and compact.
(iv) The set P contains no interval with two distinct points.
(v) The set P is perfect.

Proof.
(i) For $m \in \mathbb{N}$, let Q_m denote claim (i) at $n = m-1$. The statement Q_1 holds by $\mathcal{I}_0 = \{[0,1]\}$.
Under Q_m, each $[a,b] \in \mathcal{I}_{m-1}$ has two disjoint compact children in $\mathcal{I}_m$, each of length $\frac{b-a}{3} = 3^{-m}$.
Children of distinct parents are disjoint, so $\#\mathcal{I}_m = 2 \cdot 2^{m-1} = 2^m$ and $Q_m \Rightarrow Q_{m+1}$.
Therefore $(\forall m \in \mathbb{N})\, Q_m$ by Theorem 2.6.2, which establishes (i).
(ii) $(\forall n \in \mathbb{N}_0)\, E_{n+1} \subseteq E_n$ by Definition 4.4.3.
(iii) Fix $n \in \mathbb{N}_0$. The set E_n is nonempty by (i) and Definition 4.4.3. Each $I \in \mathcal{I}_n$ is closed by (i) and Theorem 4.1.6.
Hence E_n is closed by Theorem 3.1.19(iv). The inclusion $E_n \subseteq E_0 = [0,1]$ holds by (ii), so E_n is bounded.
Hence E_n is compact by Theorem 4.2.5, direction $(i) \Rightarrow (ii)$. Since $E_1 \subseteq E_0$, $P = \bigcap_{n=1}^{\infty} E_n \neq \emptyset$ by Corollary 4.1.10.
The set P is closed by Theorem 3.1.19(ii). Since $P \subseteq E_0$ and E_0 is compact, P is compact by Theorem 4.1.7.
(iv) Suppose $J \subseteq P$ is an interval containing $u < v$. Choose $n \in \mathbb{N}$ with $3^{-n} < v - u$ by Theorem 2.2.10(v) with $x = \frac{1}{3}$.
Choose $I_u, I_v \in \mathcal{I}_n$ with $u \in I_u$ and $v \in I_v$ by Definition 4.4.3. Intervals I_u and I_v are distinct by (i), $3^{-n} < v - u$.
Order $\mathcal{I}_n$ from left to right; then I_u precedes I_v by $u < v$. (i). Choose adjacent $[a,b], [c,d]$ in block from I_u to I_v with $b < c$.
Then $w := \frac{b+c}{2} \in (u,v) \setminus E_n$. But $w \in J \subseteq P \subseteq E_n$ by Definition 3.1.8(ii), a contradiction.
(v) Fix $x \in P$ and $\varepsilon > 0$. Choose $n \in \mathbb{N}$ with $3^{-n} < \varepsilon$ by Theorem 2.2.10(v) with $x = \frac{1}{3}$.
The point x lies in a unique $I_n(x) \in \mathcal{I}_n$ by (i) and Definition 4.4.3. Choose an endpoint $y \neq x$ of $I_n(x)$.
One has $(\forall m \in \mathbb{N}_0)\, [m \leq n \Rightarrow y \in E_m]$ by (ii). Each parent endpoint remains in one child by Definition 4.4.3.
Hence $(\forall m \in \mathbb{N}_0)\, [m \geq n \Rightarrow y \in E_m]$ by Theorem 2.6.2 with index shift $j = m - n + 1$.
Thus $y \in P$ and $0 < |x - y| \leq 3^{-n} < \varepsilon$ by (i). Hence $x \in P^{\mathrm{acc}}$ by Definition 3.1.2(v).
The set P is closed by (iii) and Theorem 4.1.6. Hence P is perfect by Definition 3.4.1(ii).
Structural Commentary: Induction establishes stage geometry; nested compactness and endpoint persistence control the limit.
Key Insight: Each stage shrinks components while preserving endpoints and opening gaps. □

4.5 Complete Metric Spaces and Completions

Completeness asks whether Cauchy approximations converge inside the ambient space.
This subsection records standard complete spaces, the contraction principle, and completion by Cauchy sequences.

Example 4.5.1. *Finite-Dimensional Complete Metric Spaces*
Let $k \in \mathbb{N}$. For $\mathbf{z}, \mathbf{w} \in \mathbb{C}^k$, set $d_2(\mathbf{z}, \mathbf{w}) := \left(\sum_{j=1}^{k} |z_j - w_j|^2\right)^{1/2}$. Then $(\mathbb{R}^k, d_2)$, $(\mathbb{C}^k, d_2)$ are complete; case $k = 1$ includes $\mathbb{R}$ and $\mathbb{C}$.

Proof. Space $\mathbb{R}^k$ is complete by Corollary 4.2.8. Write $z_j = x_j + iy_j$, $w_j = u_j + iv_j$, define $F : \mathbb{C}^k \to \mathbb{R}^{2k}$ by $F\mathbf{z} := (x_1, y_1, \ldots, x_k, y_k)$.
$d_2(F\mathbf{z}, F\mathbf{w})^2 = \sum_{j=1}^{k} [(x_j - u_j)^2 + (y_j - v_j)^2] = d_2(\mathbf{z}, \mathbf{w})^2$ by Definition 1.2.8.
The coordinate map F is bijective, and the distance identity makes it an isometry by Definition 3.1.11(i).
If $(\mathbf{z}_n)$ is Cauchy in $\mathbb{C}^k$, then $(F\mathbf{z}_n)$ is Cauchy in $\mathbb{R}^{2k}$ and converges to some $\mathbf{u} \in \mathbb{R}^{2k}$.
The identity $d_2(\mathbf{z}_n, F^{-1}\mathbf{u}) = d_2(F\mathbf{z}_n, \mathbf{u}) \to 0$ implies $\mathbf{z}_n \to F^{-1}\mathbf{u}$. Hence $\mathbb{C}^k$ is complete by Definition 4.1.23.
Structural Commentary: The coordinate isometry transfers real finite-dimensional completeness to complex coordinates.
Key Insight: Separating real and imaginary parts preserves the Euclidean distance. □

Definition 4.5.2. *Contraction*
Let (X, d) be a metric space. A map $\varphi : X \to X$ is a *contraction* iff $(\exists c \in [0,1))(\forall x, y \in X)\, d(\varphi(x), \varphi(y)) \leq c\, d(x, y)$.

Theorem 4.5.3. *Contraction Principle*
If X is a nonempty complete metric space and $\varphi : X \to X$ is a contraction, then $(\exists!\, x \in X)\, \varphi(x) = x$.

Proof.

(i) *Iteration estimate*: Choose $x_0 \in X$ and a contraction constant $c \in [0,1)$ by Definition 4.5.2.
Set $x_{n+1} := \varphi(x_n)$. The identity $d(x_1,x_0) = c^0 d(x_1,x_0)$ is the induction basis.
If $d(x_{n+1},x_n) \le c^n d(x_1,x_0)$, then $d(x_{n+2},x_{n+1}) \le c\, d(x_{n+1},x_n) \le c^{n+1} d(x_1,x_0)$ by the contraction inequality.
Hence $(\forall n \in \mathbb{N}_0)\, d(x_{n+1},x_n) \le c^n d(x_1,x_0)$ by Theorem 2.6.2 with index $n+1$.

(ii) *Cauchy control*: If $0 \le n < m$, then $d(x_n,x_m) \le \sum_{j=n}^{m-1} d(x_j,x_{j+1})$ by the triangle inequality.
By (i), $\sum_{j=n}^{m-1} d(x_j,x_{j+1}) \le d(x_1,x_0) \sum_{j=n}^{m-1} c^j$. The bound $d(x_n,x_m) \le \frac{c^n}{1-c} d(x_1,x_0)$ follows by $(1-c)\sum_{j=n}^{m-1} c^j = c^n - c^m \le c^n$.
The right side tends to 0 by Theorem 2.2.10(v) and Theorem 2.1.5(ii). Hence (x_n) is Cauchy by Definition 4.1.14.

(iii) *Fixed-point existence*: By Definition 4.1.23, choose $x \in X$ with $x_n \to x$. Bound $d(\varphi(x_n),\varphi(x)) \le c\, d(x_n,x)$ implies $\varphi(x_n) \to \varphi(x)$.
The shifted sequence satisfies $x_{n+1} \to x$ by Corollary 3.4.7. Since $\varphi(x_n) = x_{n+1}$, $\varphi(x) = x$ by Theorem 3.4.6(ii).

(iv) *Uniqueness*: If $\varphi(x) = x$ and $\varphi(y) = y$, then $d(x,y) \le c\, d(x,y)$, hence $d(x,y) = 0$ and $x = y$.

Structural Commentary: Iteration turns the contraction estimate into a geometric Cauchy estimate.
Key Insight: Completeness supplies the limiting point; the strict constant $c < 1$ forces uniqueness. □

Figure 138 combines contraction of distances with convergence of the orbit.

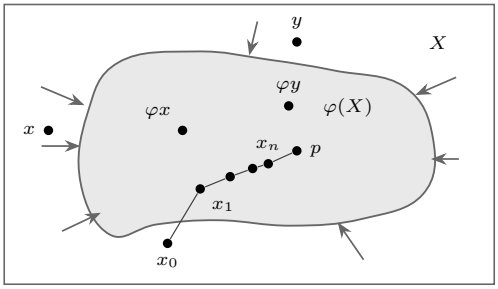

Figure 138: The iterates approach the fixed point p while φ contracts pairwise distances.

Perspective 4.5.4. *Fixed Points as Existence Proofs*
Theorem 4.5.3 solves $x = \varphi(x)$ by convergence of iterates in a complete space.
This viewpoint later motivates local inverse-function arguments but does not replace their hypotheses or proof.

Example 4.5.5. *A Noncomplete Metric Space*
The metric space $(\mathbb{Q},d)$ with $d(x,y) := |x-y|$ is not complete.

Proof. Let (r_n) be decimal truncations $1.4, 1.41, 1.414, 1.4142, \dots$ of $\sqrt{2}$. Then $(\forall n \in \mathbb{N})\, r_n \in \mathbb{Q}$, $r_n \to \sqrt{2}$ by Proposition 2.2.11(ii).
The sequence (r_n) is Cauchy in $\mathbb{R}$ by Theorem 4.1.20(i), hence also in $\mathbb{Q}$ with the inherited metric.
If $(\mathbb{Q},d)$ were complete, choose $r \in \mathbb{Q}$ with $r_n \to r$ by Definition 4.1.23. The same convergence holds in $\mathbb{R}$.
Thus $r = \sqrt{2}$ by Proposition 2.1.4(i), contrary to Proposition 1.1.13(i).
Structural Commentary: The decimal approximants are Cauchy before their missing limit is available inside $\mathbb{Q}$.
Key Insight: The inherited metric preserves Cauchy control but not the irrational limit. □

Perspective 4.5.6. *Cauchy Construction as a Parallel Model*
Example 4.5.5 exhibits a rational Cauchy sequence with a missing endpoint.
For the set $\mathcal{C}_{\mathbb{Q}}$ of rational Cauchy sequences, define $(a_n) \sim (b_n) \iff |a_n - b_n| \to 0$.
The quotient $\mathcal{C}_{\mathbb{Q}}/\!\sim$ motivates the construction below; only the proved completion theorem supplies later authority.

Figure 139 depicts the quotient relation and the embedded constant sequences.

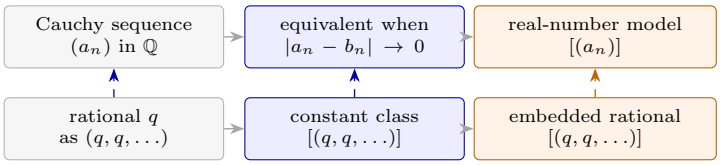

Figure 139: Equivalent rational Cauchy sequences determine one formal limit, while constant sequences embed $\mathbb{Q}$.

Definition 4.5.7. *Metric Completion*
A *completion* of a metric space (X,d) is a triple (Y,d_Y,τ) satisfying:

(i) (Y,d_Y) is complete;
(ii) $\tau : X \to Y$ is an isometry;
(iii) $\overline{\tau(X)}^{\,Y} = Y$.

Theorem 4.5.8. *Existence and Uniqueness of Metric Completions*
Let (X,d) be a metric space.

(i) The space (X,d) has a completion.
(ii) Let (Y,d_Y,τ) and (Z,d_Z,σ) be completions of (X,d). Then $(\exists!\, \Phi : Y \to Z)$ such that Φ is a bijective isometry and $\Phi \circ \tau = \sigma$.

Proof.

(i) *Existence*:

(a) *Pseudometric*: Let $\mathrm{CS}(X)$ be the set of Cauchy sequences in X.
For $a=(a_n), b=(b_n)\in \mathrm{CS}(X)$, set $D(a,b):=\lim_{n\to\infty} d(a_n,b_n)$. This limit exists by Proposition 4.1.22(ii).
The map D has zero diagonal, is nonnegative, and is symmetric by the corresponding properties of d.
Fix $a,b,c\in\mathrm{CS}(X)$. Then $(\forall n\in\mathbb{N})\, d(a_n,c_n)\le d(a_n,b_n)+d(b_n,c_n)$ by triangle inequality.
Hence $D(a,c)\le D(a,b)+D(b,c)$ by Proposition 2.1.4(iii) and Theorem 2.1.5(i). Thus D is a pseudometric.

(b) *Quotient and embedding*: Define $a\sim b \iff D(a,b)=0$ and set $\widehat{X}:=\mathrm{CS}(X)/\!\sim$. Put $\widehat{d}([a],[b]):=D(a,b)$.
Then $\sim$ is an equivalence relation and $\widehat{d}$ is a well-defined metric by Proposition 3.1.12.
For $x\in X$, let $\iota(x)$ be the class of the constant sequence with value x.
The identity $\widehat{d}(\iota(x),\iota(y))=d(x,y)$ makes $\iota: X\to\widehat{X}$ an isometry by Definition 3.1.11(i).

(c) *Density*: Fix $[a]\in\widehat{X}$ and $\varepsilon>0$. Choose $N_0\in\mathbb{N}$ with $(\forall m,n\ge N_0)\, d(a_m,a_n)<\frac{\varepsilon}{2}$.
For $N\ge N_0$, $\widehat{d}(\iota(a_N),[a])\le\frac{\varepsilon}{2}<\varepsilon$ by Proposition 2.1.4(iii). Hence $\iota(a_N)\to[a]$, and $\overline{\iota(X)}^{\widehat{X}}=\widehat{X}$ by Proposition 3.4.16.

(d) *Completeness*: Let (ξ_k) be Cauchy in $\widehat{X}$. By (c), choose $x_k\in X$ with $\widehat{d}(\iota(x_k),\xi_k)<\frac{1}{k}$.
The bound $d(x_k,x_l)\le\frac{1}{k}+\widehat{d}(\xi_k,\xi_l)+\frac{1}{l}$ follows by the triangle inequality.
Hence (x_k) is Cauchy by Definition 4.1.14 and Theorem 2.2.10(i).
Set $a:=(x_k)\in\mathrm{CS}(X)$. Then $\widehat{d}(\xi_k,[a])<\frac{1}{k}+\lim_{j\to\infty} d(x_k,x_j)$ by the triangle inequality.
Given $\varepsilon>0$, choose $K\in\mathbb{N}$ with $\frac{1}{K}<\frac{\varepsilon}{2}$ and $(\forall k,j\ge K)\, d(x_k,x_j)<\frac{\varepsilon}{2}$.
For $k\ge K$, the final limit is at most $\frac{\varepsilon}{2}$ by Proposition 2.1.4(iii). Hence $\widehat{d}(\xi_k,[a])<\varepsilon$.
Thus $\xi_k\to[a]$, and $(\widehat{X},\widehat{d},\iota)$ is a completion of (X,d) by Definitions 4.1.23 and 4.5.7.

(ii) *Uniqueness*:

(a) *Dense-copy isometry*: Let (Y,d_Y,τ) and (Z,d_Z,σ) be completions of (X,d).
If $\tau x=\tau x'$, then $d(x,x')=d_Y(\tau x,\tau x')=0$, so $x=x'$; similarly, σ is injective.
Define $\rho_0:\tau(X)\to\sigma(X)$ by $\rho_0(\tau x):=\sigma x$. Iinjectivity of τ makes ρ_0 well defined, injectivity of σ makes ρ_0 injective.
The identity $\rho_0(\tau x)=\sigma x$ implies $\rho_0(\tau(X))=\sigma(X)$, so ρ_0 is surjective.
For $x,x'\in X$, $d_Z(\rho_0(\tau x),\rho_0(\tau x'))=d(x,x')=d_Y(\tau x,\tau x')$. Hence ρ_0 is a bijective isometry by Definition 3.1.11(i).

(b) *Extension*: Fix $y\in Y$. Choose $(y_n)\subseteq\tau(X)$ with $y_n\to y$ by Proposition 3.4.16.
The sequence $(\rho_0(y_n))$ is Cauchy in Z by the isometry property, so it converges by completeness of Z.
Define $\Phi(y):=\lim_{n\to\infty}\rho_0(y_n)$. Suppose $(z_n)\subseteq\tau(X)$ also satisfies $z_n\to y$.
The sequence $(\rho_0(z_n))$ is Cauchy by the isometry property and converges by completeness of Z.
Set $p:=\lim_{n\to\infty}\rho_0(y_n)$ and $q:=\lim_{n\to\infty}\rho_0(z_n)$. Then $d_Z(\rho_0(y_n),\rho_0(z_n))=d_Y(y_n,z_n)\le d_Y(y_n,y)+d_Y(y,z_n)\to 0$.
By triangle inequality, $d_Z(p,q)\le d_Z(p,\rho_0(y_n))+d_Z(\rho_0(y_n),\rho_0(z_n))+d_Z(\rho_0(z_n),q)\to 0$. Thus $p=q$, so Φ is well defined.

(c) *Distance preservation*: For $y,y'\in Y$, choose $(y_n),(y_n')\subseteq\tau(X)$ converging to y,y', respectively.
Set $u_n:=\rho_0(y_n)$, $v_n:=\rho_0(y_n')$. Inequality $|d_Y(y_n,y_n')-d_Y(y,y')|\le d_Y(y_n,y)+d_Y(y_n',y')$ implies $d_Y(y_n,y_n')\to d_Y(y,y')$.
$|d_Z(u_n,v_n)-d_Z(\Phi(y),\Phi(y'))|\le d_Z(u_n,\Phi(y))+d_Z(v_n,\Phi(y'))$ by triangle inequality. Hence $d_Z(u_n,v_n)\to d_Z(\Phi(y),\Phi(y'))$.
$(\forall n\in\mathbb{N})\, d_Z(u_n,v_n)=d_Y(y_n,y_n')$. Hence $d_Z(\Phi(y),\Phi(y'))=d_Y(y,y')$ by Proposition 2.1.4(i).
Thus Φ is an isometry by Definition 3.1.11(i).
For $x\in X$, the constant sequence $y_n=\tau x$ in the extension satisfies $\Phi(\tau x)=\sigma x$. Hence $\Phi\circ\tau=\sigma$.

(d) *Surjectivity*: If $(\Phi(y_n))$ is Cauchy in $\Phi(Y)$, then (y_n) is Cauchy in Y and converges to some $y\in Y$.
The identity $d_Z(\Phi(y_n),\Phi(y))=d_Y(y_n,y)\to 0$ implies $\Phi(y_n)\to\Phi(y)$, so $\Phi(Y)$ is complete.
Hence $\Phi(Y)$ is closed in Z by Proposition 4.1.26(i).
The inclusions $\sigma(X)\subseteq\Phi(Y)$ and $Z=\overline{\sigma(X)}^{Z}$ imply $Z\subseteq\Phi(Y)$ by Theorem 3.1.22(iii).
Thus Φ is surjective; since every isometry is injective, it is bijective.

(e) *Uniqueness*: Let $\Psi: Y\to Z$ be another isometry satisfying $\Psi\circ\tau=\sigma$, and fix $y\in Y$.
Choose $(y_n)\subseteq\tau(X)$ with $y_n\to y$ by Proposition 3.4.16.
Then $\Phi(y_n)=\Psi(y_n)$ and $d_Z(\Phi(y),\Psi(y))\le d_Y(y,y_n)+d_Y(y_n,y)\to 0$, so $\Phi(y)=\Psi(y)$. Hence $\Phi=\Psi$.

Structural Commentary: The quotient installs formal limits; density extends the copy of X uniquely between completions.
Key Insight: Cauchy classes provide existence; dense agreement forces uniqueness. □

Figure 140 summarizes the unique extension between two completions.

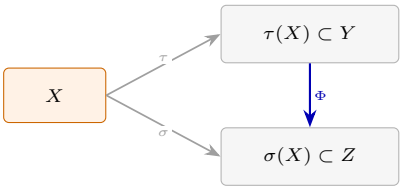

Figure 140: The dense-copy isometry $\sigma\tau^{-1}$ extends uniquely to $\Phi: Y\cong Z$; adapted from Roman (2008, Ch. 12, Fig. 12.4).

5 Connectedness and Continuity

5.1 Connectedness and Continuity

Connectedness forbids separated decompositions; continuity transfers local and global topological structure.
This subsection develops metric limits, compact-image results, the intermediate value theorem, and paths.

Definition 5.1.1. *Separated and Connected Sets*
Let X be a metric space.

(i) Subsets $A,B\subseteq X$ are *separated* iff $A\cap\overline{B}=\overline{A}\cap B=\emptyset$.

(ii) A subset $E \subseteq X$ is *connected* iff no nonempty separated $A, B \subseteq E$ satisfy $E = A \cup B$.
(iii) A subset $U \subseteq X$ is *clopen* iff it is both open and closed.

Theorem 5.1.2. *Connected Subsets of the Real Line*
A set $E \subseteq \mathbb{R}$ is connected iff $(\forall x, y \in E)\,[x < y \Longrightarrow [x, y] \subseteq E]$.

Proof.
($\Rightarrow$) If the interval property fails, choose $x, y \in E$ and $x < z < y$ with $z \notin E$. Set $A := E \cap (-\infty, z)$ and $B := E \cap (z, \infty)$.
Then $A, B \neq \emptyset$ and $E = A \cup B$. The inclusions $\overline{A} \subseteq (-\infty, z]$ and $\overline{B} \subseteq [z, \infty)$ imply $A \cap \overline{B} = \overline{A} \cap B = \emptyset$.
Thus A, B separate E, contrary to connectedness.
($\Leftarrow$) Assume the interval property and suppose $E = A \cup B$ for nonempty separated A, B.
Choose $x \in A$ and $y \in B$; interchange A, B if necessary so that $x < y$. Set $S := A \cap [x, y]$ and $z := \sup S$.
Then $z \in \overline{A}$ by Theorem 3.3.5(i). Hence $z \notin B$ by separatedness, and $z < y$ because $y \in B$.
If $z \notin A$, then $z \in [x, y] \setminus E$, contrary to the interval property. If $z \in A$, then $z \notin \overline{B}$; choose $r > 0$ with $B_r(z) \cap B = \emptyset$.
Set $z_1 := z + \frac{1}{2}\min\{r, y - z\}$. Then $z < z_1 < y$, $z_1 \notin B$, and $z_1 \notin A$ by $z = \sup S$.
Thus $z_1 \in [x, y] \setminus E$, again contrary to the interval property.

Structural Commentary: A gap induces a separation; a separation produces a gap at the supremum of one side.
Key Insight: The supremum locates the missing boundary point between separated pieces. □

Method 5.1.3. *Compactness and Connectedness Proof Patterns*
(i) *Open-cover compactness*: to prove K compact, start with open cover $\{G_\alpha\}_{\alpha \in A}$. Find finite $F \subseteq A$ with $K \subseteq \bigcup_{\alpha \in F} G_\alpha$.
(ii) *Euclidean closed-bounded compactness*: to prove a closed bounded set $E \subseteq \mathbb{R}^k$ compact, choose a compact k-cell $I \supseteq E$. Then E is compact by Theorem 4.1.7.
(iii) *Connectedness on $\mathbb{R}$*: replace connectedness of $E \subseteq \mathbb{R}$ by $(\forall x, y \in E)\,[x < y \Longrightarrow [x, y] \subseteq E]$.

Definition 5.1.4. *Limit of a Function Between Metric Spaces*
Let $(X, d_X), (Y, d_Y)$ be metric spaces, let $E \subseteq X$, let $f : E \to Y$, and let p be a limit point of E.
For $q \in Y$, $\lim_{x \to p} f(x) = q$ iff $(\forall \varepsilon > 0)(\exists \delta > 0)(\forall x \in E)\,[0 < d_X(x, p) < \delta \Longrightarrow d_Y(f(x), q) < \varepsilon]$.
The point p need not belong to E, and $f(p)$ is irrelevant when it does.
Key Insight: A punctured interval determines whether approach is two-sided, right-sided, or left-sided.

Figure 141 illustrates the punctured-neighborhood test in the definition.

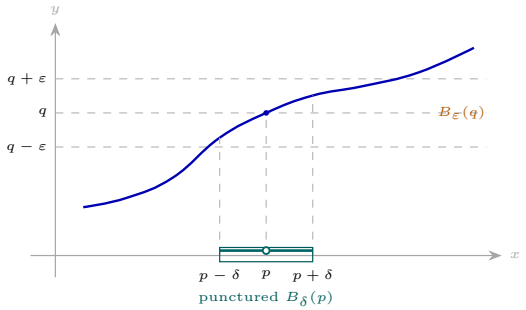

Figure 141: The epsilon–delta geometry for $\lim_{x \to p} f(x) = q$.

Theorem 5.1.5. *Sequential Characterization of Function Limits*
Let $(X, d_X), (Y, d_Y)$ be metric spaces, let $E \subseteq X$, let $f : E \to Y$, and let p be a limit point of E.
For $q \in Y$, $\lim_{x \to p} f(x) = q$ iff $f(p_n) \to q$ whenever $(p_n) \subseteq E \setminus \{p\}$ and $p_n \to p$.

Proof.
($\Rightarrow$) Let $(p_n) \subseteq E \setminus \{p\}$ satisfy $p_n \to p$, and fix $\varepsilon > 0$.
Choose $\delta > 0$ with $(\forall x \in E)\,[0 < d_X(x, p) < \delta \Longrightarrow d_Y(f(x), q) < \varepsilon]$ by Definition 5.1.4.
Eventually $0 < d_X(p_n, p) < \delta$, hence eventually $d_Y(f(p_n), q) < \varepsilon$. Thus $f(p_n) \to q$.
($\Leftarrow$) If the limit fails, choose $\varepsilon > 0$ with $(\forall \delta > 0)(\exists x \in E)\,[0 < d_X(x, p) < \delta \wedge d_Y(f(x), q) \geq \varepsilon]$.
Then p is a limit point of $A_\varepsilon := \{x \in E \setminus \{p\} : d_Y(f(x), q) \geq \varepsilon\}$.
Choose $(x_n) \subseteq A_\varepsilon$ with $x_n \to p$ by Theorem 3.4.6(iii). Since $(\forall n \in \mathbb{N})\, d_Y(f(x_n), q) \geq \varepsilon$, $f(x_n) \not\to q$.

Structural Commentary: The forward direction transfers a δ-bound; the reverse direction selects from the bad set.
Key Insight: Failure of one ε creates a sequence that defeats convergence. □

Corollary 5.1.6. *Uniqueness of Function Limits*
Let X, Y be metric spaces, $E \subseteq X$, $f : E \to Y$, p be a limit point of E. If f has a limit at p, then that limit is unique.

Proof. Let q and r be limits of f at p. Choose $(p_n) \subseteq E \setminus \{p\}$ with $p_n \to p$ by Theorem 3.4.6(iii).
Then $f(p_n) \to q$ and $f(p_n) \to r$ by Theorem 5.1.5. Hence $q = r$ by Theorem 3.4.6(ii).
Structural Commentary: Limit uniqueness is inherited from metric sequence uniqueness.
Key Insight: One approaching sequence cannot have two different limits. □

Theorem 5.1.7. *Algebra of Function Limits*
Let X be a metric space, $E \subseteq X$, p be a limit point of E. For $f, g : E \to \mathbb{C}$, assume $\lim_{x \to p} f(x) = A$ and $\lim_{x \to p} g(x) = B$. Then:

(i) $\lim_{x \to p} (f + g)(x) = A + B$;

(ii) $\lim_{x\to p}(fg)(x) = AB$;

(iii) *if* $B \neq 0$, *then* $\lim_{x\to p;\, g(x)\neq 0} \frac{f(x)}{g(x)} = \frac{A}{B}$;

(iv) *Let* $u, v : E \to \mathbb{R}^k$, $\lambda \in \mathbb{R}$. *Assume* $\lim_{x\to p} u(x) = a$, $\lim_{x\to p} v(x) = b$. *Then* $u + v \to a + b$, $\lambda u \to \lambda a$, *and* $u \cdot v \to a \cdot b$ *as* $x \to p$.

Proof. Let $(p_n) \subseteq E \setminus \{p\}$ satisfy $p_n \to p$. Then $f(p_n) \to A$ and $g(p_n) \to B$ by Theorem 5.1.5.

(i) $(f+g)(p_n) \to A + B$ by Theorem 2.1.5(i). Hence (i) by Theorem 5.1.5.

(ii) $(fg)(p_n) \to AB$ by Theorem 2.1.5(iii). Hence (ii) by Theorem 5.1.5.

(iii) Set $U := \{x \in E : g(x) \neq 0\}$. Choose $r > 0$ with $(\forall x \in E)\,[0 < d_X(x,p) < r \Longrightarrow |g(x) - B| < \frac{|B|}{2}]$ by $\lim_{x\to p} g(x) = B$.
Then $E \cap B_r(p) \setminus \{p\} \subseteq U$ by the reverse triangle inequality, so p is a limit point of U.
If $(q_n) \subseteq U \setminus \{p\}$ and $q_n \to p$, then $f(q_n) \to A$ and $g(q_n) \to B$ by Theorem 5.1.5.
Thus $\frac{f(q_n)}{g(q_n)} \to \frac{A}{B}$ by Theorem 2.1.5(iii),(iv). Hence (iii) by Theorem 5.1.5.

(iv) Under the hypotheses of (iv), $u(p_n) \to a$ and $v(p_n) \to b$ by Theorem 5.1.5.
Three vector limits hold by Theorem 3.4.13(ii)–(iv), with constant scalar sequence (λ). Hence (iv) by Theorem 5.1.5.

Structural Commentary: Sequential characterization transfers scalar and vector sequence algebra to function limits.
Key Insight: Every approaching sequence inherits the corresponding algebraic limit. □

Proposition 5.1.8. *Function Limits Are Local*
Let X, Y *be metric spaces,* $E \subseteq X$, $f : E \to Y$, p *be limit point of* E, $q \in Y$. $(\forall r > 0)\,[\lim_{x\to p;\, x\in E} f(x) = q \Longleftrightarrow \lim_{x\to p;\, x\in E\cap B_r(p)} f(x) = q]$.

Proof.

(⇒) Any δ witnessing the limit on E witnesses the limit on $E \cap B_r(p)$ by $E \cap B_r(p) \subseteq E$.

(⇐) Assume the restricted limit and fix $\varepsilon > 0$. Choose $\delta_0 > 0$ by the restricted limit.
Then $(\forall x \in E \cap B_r(p))\,[0 < d_X(x,p) < \delta_0 \Longrightarrow d_Y(f(x), q) < \varepsilon]$. Let $\delta := \min\{\delta_0, r\}$.
If $x \in E$ and $0 < d_X(x,p) < \delta$, then $x \in E \cap B_r(p)$, so $d_Y(f(x), q) < \varepsilon$.

Structural Commentary: Values away from p cannot affect the limit at p.
Key Insight: Shrink δ until every tested point lies in the chosen local neighborhood. □

Definition 5.1.9. *Continuity at a Point and on a Set*
Let $(X, d_X), (Y, d_Y)$ be metric spaces, $E \subseteq X$, and $f : E \to Y$.

(i) For $p \in E$, f is *continuous at* p iff $(\forall \varepsilon > 0)(\exists \delta > 0)(\forall x \in E)\,[d_X(x,p) < \delta \Longrightarrow d_Y(f(x), f(p)) < \varepsilon]$.

(ii) The map f is *continuous on* E iff $(\forall p \in E)$, f is continuous at p.

Corollary 5.1.10. *Every Map Is Continuous at an Isolated Point*
Let $(X, d_X), (Y, d_Y)$ *be metric spaces,* $E \subseteq X$, $f : E \to Y$, p *be isolated in* E. *Then* f *is continuous at* p.

Proof. Given $\varepsilon > 0$, choose $\delta > 0$ with $E \cap B_\delta(p) = \{p\}$. If $x \in E$ and $d_X(x,p) < \delta$, then $x = p$, so $d_Y(f(x), f(p)) = 0 < \varepsilon$.
Structural Commentary: Isolation reduces every sufficiently small domain neighborhood to the singleton $\{p\}$.
Key Insight: No distinct domain point can approach an isolated point. □

Corollary 5.1.11. *Discrete Domains Make Every Map Continuous*
Let X, Y *be metric spaces, and assume that* X *carries the discrete metric. Then every map* $f : X \to Y$ *is continuous.*

Proof. Fix $p \in X$. Then $B_{1/2}(p) = \{p\}$, p isolated; f continuous at p by Corollary 5.1.10; f continuous on X by Definition 5.1.9(ii).
Structural Commentary: In the discrete metric, no distinct point can approach p.
Key Insight: Pointwise continuity is automatic when small enough balls are singletons. □

For the case $E = X$, Figure 142 expresses continuity through nested input and output balls.

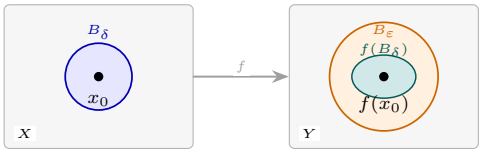

Figure 142: Nested balls encode continuity at x_0 for $E = X$; adapted from Roman (2008, Ch. 12, Fig. 12.2).

Theorem 5.1.12. *Continuity as Equality with the Function Limit*
Let X, Y *be metric spaces,* $E \subseteq X$, $p \in E$, *and* $f : E \to Y$. *If* p *is a limit point of* E, *then* f *is continuous at* p *iff* $\lim_{x\to p} f(x) = f(p)$.

Proof.

(⇒) Fix $\varepsilon > 0$, $\delta > 0$ by continuity at p. If $x \in E$, $0 < d_X(x,p) < \delta$, then $d_Y(f(x), f(p)) < \varepsilon$. Thus $\lim_{x\to p} f(x) = f(p)$.

(⇐) Fix $\varepsilon > 0$, $\delta > 0$ by $\lim_{x\to p} f(x) = f(p)$. If $x \in E \setminus \{p\}$, $d_X(x,p) < \delta$, then $d_Y(f(x), f(p)) < \varepsilon$; if $x = p$, distance is 0.

Structural Commentary: Continuity is the compatibility of the value at p with nearby values.
Key Insight: Limits ignore the point; continuity ties the point back in. □

Remark 5.1.13. *Adherent-Point Limit Convention*
The adherent-point convention takes $p \in \overline{E}$ and allows $x = p$ in the δ-test.
Definition 5.1.4 instead assumes p is a limit point and requires $0 < d_X(x,p)$.
If $p \in E$, the unpunctured convention tests $f(p)$ and forces $q = f(p)$.
For punctured limits, this condition is continuity at p by Theorem 5.1.12.
Key Insight: Punctured limits study nearby values; continuity adds compatibility with the value at the point.

Remark 5.1.14. *The Sequence-First View*
At limit points of a real domain, continuity is equivalent to $x_n \to p \Longrightarrow f(x_n) \to f(p)$.
This equivalence holds by Theorems 5.1.5 and 5.1.12. Continuity at isolated points holds by Corollary 5.1.10.

Theorem 5.1.15. *Sequential Characterization of Continuity*
Let $(X, d_X), (Y, d_Y)$ be metric spaces, $f : X \to Y$, and $p \in X$. Then f is continuous at p iff $(x_n) \subseteq X$ and $x_n \to p$ imply $f(x_n) \to f(p)$.

Proof.
($\Rightarrow$) Assume f is continuous at p and let $x_n \to p$.
Given $\varepsilon > 0$, choose $\delta > 0$ such that $(\forall\, x \in X)\,[d_X(x,p) < \delta \Longrightarrow d_Y(f(x), f(p)) < \varepsilon]$.
Since $x_n \to p$, eventually $d_X(x_n, p) < \delta$, hence eventually $d_Y(f(x_n), f(p)) < \varepsilon$. Thus $f(x_n) \to f(p)$.
($\Leftarrow$) Suppose the sequential condition holds and f is not continuous at p.
Choose $\varepsilon_0 > 0$ with $(\forall \delta > 0)(\exists x \in X)\,[d_X(x,p) < \delta \wedge d_Y(f(x), f(p)) \geq \varepsilon_0]$.
Then p is a limit point of $A := \{x \in X : d_Y(f(x), f(p)) \geq \varepsilon_0\}$.
Choose $(x_n) \subseteq A$ with $x_n \to p$ by Theorem 3.4.6(iii). Since $(\forall n \in \mathbb{N})\, d_Y(f(x_n), f(p)) \geq \varepsilon_0$, $f(x_n) \nrightarrow f(p)$, a contradiction.
Structural Commentary: Failure of epsilon–delta continuity manufactures a bad sequence.
Key Insight: In metric spaces, sequences detect continuity at points. □

Theorem 5.1.16. *Composition of Continuous Functions*
Let $E \subseteq X$ and let $f : E \to Y$, $g : f(E) \to Z$ be maps between metric spaces.
If f is continuous at $p \in E$ and g is continuous at $f(p)$, then $g \circ f$ is continuous at p.

Proof. Given $\varepsilon > 0$, choose $\eta > 0$ by continuity of g at $f(p)$. Choose $\delta > 0$ by continuity of f at p with tolerance η.
If $x \in E$ and $d_X(x,p) < \delta$, then $d_Y(f(x), f(p)) < \eta$, hence $d_Z(g(f(x)), g(f(p))) < \varepsilon$.
Structural Commentary: The output tolerance for g becomes the input tolerance for f.
Key Insight: Continuity composes by passing epsilon through an intermediate eta. □

Theorem 5.1.17. *The Distance Function Is Continuous*
Let (X, d) be a metric space and $D : X \times X \to \mathbb{R}$, $D(x,y) := d(x,y)$.
For $d_\times \in \{d_{\text{sum}}, d_E, d_{\max}\}$ on $X \times X$, $D : (X \times X, d_\times) \to \mathbb{R}$ is continuous.
Equivalently, $x_n \to x$ and $y_n \to y$ in X imply $d(x_n, y_n) \to d(x,y)$.

Proof. For $x, y, u, v \in X$, $|D(x,y) - D(u,v)| \leq d(x,u) + d(y,v)$ by triangle inequality. Thus $x_n \to x$, $y_n \to y$ imply $D(x_n, y_n) \to D(x,y)$.
Convergence under d_{sum} is equivalent to coordinate convergence because both summands are nonnegative.
Continuity for d_{sum} follows by Theorem 5.1.15. Other product metrics have same convergent sequences by Proposition 3.4.15(iii).
Structural Commentary: Distance changes continuously when both endpoints move.
Key Insight: The triangle inequality controls distance error by endpoint errors. □

Theorem 5.1.18. *Continuity via Open Preimages*
For metric spaces X, Y, a map $f : X \to Y$ is continuous iff $f^{-1}(V)$ is open in X whenever $V \subseteq Y$ is open.

Proof.
($\Rightarrow$) If $p \in f^{-1}(V)$, V is open, choose $\varepsilon > 0$ with $B_\varepsilon(f(p)) \subseteq V$. By continuity, $\exists\ \delta > 0$ with $B_\delta(p) \subseteq f^{-1}(V)$, so $f^{-1}(V)$ is open.
($\Leftarrow$) For $p \in X$ and $\varepsilon > 0$, the ball $V = B_\varepsilon(f(p))$ is open by Theorem 3.1.3.
Since $p \in f^{-1}(V)$ and $f^{-1}(V)$ is open, some $B_\delta(p) \subseteq f^{-1}(V)$; this is continuity at p.
Structural Commentary: Continuity is exactly preservation of openness under inverse image.
Key Insight: Images are not Boolean-exact, but preimages are; continuity belongs to preimages. □

Proposition 5.1.19. *Continuity on a Relative Domain*
Let (X, d_X) and (Y, d_Y) be metric spaces, let $E \subseteq X$, and let $f : E \to Y$. The following are equivalent:
(i) $f : (E, d_X|_{E\times E}) \to (Y, d_Y)$ is continuous.
(ii) The set $f^{-1}(V)$ is open relative to E whenever $V \subseteq Y$ is open.
(iii) If $V \subseteq Y$ is open, then $f^{-1}(V) = E \cap G$ for an open set $G \subseteq X$.

Proof. Every constant map $h : X \to \mathbb{R}$ is continuous by Definition 5.1.9, since $|h(x) - h(p)| = 0$.
(i) $\Rightarrow$ *(ii)* For open $V \subseteq Y$, the set $f^{-1}(V)$ is open in the metric space E by Theorem 5.1.18.
(ii) $\Rightarrow$ *(iii)* For open $V \subseteq Y$, choose open $G \subseteq X$ with $f^{-1}(V) = E \cap G$ by Theorem 3.2.3.
(iii) $\Rightarrow$ *(i)* For open $V \subseteq Y$, $f^{-1}(V) = E \cap G$ with G open in X, hence $f^{-1}(V)$ is open in E.
Therefore f is continuous by Theorem 5.1.18 on E.
Structural Commentary: Open preimages are relative opens in E.
Key Insight: Relative continuity says ordinary open sets in X are seen through intersection with E. □

Figure 143 visualizes the inverse-image characterization of continuity.

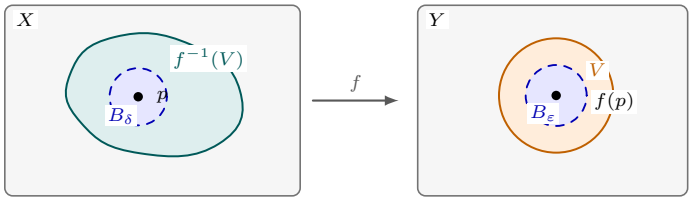

Figure 143: Continuity pulls open sets back to open sets.

Corollary 5.1.20. *Continuity via Closed Preimages*
Let X, Y be metric spaces, $f : X \to Y$. Then f is continuous iff $f^{-1}(C)$ is closed in X whenever $C \subseteq Y$ is closed.

Proof.
($\Rightarrow$) For closed $C \subseteq Y$, $X \setminus f^{-1}(C) = f^{-1}(Y \setminus C)$ is open by Theorem 5.1.18. Hence $f^{-1}(C)$ is closed.
($\Leftarrow$) For open $V \subseteq Y$, $X \setminus f^{-1}(V) = f^{-1}(Y \setminus V)$ is closed by hypothesis; hence $f^{-1}(V)$ is open.
Structural Commentary: Closed-set continuity is the complement form of open-set continuity.
Key Insight: $f^{-1}(Y \setminus C) = X \setminus f^{-1}(C)$ transfers open and closed formulations. □

Perspective 5.1.21. *Three Views of Continuity*
For metric-space maps, continuity has three equivalent forms: ε–δ control, sequence preservation, and open inverse images.
The owners are Definition 5.1.9 and Theorems 5.1.15, 5.1.18.
Key Insight: Continuity sends near points forward and pulls open sets back.

Proposition 5.1.22. *Distance-to-Set Is Continuous*
Let (X, d) be a metric space, let $\emptyset \neq E \subseteq X$, and define $f : X \to \mathbb{R}$ by $f(p) := \operatorname{dist}(p, E)$.
(i) f is 1-Lipschitz: $(\forall\, p, q \in X)\ |f(p) - f(q)| \leq d(p, q)$.
(ii) The map f is continuous.
(iii) $f^{-1}(\{0\}) = \overline{E}$.

Proof.
(i) For $p, q \in X$ and $e \in E$, $d(p, e) \leq d(p, q) + d(q, e)$. Then $f(p) - f(q) \leq d(p, q)$ by taking $\inf_{e \in E}$.
Interchanging p, q, $f(q) - f(p) \leq d(p, q)$. Thus $|f(p) - f(q)| \leq d(p, q)$.
(ii) Fix $p \in X$ and $\varepsilon > 0$, and set $\delta := \varepsilon$. If $d(p, q) < \delta$, then $|f(p) - f(q)| < \varepsilon$ by (i). Hence f is continuous on X.
(iii) For $p \in X$, $p \in f^{-1}(\{0\})$ iff $\operatorname{dist}(p, E) = 0$ iff $p \in \overline{E}$ by Proposition 3.1.26.
Structural Commentary: Distance to a fixed set changes no faster than the point itself moves.
Key Insight: The triangle inequality turns nearest-set distance into a continuous detector of closure. □

Corollary 5.1.23. *Open and Closed Sets by Distance Functions*
Let X be a metric space.
(i) A set $O \subseteq X$ is open iff $O = \{x \in X : f(x) > 0\}$ for a continuous map $f : X \to \mathbb{R}$.
(ii) A set $F \subseteq X$ is closed iff $F = g^{-1}(\{0\})$ for a continuous map $g : X \to \mathbb{R}$.

Proof.
(i) ($\Rightarrow$) If $O = X$, take $f \equiv 1$; this map is continuous and $O = \{x \in X : f(x) > 0\}$.
If $O \neq X$, set $f(x) := \operatorname{dist}(x, O^c)$. Then f is continuous by Proposition 5.1.22(ii).
Since O^c is closed, $f^{-1}(\{0\}) = O^c$ by Proposition 5.1.22(iii). Hence $O = \{x \in X : f(x) > 0\}$.
(i) ($\Leftarrow$) If $O = \{x \in X : f(x) > 0\}$ for continuous $f : X \to \mathbb{R}$, then $O = f^{-1}((0, \infty))$ is open by Theorem 5.1.18.
(ii) ($\Rightarrow$) If $F = \emptyset$, take $g \equiv 1$; this map is continuous and $F = g^{-1}(\{0\})$. If $F \neq \emptyset$, set $g(x) := \operatorname{dist}(x, F)$.
Then g is continuous by Proposition 5.1.22(ii). Since F is closed, $g^{-1}(\{0\}) = \overline{F} = F$ by Proposition 5.1.22(iii).
(ii) ($\Leftarrow$) If $F = g^{-1}(\{0\})$ for a continuous $g : X \to \mathbb{R}$, then F is closed by Corollary 5.1.20.
Structural Commentary: Metric spaces encode open and closed sets by continuous real-valued distance functions.
Key Insight: A set is closed exactly when its distance-zero locus has no extra points. □

Definition 5.1.24. *Homeomorphism*
Let X, Y be metric spaces. A *homeomorphism* from X to Y is a bijection $f : X \to Y$ such that both f and f^{-1} are continuous.
If such a map exists, X and Y are *homeomorphic*, written $X \simeq Y$.

Proposition 5.1.25. *Homeomorphisms Preserve Topology*
If $f : X \to Y$ is a homeomorphism, then $U \mapsto f(U)$ bijects open subsets of X with open subsets of Y.

Proof. If $U \subseteq X$ is open, then $f(U) = (f^{-1})^{-1}(U)$ is open in Y by continuity of f^{-1}.
If $V \subseteq Y$ is open, then $f^{-1}(V)$ is open in X by continuity of f. These assignments are inverse because f is bijective.
Structural Commentary: A homeomorphism preserves open sets in both directions.
Key Insight: Topological sameness is continuity plus continuous reversibility. □

Theorem 5.1.26. *Basic Properties of Metric Isometries*
Let $f : (X, d_X) \to (Y, d_Y)$ be an isometry.
(i) f is injective.
(ii) f is continuous.
(iii) $f^{-1} : (f(X), d_Y|_{f(X) \times f(X)}) \to (X, d_X)$ is an isometry.

Proof.
(i) If $f(x) = f(y)$, then $d_X(x, y) = d_Y(f(x), f(y)) = 0$, hence $x = y$.
(ii) If $x_n \to x$ in X, then $d_Y(f(x_n), f(x)) = d_X(x_n, x) \to 0$. Hence f is continuous by Theorem 5.1.15.
(iii) For $u = f(x), v = f(y) \in f(X)$, $d_X(f^{-1}(u), f^{-1}(v)) = d_X(x, y) = d_Y(f(x), f(y)) = d_Y(u, v)$.
Structural Commentary: An isometry preserves all distances, so injectivity and continuity are automatic.
Key Insight: Distance preservation is stronger than topological equivalence. □

Remark 5.1.27. *Metric Versus Linear Isometries*
Metric isometry is purely distance-theoretic. If $T : V \to W$ is linear between inner-product spaces, then
$(\forall v \in V)\ \|Tv\| = \|v\| \iff (\forall u, v \in V)\, d_W(Tu, Tv) = d_V(u, v)$.

Counterexample 5.1.28. *Continuous Bijection Need Not Be a Homeomorphism*
Let $S^1 := \{(x, y) \in \mathbb{R}^2 : x^2 + y^2 = 1\}$ and define $f : [0, 2\pi) \to S^1$ by $f(t) := (\cos t, \sin t)$.
This standard parametrization is a continuous bijection. Set $t_n := 2\pi - \frac{1}{n}$ and $z_n := f(t_n)$.
Then $z_n \to (1, 0) = f(0)$, while $f^{-1}(z_n) = t_n \to 2\pi \neq 0 = f^{-1}(1, 0)$.
Thus f^{-1} is not continuous by Theorem 5.1.15, so f is not a homeomorphism.

Figure 144 shows the discontinuity created by cutting the circle at one point.

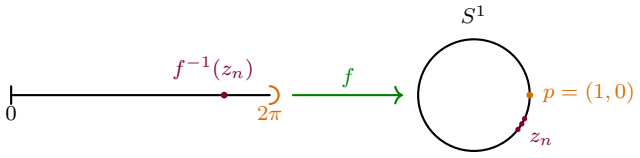

Figure 144: Parametrization $[0, 2\pi) \to S^1$ wraps continuously and bijectively, but inverse jumps at $(1, 0)$.

Remark 5.1.29. *Continuity Only Uses the Domain Metric*
For $f : E \to Y$ with $E \subseteq X$, continuity on E depends only on the restricted metric on E, not on $X \setminus E$.

Definition 5.1.30. *Product Map*
If $f : X \to Y$ and $g : X \to Z$ are maps between metric spaces, their *product map*, or direct sum, is $f \oplus g : X \to Y \times Z$.
It is defined by $(f \oplus g)(x) := (f(x), g(x))$. The product $Y \times Z$ carries any product metric from Definition 3.4.14.

Proposition 5.1.31. *Continuity of Product Maps*
Let X, Y, Z be metric spaces, let $f : X \to Y$, let $g : X \to Z$, and let $x_0 \in X$.

(i) The product map $f \oplus g : X \to Y \times Z$ is continuous at x_0 iff f and g are continuous at x_0.
(ii) The map $f \oplus g$ is continuous on X iff both f and g are continuous on X.

Proof. By Proposition 3.4.15(iii), it suffices to use d_{sum}.

(*i*) ($\Rightarrow$) Given $\varepsilon > 0$, choose $\delta > 0$ from continuity of $f \oplus g$ at x_0.
If $d_X(x, x_0) < \delta$, then $d_Y(f(x), f(x_0)), d_Z(g(x), g(x_0)) \le d_{\text{sum}}((f \oplus g)(x), (f \oplus g)(x_0)) < \varepsilon$.
(*i*) ($\Leftarrow$) Given $\varepsilon > 0$, choose δ_f, δ_g for f, g at tolerance $\frac{\varepsilon}{2}$. Set $\delta := \min\{\delta_f, \delta_g\}$.
If $d_X(x, x_0) < \delta$, then $d_{\text{sum}}((f \oplus g)(x), (f \oplus g)(x_0)) = d_Y(f(x), f(x_0)) + d_Z(g(x), g(x_0)) < \varepsilon$.
(*ii*) ($\Rightarrow$) If $f \oplus g$ is continuous on X, then $(\forall x_0 \in X)$, both f and g are continuous at x_0 by (i).
Hence both are continuous on X by Definition 5.1.9(ii).
(*ii*) ($\Leftarrow$) If f and g are continuous on X, then $(\forall x_0 \in X)$, $f \oplus g$ is continuous at x_0 by (i).
Hence $f \oplus g$ is continuous on X by Definition 5.1.9(ii).

Structural Commentary: Product continuity is exactly componentwise continuity.
Key Insight: A product metric packages two output estimates into one. □

Theorem 5.1.32. *Continuous Algebra and Components*
Let X be a metric space.

(i) If $f, g : X \to \mathbb{C}$ are continuous, then $f + g$ and fg are continuous on X, while f/g is continuous on $U := \{x \in X : g(x) \neq 0\}$.
(ii) For $f = (f_1, \dots, f_k) : X \to \mathbb{R}^k$, f is continuous iff $(\forall j \in \{1, \dots, k\})$ f_j is continuous.
(iii) If $f, g : X \to \mathbb{R}^k$ are continuous, so are $f + g$ and $f \cdot g$.

Proof.

(*i*) If $x_n \to x$ in X, then $f(x_n) \to f(x)$ and $g(x_n) \to g(x)$ by Theorem 5.1.15.
Thus $(f + g)(x_n) \to (f + g)(x)$ and $(fg)(x_n) \to (fg)(x)$ by Theorem 2.1.5(i),(iii).
If $x \in U$ and $(x_n) \subseteq U$, then $(f/g)(x_n) \to (f/g)(x)$ by Theorem 2.1.5(iii),(iv).
The three continuity conclusions follow by Theorem 5.1.15.
(*ii*) ($\Rightarrow$) If f is continuous and $x_n \to x$, then $f(x_n) \to f(x)$ by Theorem 5.1.15.
Hence $(\forall j \in \{1, \dots, k\})$ $f_j(x_n) \to f_j(x)$ by Theorem 3.4.13(i), so each f_j is continuous.
(*ii*) ($\Leftarrow$) If each f_j is continuous and $x_n \to x$, then $(\forall j \in \{1, \dots, k\})$ $f_j(x_n) \to f_j(x)$.
Hence $f(x_n) \to f(x)$ by Theorem 3.4.13(i), so f is continuous.
(*iii*) Each coordinate of $f + g$ is continuous by (i), so $f + g$ is continuous by (ii).
The map $f \cdot g = \sum_{j=1}^{k} f_j g_j$ is continuous by repeated scalar sums and products in (i).

Structural Commentary: Continuity is stable under the algebraic operations already stable for limits.
Key Insight: Componentwise control is equivalent to Euclidean control in finite dimensions. □

Theorem 5.1.33. *Pointwise Bounded Families Are Locally Uniformly Bounded*
Let (X, d) be a nonempty complete metric space, $\mathcal{F}$ be a family of continuous maps $f : X \to \mathbb{R}$.
Assume $(\forall x \in X)(\exists M_x > 0)(\forall f \in \mathcal{F})$ $|f(x)| \le M_x$.
Then there are a nonempty open set $O \subseteq X$ and $M > 0$ such that $(\forall x \in O)(\forall f \in \mathcal{F})$ $|f(x)| \le M$.

Proof. For $n \in \mathbb{N}$, set $E_n := \{x \in X : (\forall f \in \mathcal{F})\ |f(x)| \le n\}$. The interval $[-n, n] = \overline{B}_n(0)$ is closed by Corollary 3.1.18.
Hence $E_n = \bigcap_{f \in \mathcal{F}} f^{-1}([-n, n])$ closed by Corollary 5.1.20, Theorem 3.1.19(ii). $X = \bigcup_{n=1}^{\infty} E_n$ by pointwise bound, Theorem 1.1.19(i).
Choose $N \in \mathbb{N}$ with $E_N^\circ \neq \emptyset$ by Corollary 4.3.11(ii). Set $O := E_N^\circ$ and $M := N$. Then $(\forall x \in O)(\forall f \in \mathcal{F})$ $|f(x)| \le M$.
Structural Commentary: Closed inverse images form a countable cover, and Baire supplies one member with interior.
Key Insight: One interior level set bounds the entire family locally. □

Theorem 5.1.34. *Dense Continuity Set for Pointwise Limits*
Let (X, d) be a complete metric space, let $f : X \to \mathbb{R}$, and let $(f_n)_{n \in \mathbb{N}}$ be continuous maps $X \to \mathbb{R}$.
Assume $(\forall x \in X)$ $f_n(x) \to f(x)$. Then $(\exists D \subseteq X)$ satisfying:

(i) D is dense in X;
(ii) $(\forall x_0 \in D)(\forall \varepsilon > 0)(\exists \delta > 0)(\forall n \in \mathbb{N})(\forall x \in X)\,[d(x, x_0) < \delta \Longrightarrow |f_n(x) - f_n(x_0)| < \varepsilon]$;
(iii) $(\forall x_0 \in D)$, f is continuous at x_0.

Proof. For $m,n\in\mathbb{N}$, set $I_m:=[-m^{-1},m^{-1}]$ and $E_{m,n}:=\{x\in X:(\forall j,k\geq n)\,f_j(x)-f_k(x)\in I_m\}$.
For $j,k\geq n$, the map f_j-f_k is continuous by Theorem 5.1.32(i). The interval I_m is closed by Corollary 3.1.18.
Thus $E_{m,n}=\bigcap_{j,k\geq n}(f_j-f_k)^{-1}(I_m)$ is closed by Corollary 5.1.20 and Theorem 3.1.19(ii). Fix $m\in\mathbb{N}$ and $x\in X$.

Then $(f_n(x))$ is Cauchy by Theorem 4.1.20(i). Choose $N\in\mathbb{N}$ with $x\in E_{m,N}$ by Definition 4.1.14. Hence $X=\bigcup_{n=1}^{\infty}E_{m,n}$.

For $E\subseteq X$, $\operatorname{bd}(E)=\overline{E}\cap\overline{E^c}$ by Definitions 3.1.23 and 3.1.24(iii). Thus $\operatorname{bd}(E)$ is closed by Theorem 3.1.22(i) and Theorem 3.1.19(ii).
If E closed, O open with $O\subseteq\operatorname{bd}(E)=E\setminus E^\circ$, then $O\subseteq E$. Hence $O\subseteq E^\circ$ by Definition 3.1.24(i), assumed inclusion forces $O=\emptyset$.
Hence boundary of closed set is nowhere dense by Definition 4.3.1(iii). Hence $X\setminus\operatorname{bd}(E_{m,n})$ is dense and open.
Set $D:=X\setminus\bigcup_{m,n\in\mathbb{N}}\operatorname{bd}(E_{m,n})$. Then $D=\bigcap_{m,n\in\mathbb{N}}\big(X\setminus\operatorname{bd}(E_{m,n})\big)$ by Theorem 1.5.2.

(*i*) The set $\mathbb{N}^2$ is countable by Corollary 6.2.17(ii). Hence D is dense in X by Theorem 4.3.5.

(*ii*) Fix $x_0\in D$, $\varepsilon>0$. Choose $m\in\mathbb{N}$ with $\frac{3}{m}<\varepsilon$ by Theorem 1.1.19(i). Choose $N\in\mathbb{N}$ with $x_0\in E_{m,N}$ by $X=\bigcup_{n=1}^{\infty}E_{m,n}$.
Since $x_0\notin\operatorname{bd}(E_{m,N})$, $x_0\in E_{m,N}^\circ$; choose $r>0$ with $B_r(x_0)\subseteq E_{m,N}$.
For $1\leq i\leq N$, choose $\delta_i>0$ by continuity of f_i at x_0 with tolerance $\frac{1}{m}$.
Set $\delta:=\min\{r,\delta_1,\dots,\delta_N\}>0$. If $d(x,x_0)<\delta$ and $j>N$, then $x,x_0\in E_{m,N}$.
By the triangle inequality, $|f_j(x)-f_j(x_0)|\leq|f_j(x)-f_N(x)|+|f_N(x)-f_N(x_0)|+|f_N(x_0)-f_j(x_0)|$.
The three terms are bounded by m^{-1},m^{-1},m^{-1}, with the middle bound strict; hence $|f_j(x)-f_j(x_0)|<\frac{3}{m}<\varepsilon$.
The same bound holds for $1\leq j\leq N$ by the choice of δ. Hence (ii).

(*iii*) Fix $x_0\in D$, $\varepsilon>0$, $\eta:=\frac{\varepsilon}{2}$. By (ii), choose $\delta>0$ with $(\forall n\in\mathbb{N})(\forall x\in X)\,[d(x,x_0)<\delta\Longrightarrow|f_n(x)-f_n(x_0)|<\eta]$.
If $d(x,x_0)<\delta$, then $f_n(x)-f_n(x_0)\to f(x)-f(x_0)$ by Theorem 2.1.5(i),(ii).
Hence $|f_n(x)-f_n(x_0)|\to|f(x)-f(x_0)|$ by reverse triangle inequality; $|f(x)-f(x_0)|\leq\eta<\varepsilon$ by Proposition 2.1.4(iii).

Structural Commentary: Baire avoids every tail-Cauchy boundary; one interior tail set controls all indices.
Key Insight: Tail Cauchy bounds plus finitely many continuous terms create equicontinuity. □

Example 5.1.35. *Coordinate, Polynomial, Rational, and Norm Maps*
Coordinate maps on $\mathbb{R}^k$ are continuous; hence polynomials are continuous, and rational functions are continuous where defined.
The reverse triangle inequality is $\big|\|\mathbf{x}\|_2-\|\mathbf{y}\|_2\big|\leq\|\mathbf{x}-\mathbf{y}\|_2$. Hence $\mathbf{x}\mapsto\|\mathbf{x}\|_2$ is continuous by Definition 5.1.9.
Thus $p\mapsto\|f(p)\|_2$ is continuous for continuous $f:X\to\mathbb{R}^k$ by Theorem 5.1.16.

Definition 5.1.36. *Bounded Mapping*
A mapping $f:E\to\mathbb{R}^k$ is *bounded* iff $(\exists M\in\mathbb{R})(\forall x\in E)\ \|f(x)\|_2\leq M$.

Theorem 5.1.37. *Continuous Images of Compact Sets Are Compact*
Let X and Y be metric spaces. If $f:X\to Y$ is continuous and X is compact, then $f(X)$ is compact.

Proof. Let $\{V_\alpha\}$ be an open cover of $f(X)$. Then $\{f^{-1}(V_\alpha)\}$ is an open cover of X by Theorem 5.1.18.
Choose $\alpha_1,\dots,\alpha_n$ with $X\subseteq\bigcup_{i=1}^{n}f^{-1}(V_{\alpha_i})$; then $f(X)\subseteq\bigcup_{i=1}^{n}V_{\alpha_i}$.
Structural Commentary: Pull back, take a finite subcover, push forward.
Key Insight: Compactness is preserved by continuous images because inverse images preserve openness. □

Corollary 5.1.38. *Continuous Images into $\mathbb{R}^k$ Are Closed and Bounded*
Let X be a metric space. If $f:X\to\mathbb{R}^k$ is continuous, X is compact, then $f(X)$ is closed and bounded; consequently, f is bounded.

Proof. By Theorem 5.1.37, $f(X)$ is compact. By Theorem 4.2.5, compact subsets of $\mathbb{R}^k$ are closed and bounded; hence f is bounded.
Structural Commentary: Compactness in the domain becomes closed-bounded geometry in Euclidean range.
Key Insight: Continuous functions on compact spaces cannot escape to infinity. □

Theorem 5.1.39. *Extreme Value Theorem*
Let X be a nonempty compact metric space and let $f:X\to\mathbb{R}$ be continuous.
If $M:=\sup_{p\in X}f(p)$ and $m:=\inf_{p\in X}f(p)$, then $(\exists p,q\in X)\,[f(p)=M\wedge f(q)=m]$.

Proof. By Corollary 5.1.38, $f(X)$ is nonempty, closed, and bounded in $\mathbb{R}$. By Theorem 3.3.5(ii), $M=\sup f(X)$ belongs to $f(X)$.
Fix $\varepsilon>0$. Since $m+\varepsilon$ is not a lower bound for $f(X)$, choose $y_\varepsilon\in f(X)$ with $m\leq y_\varepsilon<m+\varepsilon$.
Hence $m\in\overline{f(X)}=f(X)$. Thus $(\exists p,q\in X)\,[M=f(p)\wedge m=f(q)]$.
Structural Commentary: Compactness turns suprema and infima into attained values.
Key Insight: Closed bounded images contain their endpoints. □

Theorem 5.1.40. *Compact Bijective Maps Have Continuous Inverses*
Let X and Y be metric spaces. If $f:X\to Y$ is continuous bijection, X is compact, then $f^{-1}:Y\to X$ is continuous.

Proof. By Theorem 5.1.18, it suffices that $f(V)$ be open in Y whenever $V\subseteq X$ is open.
For open $V\subseteq X$, V^c is compact by Theorem 4.1.7.
Then $f(V^c)$ is compact by Theorem 5.1.37 and closed by Theorem 4.1.6. Since f is bijective, $f(V)=Y\setminus f(V^c)$ is open.
Structural Commentary: Compactness turns closed complements into closed images.
Key Insight: A continuous bijection from compact domain has no room for inverse discontinuity. □

Remark 5.1.41. *Preimages, Not Forward Images*
Theorem 5.1.18 characterizes continuity through inverse images.
A continuous map need not preserve open or closed forward images; compactness recovers closedness through Theorem 5.1.37.

Theorem 5.1.42. *Continuous Images of Connected Sets Are Connected*
Let X and Y be metric spaces. If $f:X\to Y$ is continuous and $E\subseteq X$ is connected, then $f(E)$ is connected.

Proof. Suppose $f(E) = A \cup B$ for nonempty separated A, B, and set $G := E \cap f^{-1}(A)$ and $H := E \cap f^{-1}(B)$.
Then $G, H \neq \emptyset$ and $E = G \cup H$. The set $f^{-1}(\overline{A})$ is closed by Corollary 5.1.20. Since $G \subseteq f^{-1}(\overline{A})$, $\overline{G} \subseteq f^{-1}(\overline{A})$, so $\overline{G} \cap H = \emptyset$.
Likewise $G \cap \overline{H} = \emptyset$. Thus G, H separate E, contrary to connectedness.
Structural Commentary: A separation of the image pulls back to a separation of the domain.
Key Insight: Continuous maps cannot create a gap in the image of a connected set. □

Theorem 5.1.43. *Intermediate Value Theorem*
If $f : [a, b] \to \mathbb{R}$ is continuous and c lies strictly between $f(a)$ and $f(b)$, then $(\exists\, x \in (a, b))\ f(x) = c$.

Proof. The interval $[a, b]$ is connected by Theorem 5.1.2. Hence $f([a, b])$ is connected by Theorem 5.1.42.
The membership $c \in f([a, b])$ holds by Theorem 5.1.2. Choose $x \in [a, b]$ with $f(x) = c$. Since $c \notin \{f(a), f(b)\}$, $x \in (a, b)$.
Structural Commentary: The intermediate value theorem is connectedness of intervals transported by continuity.
Key Insight: Continuous real functions on intervals cannot jump over a value. □

Method 5.1.44. *Bisection Proof of the Intermediate Value Theorem*
Let $f : [a, b] \to \mathbb{R}$ be continuous, c lie between $f(a)$ and $f(b)$. Replacing (f, c) by $(-f, -c)$ if needed, assume $f(a) \leq c \leq f(b)$.
If $c = f(a)$ or $c = f(b)$, take the corresponding endpoint; otherwise $f(a) < c < f(b)$.

(i) Set $[a_1, b_1] := [a, b]$.
(ii) Given $[a_n, b_n]$ with $f(a_n) \leq c \leq f(b_n)$, set $m_n := \frac{a_n + b_n}{2}$.
If $f(m_n) \geq c$, set $[a_{n+1}, b_{n+1}] := [a_n, m_n]$; otherwise set $[a_{n+1}, b_{n+1}] := [m_n, b_n]$.

Then $(\forall n \in \mathbb{N})\, [a_{n+1}, b_{n+1}] \subseteq [a_n, b_n] \wedge f(a_n) \leq c \leq f(b_n)$. The length identity is $(\forall n \in \mathbb{N})\, b_n - a_n = \frac{b-a}{2^{n-1}}$.
Choose $x_0 \in \bigcap_{n=1}^{\infty} [a_n, b_n]$ by Theorem 4.2.1. Interval lengths tend to 0 by Theorem 2.2.10(v), Theorem 2.1.5(ii).
Since $0 \leq x_0 - a_n, b_n - x_0 \leq b_n - a_n$, $a_n, b_n \to x_0$ by Theorem 2.2.9. If $y \in \bigcap_{n=1}^{\infty} [a_n, b_n]$, then $(\forall n \in \mathbb{N})\ |y - x_0| \leq b_n - a_n$, so $y = x_0$.
By Theorem 5.1.15, $f(a_n), f(b_n) \to f(x_0)$, so $f(x_0) \leq c \leq f(x_0)$; hence $f(x_0) = c$. If $f(a) < c < f(b)$, then $x_0 \in (a, b)$.
Key Insight: Bisection keeps the target value bracketed while nested intervals collapse to one point.

Definition 5.1.45. *Path-Connected Set*
A *path* in E from p to q is a continuous map $\gamma : [0, 1] \to E$ satisfying $\gamma(0) = p$ and $\gamma(1) = q$.
The set E is *path-connected* iff any $p, q \in E$ are joined by a path in E.

Theorem 5.1.46. *Path-Connected Sets Are Connected*
Let E be a path-connected subset of a metric space. Then E is connected.

Proof. Suppose $E = A \cup B$ with A, B nonempty separated. Choose $p \in A$, $q \in B$, and a path $\gamma : [0, 1] \to E$ from p to q.
The interval $[0, 1]$ is connected by Theorem 5.1.2. Hence $\gamma([0, 1])$ is connected by Theorem 5.1.42.
Set $G := \gamma([0, 1]) \cap A$ and $H := \gamma([0, 1]) \cap B$. Then $p \in G$, $q \in H$, and $\gamma([0, 1]) = G \cup H$.
Since $G \subseteq A$ and $H \subseteq B$, $\overline{G} \cap H = G \cap \overline{H} = \emptyset$. Thus G, H separate $\gamma([0, 1])$, a contradiction.
Structural Commentary: A path transports connectedness from an interval to the set.
Key Insight: To connect two points by a path, the path image cannot be split into two separated pieces. □

Corollary 5.1.47. *Convex Sets Are Path-Connected*
Let $E \subseteq \mathbb{R}^k$ be convex. Then E is path-connected.

Proof. For $\mathbf{x}, \mathbf{y} \in E$, set $\gamma(t) := (1 - t)\mathbf{x} + t\mathbf{y}$ on $[0, 1]$. By convexity, $\gamma([0, 1]) \subseteq E$, with $\gamma(0) = \mathbf{x}$ and $\gamma(1) = \mathbf{y}$.
For $s, t \in [0, 1]$, $\|\gamma(t) - \gamma(s)\|_2 = |t - s|\, \|\mathbf{y} - \mathbf{x}\|_2$. Hence γ is continuous by Definition 5.1.9, so E is path-connected.
Structural Commentary: Convexity supplies the whole straight path between any two points.
Key Insight: In Euclidean space, line segments are continuous paths. □

5.2 Uniform Continuity and Compactness

Definition 5.2.1. *Uniform Continuity*
Let (X, d_X) and (Y, d_Y) be metric spaces, and let $f : X \to Y$.
The map f is *uniformly continuous* iff $(\forall\, \varepsilon > 0)(\exists\, \delta > 0)(\forall\, p, q \in X)\, [d_X(p, q) < \delta \implies d_Y(f(p), f(q)) < \varepsilon]$.
Key Insight: The choice of δ may depend on ε, but not on either point in the pair.

Principle 5.2.2. *Challenge–Response Order*
Limits and continuity depend on quantifier order. Definition 5.1.4 answers a range challenge ε by a domain radius δ at the base point. Definition 5.2.1 strengthens this pattern by requiring δ to be independent of the domain point.

Proposition 5.2.3. *Sequential Test for Uniform Continuity*
Let X, Y be metric spaces, $f : X \to Y$. Then f uniformly continuous iff $d_Y(f(p_n), f(q_n)) \to 0$ when $(p_n), (q_n) \subseteq X$, $d_X(p_n, q_n) \to 0$.

Proof.
($\Rightarrow$) Let $\varepsilon > 0$. By uniform continuity, choose $\delta > 0$ such that $x, y \in X$ and $d_X(x, y) < \delta$ imply $d_Y(f(x), f(y)) < \varepsilon$.
Since $d_X(p_n, q_n) \to 0$, eventually $d_X(p_n, q_n) < \delta$, and hence eventually $d_Y(f(p_n), f(q_n)) < \varepsilon$.
($\Leftarrow$) Prove contrapositive. If f not uniformly continuous, $(\exists \varepsilon_0 > 0)(\forall n \geq 1)(\exists p_n, q_n \in X)\, [d_X(p_n, q_n) < \frac{1}{n} \wedge d_Y(f(p_n), f(q_n)) \geq \varepsilon_0]$.
$\frac{1}{n} \to 0$ by Theorem 2.2.10(i), $d_X(p_n, q_n) \to 0$ by Theorem 2.2.9; $d_Y(f(p_n), f(q_n)) \not\to 0$, contradicting sequential condition.
Structural Commentary: The forward estimate transfers to pairs; the negation selects a separated pair at each scale.
Key Insight: Failed uniformity produces close inputs whose outputs stay apart. □

Definition 5.2.4. *Lipschitz Map*
Let (X, d_X) and (Y, d_Y) be metric spaces, $f : X \to Y$, $L \geq 0$. The map f is *L-Lipschitz* if $(\forall\, p, q \in X)\ d_Y(f(p), f(q)) \leq L d_X(p, q)$.
It is *Lipschitz* if $(\exists\, L \geq 0)$ such that it is L-Lipschitz.
Key Insight: Lipschitz control is one global linear modulus of continuity.

Proposition 5.2.5. *Lipschitz Implies Uniform Continuity*
Let (X, d_X) and (Y, d_Y) be metric spaces, and let $f : X \to Y$. If f is Lipschitz, then f is uniformly continuous and continuous.

Proof. Choose $L \geq 0$ such that f is L-Lipschitz by Definition 5.2.4, and let $\varepsilon > 0$.
If $L = 0$, set $\delta := 1$; then $(\forall\, p, q \in X)\ d_Y(f(p), f(q)) = 0 < \varepsilon$.
If $L > 0$, take $\delta := \frac{\varepsilon}{L}$; if $p, q \in X$ and $d_X(p, q) < \delta$, then $d_Y(f(p), f(q)) \leq L d_X(p, q) < \varepsilon$. Thus f is uniformly continuous.
Fix $a \in X$. If $p \in X$ and $d_X(p, a) < \delta$, the uniform estimate with $q = a$ verifies continuity at a.
Structural Commentary: The cases $L = 0$ and $L > 0$ provide a point-independent δ; specialization proves continuity.
Key Insight: The linear bound supplies a global modulus. □

Theorem 5.2.6. *Continuity on Compact Sets Is Uniform*
Let (X, d_X), (Y, d_Y) be metric spaces. If $f : X \to Y$ is continuous and X is compact, then f is uniformly continuous.

Proof. If $X = \emptyset$, the conclusion is vacuous. Assume $X \neq \emptyset$, and fix $\varepsilon > 0$. For $a \in X$, set $U_a := f^{-1}(B_{\frac{\varepsilon}{2}}(f(a)))$.
Each U_a is open by Theorems 3.1.3 and 5.1.18, while $a \in U_a$. Hence $\mathcal{U} := \{U_a : a \in X\}$ is an open cover of X.
Choose Lebesgue number $\delta > 0$ for $\mathcal{U}$ by Lemma 4.1.33(ii). If $p, q \in X$, $d_X(p, q) < \delta$, choose $a \in X$, $B_\delta(p) \subseteq U_a$ by Definition 4.1.32.
Then $p, q \in U_a$, so $d_Y(f(p), f(a)) < \frac{\varepsilon}{2}$ and $d_Y(f(q), f(a)) < \frac{\varepsilon}{2}$. Thus $d_Y(f(p), f(q)) < \varepsilon$ by the triangle inequality.
Structural Commentary: Output balls induce an inverse-image cover; its Lebesgue number controls every input pair.
Key Insight: One cover-scale replaces all point-dependent continuity radii. □

Counterexample 5.2.7. *The Reverse Implications Fail*

(i) The identity on $\mathbb{R}$ is an isometry, so it is continuous by Theorem 5.1.26(ii).
Thus $f : \mathbb{R} \to \mathbb{R}$, $f(x) := x^2$, is continuous by Theorem 5.1.32(i).
For $p_n := n$ and $q_n := n + \frac{1}{n}$, $|p_n - q_n| = \frac{1}{n} \to 0$, whereas $|f(q_n) - f(p_n)| = 2 + \frac{1}{n^2} \not\to 0$.
Thus f is not uniformly continuous by Proposition 5.2.3.

(ii) Define $g : [0, 1] \to \mathbb{R}$ by $g(x) := \sqrt{x}$. For $\varepsilon > 0$, the inequality $\left|\sqrt{x} - \sqrt{y}\right| \leq \sqrt{|x - y|}$ shows that $\delta := \varepsilon^2$ verifies continuity.
The set $[0, 1]$ is compact by Theorem 4.2.5. Hence g is uniformly continuous by Theorem 5.2.6.
If g were L-Lipschitz, then $(\forall n \in \mathbb{N})\ \frac{1}{n} = \left|g(\frac{1}{n^2}) - g(0)\right| \leq \frac{L}{n^2}$, so $n \leq L$.
Choose $n \in \mathbb{N}$ with $n > L$ by Theorem 1.1.19(i), a contradiction. Hence g is not Lipschitz.

Structural Commentary: The quadratic breaks uniformity; the square root has no linear modulus.
Key Insight: Compactness supplies a modulus, but not necessarily a linear one.

Theorem 5.2.8. *Compactness Hypotheses Are Essential*
Let $E \subseteq \mathbb{R}$ be noncompact in the subspace metric. Then:

(i) $\exists f : E \to \mathbb{R}$ continuous and unbounded;
(ii) $\exists g : E \to \mathbb{R}$ continuous and bounded with no maximum;
(iii) if E is bounded, then $\exists h : E \to \mathbb{R}$ continuous and not uniformly continuous.

Proof. The inclusion $\iota : E \to \mathbb{R}$ is an isometry, so it is continuous by Theorem 5.1.26(ii).
For $c \in \mathbb{R}$, define $\kappa_c : E \to \mathbb{R}$ by $\kappa_c(x) := c$. Since $(\forall p, x \in E)\ |\kappa_c(x) - \kappa_c(p)| = 0$, κ_c is continuous by Definition 5.1.9.
Their denominators are nonzero on E, so the rational expressions below are continuous by Theorem 5.1.32(i).

(i) If E is unbounded, $f := \iota$ is continuous and unbounded. Suppose E is bounded.
Then E not closed by Theorem 4.2.5; choose $x_0 \in \overline{E} \setminus E$. Point x_0 is limit point of E by Definition 3.1.21.
Define $f(x) := \frac{1}{x - x_0}$. For $M > 0$, choose $x \in E \cap B_{\frac{1}{M}}(x_0)$ by limit-point property of x_0. Then $|f(x)| > M$, so f is unbounded.

(ii) Suppose first that E is unbounded, and define $g(x) := \frac{x^2}{1 + x^2}$. Then $(\forall x \in E)\ 0 \leq g(x) < 1$.
Given $\varepsilon > 0$, choose $n \in \mathbb{N}$ with $n > \varepsilon^{-\frac{1}{2}}$ by Theorem 1.1.19(i). Choose $x \in E$ with $|x| > n$ by unboundedness.
Then $1 - g(x) = \frac{1}{1 + x^2} < \varepsilon$. Since $g < 1$ on E, $\sup_E g = 1$, which is not attained. Suppose next that E is bounded.
Choose $x_0 \in \overline{E} \setminus E$ as in (i), define $g(x) := \frac{1}{1 + (x - x_0)^2}$. Then $(\forall x \in E)\ 0 < g(x) < 1$.
Given $\varepsilon > 0$, $x \in E \cap B_{\sqrt{\varepsilon}}(x_0)$ by limit-point property of x_0; $1 - g(x) = \frac{(x - x_0)^2}{1 + (x - x_0)^2} < \varepsilon$. Hence $\sup_E g = 1$, which is not attained.

(iii) Suppose E is bounded. Choose $x_0 \in \overline{E} \setminus E$ as in (i), and define $h(x) := \frac{1}{x - x_0}$.
For $\delta > 0$, $x \in E \cap B_{\frac{\delta}{2}}(x_0)$ by limit-point property of x_0. Choose $y \in E$, $|y - x_0| < \min\{\frac{\delta}{2}, \frac{1}{|h(x)| + 1}\}$ by same property.
Then $|x - y| < \delta$ and $|h(y)| > |h(x)| + 1$, so $|h(y) - h(x)| > 1$ by the reverse triangle inequality.
Thus h is not uniformly continuous by Definition 5.2.1.

Structural Commentary: Unbounded sets support escape functions; bounded nonclosed sets support singular boundary functions.
Key Insight: Every noncompact subset of $\mathbb{R}$ has an escape or boundary obstruction. □

Figure 145 illustrates the boundary obstruction.
Near 0, a fixed output tolerance for $x \mapsto \frac{1}{x^2}$ requires progressively smaller input radii.

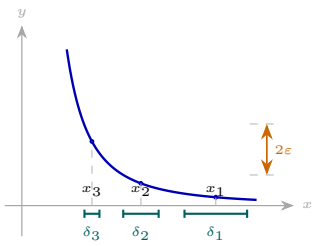

Figure 145: Dimensionless $y = \frac{1}{x^2}$ graph for $x > 0$: input radii δ_i shrink as $x_i \to 0$; orange marks the fixed 2ε output tolerance.

Proof Method 5.2.9. *Continuity Proof Patterns*
Let (X, d_X) and (Y, d_Y) be metric spaces, $E \subseteq X$, $f : E \to Y$, $p \in X$ and $q \in Y$.

(i) *ε–δ at p*: for $p \in E$, prove $(\forall\, \varepsilon > 0)(\exists\, \delta > 0)(\forall\, x \in E)\,[d_X(x,p) < \delta \Longrightarrow d_Y(f(x), f(p)) < \varepsilon]$.
(ii) *Limit at p*: for $p \in E^{\mathrm{acc}}$, replace antecedent by $0 < d_X(x,p) < \delta$ and target by q.
Equivalently, test sequences with $x_n \to p$ and $x_n \neq p$.
(iii) *Topological continuity*: prove that open subsets of Y have relatively open preimages in E.
Equivalently, prove that closed subsets of Y have relatively closed preimages.
(iv) *Compact-image argument*: for compact E, pull an open cover $\{V_\alpha\}$ of $f(E)$ back to $\{f^{-1}(V_\alpha)\}$ of E.
Extract a finite subcover of E and push it forward to $f(E)$.
(v) *Uniform continuity*: for compact E and $\varepsilon > 0$, form $U_a := f^{-1}(B_{\frac{\varepsilon}{2}}(f(a)))$ for $a \in E$.
Choose a Lebesgue number $\delta > 0$ by Lemma 4.1.33(ii).

Key Insight: Match the target property to pointwise, sequential, inverse-image, or compact-cover control.

5.3 One-Sided Limits, Monotone Functions, and Extended Limits

Definition 5.3.1. *One-Sided Limits and Types of Discontinuity*
Let $X \subseteq \mathbb{R}$, $f : X \to \mathbb{R}$, $x_0 \in \mathbb{R}$, $q \in \mathbb{R}$, $X_+ := X \cap (x_0, \infty)$, and $X_- := X \cap (-\infty, x_0)$.

(i) If x_0 is a limit point of X_+, then $f(x_0+) = q$ means $\lim\limits_{x \to x_0} (f|_{X_+})(x) = q$.
(ii) If x_0 is a limit point of X_-, then $f(x_0-) = q$ means $\lim\limits_{x \to x_0} (f|_{X_-})(x) = q$.

For an interval I, $f : I \to \mathbb{R}$, and an interior discontinuity $x_0 \in I^\circ$:

(i) The discontinuity is of the *first kind*, or *simple*, iff both $f(x_0+)$ and $f(x_0-)$ exist.
(ii) A first-kind discontinuity is a *jump* iff $f(x_0+) \neq f(x_0-)$.
(iii) A first-kind discontinuity is *removable* iff $f(x_0+) = f(x_0-) \neq f(x_0)$.
(iv) The discontinuity is of the *second kind* iff at least one of $f(x_0+)$ and $f(x_0-)$ fails to exist.

Proposition 5.3.2. *Two-Sided Limits from One-Sided Limits*
Let $X \subseteq \mathbb{R}$, let $f : X \to \mathbb{R}$, let $x_0 \in \mathbb{R}$, and set $X_+ := X \cap (x_0, \infty)$ and $X_- := X \cap (-\infty, x_0)$.
If x_0 is a limit point of both X_+ and X_-, then, for $q \in \mathbb{R}$, $\lim\limits_{x \to x_0} f(x) = q$ iff $f(x_0-) = f(x_0+) = q$.

Proof.
(⇒) Assume $\lim\limits_{x \to x_0} f(x) = q$, $\varepsilon > 0$. Choose $\delta > 0$ such that $t \in X$ and $0 < |t - x_0| < \delta$ imply $|f(t) - q| < \varepsilon$.
Restricting this estimate to X_+ and X_- proves $f(x_0+) = f(x_0-) = q$ by Definitions 5.1.4 and 5.3.1.
(⇐) Assume $f(x_0+) = f(x_0-) = q$, and fix $\varepsilon > 0$. Choose $\delta_+, \delta_- > 0$ by the right and left limits, and set $\delta := \min\{\delta_+, \delta_-\}$.
If $t \in X$ and $0 < |t - x_0| < \delta$, then $t \in X_+ \cup X_-$, so $|f(t) - q| < \varepsilon$. Hence $\lim\limits_{x \to x_0} f(x) = q$ by Definition 5.1.4.

Structural Commentary: The punctured domain splits into its right and left approach sets.
Key Insight: A common one-sided value controls every punctured approach. □

Example 5.3.3. *Basic Discontinuity Types*
Let $D := \mathbf{1}_{\mathbb{Q}}$. Rational and irrational approaches have values 1 and 0, respectively.
Thus D has a second-kind discontinuity throughout $\mathbb{R}$ by Corollary 1.1.20.
Let $h(x) := x$ for $x \in \mathbb{Q}$ and $h(x) := 0$ otherwise. Since $|h(x)| \leq |x|$, the function h is continuous at 0.
At $c \neq 0$, rational and irrational approaches tend to c and 0, so both one-sided limits fail.
A piecewise linear function with unequal finite one-sided values has a jump and hence a first-kind discontinuity.

Figure 146 depicts both values arbitrarily near c, precluding either one-sided limit of $\mathbf{1}_{\mathbb{Q}}$.

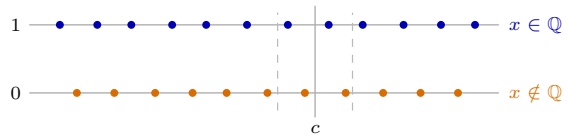

Figure 146: For $g = \mathbf{1}_{\mathbb{Q}}$, rational inputs map to 1 and irrational inputs to 0 in every interval about c.

Definition 5.3.4. *Monotone Functions*
Let $f : (a, b) \to \mathbb{R}$.

(i) f is *monotonically increasing* iff $(\forall x, y \in (a,b))\,[x < y \Rightarrow f(x) \leq f(y)]$.
(ii) f is *monotonically decreasing* iff $(\forall x, y \in (a,b))\,[x < y \Rightarrow f(x) \geq f(y)]$.
(iii) f is *monotone* iff f is monotonically increasing or monotonically decreasing.

Theorem 5.3.5. *One-Sided Limits of Monotone Functions*
Let $f : (a, b) \to \mathbb{R}$.

(i) If f is increasing, then $(\forall x \in (a,b))\, f(x-) = \sup\limits_{a<t<x} f(t) \leq f(x) \leq \inf\limits_{x<t<b} f(t) = f(x+)$.
(ii) If f is increasing, then $(\forall x, y \in (a,b))\,[x < y \Rightarrow f(x+) \leq f(y-)]$.
(iii) If f is decreasing, then $(\forall x \in (a,b))\, f(x-) = \inf\limits_{a<t<x} f(t) \geq f(x) \geq \sup\limits_{x<t<b} f(t) = f(x+)$.
(iv) If f is decreasing, then $(\forall x, y \in (a,b))\,[x < y \Rightarrow f(x+) \geq f(y-)]$.

Proof.
(i) Fix $x \in (a,b)$, $L_x := \{f(t) : a < t < x\}$, $R_x := \{f(t) : x < t < b\}$. Sets are nonempty as $f(\frac{a+x}{2}) \in L_x$ and $f(\frac{x+b}{2}) \in R_x$.
Monotonicity makes $f(x)$ an upper bound of L_x and a lower bound of R_x.

Thus $A := \sup L_x \in \mathbb{R}$ by Theorem 1.1.9, and $B := \inf R_x \in \mathbb{R}$ by Corollary 1.1.15.
For $\varepsilon > 0$, choose $s \in (a, x)$ with $A - \varepsilon < f(s) \le A$. If $s < t < x$, then $A - \varepsilon < f(t) \le A$, so $f(x-) = A$.
Likewise, choose $u \in (x, b)$ with $B \le f(u) < B + \varepsilon$. If $x < t < u$, then $B \le f(t) < B + \varepsilon$, so $f(x+) = B$.
Finally, $A \le f(x) \le B$ by monotonicity. Since x was arbitrary, (i) follows.

(ii) If $a < x < y < b$ and $t := \frac{x+y}{2}$, then $f(x+) \le f(t) \le f(y-)$ by (i).

(iii) Set $h := -f$. Then h is increasing, so its one-sided limits exist by (i).
Since $f = -h$, one has $f(x\pm) = -h(x\pm)$ by Theorem 5.1.7. Identities in (iii) follow by (i) applied to h, Corollary 1.1.15.

(iv) By (ii), $h(x+) \le h(y-)$ whenever $x < y$. By (iii), multiplication by -1 establishes $f(x+) \ge f(y-)$.

Structural Commentary: Suprema and infima identify the increasing limits; reflection transfers both conclusions to decreasing maps.
Key Insight: Order traps each one-sided tail at its extremal value. □

Corollary 5.3.6. *Monotone Functions Have No Second-Kind Discontinuities*
Let $I \subseteq \mathbb{R}$ be an interval and let $f : I \to \mathbb{R}$ be monotone. Every discontinuity at $x \in I^\circ$ is a jump, and hence is not of the second kind.

Proof. Fix discontinuity $x \in I^\circ$, choose $\rho > 0$ with $(x - \rho, x + \rho) \subseteq I$. Both one-sided limits of $f|_{(x-\rho,x+\rho)}$ exist by Theorem 5.3.5.
They equal one-sided limits of f at x by Proposition 5.1.8, common value would equal $f(x)$ by Theorem 5.3.5(i),(iii).
Then $\lim_{t\to x} f(t) = f(x)$ by Proposition 5.3.2. The function f would be continuous at x by Theorem 5.1.12, a contradiction.
Thus the one-sided limits are unequal, and x is a jump by Definition 5.3.1(ii).
Structural Commentary: Local one-sided extrema combine into continuity unless their finite values form a jump.
Key Insight: Monotonicity leaves unequal side limits as the only discontinuity mechanism. □

Theorem 5.3.7. *Monotone Continuity and Interval Images*
Let $f : (a, b) \to \mathbb{R}$ be monotone. Then f is continuous iff $f((a, b))$ is an interval.

Proof. Put $I = (a, b)$.

(⇒) The image $f(I)$ is connected by Theorem 5.1.42. It is therefore an interval by Theorem 5.1.2.

(⇐) Prove contrapositive. Suppose f is discontinuous at $x_0 \in I$. After replacing f by $-f$ if necessary, assume f is increasing.
Reflection preserves discontinuity, interval property of image. Then $f(x_0-) < f(x_0+)$ by Corollary 5.3.6, Theorem 5.3.5(i).
Choose $y \in (f(x_0-), f(x_0+)) \setminus \{f(x_0)\}$. If $x < x_0$, then $f(x) \le f(x_0-) < y$; if $x > x_0$, then $f(x) \ge f(x_0+) > y$; and $f(x_0) \ne y$.
So $y \notin f(I)$ while $f(I)$ has values below and above y. Hence $f(I)$ is not an interval.

Structural Commentary: Monotone discontinuities create image gaps.
Key Insight: Interval images exclude jumps. □

Figure 147 depicts the range gap created by a monotone jump.

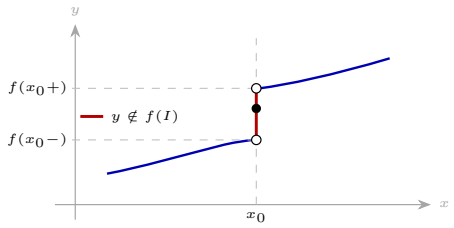

Figure 147: A jump of an increasing function omits $y \in (f(x_0-), f(x_0+))$ from $f(I)$, so the image is not an interval.

Theorem 5.3.8. *Monotone Discontinuities Are Countable*
If f is monotone on (a, b), then the set of points of (a, b) at which f is discontinuous is at most countable.

Proof.

(i) *Jump gaps*: Assume f is increasing, E be its discontinuity set. For $x \in E$, side limits unequal by Corollary 5.3.6.
By Theorem 5.3.5(i), $f(x-) \le f(x+)$, so $f(x-) < f(x+)$.

(ii) *Canonical markers*: Fix a bijection $n \mapsto q_n$ from $\mathbb{N}$ onto $\mathbb{Q}$ by Corollary 6.2.19.
For $x \in E$, the set $J_x := \{n \in \mathbb{N} : f(x-) < q_n < f(x+)\}$ is nonempty by Corollary 1.1.20.
Set $m(x) := \min J_x$ by Assumption 2.6.1, and put $r(x) := q_{m(x)}$.

(iii) *Injection*: If $x_1, x_2 \in E$ and $x_1 < x_2$, then $r(x_1) < f(x_1+) \le f(x_2-) < r(x_2)$ by Theorem 5.3.5(ii).
Thus $r : E \to \mathbb{Q}$ is injective. The set $r(E) \subseteq \mathbb{Q}$ is at most countable by Proposition 6.2.12(i) and Corollary 6.2.19.
The corestriction $r : E \to r(E)$ is bijective, so E is at most countable by Definitions 6.2.1 and 6.2.4.

(iv) *Decreasing case*: If f is decreasing, then $-f$ is increasing, has same discontinuity set. Result follows by increasing case.

Structural Commentary: Each jump contains a rational marker, and monotonicity keeps the markers distinct.
Key Insight: Countability enters by injecting discontinuities into $\mathbb{Q}$. □

Counterexample 5.3.9. *Dense Monotone Discontinuities*
Let $a < b$. The set $\mathbb{Q} \cap (a, b)$ is at most countable by Proposition 6.2.12(i) and Corollary 6.2.19.
It is infinite by Corollary 1.1.20, and hence countably infinite by Definition 6.2.4. Fix a bijection $n \mapsto q_n$ from $\mathbb{N}$ onto $\mathbb{Q} \cap (a, b)$.

For $N \in \mathbb{N}$, define $F_N : (a, b) \to \mathbb{R}$ by $F_N(x) := \sum_{n=1}^{N} 2^{-n} \mathbf{1}_{(-\infty,x)}(q_n)$. Define $F : (a, b) \to \mathbb{R}$ by $F(x) := \sup_{N\in\mathbb{N}} F_N(x)$.

The identity $\sum_{n=1}^{N} 2^{-n} = 1 - 2^{-N}$ makes $\{F_N(x) : N \in \mathbb{N}\}$ nonempty and bounded above, so $F(x) \in \mathbb{R}$ by Theorem 1.1.9.

If $x < y$, then $(\forall N \in \mathbb{N})\, F_N(x) \le F_N(y)$, so $F(x) \le F(y)$. Thus F is increasing. For $M > N$, $0 \le F_M(x) - F_N(x) \le \sum_{n=N+1}^{M} 2^{-n} < 2^{-N}$.

Taking the supremum over M proves $0 \le F(x) - F_N(x) \le 2^{-N}$. Fix $x \notin \mathbb{Q}$ and $\varepsilon > 0$. Choose N with $2^{1-N} < \varepsilon$ by Theorem 2.2.10(v).
Choose $\delta > 0$ such that $(x - \delta, x + \delta) \cap \{q_1, \ldots, q_N\} = \emptyset$. If $|y - x| < \delta$, then $F_N(y) = F_N(x)$, so $|F(y) - F(x)| \le 2^{1-N} < \varepsilon$.

Hence F continuous at x. Fix $k \in \mathbb{N}$, $\varepsilon > 0$. Choose $N \geq k$ with $2^{1-N} < \varepsilon$. Choose $\delta > 0$ such that $(q_k - \delta, q_k + \delta) \cap \{q_1, \ldots, q_N\} = \{q_k\}$.
If $q_k - \delta < y < q_k$, then $F_N(y) = F_N(q_k)$; if $q_k < y < q_k + \delta$, then $F_N(y) = F_N(q_k) + 2^{-k}$.
The tail bound therefore proves $F(q_k-) = F(q_k)$ and $F(q_k+) = F(q_k) + 2^{-k}$.
Thus the discontinuity set of F is $\mathbb{Q} \cap (a, b)$, which is dense by Corollary 1.1.20. This countable set has no isolated points.

Definition 5.3.10. *Extended Limits and Limits at Infinity*
On $\overline{\mathbb{R}}$ from Definition 1.1.21, retain the usual neighborhoods at finite points.
For $c \in \mathbb{R}$, take $(c, +\infty]$ and $[-\infty, c)$ as basic neighborhoods of $+\infty$ and $-\infty$, respectively.
Let $E \subseteq \mathbb{R}$, let $f : E \to \mathbb{R}$, let $x \in \overline{\mathbb{R}}$ be a limit point of E, and let $A \in \overline{\mathbb{R}}$.
The notation $f(t) \to A$ as $t \to x$ means $(\forall U \ni A)(\exists V \ni x)(\forall t \in (V \cap E) \setminus \{x\})\, f(t) \in U$.
Here U and V range over neighborhoods in $\overline{\mathbb{R}}$. If $A, x \in \mathbb{R}$, this agrees with Definition 5.1.4.
Key Insight: The same neighborhood test permits $\pm\infty$ as input or output limits.

Figure 148 depicts the opposite extended side limits of x^{-3} at 0.

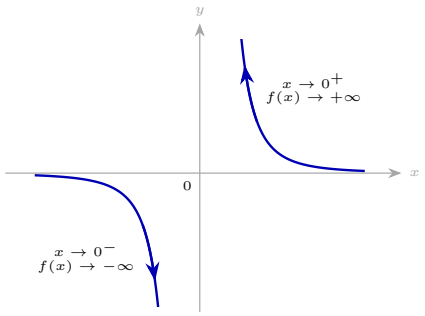

Figure 148: Qualitative dimensionless plot: a positive vertical rescaling of $y = x^{-3}$ tends to $-\infty$ as $x \to 0^-$ and to $+\infty$ as $x \to 0^+$.

Theorem 5.3.11. *Algebra of Extended Limits*
Let $E \subseteq \mathbb{R}$, let $x \in \overline{\mathbb{R}}$ be a limit point of E, and let $f, g : E \to \mathbb{R}$ satisfy $f(t) \to A$ and $g(t) \to B$ as $t \to x$, where $A, B \in \overline{\mathbb{R}}$.

(i) if $A' \in \overline{\mathbb{R}}$ and $f(t) \to A'$ as $t \to x$, then $A' = A$;
(ii) if $A + B$ is defined by ordinary real arithmetic or Definition 1.1.22, then $(f + g)(t) \to A + B$;
(iii) if AB is defined by ordinary real arithmetic or Definition 1.1.22, then $(fg)(t) \to AB$;
(iv) if $A, B \in \mathbb{R}$ and $B \neq 0$, then $\frac{f(t)}{g(t)} \to \frac{A}{B}$ on the domain where $g(t) \neq 0$.

Theorem makes no claim for $(+\infty) + (-\infty)$, $0(\pm\infty)$, product of two infinite factors, zero denominator, or quotient involving $\pm\infty$.

Proof. For $C := A \star B$, define $\mathcal{P}_\star(A, B, C) := (\forall W \ni C)(\exists U \ni A)(\exists V \ni B)\, (U \cap \mathbb{R}) \star (V \cap \mathbb{R}) \subseteq W$.
If $A, B \in \mathbb{R}$, the addition property follows from $|(u + v) - (A + B)| \leq |u - A| + |v - B|$.
The product property follows from $|uv - AB| \leq |u|\,|v - B| + |B|\,|u - A|$ by taking u near A and v near B.
For $B \neq 0$, restrict to $|v| \geq \frac{|B|}{2}$ and use $\left|\frac{u}{v} - \frac{A}{B}\right| \leq \frac{|u-A|}{|v|} + \frac{|A||v-B|}{|v||B|}$. Thus the quotient property holds with $0 \notin V$.
If $A + B = +\infty$ and $W \ni +\infty$, choose $c \in \mathbb{R}$ with $(c, +\infty] \subseteq W$. Choose $\alpha < A$ and $\beta < B$ in $\mathbb{R}$ with $\alpha + \beta > c$.
For $U = (\alpha, +\infty]$ and $V = (\beta, +\infty]$, one has $(U \cap \mathbb{R}) + (V \cap \mathbb{R}) \subseteq (c, +\infty] \subseteq W$. The case $A + B = -\infty$ is symmetric.
If $AB = \pm\infty$, exactly one factor is infinite and the other is finite and nonzero by Definition 1.1.22.
Let d be the finite factor, and restrict its neighboring values v by $vd > 0$ and $|v| \geq \frac{|d|}{2}$.
For a target tail with threshold c, restrict the infinite factor to the required sign and $|u| > \frac{2(|c|+1)}{|d|}$; then uv lies in that tail.
Thus $\mathcal{P}_\star(A, B, C)$ holds in (ii)–(iv).

(i) If $A' \neq A$, choose disjoint neighborhoods U of A and U' of A'.
By $f(t) \to A$, choose a neighborhood P of x with $f((P \cap E) \setminus \{x\}) \subseteq U$.
By $f(t) \to A'$, choose a neighborhood P' of x with $f((P' \cap E) \setminus \{x\}) \subseteq U'$.
Since x is a limit point of E, $(P \cap P' \cap E) \setminus \{x\} \neq \emptyset$, contradicting $U \cap U' = \emptyset$.
(ii) Let W be a neighborhood of $A + B$, and choose U, V by $\mathcal{P}_+(A, B, A + B)$.
By $f(t) \to A$, choose a neighborhood P of x with $f((P \cap E) \setminus \{x\}) \subseteq U$.
By $g(t) \to B$, choose a neighborhood Q of x with $g((Q \cap E) \setminus \{x\}) \subseteq V$. Then $(f + g)(t) \in W$ on $(P \cap Q \cap E) \setminus \{x\}$.
(iii) Let W be a neighborhood of AB, and choose U, V by $\mathcal{P}.(A, B, AB)$.
Intersecting the corresponding approach neighborhoods produces a punctured neighborhood on which $(fg)(t) \in W$.
(iv) Let W be a neighborhood of $\frac{A}{B}$, and choose U, V by $\mathcal{P}_{\text{div}}(A, B, \frac{A}{B})$, with $0 \notin V$.
Intersecting the corresponding approach neighborhoods produces a punctured neighborhood on which $g(t) \neq 0$ and $\frac{f(t)}{g(t)} \in W$.

Structural Commentary: Operation-compatible neighborhoods transfer two input tails, while disjoint neighborhoods force uniqueness.
Key Insight: Finite sign separation controls every defined infinite product and excludes the indeterminate cases. □

6 General Topology for Analysis

6.1 Topological Spaces, Bases, and Separation

General topology retains the open-set structure underlying metric limits and continuity.
The basic objects here are topological spaces, bases, subspaces, closure operations, and separation axioms.

Definition 6.1.1. *Topological Space*
A *topology* on a set X is a collection $\mathcal{T} \subseteq 2^X$ such that:

(i) $\emptyset, X \in \mathcal{T}$;
(ii) if $\{\mathcal{O}_\alpha\}_{\alpha \in A} \subseteq \mathcal{T}$, then $\bigcup_{\alpha \in A} \mathcal{O}_\alpha \in \mathcal{T}$;

(iii) if $\mathcal{O}_1, \dots, \mathcal{O}_n \in \mathcal{T}$ with $n \geq 1$, then $\bigcap_{j=1}^{n} \mathcal{O}_j \in \mathcal{T}$.

Then $(X, \mathcal{T})$ is a *topological space*.

Definition 6.1.2. *Open, Closed, and Neighborhoods*
Let $(X, \mathcal{T})$ be a topological space.

(i) A set $U \subseteq X$ is *open* iff $U \in \mathcal{T}$.
(ii) A set $F \subseteq X$ is *closed* iff $X \setminus F \in \mathcal{T}$.
(iii) For $x \in X$, a *neighborhood* of x is an open set $U \subseteq X$ with $x \in U$.
(iv) For $A \subseteq X$, a *neighborhood* of A is an open set $U \subseteq X$ with $A \subseteq U$.

Proposition 6.1.3. *Open Sets by Neighborhoods*
Let $(X, \mathcal{T})$ be a topological space and let $E \subseteq X$. Then $E \in \mathcal{T}$ iff $(\forall x \in E)(\exists U \in \mathcal{T})\,[x \in U \subseteq E]$.

Proof.
($\Rightarrow$) If $E \in \mathcal{T}$, take $U = E$ for $x \in E$.
($\Leftarrow$) Set $\mathcal{U}_E := \{U \in \mathcal{T} : U \subseteq E\}$. The hypothesis implies $E = \bigcup \mathcal{U}_E$, so $E \in \mathcal{T}$ by Definition 6.1.1(ii).
Structural Commentary: The union axiom assembles pointwise open witnesses into the entire set.
Key Insight: Local open containment is equivalent to global openness. □

Proposition 6.1.4. *Metric Open Sets Form a Topology*
Let (X, d) be a metric space, τ_d be collection of metric-open sets from Definition 3.1.2. Then τ_d is a topology on X.

Proof. $\emptyset, X \in \tau_d$ by Definition 3.1.2. Collection τ_d is closed under arbitrary unions and finite intersections by Theorem 3.1.19(i),(iii). Hence τ_d is a topology by Definition 6.1.1.
Structural Commentary: Metric union and finite-intersection calculus verifies the three topology axioms.
Key Insight: General topology keeps the open-set calculus and forgets the distance function. □

Example 6.1.5. *Discrete and Trivial Topologies*
On a nonempty set X, the *discrete topology* is 2^X, so every subset is open and closed.
It is induced by the discrete metric. The *trivial topology* is $\{\emptyset, X\}$, so the only neighborhood of any point is X.

Definition 6.1.6. *Closure, Interior, and Boundary*
Let $(X, \mathcal{T})$ be a topological space and let $E \subseteq X$.

(i) The *closure* is $\overline{E} := \{x \in X : (\forall U \in \mathcal{T})\,[x \in U \Rightarrow U \cap E \neq \emptyset]\}$.
(ii) The *interior* is $\operatorname{int}(E) := \bigcup \{U \in \mathcal{T} : U \subseteq E\}$.
(iii) The *exterior* is $\operatorname{ext}(E) := \operatorname{int}(X \setminus E)$.
(iv) The *boundary* of E is $\operatorname{bd}(E) := \overline{E} \setminus \operatorname{int}(E)$.

Proposition 6.1.7. *Closure, Interior, and Boundary Tests*
Let $(X, \mathcal{T})$ be a topological space and let $E \subseteq X$.

(i) $\operatorname{int}(E)$ *is the largest open subset of* E.
(ii) E *is open iff* $E = \operatorname{int}(E)$.
(iii) $\overline{E}$ *is the smallest closed subset of* X *containing* E.
(iv) E *is closed iff* $E = \overline{E}$.
(v) For $x \in X$, $x \in \operatorname{bd}(E)$ *iff* $(\forall U \in \mathcal{T})\,[x \in U \Rightarrow U \cap E \neq \emptyset \wedge U \cap (X \setminus E) \neq \emptyset]$.
(vi) $\operatorname{bd}(E) = \overline{E} \cap \overline{X \setminus E}$.
(vii) $\operatorname{bd}(E)$ *is closed.*

Proof.
(i) The set $\operatorname{int}(E) = \bigcup \{U \in \mathcal{T} : U \subseteq E\}$ is open by Definition 6.1.1(ii).
It contains every open subset of E and is contained in E, so it is the largest open subset of E.
(ii) ($\Rightarrow$) If E is open, then $E \subseteq \operatorname{int}(E) \subseteq E$, so $E = \operatorname{int}(E)$.
(ii) ($\Leftarrow$) If $E = \operatorname{int}(E)$, then E is open by (i).
(iii) Every $x \in E$ belongs to $\overline{E}$ by Definition 6.1.6(i). If $x \notin \overline{E}$, choose neighborhood U of x with $U \cap E = \emptyset$ by same definition.
Then $U \subseteq X \setminus \overline{E}$. Thus $X \setminus \overline{E}$ open by Proposition 6.1.3, so $\overline{E}$ closed.
If F is closed and $E \subseteq F$, then $X \setminus F$ is an open neighborhood of each $x \notin F$ and is disjoint from E.
Hence $\overline{E} \subseteq F$, proving the smallest-closed-superset claim.
(iv) ($\Rightarrow$) If E is closed, then $\overline{E} \subseteq E$ by (iii), while $E \subseteq \overline{E}$. Hence $E = \overline{E}$.
(iv) ($\Leftarrow$) If $E = \overline{E}$, then E is closed by (iii).
(v) ($\Rightarrow$) If $x \in \operatorname{bd}(E)$, then $x \in \overline{E} \setminus \operatorname{int}(E)$ by Definition 6.1.6(iv). Thus every neighborhood of x meets E by Definition 6.1.6(i).
No neighborhood of x lies in E, so each neighborhood also meets $X \setminus E$.
(v) ($\Leftarrow$) If every neighborhood of x meets both E and $X \setminus E$, then $x \in \overline{E}$ and $x \notin \operatorname{int}(E)$. Hence $x \in \operatorname{bd}(E)$ by Definition 6.1.6(iv).
(vi) By (v), $x \in \operatorname{bd}(E)$ iff $x \in \overline{E} \cap \overline{X \setminus E}$. Thus $\operatorname{bd}(E) = \overline{E} \cap \overline{X \setminus E}$.
(vii) Both factors in (vi) are closed by (iii), intersection is closed because its complement is the union of their open complements.
Structural Commentary: Open complements make closure minimal; two-sided neighborhood contact identifies the boundary.
Key Insight: Boundary points persist under approaches from both E and its complement. □

Definition 6.1.8. *Bases and Subbases*
Let X be a set.

(i) Let $\mathcal{T}$ be a topology on X, let $x \in X$, and let $\mathcal{B}_x$ be a collection of neighborhoods of x.
Then $\mathcal{B}_x$ is a *neighborhood basis at* x iff $(\forall U \in \mathcal{T})\,[x \in U \Rightarrow (\exists B \in \mathcal{B}_x)\, B \subseteq U]$.
(ii) A collection $\mathcal{B} \subseteq 2^X$ is a *basis* for a topology on X iff:
  (a) $X = \bigcup_{B \in \mathcal{B}} B$;
  (b) $(\forall B_1, B_2 \in \mathcal{B})(\forall x \in B_1 \cap B_2)(\exists B_3 \in \mathcal{B})\, x \in B_3 \subseteq B_1 \cap B_2$.

(iii) If $\mathcal{B}$ is a basis on X, the collection generated by $\mathcal{B}$ is $\mathcal{T}_{\mathcal{B}} := \{\bigcup_{B\in\mathcal{U}} B : \mathcal{U} \subseteq \mathcal{B}\}$.

(iv) For $\mathcal{S} \subseteq 2^X$, set $\mathcal{B}_{\mathcal{S}} := \{\bigcap_{j=1}^{n} S_j : n \in \mathbb{N},\ S_1, \dots, S_n \in \mathcal{S}\}$. The collection $\mathcal{S}$ is a *subbasis* on X iff $\bigcup \mathcal{S} = X$ and $\mathcal{B}_{\mathcal{S}}$ is a basis on X.

Key Insight: Bases generate open sets by unions; subbases generate bases by finite intersections.

Proposition 6.1.9. *Basis Characterization*
Let X be a set and let $\mathcal{B} \subseteq 2^X$.
(i) If $\mathcal{B}$ is a basis on X, then $\mathcal{T}_{\mathcal{B}} := \{\bigcup \mathcal{U} : \mathcal{U} \subseteq \mathcal{B}\}$ is a topology on X.
(ii) Let $\mathcal{T}$ be a topology on X with $\mathcal{B} \subseteq \mathcal{T}$ and $(\forall U \in \mathcal{T} \setminus \{\emptyset\})(\exists \mathcal{U} \subseteq \mathcal{B})\, U = \bigcup \mathcal{U}$. Then $\mathcal{B}$ is a basis on X.
(iii) Under the hypotheses of (ii), $\mathcal{T} = \mathcal{T}_{\mathcal{B}}$.

Proof.
(i) Set $O_{\mathcal{U}} := \bigcup \mathcal{U}$ for $\mathcal{U} \subseteq \mathcal{B}$. Then $X = O_{\mathcal{B}}$, $\emptyset = O_{\emptyset}$, and $\bigcup_{\alpha} O_{\mathcal{U}_\alpha} = O_{\bigcup_\alpha \mathcal{U}_\alpha}$.
If $x \in O_{\mathcal{U}} \cap O_{\mathcal{V}}$, choose $B_1 \in \mathcal{U}$ and $B_2 \in \mathcal{V}$ with $x \in B_1 \cap B_2$.
Choose $B_3 \in \mathcal{B}$ with $x \in B_3 \subseteq B_1 \cap B_2$ by the basis refinement property. Hence $O_{\mathcal{U}} \cap O_{\mathcal{V}} = \bigcup\{B \in \mathcal{B} : B \subseteq O_{\mathcal{U}} \cap O_{\mathcal{V}}\}$.
Closure under finite intersections follows from this binary identity by Theorem 2.6.2. Thus $\mathcal{T}_{\mathcal{B}}$ is a topology.
(ii) If $X \neq \emptyset$, the hypothesis for $U = X$ supplies $\mathcal{U} \subseteq \mathcal{B}$ with $X = \bigcup \mathcal{U}$. If $X = \emptyset$, then $\bigcup \mathcal{B} = X$.
If $B_1, B_2 \in \mathcal{B}$ and $x \in B_1 \cap B_2$, then $B_1 \cap B_2 \in \mathcal{T} \setminus \{\emptyset\}$. Choose $\mathcal{V} \subseteq \mathcal{B}$ with $B_1 \cap B_2 = \bigcup \mathcal{V}$ by the hypothesis.
Then choose $B_3 \in \mathcal{V}$ with $x \in B_3 \subseteq B_1 \cap B_2$. Hence $\mathcal{B}$ is a basis on X by Definition 6.1.8(ii).
(iii) The inclusion $\mathcal{T}_{\mathcal{B}} \subseteq \mathcal{T}$ follows by $\mathcal{B} \subseteq \mathcal{T}$ and closure under arbitrary unions.
Every nonempty $U \in \mathcal{T}$ belongs to $\mathcal{T}_{\mathcal{B}}$ by the hypothesis. Since $\emptyset = \bigcup \emptyset \in \mathcal{T}_{\mathcal{B}}$, one has $\mathcal{T} \subseteq \mathcal{T}_{\mathcal{B}}$ and therefore $\mathcal{T} = \mathcal{T}_{\mathcal{B}}$.

Structural Commentary: Basis refinements rewrite binary intersections as basis unions; topology axioms complete the generation.
Key Insight: Refinement is precisely the intersection mechanism missing from arbitrary unions. □

Example 6.1.10. *Metric Balls as a Basis*
In metric space (X, d), every point x lies in $B_1(x)$. If $z \in B_r(x) \cap B_s(y)$, $B_\varepsilon(z) \subseteq B_r(x) \cap B_s(y)$ for $\varepsilon := \min\{r - d(x,z), s - d(y,z)\} > 0$. Hence $\{B_r(x) : x \in X,\ r > 0\}$ is a basis. The family $\{B_r(q) : q \in \mathbb{Q}^k,\ r \in \mathbb{Q}_{>0}\}$ is countable by Theorem 6.2.18 and Corollary 6.2.19. Coordinatewise rational density and the triangle inequality make this family a basis on $\mathbb{R}^k$ by Theorem 1.1.19(ii).
If $a < b$, then $\{[a, c) : a < c < b\} \cup \{(c, b] : a < c < b\}$ is a subbasis for the usual topology on $[a, b]$.

Definition 6.1.11. *Subspace Topology*
Let $(X, \mathcal{T})$ be topological space, $E \subseteq X$. The *subspace topology* on E is $\mathcal{T}_E := \{E \cap U : U \in \mathcal{T}\}$, and $(E, \mathcal{T}_E)$ is a *subspace* of X.

Proposition 6.1.12. *The Subspace Collection Is a Topology*
Let $(X, \mathcal{T})$ be a topological space and let $E \subseteq X$. Then $\mathcal{T}_E$ from Definition 6.1.11 is a topology on E.

Proof. The identities $\emptyset = E \cap \emptyset$ and $E = E \cap X$ put $\emptyset, E$ in $\mathcal{T}_E$. For $(U_\alpha)_{\alpha\in A} \subseteq \mathcal{T}$, $\bigcup_{\alpha\in A} (E \cap U_\alpha) = E \cap \bigcup_{\alpha\in A} U_\alpha \in \mathcal{T}_E$.
For $U_1, \dots, U_n \in \mathcal{T}$ with $n \geq 1$, $\bigcap_{j=1}^{n} (E \cap U_j) = E \cap \bigcap_{j=1}^{n} U_j \in \mathcal{T}_E$. Thus $\mathcal{T}_E$ is a topology on E by Definition 6.1.1.

Structural Commentary: Intersecting ambient opens with E preserves the topology axioms.
Key Insight: Unions and finite intersections commute with restriction to E. □

Definition 6.1.13. *Separation Properties*
Let $(X, \mathcal{T})$ be a topological space.
Disjoint sets $A, B \subseteq X$ are *separated by disjoint neighborhoods* iff $(\exists U, V \in \mathcal{T})\,[A \subseteq U \wedge B \subseteq V \wedge U \cap V = \emptyset]$. Space X is:
(i) T_1 iff $(\forall x \in X)\,\{x\}$ is closed;
(ii) *Hausdorff* iff $\{x\}$ and $\{y\}$ are separated by disjoint neighborhoods whenever $x, y \in X$ and $x \neq y$;
(iii) *regular* iff X is T_1 and $\{x\}, F$ can be separated by disjoint neighborhoods when $F \subseteq X$ is closed and $x \in X \setminus F$;
(iv) *normal* iff X is T_1 and any disjoint closed $F, G \subseteq X$ can be separated by disjoint neighborhoods.

Key Insight: Successive axioms separate distinct points, point–closed-set pairs, and closed-set pairs.

Proposition 6.1.14. *T_1 Spaces and Closed Points*
Let $(X, \mathcal{T})$ be a topological space. Then X is T_1 iff $(\forall x, y \in X)\,[x \neq y \Rightarrow (\exists U \in \mathcal{T})\,[x \in U \wedge y \notin U]]$.

Proof.
($\Rightarrow$) Assume X is T_1, and fix $x, y \in X$ with $x \neq y$. Then $\{y\}$ is closed, so $U = X \setminus \{y\} \in \mathcal{T}$ satisfies $x \in U$ and $y \notin U$.
($\Leftarrow$) Assume the stated condition. Fix $y \in X$ and set $\mathcal{U}_y := \{U \in \mathcal{T} : y \notin U\}$.
Every $x \in X \setminus \{y\}$ belongs to a member of $\mathcal{U}_y$ by the condition, while no member contains y.
Hence $X \setminus \{y\} = \bigcup \mathcal{U}_y \in \mathcal{T}$ by Definition 6.1.1(ii), so $\{y\}$ is closed. Thus X is T_1 by Definition 6.1.13(i).

Structural Commentary: Point exclusion makes singleton complements open.
Key Insight: T_1 means each point can be omitted near every other point. □

Proposition 6.1.15. *Metric Spaces Are Normal*
Let (X, d) be a metric space with metric topology τ_d.
(i) $(\forall x \in X)\,\{x\}$ is closed.
(ii) If $F_1, F_2 \subseteq X$ are closed and $F_1 \cap F_2 = \emptyset$, then $(\exists O_1, O_2 \in \tau_d)\,[F_1 \subseteq O_1 \wedge F_2 \subseteq O_2 \wedge O_1 \cap O_2 = \emptyset]$.
(iii) X is normal.

Proof.
(i) Fix $x \in X$. For $y \in X \setminus \{x\}$, $B_{\frac{d(x,y)}{2}}(y) \subseteq X \setminus \{x\}$. Thus $X \setminus \{x\}$ is open and $\{x\}$ is closed.
(ii)
(a) *Empty cases*: If $F_1 = \emptyset$, take $(O_1, O_2) = (\emptyset, X)$. If $F_1 \neq \emptyset$, $F_2 = \emptyset$, take $(O_1, O_2) = (X, \emptyset)$. Hence assume $F_1, F_2 \neq \emptyset$.

(b) *Distance construction*: For $i = 1, 2$, set $d_i(x) := \operatorname{dist}(x, F_i)$ and $O_i := \{x \in X : d_i(x) < d_{3-i}(x)\}$.
The complement of F_i lies in τ_d by Definition 6.1.2(ii). It is therefore metric-open by Definition 3.1.2(iii).
Thus F_i is metric-closed by Corollary 3.1.17. The map d_i is continuous by Proposition 5.1.22(ii).
Its zero set satisfies $d_i^{-1}(\{0\}) = \overline{F_i} = F_i$ by Proposition 5.1.22(iii) and Theorem 3.1.22(ii).
(c) *Open containment*: The map $d_i - d_{3-i}$ is continuous by Theorem 5.1.32(i).
Hence O_i is open by Theorem 5.1.18. If $x \in F_i$, then $d_i(x) = 0 < d_{3-i}(x)$ because $x \notin F_{3-i} = d_{3-i}^{-1}(\{0\})$. Thus $F_i \subseteq O_i$.
(d) *Disjointness*: The intersection $O_1 \cap O_2$ is empty because $d_1(x) < d_2(x)$ and $d_2(x) < d_1(x)$ cannot both hold.

(iii) The space X is normal by (i), (ii), and Definition 6.1.13(iv).

Structural Commentary: Distance zero sets and strict distance comparisons construct the required disjoint open neighborhoods.
Key Insight: No point can be closer to each closed set than to the other. □

Proposition 6.1.16. *Normality by Nested Neighborhoods*
Let X be a T_1 topological space. Then X is normal iff each closed–open inclusion $F \subseteq U$ admits an open O with $F \subseteq O \subseteq \overline{O} \subseteq U$.

Proof.

(⇒) Assume X is normal. Let $F \subseteq X$ be closed and let $U \subseteq X$ be open with $F \subseteq U$.
Choose disjoint open sets O, V with $F \subseteq O$ and $X \setminus U \subseteq V$ by Definition 6.1.13(iv).
Then $O \subseteq X \setminus V \subseteq U$. Since $X \setminus V$ is closed, $\overline{O} \subseteq X \setminus V \subseteq U$ by Proposition 6.1.7(iii).
(⇐) Assume the nested-neighborhood property. Let $A, B \subseteq X$ be closed with $A \cap B = \emptyset$.
By the property with $F = A$ and $U = X \setminus B$, choose open O with $A \subseteq O \subseteq \overline{O} \subseteq X \setminus B$.
The set $\overline{O}$ is closed by Proposition 6.1.7(iii). Hence O and $X \setminus \overline{O}$ are disjoint open neighborhoods of A and B, respectively.
Since X is T_1, X is normal by Definition 6.1.13(iv).

Structural Commentary: Disjoint neighborhoods place $\overline{O}$ inside U; taking its complement reverses the construction.
Key Insight: Separating F from $X \setminus U$ is equivalent to closing O within U. □

Figure 149 depicts the nested-neighborhood criterion inside X.

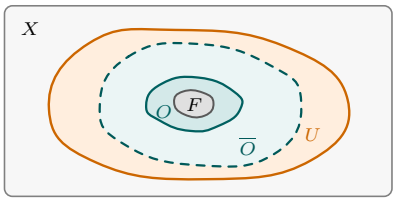

Figure 149: Normality thickens closed $F \subseteq U$ to an open O with $F \subseteq O \subseteq \overline{O} \subseteq U$.

6.2 Continuity and Topological Constructions

Inverse images organize topological constructions; homeomorphisms preserve open-set structure.
Products, quotients, and weak topologies are characterized by the maps they make continuous.

Definition 6.2.1. *Continuity Between Topological Spaces*
Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be topological spaces, and let $f : X \to Y$.
For $x \in X$, set $\mathcal{N}_X(x) := \{U \in \mathcal{T}_X : x \in U\}$. For $y \in Y$, set $\mathcal{N}_Y(y) := \{O \in \mathcal{T}_Y : y \in O\}$.

(i) For $x_0 \in X$, f is *continuous at x_0* iff $(\forall O \in \mathcal{N}_Y(f(x_0)))(\exists U \in \mathcal{N}_X(x_0))\, f(U) \subseteq O$.
(ii) f is *continuous* iff $(\forall x \in X)$, f is continuous at x.

Proposition 6.2.2. *Continuity by Open Preimages*
Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be topological spaces, and let $f : X \to Y$.

(i) f is continuous iff $(\forall O \in \mathcal{T}_Y)\, f^{-1}(O) \in \mathcal{T}_X$.
(ii) Let $A \subseteq X$ carry the subspace topology $\mathcal{T}_A$. If f is continuous, then $f|_A : (A, \mathcal{T}_A) \to (Y, \mathcal{T}_Y)$ is continuous.
(iii) Let $(Z, \mathcal{T}_Z)$ be topological space, $g : (Y, \mathcal{T}_Y) \to (Z, \mathcal{T}_Z)$ continuous. If f continuous, then $g \circ f : (X, \mathcal{T}_X) \to (Z, \mathcal{T}_Z)$ continuous.

Proof.

(i) (⇒) For $O \in \mathcal{T}_Y$ and $x \in f^{-1}(O)$, choose $U \in \mathcal{N}_X(x)$ with $f(U) \subseteq O$ by continuity at x.
The relations $x \in U \subseteq f^{-1}(O)$ imply $f^{-1}(O) \in \mathcal{T}_X$ by Proposition 6.1.3.
(i) (⇐) Assume $(\forall O \in \mathcal{T}_Y)\, f^{-1}(O) \in \mathcal{T}_X$. For $x_0 \in X$ and $O \in \mathcal{N}_Y(f(x_0))$, set $U := f^{-1}(O)$.
Then $U \in \mathcal{N}_X(x_0)$ and $f(U) \subseteq O$, so f is continuous at x_0 by Definition 6.2.1(i). Thus f is continuous by Definition 6.2.1(ii).
(ii) For $O \in \mathcal{T}_Y$, $f^{-1}(O) \in \mathcal{T}_X$ by (i), $(f|_A)^{-1}(O) = A \cap f^{-1}(O) \in \mathcal{T}_A$ by definition of $\mathcal{T}_A$; $f|_A$ is continuous by (i).
(iii) For $W \in \mathcal{T}_Z$, $g^{-1}(W) \in \mathcal{T}_Y$ by (i), $(g \circ f)^{-1}(W) = f^{-1}(g^{-1}(W)) \in \mathcal{T}_X$ by (i) for f; $g \circ f$ continuous by (i).

Structural Commentary: Neighborhood witnesses build opens; intersection and nesting preserve them.
Key Insight: Continuity is exactly preservation of openness under inverse images. □

Corollary 6.2.3. *Metric and Topological Continuity Agree*
Let $(X, d_X), (Y, d_Y)$ be metric spaces with metric topologies τ_X, τ_Y, and let $f : X \to Y$.
Then f is metrically continuous iff $f : (X, \tau_X) \to (Y, \tau_Y)$ is topologically continuous.

Proof.

(⇒) If f is metrically continuous, then $(\forall O \in \tau_Y)\, f^{-1}(O) \in \tau_X$ by Theorem 5.1.18.
Hence $f : (X, \tau_X) \to (Y, \tau_Y)$ is continuous by Proposition 6.2.2(i).
(⇐) Assume $f : (X, \tau_X) \to (Y, \tau_Y)$ is continuous. Then $(\forall O \in \tau_Y)\, f^{-1}(O) \in \tau_X$ by Proposition 6.2.2(i).
Hence f is metrically continuous by Theorem 5.1.18.

Structural Commentary: The common open-preimage condition identifies the two notions.
Key Insight: Their open-preimage conditions coincide. □

Proposition 6.2.4. *Continuity Tested on a Subbasis*
Let $(X, \mathcal{T}_X)$ be topological space, $\mathcal{S}$ be a subbasis generating $\mathcal{T}_Y$ on Y. For $f : X \to Y$, f is continuous iff $(\forall S \in \mathcal{S})\, f^{-1}(S) \in \mathcal{T}_X$.

Proof.
(⇒) For $S \in \mathcal{S} \subseteq \mathcal{T}_Y$, $f^{-1}(S) \in \mathcal{T}_X$ by Proposition 6.2.2(i).
(⇐) Assume $(\forall S \in \mathcal{S})\, f^{-1}(S) \in \mathcal{T}_X$, and let $\mathcal{B}_{\mathcal{S}}$ be the basis of finite intersections from $\mathcal{S}$.
For $B \in \mathcal{B}_{\mathcal{S}}$, choose $n \in \mathbb{N}$ and $S_1, \ldots, S_n \in \mathcal{S}$ with $B = \bigcap_{j=1}^{n} S_j$ by Definition 6.1.8(iv).
Then $f^{-1}(B) = \bigcap_{j=1}^{n} f^{-1}(S_j) \in \mathcal{T}_X$ by the hypothesis and Definition 6.1.1(iii).
For $O \in \mathcal{T}_Y$, choose $\mathcal{U} \subseteq \mathcal{B}_{\mathcal{S}}$ with $O = \bigcup \mathcal{U}$ by Definition 6.1.8(iii),(iv).
Then $f^{-1}(O) = \bigcup_{B \in \mathcal{U}} f^{-1}(B) \in \mathcal{T}_X$ by Definition 6.1.1(ii). Hence f is continuous by Proposition 6.2.2(i).
Structural Commentary: Finite intersections reach the basis; unions reach the topology.
Key Insight: Inverse images preserve both topology-generating operations. □

Definition 6.2.5. *Homeomorphism*
Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be topological spaces.
(i) A bijection $f : X \to Y$ is a *homeomorphism* iff f and f^{-1} are continuous.
(ii) The spaces X and Y are *homeomorphic*, written $X \simeq Y$, iff a homeomorphism $f : X \to Y$ exists.

Proposition 6.2.6. *Homeomorphic Spaces Have the Same Open-Set Structure*
Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be topological spaces, let $f : X \to Y$ be a homeomorphism, and let $E \subseteq X$.
(i) $E \in \mathcal{T}_X$ iff $f(E) \in \mathcal{T}_Y$.
(ii) E is closed in X iff $f(E)$ is closed in Y.

Proof. The map f is bijective, and f, f^{-1} are continuous by Definition 6.2.5(i).
(i) (⇒) If $E \in \mathcal{T}_X$, then $f(E) = (f^{-1})^{-1}(E) \in \mathcal{T}_Y$ by Proposition 6.2.2(i) for f^{-1}.
(i) (⇐) If $f(E) \in \mathcal{T}_Y$, then $E = f^{-1}(f(E))$ by bijectivity. Hence $E \in \mathcal{T}_X$ by Proposition 6.2.2(i) for f.
(ii) (⇒) If E is closed in X, then $f(X \setminus E) \in \mathcal{T}_Y$ by (i).
The identity $f(X \setminus E) = Y \setminus f(E)$ holds by bijectivity, so $f(E)$ is closed in Y by Definition 6.1.2(ii).
(ii) (⇐) If $f(E)$ is closed in Y, then $Y \setminus f(E) \in \mathcal{T}_Y$ by Definition 6.1.2(ii). Thus $X \setminus E = f^{-1}(Y \setminus f(E)) \in \mathcal{T}_X$ by Proposition 6.2.2(i).
Hence E is closed in X by Definition 6.1.2(ii).
Structural Commentary: Continuity of f, f^{-1} transfers opens; bijectivity transfers complements.
Key Insight: A homeomorphism preserves and reflects the topology. □

Definition 6.2.7. *Product Topology*
Let $(X, \mathcal{T}_X), (Y, \mathcal{T}_Y)$ and $(X_i, \mathcal{T}_i)$, $i \in I$, be topological spaces.
(i) Set $\mathcal{B}_{X\times Y} := \{U \times V : U \in \mathcal{T}_X,\ V \in \mathcal{T}_Y\}$. The *product topology* on $X \times Y$ is generated by $\mathcal{B}_{X\times Y}$.
(ii) Set $\mathcal{B}_{\Pi} := \{\prod_{i\in I} U_i : (\forall i \in I)\, U_i \in \mathcal{T}_i,\ |\{i \in I : U_i \neq X_i\}| < \infty\}$. The *product topology* on $\prod_{i\in I} X_i$ is generated by $\mathcal{B}_{\Pi}$.

Proposition 6.2.8. *Product Collections Are Bases*
Let $(X, \mathcal{T}_X), (Y, \mathcal{T}_Y)$ and $(X_i, \mathcal{T}_i)$, $i \in I$, be topological spaces.
(i) $\mathcal{B}_{X\times Y}$ is a basis on $X \times Y$.
(ii) $\mathcal{B}_{\Pi}$ is a basis on $\prod_{i\in I} X_i$.

Proof.
(i) The rectangle $X \times Y$ belongs to $\mathcal{B}_{X\times Y}$. For $(x, y) \in (U_1 \times V_1) \cap (U_2 \times V_2)$, set $W := (U_1 \cap U_2) \times (V_1 \cap V_2)$.
Then $W \in \mathcal{B}_{X\times Y}$ by Definitions 6.1.1(iii) and 6.2.7(i).
Refinement relation $(x, y) \in W \subseteq (U_1 \times V_1) \cap (U_2 \times V_2)$ holds by definition of W. Hence $\mathcal{B}_{X\times Y}$ is a basis by Definition 6.1.8(ii).
(ii) The full product $\prod_{i\in I} X_i$ belongs to $\mathcal{B}_{\Pi}$. For boxes $U = \prod_{i\in I} U_i$ and $V = \prod_{i\in I} V_i$ in $\mathcal{B}_{\Pi}$ and $x \in U \cap V$, set $W_i := U_i \cap V_i$.
Then $(\forall i \in I)\, W_i \in \mathcal{T}_i$ by Definition 6.1.1(iii). The index sets satisfy $\{i \in I : W_i \neq X_i\} \subseteq \{i \in I : U_i \neq X_i\} \cup \{i \in I : V_i \neq X_i\}$.
Right-hand side finite by $U, V \in \mathcal{B}_{\Pi}$; $\prod_{i\in I} W_i \in \mathcal{B}_{\Pi}$ by Definition 6.2.7(ii), $x \in \prod_{i\in I} W_i \subseteq U \cap V$; $\mathcal{B}_{\Pi}$ is basis by Definition 6.1.8(ii).
Structural Commentary: Box intersections preserve finite support.
Key Insight: Intersecting product boxes introduces only finitely many restrictions. □

Proposition 6.2.9. *Product Topology and Coordinate Maps*
Let $(Z, \mathcal{T}_Z), (X, \mathcal{T}_X), (Y, \mathcal{T}_Y)$ be topological spaces, and equip $X \times Y$ with product topology $\mathcal{T}_{X\times Y}$.
Define $\pi_X : X \times Y \to X$ by $\pi_X(x, y) := x$. Define $\pi_Y : X \times Y \to Y$ by $\pi_Y(x, y) := y$.
For $f : Z \to X \times Y$, f is continuous iff $\pi_X \circ f$ and $\pi_Y \circ f$ are continuous.

Proof.
(⇒) For $U \in \mathcal{T}_X$, $U \times Y \in \mathcal{T}_{X\times Y}$ by Definition 6.2.7(i). Thus $(\pi_X \circ f)^{-1}(U) = f^{-1}(U \times Y) \in \mathcal{T}_Z$ by Proposition 6.2.2(i) for f.
For $V \in \mathcal{T}_Y$, $X \times V \in \mathcal{T}_{X\times Y}$ by Definition 6.2.7(i). Thus $(\pi_Y \circ f)^{-1}(V) = f^{-1}(X \times V) \in \mathcal{T}_Z$ by Proposition 6.2.2(i) for f.
Hence both coordinate maps are continuous by Proposition 6.2.2(i).
(⇐) Let $U \times V \in \mathcal{B}_{X\times Y}$. Both coordinate preimages $(\pi_X \circ f)^{-1}(U)$ and $(\pi_Y \circ f)^{-1}(V)$ are open by Proposition 6.2.2(i).
Intersection $= f^{-1}(U \times V)$, lies in $\mathcal{T}_Z$ by Definition 6.1.1(iii). For $O \in \mathcal{T}_{X\times Y}$, $\mathcal{U} \subseteq \mathcal{B}_{X\times Y}$ with $O = \bigcup \mathcal{U}$ by Definition 6.2.7(i).
Then $f^{-1}(O) = \bigcup_{B \in \mathcal{U}} f^{-1}(B) \in \mathcal{T}_Z$ by Definition 6.1.1(ii). Hence f is continuous by Proposition 6.2.2(i).

Structural Commentary: Coordinate preimages handle rectangles; unions handle all product opens.
Key Insight: A product map is continuous exactly coordinatewise. □

Definition 6.2.10. *Quotient Topology*
Let $q : (X, \tau_X) \twoheadrightarrow Y$. The *quotient topology* on Y induced by q is $\tau_q := \{V \subseteq Y : q^{-1}(V) \in \tau_X\}$.

Proposition 6.2.11. *The Quotient Collection Is a Topology*
Let $q : (X, \tau_X) \twoheadrightarrow Y$, and let τ_q be the quotient topology induced by q.

(i) τ_q is a topology on Y.
(ii) $q : (X, \tau_X) \to (Y, \tau_q)$ is continuous.
(iii) If σ is a topology on Y and $q : (X, \tau_X) \to (Y, \sigma)$ is continuous, then $\sigma \subseteq \tau_q$.

Proof.

(i) The identities $q^{-1}(\emptyset) = \emptyset$ and $q^{-1}(Y) = X$ imply $\emptyset, Y \in \tau_q$ by Definitions 6.1.1(i) and 6.2.10.
For $(V_\alpha)_{\alpha\in A} \subseteq \tau_q$, $q^{-1}(\bigcup_{\alpha\in A} V_\alpha) = \bigcup_{\alpha\in A} q^{-1}(V_\alpha) \in \tau_X$ by Definition 6.1.1(ii). Hence $\bigcup_{\alpha\in A} V_\alpha \in \tau_q$ by Definition 6.2.10.
If $n \geq 1$ and $(V_j)_{j=1}^n \subseteq \tau_q$, then $q^{-1}(\bigcap_{j=1}^n V_j) = \bigcap_{j=1}^n q^{-1}(V_j) \in \tau_X$ by Definition 6.1.1(iii).
Hence $\bigcap_{j=1}^n V_j \in \tau_q$ by Definition 6.2.10. Hence τ_q is a topology by Definition 6.1.1.
(ii) For $V \in \tau_q$, $q^{-1}(V) \in \tau_X$ by Definition 6.2.10. Hence q is continuous by Proposition 6.2.2(i).
(iii) For $V \in \sigma$, $q^{-1}(V) \in \tau_X$ by Proposition 6.2.2(i), so $V \in \tau_q$ by Definition 6.2.10. Thus $\sigma \subseteq \tau_q$.

Structural Commentary: Inverse-image identities prove the axioms and compare admissible topologies.
Key Insight: Quotient-open sets are exactly those with open pullbacks. □

Proposition 6.2.12. *Quotient Universal Property*
Let $q : (X, \tau_X) \twoheadrightarrow Y$, and equip Y with the quotient topology τ_Y induced by q.
For $g : Y \to (Z, \tau_Z)$, $g : (Y, \tau_Y) \to (Z, \tau_Z)$ is continuous iff $g \circ q : (X, \tau_X) \to (Z, \tau_Z)$ is continuous.

Proof.

($\Rightarrow$) If g is continuous, then q is continuous by Proposition 6.2.11(ii). Hence $g \circ q$ is continuous by Proposition 6.2.2(iii).
($\Leftarrow$) Assume $g \circ q$ is continuous. For $W \in \tau_Z$, $q^{-1}(g^{-1}(W)) = (g \circ q)^{-1}(W) \in \tau_X$ by Proposition 6.2.2(i).
Thus $g^{-1}(W) \in \tau_Y$ by Definition 6.2.10, so g is continuous by Proposition 6.2.2(i).

Structural Commentary: Precomposition with q converts continuity into the quotient test.
Key Insight: Continuity descends precisely through quotient-open pullbacks. □

Definition 6.2.13. *Weak Topology Induced by Maps*
Let X be a set.

(i) For topologies $\mathcal{T}_1, \mathcal{T}_2$ on X, $\mathcal{T}_2$ is *weaker* than $\mathcal{T}_1$ iff $\mathcal{T}_2 \subseteq \mathcal{T}_1$. Equivalently, $\mathcal{T}_1$ is *stronger* than $\mathcal{T}_2$.
(ii) Let $\{(X_\alpha, \mathcal{T}_\alpha)\}_{\alpha\in A}$ be topological spaces, and let $(f_\alpha : X \to X_\alpha)_{\alpha\in A}$ be maps.
Set $\mathcal{S} := \{X\} \cup \{f_\alpha^{-1}(O) : \alpha \in A,\ O \in \mathcal{T}_\alpha\}$. The *weak topology induced by* $\{f_\alpha\}_{\alpha\in A}$ is the topology generated by $\mathcal{S}$.

Proposition 6.2.14. *Weak Topology Universal Property*
Let X be a set, let $\{(X_\alpha, \mathcal{T}_\alpha)\}_{\alpha\in A}$ be topological spaces, and let $(f_\alpha : X \to X_\alpha)_{\alpha\in A}$ be maps.
Let $\mathcal{T}_w$ be generated by $\mathcal{S} := \{X\} \cup \{f_\alpha^{-1}(O) : \alpha \in A,\ O \in \mathcal{T}_\alpha\}$.

(i) $\mathcal{T}_w$ is a topology on X.
(ii) $(\forall \alpha \in A)(\forall O \in \mathcal{T}_\alpha)\ f_\alpha^{-1}(O) \in \mathcal{T}_w$.
(iii) Let $\mathcal{T}$ be a topology on X satisfying $(\forall \alpha \in A)(\forall O \in \mathcal{T}_\alpha)\ f_\alpha^{-1}(O) \in \mathcal{T}$. Then the weak topology satisfies $\mathcal{T}_w \subseteq \mathcal{T}$.

Proof.

(i) Let $\mathcal{B}_w$ be finite intersections of members of $\mathcal{S}$. Then $X \in \mathcal{B}_w$ and $(\forall B_1, B_2 \in \mathcal{B}_w)\, B_1 \cap B_2 \in \mathcal{B}_w$ by definition of $\mathcal{B}_w$.
$\mathcal{B}_w$ is basis by Definition 6.1.8(ii); $\mathcal{T}_w = \{\bigcup \mathcal{U} : \mathcal{U} \subseteq \mathcal{B}_w\}$ by Definition 6.1.8(iii),(iv); $\mathcal{T}_w$ is topology by Proposition 6.1.9(i).
(ii) For $\alpha \in A$ and $O \in \mathcal{T}_\alpha$, $f_\alpha^{-1}(O) \in \mathcal{S} \subseteq \mathcal{T}_w$ by the definitions of $\mathcal{S}$ and $\mathcal{T}_w$.
(iii) If $\mathcal{T}$ satisfies the stated predicate, then $\mathcal{S} \subseteq \mathcal{T}$.
Every member of $\mathcal{B}_w$, every union of members lies in $\mathcal{T}$ by Definition 6.1.1(ii),(iii). Hence $\mathcal{T}_w \subseteq \mathcal{T}$ by union representation in (i).

Structural Commentary: Finite intersections and unions generate the least admissible topology.
Key Insight: Only subbasic preimages are forced to be open. □

6.3 Topological Compactness and Normality Tools

Compactness retains the open-cover principle without requiring a metric.
Together with Hausdorff and normal separation, it also supports strong closed-set and continuous-function tools.

Definition 6.3.1. *Compactness in Topological Spaces*
Let $(X, \mathcal{T})$ be a topological space.

(i) Let $E \subseteq X$, $(O_\alpha)_{\alpha\in A}$ be family of subsets of X. It is an *open cover* of E iff $(\forall \alpha \in A)\, O_\alpha \in \mathcal{T}$ and $E \subseteq \bigcup_{\alpha\in A} O_\alpha$.
(ii) The space X is *compact* iff $(\forall A)(\forall\, (O_\alpha)_{\alpha\in A})\, [((\forall \alpha \in A)\, O_\alpha \in \mathcal{T} \wedge X \subseteq \bigcup_{\alpha\in A} O_\alpha) \Longrightarrow (\exists\, J \subseteq A)\, (|J| < \infty \wedge X \subseteq \bigcup_{\alpha\in J} O_\alpha)]$.
(iii) For $K \subseteq X$, let $\mathcal{T}_K$ be subspace topology from Definition 6.1.11. The set K is *compact* iff $(K, \mathcal{T}_K)$ is compact.

Proposition 6.3.2. *Ambient Covers Test Subspace Compactness*
Let $(X, \mathcal{T})$ be topological space, $K \subseteq X$. Then K is compact iff every cover of K by members of $\mathcal{T}$ has a finite subcover.

Proof.

(⇒) Let $(O_\alpha)_{\alpha\in A} \subseteq \mathcal{T}$ cover K. By Definition 6.1.11, $(K \cap O_\alpha)_{\alpha\in A}$ is an open cover of $(K, \mathcal{T}_K)$.
By compactness of K, choose a finite $J \subseteq A$ such that $K = \bigcup_{\alpha\in J} (K \cap O_\alpha) \subseteq \bigcup_{\alpha\in J} O_\alpha$.

(⇐) Assume every cover of K by members of $\mathcal{T}$ has a finite subcover. Let $(V_\alpha)_{\alpha\in A} \subseteq \mathcal{T}_K$ cover K.
For $\alpha \in A$, set $O_\alpha := \bigcup\{O \in \mathcal{T} : K \cap O \subseteq V_\alpha\}$. By Definitions 6.1.1(ii) and 6.1.11, $O_\alpha \in \mathcal{T}$ and $K \cap O_\alpha = V_\alpha$.
Thus $(O_\alpha)_{\alpha\in A}$ covers K. By the hypothesis, choose a finite $J \subseteq A$ for which $(O_\alpha)_{\alpha\in J}$ covers K.
Hence $(V_\alpha)_{\alpha\in J}$ covers K, and K is compact by Definition 6.3.1(ii),(iii).

Structural Commentary: Intersecting ambient opens with K preserves exactly the cover seen by the subspace.
Key Insight: Subspace compactness can be tested without changing the ambient open sets. □

Proposition 6.3.3. *Finite-Intersection Compactness Test*
Let $(X, \mathcal{T})$ be topological space, $\mathfrak{C}_X$ be collection of nonempty families of closed subsets of X with finite intersection property. The finite intersection property is as in Definition 4.1.2. Then X is compact iff $(\forall \mathcal{F} \in \mathfrak{C}_X) \bigcap_{F\in\mathcal{F}} F \neq \emptyset$.

Proof.

(⇒) Assume X is compact. Let $\emptyset \neq \mathcal{F} \subseteq \mathcal{P}(X)$ be a family of closed subsets with finite intersection property.
Suppose $\bigcap_{F\in\mathcal{F}} F = \emptyset$. By Definition 6.1.2(ii) and De Morgan's law, $(X \setminus F)_{F\in\mathcal{F}}$ is an open cover of X.
By compactness, choose $n \in \mathbb{N}$ and $F_1, \ldots, F_n \in \mathcal{F}$ such that $X = \bigcup_{j=1}^{n} (X \setminus F_j)$.
By De Morgan's law, $\bigcap_{j=1}^{n} F_j = \emptyset$, contradicting the finite intersection property.

(⇐) Assume the closed-family condition, and let $(O_\alpha)_{\alpha\in A}$ be an open cover of X.
If $X = \emptyset$, then the empty subfamily is a finite subcover. Suppose $X \neq \emptyset$ and no finite subfamily covers X.
Then $A \neq \emptyset$, and $\mathcal{F} := \{X \setminus O_\alpha : \alpha \in A\}$ is a nonempty family of closed subsets.
By the absence of a finite subcover and De Morgan's law, $\mathcal{F}$ has the finite intersection property.
By hypothesis, $\emptyset \neq \bigcap_{\alpha\in A} (X \setminus O_\alpha) = X \setminus \bigcup_{\alpha\in A} O_\alpha$. This contradicts that $(O_\alpha)_{\alpha\in A}$ covers X.

Structural Commentary: Complements exchange covers and intersections.
Key Insight: Compactness forbids closed FIP families from missing every point. □

Proposition 6.3.4. *Closed Subsets of Compact Spaces Are Compact*
Let $(X, \mathcal{T})$ be compact and let $K \subseteq X$ be closed. Then K is compact in the subspace topology.

Proof. Let $(O_\alpha)_{\alpha\in A} \subseteq \mathcal{T}$ cover K. By closedness of K, $X \setminus K \in \mathcal{T}$, so $(O_\alpha)_{\alpha\in A} \cup \{X \setminus K\}$ is an open cover of X.
By compactness of X, this cover has a finite subcover. After discarding $X \setminus K$, the remaining members still cover K.
Hence K is compact by Proposition 6.3.2.
Structural Commentary: Add the open complement to cover X.
Key Insight: Compactness passes to closed subspaces. □

Proposition 6.3.5. *Compact Sets Separate from Points and Are Closed*
Let $(X, \mathcal{T})$ be Hausdorff and let $K \subseteq X$ be compact in the subspace topology.

(i) If $y \in X \setminus K$, then $(\exists U, V \in \mathcal{T})\,[y \in U \wedge K \subseteq V \wedge U \cap V = \emptyset]$.
(ii) K is closed in X.

Proof.

(i) If $K = \emptyset$, then $U = X$, $V = \emptyset$. Suppose $K \neq \emptyset$.
For $x \in K$, choose disjoint $V_x, U_x \in \mathcal{T}$ such that $x \in V_x$ and $y \in U_x$ by the Hausdorff property.
By Proposition 6.3.2, choose $x_1, \ldots, x_n \in K$ such that $K \subseteq \bigcup_{j=1}^{n} V_{x_j}$. Set $V := \bigcup_{j=1}^{n} V_{x_j}$ and $U := \bigcap_{j=1}^{n} U_{x_j}$.
By Definitions 6.1.1(ii),(iii), $U, V \in \mathcal{T}$. By construction, $y \in U$, $K \subseteq V$, and $U \cap V = \emptyset$.

(ii) For $y \in X \setminus K$, choose $U_y \in \mathcal{T}$ as in (i); $X \setminus K = \bigcup_{y\in X\setminus K} U_y \in \mathcal{T}$ by Definition 6.1.1(ii); K closed by Definition 6.1.2(ii).

Structural Commentary: Compactness turns pointwise Hausdorff separations into a finite one.
Key Insight: Every exterior point has an open neighborhood avoiding K. □

Theorem 6.3.6. *Compact Hausdorff Spaces Are Normal*
Let $(X, \mathcal{T})$ be compact and Hausdorff. Then X is normal.

Proof. For distinct $x, y \in X$, choose open neighborhood of x that omits y by Hausdorff property; X is T_1 by Proposition 6.1.14.
Let $A, B \subseteq X$ be disjoint closed sets. By Proposition 6.3.4, A and B are compact. If $A = \emptyset$ or $B = \emptyset$, then $\emptyset$, X separate them.
Suppose $A, B \neq \emptyset$. For $b \in B$, choose disjoint $U_b, V_b \in \mathcal{T}$ such that $b \in U_b$ and $A \subseteq V_b$ by Proposition 6.3.5(i).
By Proposition 6.3.2, choose $b_1, \ldots, b_n \in B$ such that $B \subseteq \bigcup_{j=1}^{n} U_{b_j}$. Set $U := \bigcup_{j=1}^{n} U_{b_j}$ and $V := \bigcap_{j=1}^{n} V_{b_j}$.
Then $U, V \in \mathcal{T}$, $B \subseteq U$, $A \subseteq V$, and $U \cap V = \emptyset$. Thus X is normal by Definition 6.1.13.
Structural Commentary: Compactness makes finitely many Hausdorff separations suffice.
Key Insight: Disjoint closed compact sets have disjoint neighborhoods. □

Theorem 6.3.7. *Continuous Images of Compact Spaces Are Compact*
Let $f : (X, \mathcal{T}_X) \to (Y, \mathcal{T}_Y)$ be continuous. If X is compact, then $f(X)$ is compact in the subspace topology.

Proof. Let $(V_\alpha)_{\alpha\in A} \subseteq \mathcal{T}_Y$ cover $f(X)$. By Proposition 6.2.2(i), $(f^{-1}(V_\alpha))_{\alpha\in A} \subseteq \mathcal{T}_X$, and this family covers X.
By compactness, choose finite $J \subseteq A$ such that $X = \bigcup_{\alpha\in J} f^{-1}(V_\alpha)$. Then $f(X) \subseteq \bigcup_{\alpha\in J} V_\alpha$, so $f(X)$ is compact by Proposition 6.3.2.
Structural Commentary: Pull the cover back to the compact domain.
Key Insight: Finite subcovers descend through the image. □

Corollary 6.3.8. *Extreme Values on Compact Spaces*
Let X be nonempty compact topological space, $f : X \to \mathbb{R}$ be continuous.
Then $(\exists x_{\min}, x_{\max} \in X)\,[f(x_{\min}) = \inf f(X) \wedge f(x_{\max}) = \sup f(X)]$.

Proof. By Theorem 6.3.7, $f(X)$ is nonempty and compact in its subspace topology.
By Proposition 6.3.2 and Definition 4.1.1, $f(X)$ is compact as a metric subspace of $\mathbb{R}$.
Let $\iota : f(X) \to \mathbb{R}$ be the inclusion map. Since ι preserves the induced metric, it is continuous by Theorem 5.1.26(ii).
By Theorem 5.1.39, choose $m, M \in f(X)$ such that $m = \min f(X)$ and $M = \max f(X)$.
Choose $x_{\min}, x_{\max} \in X$ such that $f(x_{\min}) = m$ and $f(x_{\max}) = M$.
Structural Commentary: The image converts topological compactness into the metric hypothesis of the earlier extreme-value theorem.
Key Insight: Applying the metric result to the inclusion $f(X) \hookrightarrow \mathbb{R}$ locates both endpoint values in the image. □

Theorem 6.3.9. *Compact-to-Hausdorff Bijection Criterion*
Let $f : (X, \mathcal{T}_X) \to (Y, \mathcal{T}_Y)$ be a continuous bijection. If X is compact and Y is Hausdorff, then f is a homeomorphism.

Proof. Let $O \in \mathcal{T}_X$, and set $F := X \setminus O$. By Proposition 6.3.4, F is compact. By Theorem 6.3.7, $f(F)$ is compact.
By Proposition 6.3.5(ii), $f(F)$ is closed in Y. By bijectivity of f, $(f^{-1})^{-1}(O) = f(O) = Y \setminus f(F) \in \mathcal{T}_Y$.
Thus f^{-1} is continuous by Proposition 6.2.2(i). Hence f is a homeomorphism by Definition 6.2.5(i).
Structural Commentary: Closed sets map compact, then closed.
Key Insight: Compact-to-Hausdorff bijections have continuous inverses. □

Proposition 6.3.10. *Compact Hausdorff Topologies Are Rigid*
Let X be a set and let $\mathcal{T}, \mathcal{T}_1, \mathcal{T}_2$ be topologies on X.

(i) If $(X, \mathcal{T})$ is compact and $\mathcal{T}_1 \subseteq \mathcal{T}$, then $(X, \mathcal{T}_1)$ is compact.
(ii) If $(X, \mathcal{T})$ is Hausdorff and $\mathcal{T} \subseteq \mathcal{T}_2$, then $(X, \mathcal{T}_2)$ is Hausdorff.
(iii) If $(X, \mathcal{T})$ is compact Hausdorff, $\mathcal{T}_1 \subseteq \mathcal{T}$, and $(X, \mathcal{T}_1)$ is Hausdorff, then $\mathcal{T}_1 = \mathcal{T}$.
(iv) If $(X, \mathcal{T})$ is compact Hausdorff, $\mathcal{T} \subseteq \mathcal{T}_2$, and $(X, \mathcal{T}_2)$ is compact, then $\mathcal{T}_2 = \mathcal{T}$.

Proof.

(i) Every $\mathcal{T}_1$-open cover is a $\mathcal{T}$-open cover. Hence it has a finite subcover by compactness of $(X, \mathcal{T})$.
(ii) For distinct $x, y \in X$, choose disjoint $\mathcal{T}$-open neighborhoods by Hausdorff property. They are $\mathcal{T}_2$-open because $\mathcal{T} \subseteq \mathcal{T}_2$.
(iii) The map $\mathrm{id} : (X, \mathcal{T}) \to (X, \mathcal{T}_1)$ is bijective. It is continuous by $\mathcal{T}_1 \subseteq \mathcal{T}$ and Proposition 6.2.2(i).
By Theorem 6.3.9, it is a homeomorphism. Hence $\mathcal{T}_1 = \mathcal{T}$ by Proposition 6.2.6(i).
(iv) The map $\mathrm{id} : (X, \mathcal{T}_2) \to (X, \mathcal{T})$ is bijective. It is continuous by $\mathcal{T} \subseteq \mathcal{T}_2$ and Proposition 6.2.2(i).
By Theorem 6.3.9, it is a homeomorphism. Hence $\mathcal{T}_2 = \mathcal{T}$ by Proposition 6.2.6(i).

Structural Commentary: Weakening preserves covers; strengthening preserves separations.
Key Insight: Compact Hausdorff topologies cannot be enlarged or shrunk compatibly. □

Lemma 6.3.11. *Maximal Finite-Intersection Families*
Assume Zorn's lemma. Let X be a set, and let $\mathcal{A} \subseteq \mathcal{P}(X)$ have the finite intersection property.
Then $\mathcal{A}$ is contained in a maximal family $\mathcal{M} \subseteq \mathcal{P}(X)$ with the finite intersection property.

Proof.

(i) *Extension poset*: Write $\mathrm{FIP}(\mathcal{B})$ when $\mathcal{B}$ has the finite intersection property.
Set $\mathfrak{P} := \{\mathcal{B} \subseteq \mathcal{P}(X) : \mathcal{A} \subseteq \mathcal{B} \wedge \mathrm{FIP}(\mathcal{B})\}$. Then $\mathcal{A} \in \mathfrak{P}$, and inclusion partially orders $\mathfrak{P}$ by Proposition 6.1.5.
(ii) *Chain upper bounds*: The empty chain has upper bound $\mathcal{A}$. Let $\emptyset \neq \mathfrak{C} \subseteq \mathfrak{P}$ be a chain, and set $\mathcal{U} := \bigcup \mathfrak{C}$.
For a finite nonempty family $\{E_1, \ldots, E_n\} \subseteq \mathcal{U}$, choose $\mathcal{B}_j \in \mathfrak{C}$ such that $E_j \in \mathcal{B}_j$.
Because $\mathfrak{C}$ is a chain, one of $\mathcal{B}_1, \ldots, \mathcal{B}_n$ contains all the others.
Thus $\bigcap_{j=1}^n E_j \neq \emptyset$ by the finite intersection property of that member. Hence $\mathcal{U} \in \mathfrak{P}$ and $\mathcal{U}$ is an upper bound of $\mathfrak{C}$.
(iii) *Maximal extension*: By the Zorn hypothesis, $\mathfrak{P}$ has a maximal member $\mathcal{M}$.
By the definition of $\mathfrak{P}$, $\mathcal{A} \subseteq \mathcal{M}$ and $\mathcal{M}$ has the finite intersection property.
Maximality in $\mathfrak{P}$ is exactly maximality among families in $\mathcal{P}(X)$ with that property.

Structural Commentary: Chain unions preserve FIP because tests are finite.
Key Insight: Zorn extends any FIP family to a maximal one. □

Lemma 6.3.12. *Closure Properties of Maximal FIP Families*
Let X be a nonempty set, and let $\mathcal{M} \subseteq \mathcal{P}(X)$ be maximal with respect to the finite intersection property.

(i) $X \in \mathcal{M}$.
(ii) If $n \in \mathbb{N}$ and $M_1, \ldots, M_n \in \mathcal{M}$, then $\bigcap_{j=1}^{n} M_j \in \mathcal{M}$.
(iii) If $C \subseteq X$ and $(\forall n \in \mathbb{N})(\forall M_1, \ldots, M_n \in \mathcal{M})\, C \cap \bigcap_{j=1}^{n} M_j \neq \emptyset$, then $C \in \mathcal{M}$.

Proof.

(i) Since $X \neq \emptyset$, adjoining X to $\mathcal{M}$ preserves every nonempty finite intersection.
Thus $\mathcal{M} \cup \{X\}$ has the finite intersection property, so $X \in \mathcal{M}$ by maximality.
(ii) Set $N := \bigcap_{j=1}^{n} M_j$. Every nonempty finite intersection from $\mathcal{M} \cup \{N\}$ is a finite intersection of members of $\mathcal{M}$.
Hence $\mathcal{M} \cup \{N\}$ has the finite intersection property, and $N \in \mathcal{M}$ by maximality.
(iii) By (i) and the hypothesis with $n = 1$ and $M_1 = X$, $C \neq \emptyset$.
Every nonempty finite intersection from $\mathcal{M} \cup \{C\}$ is nonempty by the hypothesis and the finite intersection property of $\mathcal{M}$.
Hence $\mathcal{M} \cup \{C\}$ has the finite intersection property, and $C \in \mathcal{M}$ by maximality.

Structural Commentary: Maximality absorbs every FIP-compatible set.
Key Insight: Finite intersections are already forced inside $\mathcal{M}$. □

Theorem 6.3.13. *Tychonoff Product Theorem*
Assume the axiom of choice and Zorn's lemma. Let $(X_\lambda)_{\lambda\in\Lambda}$ be a family of compact topological spaces. Then $X := \prod_{\lambda\in\Lambda} X_\lambda$ is compact in the product topology.

Proof.

(i) *Maximal family*: If $X = \emptyset$, then its empty subfamily is a finite subcover of any open cover.
Suppose $X \neq \emptyset$, and let $\mathcal{F}$ be a nonempty family of closed subsets of X with the finite intersection property.
By Lemma 6.3.11, choose a maximal family $\mathcal{M} \supseteq \mathcal{F}$ with the finite intersection property.

(ii) *Coordinate choice*: For $\lambda \in \Lambda$, define $\pi_\lambda : X \to X_\lambda$ by $\pi_\lambda(x) := x_\lambda$. For $n \in \mathbb{N}$ and $M_1, \dots, M_n \in \mathcal{M}$, set $P := \bigcap_{j=1}^{n} M_j$.
By the finite intersection property, $P \neq \emptyset$ and $\pi_\lambda(P) \subseteq \bigcap_{j=1}^{n} \overline{\pi_\lambda(M_j)}$.
Thus $(\overline{\pi_\lambda(M)})_{M\in\mathcal{M}}$ is a nonempty family of closed subsets of X_λ with the finite intersection property.
Set $I_\lambda := \bigcap_{M\in\mathcal{M}} \overline{\pi_\lambda(M)}$. Then $I_\lambda \neq \emptyset$ by compactness of X_λ and Proposition 6.3.3.
By the choice hypothesis, select $(x_\lambda)_{\lambda\in\Lambda} \in \prod_{\lambda\in\Lambda} I_\lambda$. Set $x := (x_\lambda)_{\lambda\in\Lambda} \in X$.

(iii) *Coordinate cylinders*: Let $\lambda \in \Lambda$, and let $O \subseteq X_\lambda$ be an open neighborhood of x_λ. Set $N := \pi_\lambda^{-1}(O)$.
For $n \in \mathbb{N}$ and $M_1, \dots, M_n \in \mathcal{M}$, set $P := \bigcap_{j=1}^{n} M_j$. By Lemma 6.3.12(ii), $P \in \mathcal{M}$.
Since $x_\lambda \in \overline{\pi_\lambda(P)}$, one has $O \cap \pi_\lambda(P) \neq \emptyset$, and hence $N \cap P \neq \emptyset$. Therefore $N \in \mathcal{M}$ by Lemma 6.3.12(iii).

(iv) *Basic neighborhoods*: Let $B = \prod_{\lambda\in\Lambda} U_\lambda$ be a basic neighborhood of x. Set $S := \{\lambda \in \Lambda : U_\lambda \neq X_\lambda\}$.
If $S = \emptyset$, then $B = X \in \mathcal{M}$ by Lemma 6.3.12(i). If $S = \{\lambda_1, \dots, \lambda_n\}$, then $B = \bigcap_{j=1}^{n} \pi_{\lambda_j}^{-1}(U_{\lambda_j})$.
By (iii), $(\forall j \in \{1, \dots, n\})\, \pi_{\lambda_j}^{-1}(U_{\lambda_j}) \in \mathcal{M}$. Hence $B \in \mathcal{M}$ by Lemma 6.3.12(ii).

(v) *Common point*: Fix $F \in \mathcal{F}$, and let U be a neighborhood of x.
By Definition 6.2.7(ii) and Proposition 6.2.8(ii), U contains a basic neighborhood B of x.
By (iv), $B \in \mathcal{M}$, while $F \in \mathcal{M}$ by $\mathcal{F} \subseteq \mathcal{M}$. By the finite intersection property, $U \cap F \supseteq B \cap F \neq \emptyset$.
Thus $x \in \overline{F} = F$ by Proposition 6.1.7(iv). Therefore $x \in \bigcap_{F\in\mathcal{F}} F$, and X is compact by Proposition 6.3.3.

Structural Commentary: Coordinate compactness selects a candidate point.
Key Insight: Maximal FIP forces all basic neighborhoods of that point to remain compatible. □

Definition 6.3.14. *Compact-Open Topology*
Let X, Y be topological spaces, and set $Y^X := \{f : X \to Y\}$. For compact $K \subseteq X$ and open $O \subseteq Y$, set $\mathcal{U}_{K,O} := \{f \in Y^X : f(K) \subseteq O\}$.
Let $\mathcal{S}_{\text{co}}$ be the collection of all such sets $\mathcal{U}_{K,O}$. The *compact-open topology* on Y^X is the topology generated by the subbasis $\mathcal{S}_{\text{co}}$.

Proposition 6.3.15. *The Compact-Open Collection Is a Subbasis*
Let X, Y be topological spaces, $Y^X := \{f : X \to Y\}$. For compact $K \subseteq X$ and open $O \subseteq Y$, set $\mathcal{U}_{K,O} := \{f \in Y^X : f(K) \subseteq O\}$. Then the collection $\mathcal{S}_{\text{co}}$ of all such sets $\mathcal{U}_{K,O}$ is a subbasis on Y^X.

Proof. The set $\emptyset \subseteq X$ is compact, $\emptyset \subseteq Y$ is open, and $\mathcal{U}_{\emptyset,\emptyset} = Y^X$. Thus $Y^X \in \mathcal{S}_{\text{co}}$.
Let $\mathcal{B}_{\text{co}}$ be collection of all nonempty finite intersections of members of $\mathcal{S}_{\text{co}}$. Then $Y^X \in \mathcal{B}_{\text{co}}$, $\mathcal{B}_{\text{co}}$ is closed under finite intersections.
Hence $\mathcal{B}_{\text{co}}$ is a basis by Definition 6.1.8(ii). Thus $\mathcal{S}_{\text{co}}$ is a subbasis by Definition 6.1.8(iv).
Structural Commentary: Finite compact-open constraints remain closed under finite intersection.
Key Insight: The empty-domain constraint supplies the full function space. □

Remark 6.3.16. *Compact-Open Versus Product Topology*
On $Y^X = \prod_{x\in X} Y$, the product topology tests finitely many coordinates $f(x)$.
The compact-open topology tests compact sets at once through $\mathcal{U}_{K,O} = \{f \in Y^X : f(K) \subseteq O\}$.
When K is infinite, one subbasic constraint can restrict infinitely many coordinates.

Definition 6.3.17. *Normally Ascending Families*
Let X be a topological space, $\Lambda \subseteq \mathbb{R}$, $(O_\lambda)_{\lambda\in\Lambda}$ be family of open subsets of X.
It is *normally ascending* iff $(\forall \lambda_1, \lambda_2 \in \Lambda)\, [\lambda_1 < \lambda_2 \Rightarrow \overline{O_{\lambda_1}} \subseteq O_{\lambda_2}]$.
Key Insight: Later open sets contain the closures of earlier ones.

Lemma 6.3.18. *Normally Ascending Families Define Continuous Functions*
Let X be a topological space, let $a < b$, let $\Lambda \subseteq (a, b)$ be dense, and let $(O_\lambda)_{\lambda\in\Lambda}$ be normally ascending. For $x \in X$, set $\Lambda_x := \{\lambda \in \Lambda : x \in O_\lambda\}$ and $g(x) := \inf \Lambda_x$, with $\inf \emptyset := b$. Then $g : X \to [a, b]$ is continuous.

Proof. Fix $x \in X$. If $\Lambda_x \neq \emptyset$, then Λ_x is bounded below by a. By Corollary 1.1.15, $\inf \Lambda_x$ exists, and $a \leq \inf \Lambda_x < b$.
Together with the empty-set convention, this proves that $g : X \to [a, b]$ is well-defined. Fix $c \in (a, b)$.
By the defining property of the infimum, $\{x \in X : g(x) < c\} = \bigcup_{\substack{\lambda\in\Lambda \\ \lambda<c}} O_\lambda$.
If $\lambda \in \Lambda$, $\lambda > c$, and $x \notin \overline{O_\lambda}$, then $(\forall \mu \in \Lambda)\, [\mu < \lambda \Rightarrow x \notin O_\mu]$ by normal ascent. Hence $g(x) \geq \lambda > c$.
Conversely, if $g(x) > c$, choose $\mu, \lambda \in \Lambda$ by density such that $c < \mu < \lambda < g(x)$.
Then $x \notin O_\lambda$, while $\overline{O_\mu} \subseteq O_\lambda$ by normal ascent. Thus $x \notin \overline{O_\mu}$, and therefore $\{x \in X : g(x) > c\} = \bigcup_{\substack{\lambda\in\Lambda \\ \lambda>c}} (X \setminus \overline{O_\lambda})$.
Both threshold sets are open. Set $\mathcal{R} := \{[a, c) : c \in (a, b)\} \cup \{(c, b] : c \in (a, b)\}$.
Its finite intersections form the relative-interval basis, so $\mathcal{R}$ is a subbasis for the metric topology on $[a, b]$.
For $c \in (a, b)$, $g^{-1}([a, c)) = \{g < c\}$ and $g^{-1}((c, b]) = \{g > c\}$ are open. Hence g is continuous by Proposition 6.2.4.
Structural Commentary: Threshold preimages reduce to unions of nested open or closed-complement sets.
Key Insight: Normal ascent makes upper thresholds open. □

Lemma 6.3.19. *Dyadic Neighborhood Ladders in Normal Spaces*
Let X be normal, let $F \subseteq X$ be closed, let U be an open neighborhood of F, and let $a < b$.
Then dense set $\Lambda \subseteq (a,b)$ and normally ascending family $(O_\lambda)_{\lambda\in\Lambda}$ of open sets exist, chosen so that $(\forall \lambda \in \Lambda)\, F \subseteq O_\lambda \subseteq \overline{O_\lambda} \subseteq U$.

Proof. The space X is T_1 by Definition 6.1.13.

(i) *Index set*: First construct the family on $(0,1)$. For $n \in \mathbb{N}$, set $D_n := \{m2^{-n} : 0 < m < 2^n\}$, and set $D := \bigcup_{n\in\mathbb{N}} D_n$.

(ii) *Base*: By Proposition 6.1.16, choose an open set $O_{1/2}$. The choice satisfies $F \subseteq O_{1/2} \subseteq \overline{O_{1/2}} \subseteq U$.

(iii) *Dyadic insertion*: Suppose the sets indexed by D_n have been chosen with the required containments between adjacent indices.
Let $r = m2^{-(n+1)}$ be a new index, where m is odd. Set $p := (m-1)2^{-(n+1)}$ and $q := (m+1)2^{-(n+1)}$.
Set $L_p := F$ when $p = 0$ and $L_p := \overline{O_p}$ otherwise. Set $W_q := U$ when $q = 1$ and $W_q := O_q$ otherwise.
By the induction hypothesis, L_p is closed, W_q is open, and $L_p \subseteq W_q$.
By Proposition 6.1.16, choose an open set O_r such that $L_p \subseteq O_r \subseteq \overline{O_r} \subseteq W_q$.
Perform the finitely many insertions at level $n+1$; all adjacent containments remain valid.

(iv) *Conclusion*: Fix $0 < s < t < 1$. By Theorem 2.2.10(v), choose $n \in \mathbb{N}$ such that $2^{-n} < t - s$.
The finite set $S := \{k \in \mathbb{Z} : 0 \le k \le 2^n,\ k \le 2^n s\}$ is nonempty; set $m := \max S$.
Then $s < (m+1)2^{-n} < s + 2^{-n} < t$, so $(m+1)2^{-n} \in D \cap (s,t)$. Thus D is dense in $(0,1)$.
If $\lambda_1, \lambda_2 \in D$ and $\lambda_1 < \lambda_2$, choose $n \in \mathbb{N}$ such that $\lambda_1, \lambda_2 \in D_n$. Then $\overline{O_{\lambda_1}} \subseteq O_{\lambda_2}$ by the adjacent containment chain.
By the endpoint containments, $(\forall \lambda \in D)\, F \subseteq O_\lambda \subseteq \overline{O_\lambda} \subseteq U$. Set $\Lambda := \{a + (b-a)r : r \in D\}$ and assign $O_{a+(b-a)r} := O_r$.
Since $r \mapsto a + (b-a)r$ is an order-preserving bijection from $(0,1)$ to (a,b), the transported family has all the required properties.

Structural Commentary: Normality inserts closed-neighborhood buffers.
Key Insight: Dyadic induction builds the whole ascending ladder. □

Theorem 6.3.20. *Urysohn's Lemma*
Let X be normal, $A, B \subseteq X$ be disjoint closed sets, $a < b$ in $\mathbb{R}$.
Then continuous map $f : X \to [a,b]$ exists such that $f|_A = a$ and $f|_B = b$.

Proof.

(i) *Open ladder*: The set $X \setminus B$ is an open neighborhood of A.
By Lemma 6.3.19, choose dense $\Lambda \subseteq (a,b)$, normally ascending family $(O_\lambda)_{\lambda\in\Lambda}$. Choice satisfies $(\forall \lambda \in \Lambda)\, A \subseteq O_\lambda \subseteq \overline{O_\lambda} \subseteq X \setminus B$.

(ii) *Separator*: Define $f(x) := \inf\{\lambda \in \Lambda : x \in O_\lambda\}$, with $\inf \emptyset := b$. By Lemma 6.3.18, $f : X \to [a,b]$ is continuous.

(iii) *Boundary values*: If $x \in A$, then $(\forall \lambda \in \Lambda)\, x \in O_\lambda$. Since Λ is dense in (a,b), $\inf \Lambda = a$, and hence $f(x) = a$.
If $x \in B$, then $(\forall \lambda \in \Lambda)\, x \notin O_\lambda$, so $f(x) = b$ by the empty-set convention. Thus $f|_A = a$ and $f|_B = b$.

Structural Commentary: A nested open ladder becomes a continuous separator.
Key Insight: Normality separates closed sets by a real-valued function. □

Proposition 6.3.21. *Real-Valued Continuity under Sums and Uniform Error Bounds*
Let X be a topological space.

(i) If $u, v : X \to \mathbb{R}$ are continuous and $c, d \in \mathbb{R}$, then $cu + dv$ is continuous.

(ii) Let (s_n) be a sequence of continuous maps from X to $\mathbb{R}$, and let $g : X \to \mathbb{R}$.
If $(\forall \varepsilon > 0)(\exists N \in \mathbb{N})(\forall n \ge N)(\forall x \in X)\ |s_n(x) - g(x)| < \varepsilon$, then g is continuous.

Proof.

(i) Define $A : \mathbb{R}^2 \to \mathbb{R}$ and $M_c : \mathbb{R} \to \mathbb{R}$ by $A(r,s) := r + s$ and $M_c(r) := cr$. Fix $(r,s) \in \mathbb{R}^2$ and an open neighborhood W of $r + s$.
Choose $\varepsilon > 0$ such that $B_\varepsilon(r+s) \subseteq W$. Then $A\big((r - \frac{\varepsilon}{2}, r + \frac{\varepsilon}{2}) \times (s - \frac{\varepsilon}{2}, s + \frac{\varepsilon}{2})\big) \subseteq W$.
Thus A is continuous in the product topology by Definition 6.2.1. The map M_0 is continuous because it is constant.
Suppose $c \neq 0$, fix $r \in \mathbb{R}$, and let W_c be an open neighborhood of cr. Choose $\eta > 0$ such that $B_\eta(cr) \subseteq W_c$.
Then $M_c(B_{\frac{\eta}{|c|}}(r)) \subseteq B_\eta(cr) \subseteq W_c$, so M_c is continuous at r by Definition 6.2.1(i). Thus M_c is continuous by Definition 6.2.1(ii).
Hence $M_c \circ u$ and $M_d \circ v$ are continuous by Proposition 6.2.2(iii). Their pair is continuous by Proposition 6.2.9.
Therefore $cu + dv = A \circ (M_c \circ u, M_d \circ v)$ is continuous by Proposition 6.2.2(iii).

(ii) Fix $x_0 \in X$ and an open neighborhood O of $g(x_0)$. Choose $\varepsilon > 0$ such that $B_\varepsilon(g(x_0)) \subseteq O$.
By the uniform-convergence hypothesis, choose $n \in \mathbb{N}$ such that $(\forall x \in X)\ |s_n(x) - g(x)| < \frac{\varepsilon}{3}$. Set $U := s_n^{-1}(B_{\frac{\varepsilon}{3}}(s_n(x_0)))$.
Then U is an open neighborhood of x_0 by continuity of s_n and Proposition 6.2.2(i).
For $x \in U$, $|g(x) - g(x_0)| \le |g(x) - s_n(x)| + |s_n(x) - s_n(x_0)| + |s_n(x_0) - g(x_0)| < \varepsilon$.
Thus $g(U) \subseteq O$, so g is continuous by Definition 6.2.1.

Structural Commentary: Product continuity controls finite sums; uniform error transfers neighborhoods through approximants.
Key Insight: A domain-wide error bound lets one continuous approximant control the limit throughout X. □

Theorem 6.3.22. *Tietze Extension Theorem, Bounded Form*
Let X be normal, let $F \subseteq X$ be closed, let $a < b$ in $\mathbb{R}$, and let $f : F \to [a,b]$ be continuous.
Then a continuous map $g : X \to [a,b]$ exists with $g|_F = f$.

Proof.

(i) *Correction step*: Constant maps on F are continuous because their open preimages belong to $\{\emptyset, F\}$.
Hence $\widetilde{f} := \frac{2f - a - b}{b - a} : F \to [-1,1]$ is continuous by Proposition 6.3.21(i). Let $A > 0$, and let $h : F \to [-A, A]$ be continuous.
Set $C_- := \{x \in F : h(x) \le -\frac{A}{3}\}$ and $C_+ := \{x \in F : h(x) \ge \frac{A}{3}\}$.
The sets are disjoint, and $F \setminus C_- = h^{-1}((-\frac{A}{3}, A])$ and $F \setminus C_+ = h^{-1}([-A, \frac{A}{3}))$.
Both complements are open in F by Proposition 6.2.2(i), so C_- and C_+ are closed in F.
If $C \subseteq F$ is closed in F, choose an open $O \subseteq X$ such that $F \setminus C = F \cap O$. Then $X \setminus C = (X \setminus F) \cup O$ is open, so C is closed in X.
Thus C_- and C_+ are closed in X. By Theorem 6.3.20, choose a continuous $u : X \to [-\frac{A}{3}, \frac{A}{3}]$.
Choice satisfies $u|_{C_-} = -\frac{A}{3}$ and $u|_{C_+} = \frac{A}{3}$. By cases $h(x) \le -\frac{A}{3}$, $|h(x)| < \frac{A}{3}$, and $h(x) \ge \frac{A}{3}$, $(\forall x \in F)\ |h(x) - u(x)| \le \frac{2A}{3}$.

(ii) *Recursive approximation*: Set $s_0 := 0$, which is continuous.
For $n \in \mathbb{N}$, suppose $s_{n-1} : X \to \mathbb{R}$ is continuous and $(\forall x \in F)\ \left|\widetilde{f}(x) - s_{n-1}(x)\right| \le (\frac{2}{3})^{n-1}$.
By Proposition 6.2.2(ii), $s_{n-1}|_F$ is continuous. Set $A_n := (\frac{2}{3})^{n-1}$ and $h := \widetilde{f} - s_{n-1}|_F$.
Then $h : F \to [-A_n, A_n]$ is continuous by the induction bound and Proposition 6.3.21(i).
By the correction step with $A = A_n$, choose a continuous $u_n : X \to \mathbb{R}$.
The domain-wide bound $(\forall x \in X)\ |u_n(x)| \le \frac{1}{3}(\frac{2}{3})^{n-1}$ holds.
The residual bound $(\forall x \in F)\ \left|\widetilde{f}(x) - s_{n-1}(x) - u_n(x)\right| \le (\frac{2}{3})^n$ also holds.
Set $s_n := s_{n-1} + u_n$. By Proposition 6.3.21(i), s_n is continuous. Sequence (s_n) follows by induction.

(iii) *Limit and continuity*: Fix $x \in X$. If $m < n$, then $|s_n(x) - s_m(x)| \le \sum_{k=m+1}^{n} \frac{1}{3}(\frac{2}{3})^{k-1} \le (\frac{2}{3})^m$.
By Theorem 2.2.10(v), $(\frac{2}{3})^m \to 0$. Thus $(s_n(x))$ is Cauchy by Definition 2.1.13.
By Theorem 2.1.15, set $\widetilde{g}(x) := \lim_{n\to\infty} s_n(x) \in \mathbb{R}$. Fix $m \in \mathbb{N}$, $x \in X$, and $\delta > 0$.
Choose $n > m$ such that $|\widetilde{g}(x) - s_n(x)| < \delta$. Then $|\widetilde{g}(x) - s_m(x)| < \delta + (\frac{2}{3})^m$.
Since $\delta > 0$ is arbitrary, $(\forall m \in \mathbb{N})(\forall x \in X)\ |\widetilde{g}(x) - s_m(x)| \le (\frac{2}{3})^m$.
Hence $s_m \to \widetilde{g}$ uniformly, and $\widetilde{g}$ is continuous by Proposition 6.3.21(ii).

(iv) *Extension and range*: For $x \in F$, $\left|\widetilde{f}(x) - s_n(x)\right| \le (\frac{2}{3})^n \to 0$, so $\widetilde{g}|_F = \widetilde{f}$. For $x \in X$, $|s_n(x)| \le \sum_{k=1}^{n} \frac{1}{3}(\frac{2}{3})^{k-1} = 1 - (\frac{2}{3})^n$.
By the uniform error bound, $|\widetilde{g}(x)| \le |\widetilde{g}(x) - s_n(x)| + |s_n(x)| \le 1$. Hence $\widetilde{g}(X) \subseteq [-1, 1]$.
Set $g := \frac{(b-a)\widetilde{g}+a+b}{2} : X \to [a, b]$. By Proposition 6.3.21(i), g is continuous. By the definition of $\widetilde{f}$, $g|_F = f$.

Structural Commentary: Urysohn corrections shrink the residual geometrically.
Key Insight: Geometric domain-wide error decay turns approximate extensions into an exact one. □

6.4 Sequences, Countability, and Metrization

Countability axioms control when topological questions reduce to sequences and countable tests.
They also separate metric phenomena from genuinely non-metric topologies.

Definition 6.4.1. *Sequence Convergence*
Let X be a topological space, and let $\mathcal{N}_X(x)$ denote the neighborhoods of $x \in X$.
For $(x_n) \subseteq X$ and $x \in X$, the sequence (x_n) *converges* to x, written $x_n \to x$, iff $(\forall U \in \mathcal{N}_X(x))(\exists N \in \mathbb{N})(\forall n \ge N)\, x_n \in U$.

Definition 6.4.2. *Sequential Compactness*
A topological space X is *sequentially compact* iff $(\forall (x_n) \subseteq X)(\exists (n_k) \subseteq \mathbb{N})(\exists x \in X)\, [n_1 < n_2 < \cdots \wedge x_{n_k} \to x]$.
Key Insight: Sequential compactness is compactness tested by subsequences.

Proposition 6.4.3. *Product Convergence Is Pointwise*
Let $X^\Lambda = \prod_{\lambda\in\Lambda} X_\lambda$ carry the product topology from $\{(X_\lambda, \mathcal{T}_\lambda)\}_{\lambda\in\Lambda}$. For $\lambda \in \Lambda$, define $\pi_\lambda : X^\Lambda \to X_\lambda$ by $\pi_\lambda(z) := z(\lambda)$.
For $(x_n) \subseteq X^\Lambda$ and $x \in X^\Lambda$, $x_n \to x$ iff $(\forall \lambda \in \Lambda)\, x_n(\lambda) \to x(\lambda)$ in X_λ.

Proof.
(⇒) Fix $\lambda \in \Lambda$ and let $U \in \mathcal{T}_\lambda$ contain $x(\lambda)$. Cylinder $\pi_\lambda^{-1}(U)$ is basic neighborhood of x by Proposition 6.2.8(ii).
If $x_n \to x$, then $x_n \in \pi_\lambda^{-1}(U)$ eventually, equivalently $x_n(\lambda) \in U$ eventually. Hence $x_n(\lambda) \to x(\lambda)$.
(⇐) Assume $(\forall \lambda \in \Lambda)\, x_n(\lambda) \to x(\lambda)$, and let $G \in \mathcal{N}_{X^\Lambda}(x)$.
Choose a basic neighborhood $W = \prod_{\lambda\in\Lambda} U_\lambda$ with $x \in W \subseteq G$ by Proposition 6.2.8(ii).
Set $F := \{\lambda \in \Lambda : U_\lambda \ne X_\lambda\}$; then F is finite. For $\lambda \in F$, choose $N_\lambda \in \mathbb{N}$ such that $(\forall n \ge N_\lambda)\, x_n(\lambda) \in U_\lambda$.
If $F = \emptyset$, set $N := 1$; otherwise set $N := \max_{\lambda\in F} N_\lambda$. Then $(\forall n \ge N)\, x_n \in W \subseteq G$, so $x_n \to x$.

Structural Commentary: Product neighborhoods impose finitely many coordinate constraints.
Key Insight: Coordinate convergence satisfies every finite constraint. □

Proposition 6.4.4. *Hausdorff Sequence Limits Are Unique*
Let X be a topological space and let $(x_n) \subseteq X$.
(i) If X is Hausdorff, then (x_n) has at most one limit.
(ii) If X has the trivial topology $\{\emptyset, X\}$, then $(\forall x \in X)\, x_n \to x$.

Proof.
(*i*) If $x_n \to x$ and $x_n \to y$ with $x \ne y$, choose disjoint neighborhoods $U \in \mathcal{N}_X(x)$ and $V \in \mathcal{N}_X(y)$.
Eventually $x_n \in U$ and $x_n \in V$, contradicting $U \cap V = \emptyset$.
(*ii*) In the trivial topology, $(\forall x \in X)\, \mathcal{N}_X(x) = \{X\}$, and every sequence is eventually in X.

Structural Commentary: Hausdorff neighborhoods separate competing limits.
Key Insight: A sequence tail cannot lie in two disjoint neighborhoods. □

Definition 6.4.5. *Countability Axioms*
Let (X, τ) be a topological space.
(i) X is *first countable* iff each $x \in X$ has an at most countable neighborhood basis.
(ii) X is *second countable* iff τ has an at most countable basis.
(iii) X is *separable* iff $(\exists D \subseteq X)[D$ is at most countable $\wedge\ \overline{D} = X]$. Equivalently, such a D satisfies $(\forall U \in \tau \setminus \{\emptyset\})\, U \cap D \ne \emptyset$.
Key Insight: Countability axioms reduce topology to at most countably many local, global, or dense tests.

Proposition 6.4.6. *Metric Spaces Are First Countable*
Let (X, d) be a metric space. Then X is first countable.

Proof. Let $x \in X$. The collection $\mathcal{B}_x := \{B_{1/n}(x) : n \in \mathbb{N}\}$ is at most countable.
If U is a neighborhood of x, choose $r > 0$ with $B_r(x) \subseteq U$ and $n \in \mathbb{N}$ with $n > r^{-1}$ by Theorem 1.1.19(i).
Then $B_{1/n}(x) \subseteq B_r(x) \subseteq U$, so $\mathcal{B}_x$ is a neighborhood basis at x.
Structural Commentary: Archimedean reciprocal radii refine every metric neighborhood.
Key Insight: Reciprocal-radius balls form one local test sequence. □

Proposition 6.4.7. *Second Countable Implies First Countable*
Let (X, τ) be second countable. Then X is first countable.

Proof. Let $\mathcal{B}$ be an at most countable basis for τ. For $x \in X$, set $\mathcal{B}_x := \{B \in \mathcal{B} : x \in B\}$.
Then $\mathcal{B}_x$ is at most countable, and $(\forall U \in \mathcal{N}_X(x))(\exists B \in \mathcal{B}_x)\, x \in B \subseteq U$.
Structural Commentary: Restrict the global basis to sets containing x.
Key Insight: At most countably many global tests become at most countably many local tests. □

Proposition 6.4.8. *First Countable Sequential Closure*
Let X be first countable, let $E \subseteq X$, and let $x \in X$.

(i) $x \in \overline{E}$ iff $\exists (x_n) \subseteq E$ with $x_n \to x$.
(ii) E is closed iff $(\forall (x_n) \subseteq E)(\forall y \in X)\, [x_n \to y \Rightarrow y \in E]$.

Proof.

(*i*) ($\Rightarrow$) The neighborhood basis at x is nonempty, so write it as $\{B_n : n \in \mathbb{N}\}$ by Proposition 6.2.13.
Since $x \in \overline{E}$ and $\bigcap_{j=1}^{n} B_j \in \mathcal{N}_X(x)$, choose $x_n \in E \cap \bigcap_{j=1}^{n} B_j$.
If $U \in \mathcal{N}_X(x)$, choose $m \in \mathbb{N}$ with $B_m \subseteq U$. Then $(\forall n \geq m)\, x_n \in B_m \subseteq U$, so $x_n \to x$.
(*i*) ($\Leftarrow$) If $(x_n) \subseteq E$ and $x_n \to x$, then every neighborhood of x contains some $x_n \in E$, so $x \in \overline{E}$.
(*ii*) ($\Rightarrow$) If E is closed and $(x_n) \subseteq E$ with $x_n \to x$, then $x \in \overline{E} = E$ by (*i*).
(*ii*) ($\Leftarrow$) Assume $(\forall (x_n) \subseteq E)(\forall y \in X)\, [x_n \to y \Rightarrow y \in E]$. Then $\overline{E} \subseteq E$ by (*i*). Hence $E = \overline{E}$.

Structural Commentary: Countable local bases produce one testing sequence.
Key Insight: In first countable spaces, closure is sequential closure. □

Proposition 6.4.9. *Second Countable Consequences*
Let (X, τ) be second countable.

(i) An at most countable $D \subseteq X$ exists with $\overline{D} = X$.
(ii) $(\forall Y \subseteq X)$, the subspace Y is second countable.

Proof.

(i) Let $\mathcal{B} = \{B_n : n \in I\}$ be an at most countable basis, where $I \subseteq \mathbb{N}$.
For $n \in I$ with $B_n \neq \emptyset$, choose $x_n \in B_n$ and set $D := \{x_n : n \in I,\ B_n \neq \emptyset\}$.
Then D is at most countable by Proposition 6.2.12(i),(ii).
If $U \in \tau \setminus \{\emptyset\}$, choose $x \in U$ and $B_n \in \mathcal{B}$ with $x \in B_n \subseteq U$. Then $x_n \in D \cap U$, so $\overline{D} = X$.
(ii) If $Y \subseteq X$, then $\{B_n \cap Y : n \in I\}$ is an at most countable basis for the subspace topology on Y.

Structural Commentary: Basis representatives establish density; basis restrictions preserve second countability.
Key Insight: One basis indexed within $\mathbb{N}$ controls both dense points and subspaces. □

Proposition 6.4.10. *Separable Metric Spaces and Countable Bases*
Let (X, d) be a metric space, and let τ_d be its metric topology. The following are equivalent:

(i) An at most countable $D \subseteq X$ exists with $\overline{D}^{\,X} = X$.
(ii) An at most countable basis $\mathcal{B} \subseteq \tau_d$ exists for τ_d.

Proof.

(*i*) $\Rightarrow$ (*ii*) Let $D \subseteq X$ be at most countable with $\overline{D}^{\,X} = X$, and set $\mathcal{B} := \{B_q(x) : x \in D,\ q \in \mathbb{Q},\ q > 0\}$.
The parameter set $D \times \mathbb{Q}_{>0}$ is at most countable by Proposition 6.2.12(i) and Corollary 6.2.17(i).
Hence $\mathcal{B}$ is at most countable by Proposition 6.2.12(ii).
For $U \in \tau_d$ and $y \in U$, choose $r > 0$ with $B_r(y) \subseteq U$ and $q \in \mathbb{Q}$ with $0 < q < r/2$ by Theorem 1.1.19(ii).
Then choose $x \in D \cap B_q(y)$ by $\overline{D}^{\,X} = X$. If $z \in B_q(x)$, then $d(z, y) < 2q < r$, so $y \in B_q(x) \subseteq B_r(y) \subseteq U$.
(*ii*) $\Rightarrow$ (*i*) Let $\mathcal{B} = \{U_n : n \in I\}$ be an at most countable basis for τ_d, where $I \subseteq \mathbb{N}$.
For $n \in I$ with $U_n \neq \emptyset$, choose $x_n \in U_n$ and set $D := \{x_n : n \in I,\ U_n \neq \emptyset\}$.
Then D is at most countable by Proposition 6.2.12(i),(ii).
If $\emptyset \neq U \in \tau_d$, choose $y \in U$ and $n \in I$ with $y \in U_n \subseteq U$; then $x_n \in D \cap U$.
Hence every nonempty open set meets D, so $\overline{D}^{\,X} = X$.

Structural Commentary: In metric spaces, a dense set indexed within $\mathbb{N}$ produces all rational-radius local tests.
Key Insight: Separability and second countability coincide for metric spaces. □

Proposition 6.4.11. *Subspaces of Separable Metric Spaces*
Let (X, d) be a separable metric space and let $E \subseteq X$ with the subspace metric $d|_{E \times E}$. Then E is separable.

Proof. The metric topology τ_d has an at most countable basis $\mathcal{B}$ by Proposition 6.4.10.
Set $\mathcal{B}_E := \{B \cap E : B \in \mathcal{B}\}$. Then $\mathcal{B}_E$ is at most countable by Proposition 6.2.12(ii).
If U is open in E and $x \in U$, choose $G \in \tau_d$ with $U = E \cap G$ and $B \in \mathcal{B}$ with $x \in B \subseteq G$.
Hence $x \in B \cap E \subseteq U$, so $\mathcal{B}_E$ is an at most countable basis for E. Therefore E is separable by Proposition 6.4.10.
Structural Commentary: An ambient basis indexed within $\mathbb{N}$ restricts to a subspace basis indexed within $\mathbb{N}$.
Key Insight: Metric separability passes to all subspaces through countable bases. □

Corollary 6.4.12. *Euclidean Subsets Are Separable*
Let $k \in \mathbb{N}$ and let $E \subseteq \mathbb{R}^k$ have the subspace Euclidean metric. Then E is separable.

Proof. The set $\mathbb{Q}^k$ is countable by Theorem 6.2.18 and Corollary 6.2.19.
For $x \in \mathbb{R}^k$ and $r > 0$, choose $q = (q_1, \dots, q_k) \in \mathbb{Q}^k$ with $(\forall i \in \{1, \dots, k\})\ |x_i - q_i| < r/\sqrt{k}$, so $\|x - q\|_2 < r$.
Hence $\mathbb{Q}^k$ is dense in $\mathbb{R}^k$. Thus $\mathbb{R}^k$ is separable, and E is separable by Proposition 6.4.11.
Structural Commentary: Rational grids are countable dense nets.
Key Insight: Euclidean separability passes to subspaces. □

Counterexample 6.4.13. *T_1 Spaces Need Not Be First Countable*
Let X be uncountable and let $\tau := \{\emptyset\} \cup \{U \subseteq X : X \setminus U \text{ is finite}\}$.

(i) τ is a topology on X.
(ii) (X, τ) is T_1.
(iii) (X, τ) is not first countable.

Proof.

(*i*) One has $\emptyset, X \in \tau$, and a finite intersection of cofinite sets is cofinite.
If $\{U_\alpha\}_{\alpha \in A} \subseteq \tau$ and some U_{α_0} is nonempty, then $X \setminus \bigcup_{\alpha \in A} U_\alpha \subseteq X \setminus U_{\alpha_0}$ is finite.
If every U_α is empty, then the union is empty. Hence τ is a topology.
(*ii*) For $x \in X$, $X \setminus \{x\} \in \tau$, so $\{x\}$ is closed. Hence (X, τ) is T_1.
(*iii*) Fix $x \in X$. If an at most countable neighborhood basis existed at x, write it as $\{B_n : n \in \mathbb{N}\}$ by Proposition 6.2.13.
For $n \in \mathbb{N}$, choose $O_n \in \tau$ with $x \in O_n \subseteq B_n$; then $X \setminus B_n \subseteq X \setminus O_n$ is finite.
Thus $C := \{x\} \cup \bigcup_{n \in \mathbb{N}} (X \setminus B_n)$ is at most countable by Corollary 6.2.16.
Choose $y \in X \setminus C$. Then $U := X \setminus \{y\} \in \mathcal{N}_X(x)$, but $(\forall n \in \mathbb{N})\, y \in B_n$, so no B_n is contained in U.

Key Insight: Countably many finite complements miss a point needed to refine one cofinite neighborhood. □

Definition 6.4.14. *Lindelöf Spaces*
Let (X, τ) be a topological space. The space X is *Lindelöf* iff every open cover has an at most countable subcover.
Key Insight: Lindelöfness reduces arbitrary covers to at most countable subcovers.

Definition 6.4.15. *Countably Compact Spaces*
Let (X, τ) be a topological space. The space X is *countably compact* iff every at most countable open cover has a finite subcover.
Key Insight: Countable compactness reduces at most countable covers to finite subcovers.

Proposition 6.4.16. *Fréchet Intersection Test for Countable Compactness*
Let X be a topological space.
Then X is countably compact iff every descending sequence of nonempty closed subsets of X has nonempty intersection.

Proof.

(⇒) Assume X is countably compact. If $\bigcap_{n \geq 1} F_n = \emptyset$, then $\{X \setminus F_n : n \geq 1\}$ is an at most countable open cover.
A finite subcover exists; since F_n descends, some $X \setminus F_N$ covers X, contradicting $F_N \neq \emptyset$.
(⇐) Suppose an at most countable open cover has no finite subcover. It has the form $\{O_n : n \in \mathbb{N}\}$ by Proposition 6.2.13.
Then $F_n := X \setminus \bigcup_{j=1}^{n} O_j$ is nonempty, closed, and descending, while $\bigcap_{n \geq 1} F_n = \emptyset$, a contradiction.

Structural Commentary: Complements turn at most countable covers into descending closed sequences.
Key Insight: Countable compactness is nested closed intersection. □

Theorem 6.4.17. *Dini's Theorem on Countably Compact Spaces*
Let X be countably compact, and let $f_n : X \to \mathbb{R}$ be continuous with $(\forall x \in X)\, f_n(x) \downarrow 0$.
Then $f_n \to 0$ uniformly: $(\forall \varepsilon > 0)(\exists N \in \mathbb{N})(\forall x \in X)(\forall n \geq N)\, 0 \leq f_n(x) < \varepsilon$.

Proof. Fix $\varepsilon > 0$ and set $O_n := \{x \in X : f_n(x) < \varepsilon\}$. The set O_n is open by Proposition 6.2.2(i), while $O_n \subseteq O_{n+1}$ and $\bigcup_{n \geq 1} O_n = X$.
Choose $m, n_1, \dots, n_m \in \mathbb{N}$ with $X = \bigcup_{j=1}^{m} O_{n_j}$ by countable compactness. Set $N := \max_{1 \leq j \leq m} n_j$; $O_N = X$ by increasingness of (O_n).
Hence $(\forall x \in X)(\forall n \geq N)\, 0 \leq f_n(x) \leq f_N(x) < \varepsilon$.
Structural Commentary: Increasing sublevel covers reduce finite subcovers to one index.
Key Insight: Monotone pointwise convergence becomes uniform convergence. □

Proposition 6.4.18. *Second Countable Implies Lindelöf*
Let (X, τ) be second countable. Then X is Lindelöf.

Proof. Let $\mathcal{B} = \{B_n : n \in I\}$ be an at most countable basis with $I \subseteq \mathbb{N}$, and let $\mathcal{U} \subseteq \tau$ cover X.
Set $I_0 := \{n \in I : (\exists U \in \mathcal{U})\, B_n \subseteq U\}$, and choose $U_n \in \mathcal{U}$ with $B_n \subseteq U_n$ for $n \in I_0$.
The family $\{U_n : n \in I_0\}$ is at most countable by Proposition 6.2.12(i),(ii).
If $x \in X$, choose $U \in \mathcal{U}$ with $x \in U$ and $B_n \in \mathcal{B}$ with $x \in B_n \subseteq U$; then $n \in I_0$ and $x \in U_n$.
Structural Commentary: Basis elements refine arbitrary open covers.
Key Insight: An at most countable basis produces an at most countable subcover. □

Proposition 6.4.19. *Second Countable Countable Compactness Is Compactness*
Let (X, τ) be second countable. Then X is compact iff X is countably compact.

Proof.

(⇒) If an at most countable $\mathcal{U} \subseteq \tau$ covers X, then a finite $\mathcal{V} \subseteq \mathcal{U}$ with $X = \bigcup \mathcal{V}$ exists by compactness.

(⇐) Let $\mathcal{U} \subseteq \tau$ cover X. An at most countable $\mathcal{V} \subseteq \mathcal{U}$ with $X = \bigcup \mathcal{V}$ exists by Proposition 6.4.18.
A finite $\mathcal{W} \subseteq \mathcal{V}$ with $X = \bigcup \mathcal{W}$ exists by countable compactness.

Structural Commentary: Second countability reduces covers to at most countable subcovers.
Key Insight: Countable compactness then makes the subcover finite. □

Theorem 6.4.20. *Second Countable Compactness and Sequential Compactness*
Let X be a second countable topological space. Then X is compact iff X is sequentially compact.

Proof.
(⇒) Assume X is compact. Let $(x_n) \subseteq X$ and set $F_n := \overline{\{x_k : k \geq n\}}$.
The sets $F_1 \supseteq F_2 \supseteq \cdots$ are nonempty, closed, and have the finite intersection property.
Hence $\exists x \in \bigcap_{n \geq 1} F_n$ by Proposition 6.3.3. The space is first countable by Proposition 6.4.7.

Write a neighborhood basis at x as $\{C_j : j \in \mathbb{N}\}$ by Proposition 6.2.13, and set $B_j := \bigcap_{i=1}^{j} C_i$.

With $n_0 := 0$, recursively choose $n_j > n_{j-1}$ with $x_{n_j} \in B_j$ by $x \in F_{n_{j-1}+1}$ and $B_j \cap \{x_k : k \geq n_{j-1} + 1\} \neq \emptyset$.
If $U \in \mathcal{N}_X(x)$, choose $i \in \mathbb{N}$ with $C_i \subseteq U$. Then $(\forall j \geq i)\, x_{n_j} \in B_j \subseteq C_i \subseteq U$, so $x_{n_j} \to x$.
(⇐) Assume X is sequentially compact. Countable compactness suffices by Proposition 6.4.19.
Suppose an at most countable open cover has no finite subcover.

It has the form $\{O_n : n \in \mathbb{N}\}$ by Proposition 6.2.13; choose $x_n \in X \setminus \bigcup_{j=1}^{n} O_j$.

There are a subsequence (x_{n_k}) and $x \in X$ with $x_{n_k} \to x$ by sequential compactness. Choose $N \in \mathbb{N}$ with $x \in O_N$.
Eventually $n_k \geq N$ and $x_{n_k} \in O_N$, contradicting $x_{n_k} \notin O_N$.

Structural Commentary: Compact closed tails locate a cluster point; an enumerated local basis extracts its subsequence.
Key Insight: At most countable covers and bases make compactness sequential. □

Definition 6.4.21. *Metrizable Space*
A topological space is *metrizable* if its topology is induced by some metric.

Definition 6.4.22. *Sorgenfrey Line*
Let $\mathcal{B}_S := \{[a, b) : a < b\}$ on $\mathbb{R}$. The *Sorgenfrey line* is $\mathbb{R}_S := (\mathbb{R}, \tau_S)$, where τ_S is the topology generated by $\mathcal{B}_S$.

Counterexample 6.4.23. *First Countable Separable Spaces Need Not Be Second Countable*
The Sorgenfrey line $\mathbb{R}_S$ satisfies:

(i) $\mathcal{B}_S$ is a basis for τ_S;
(ii) $\mathbb{R}_S$ is first countable;
(iii) $\mathbb{R}_S$ is separable;
(iv) $\mathbb{R}_S$ is not second countable;
(v) $\mathbb{R}_S$ is not metrizable.

Proof.
(i) Every $x \in \mathbb{R}$ belongs to $[x, x + 1)$. If $x \in [a, b) \cap [c, d)$, choose e with $x < e \leq \min\{b, d\}$.
Then $x \in [x, e) \subseteq [a, b) \cap [c, d)$, so $\mathcal{B}_S$ is a basis by Definition 6.1.8(ii).
(ii) Fix $x \in \mathbb{R}$. If $x \in [a, b)$, choose $n \in \mathbb{N}$ with $n > (b - x)^{-1}$ by Theorem 1.1.19(i).
Then $[x, x + 1/n) \subseteq [a, b)$, so $\{[x, x + 1/n) : n \in \mathbb{N}\}$ is a neighborhood basis at x by (i).
(iii) Every $[a, b) \in \mathcal{B}_S$ meets $\mathbb{Q}$ by Theorem 1.1.19(ii). Hence $\overline{\mathbb{Q}}^{\mathbb{R}_S} = \mathbb{R}_S$ by (i), and $\mathbb{R}_S$ is separable by Corollary 6.2.19.
(iv) Let $\mathcal{C}$ be a basis for τ_S. For $x \in \mathbb{R}$, choose $C_x \in \mathcal{C}$ with $x \in C_x \subseteq [x, x + 1)$.
If $x < y$, then $x \in C_x \setminus C_y$, so $C_x \neq C_y$. Thus $x \mapsto C_x$ is injective. The space $\mathbb{R}$ is uncountable by Corollary 4.4.2.
Hence $\mathcal{C}$ is not at most countable by Proposition 6.2.12(i), so $\mathbb{R}_S$ is not second countable.
(v) If $\mathbb{R}_S$ were metrizable, then it would be second countable by (iii) and Proposition 6.4.10, contradicting (iv).

Structural Commentary: Half-open neighborhoods assign distinct left-anchored refinements to every real point.
Key Insight: Local countability coexists with an uncountable global basis obstruction. □

Definition 6.4.24. *Moore Plane*
Let $\mathbb{M} := \{(x, y) \in \mathbb{R}^2 : y \geq 0\}$ and $L := \mathbb{R} \times \{0\}$. Let $\mathcal{B}_{\mathbb{M}}$ consist of:

(i) $B_{\text{euc}}(p, r) \subseteq \mathbb{M}$ for $p \in \mathbb{M} \setminus L$ and $r > 0$;
(ii) $N(x, r) := \{(x, 0)\} \cup B_{\text{euc}}((x, r), r)$ for $(x, 0) \in L$ and $r > 0$.

The *Moore plane* is $(\mathbb{M}, \tau_{\mathbb{M}})$, where $\tau_{\mathbb{M}}$ is generated by $\mathcal{B}_{\mathbb{M}}$.

Figure 150 depicts the two generators from Definition 6.4.24: interior balls and boundary points augmented by tangent disks.

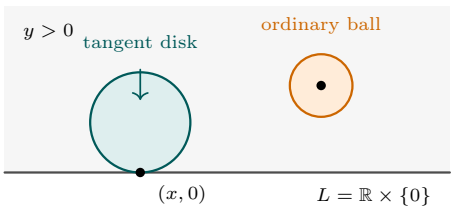

Figure 150: The Moore-plane generators are ordinary interior balls and tangent disks augmented by their boundary points.

Counterexample 6.4.25. *Separable Hausdorff Spaces Need Not Be Metrizable*
The Moore plane $(\mathbb{M}, \tau_{\mathbb{M}})$ satisfies:

(i) $\mathcal{B}_{\mathbb{M}}$ is a basis for $\tau_{\mathbb{M}}$;

(ii) $(\mathbb{M}, \tau_{\mathbb{M}})$ is Hausdorff;
(iii) $(\mathbb{M}, \tau_{\mathbb{M}})$ is separable;
(iv) $(\mathbb{M}, \tau_{\mathbb{M}})$ is not second countable;
(v) $(\mathbb{M}, \tau_{\mathbb{M}})$ is not metrizable.

Proof.

(i) Every interior point belongs to a sufficiently small Euclidean ball contained in $\mathbb{M}$, and $(x,0) \in N(x,1)$ for $(x,0) \in L$.
If an interior point lies in two members of $\mathcal{B}_{\mathbb{M}}$, their intersection contains a sufficiently small Euclidean ball around it.
Every member of $\mathcal{B}_{\mathbb{M}}$ containing $(x,0) \in L$ has the form $N(x,r)$, and $N(x, \min\{r,s\}) \subseteq N(x,r) \cap N(x,s)$.
Hence $\mathcal{B}_{\mathbb{M}}$ is a basis by Definition 6.1.8(ii).

(ii) Distinct interior points have disjoint Euclidean balls contained in $\mathbb{M}$. If $(x,0),(y,0) \in L$ with $x \neq y$, then $N(x,r) \cap N(y,r) = \emptyset$ when $0 < 2r < |x-y|$. Let $p = (x,0) \in L$, $q = (u,v) \in \mathbb{M} \setminus L$, $\delta := \|p-q\|_2$. Choose $0 < r < \delta/4$, $0 < s < \min\{v, \delta/2\}$.
Then $N(x,r) \subseteq B^{\mathrm{euc}}_{\delta/2}(p)$ and $B_{\mathrm{euc}}(q,s) \in \mathcal{B}_{\mathbb{M}}$ are disjoint neighborhoods of p and q. Hence $(\mathbb{M}, \tau_{\mathbb{M}})$ is Hausdorff by (i).

(iii) Set $D := \mathbb{Q} \times (\mathbb{Q} \cap (0,\infty))$. Then D is at most countable by Proposition 6.2.12(i) and Corollary 6.2.17(i).
Every member of $\mathcal{B}_{\mathbb{M}}$ contains some $B_{\mathrm{euc}}((a,b),s)$ with $b > s > 0$.
Choose $q_1, q_2 \in \mathbb{Q}$ with $|a - q_1| < s/\sqrt{2}$ and $|b - q_2| < s/\sqrt{2}$ by Theorem 1.1.19(ii).
Then $(q_1,q_2) \in D \cap B_{\mathrm{euc}}((a,b),s)$. Hence every basis set meets D, so $\overline{D}^{\mathbb{M}} = \mathbb{M}$ by (i), and $(\mathbb{M}, \tau_{\mathbb{M}})$ is separable.

(iv) For $(x,0) \in L$, $N(x,r) \cap L = \{(x,0)\}$, so L is discrete. Map $x \mapsto (x,0)$ is a bijection $\mathbb{R} \to L$, so L is uncountable by Corollary 4.4.2.
A dense subset of the discrete space L equals L, so L is not separable.
If $\mathbb{M}$ were second countable, then L would be second countable by Proposition 6.4.9(ii).
Then L would be separable by Proposition 6.4.9(i), a contradiction.

(v) If $\mathbb{M}$ were metrizable, then it would be second countable by (iii) and Proposition 6.4.10, contradicting (iv).

Structural Commentary: Rational interior points establish density, while singleton boundary traces force a nonseparable subspace.
Key Insight: The uncountable discrete boundary obstructs every at most countable basis. □

Theorem 6.4.26. *Urysohn Metrization Theorem*
Let (X,τ) be second countable. Then τ is induced by a metric iff (X,τ) is normal.

Proof.

($\Rightarrow$) Let d induce τ. Then (X,τ) is normal by Proposition 6.1.15.

($\Leftarrow$) Assume (X,τ) is normal.

(a) *Separating family*: Let $\{U_n : n \in I\}$ be an at most countable basis with $I \subseteq \mathbb{N}$, and set $A := \{(n,m) \in I^2 : \overline{U_n} \subseteq U_m\}$.
For $(n,m) \in A$, the closed sets $\overline{U_n}$ and $X \setminus U_m$ are disjoint.
Choose a continuous $f_{n,m} : X \to [0,1]$ such that $f_{n,m}|_{\overline{U_n}} = 0$ and $f_{n,m}|_{X \setminus U_m} = 1$ by Theorem 6.3.20.

(b) *Weighted limit*: For $k \in \mathbb{N}$, set $A_k := A \cap \{1,\dots,k\}^2$ and $\rho_k(x,y) := \sum_{(n,m) \in A_k} 2^{-(n+m)} |f_{n,m}(x) - f_{n,m}(y)|$.
For $x,y \in X$ and $(n,m) \in A$, one has $0 \le |f_{n,m}(x) - f_{n,m}(y)| \le 1$.
Thus $(\rho_k(x,y))$ is increasing and $0 \le \rho_k(x,y) \le (\sum_{j=1}^{k} 2^{-j})^2 = (1 - 2^{-k})^2 < 1$.
Hence $\rho(x,y) := \lim_{k \to \infty} \rho_k(x,y)$ exists by Theorem 2.1.11.
Let $k, \ell \in \mathbb{N}$ with $\ell > k$, and let $x,y \in X$. Every pair in $A_\ell \setminus A_k$ has at least one coordinate exceeding k.
Thus $0 \le \rho_\ell(x,y) - \rho_k(x,y) \le 2 \sum_{j=k+1}^{\ell} 2^{-j} = 2^{1-k}(1 - 2^{k-\ell}) \le 2^{1-k}$.
For fixed k,x,y, one has $\rho_\ell(x,y) - \rho_k(x,y) \to \rho(x,y) - \rho_k(x,y)$ by Theorem 2.1.5(ii).
Hence $(\forall k \in \mathbb{N})(\forall x,y \in X)\, 0 \le \rho(x,y) - \rho_k(x,y) \le 2^{1-k}$ by Proposition 2.1.4(iii).

(c) *Pseudometric and continuity*: Each summand defining ρ_k is nonnegative, vanishes on diagonal by Proposition 1.1.17(i).
It is symmetric by Proposition 1.1.17(ii) with $|-1| = 1$.
It satisfies the triangle inequality by Proposition 1.1.17(iv). Hence ρ_k is a pseudometric.
The diagonal and symmetry identities pass directly to ρ. For $x,y,z \in X$, $\rho_k(x,z) \le \rho_k(x,y) + \rho_k(y,z)$.
The right side converges to $\rho(x,y) + \rho(y,z)$ by Theorem 2.1.5(ii).
Thus $\rho(x,z) \le \rho(x,y) + \rho(y,z)$ by Proposition 2.1.4(iii), so ρ is a pseudometric.
Fix $x \in X$. For $(n,m) \in A$, set $h_{n,m,x}(y) := |f_{n,m}(x) - f_{n,m}(y)|$.
The inequality $|h_{n,m,x}(y) - h_{n,m,x}(z)| \le |f_{n,m}(y) - f_{n,m}(z)|$ holds by two instances of Proposition 1.1.17(iv).
For $y \in X$ and $\varepsilon > 0$, choose a neighborhood W of y such that $(\forall z \in W)\ |f_{n,m}(y) - f_{n,m}(z)| < \varepsilon$ by continuity of $f_{n,m}$.
Hence $h_{n,m,x}$ is continuous. Therefore $\rho_k(x,\cdot)$ is continuous by Proposition 6.3.21(i).
The map $\rho(x,\cdot)$ is continuous by Proposition 6.3.21(ii) with the estimate in (b) and $2^{1-k} \to 0$ by Theorem 2.2.10(v).

(d) *Local metric balls*: Let $G \in \tau$ and $x \in G$. Since normality includes T_1, the set $\{x\}$ is closed.
Choose open O with $x \in O \subseteq \overline{O} \subseteq G$ by Proposition 6.1.16, and choose $m \in I$ with $x \in U_m \subseteq O$.
Choose open V with $x \in V \subseteq \overline{V} \subseteq U_m$ by same proposition, $n \in I$ with $x \in U_n \subseteq V$. Then $\overline{U_n} \subseteq \overline{V} \subseteq U_m$, so $(n,m) \in A$.
If $y \notin U_m$, then $f_{n,m}(x) = 0$ and $f_{n,m}(y) = 1$, so $\rho(x,y) \ge 2^{-(n+m)}$. Hence $B_\rho(x, 2^{-(n+m+1)}) \subseteq U_m \subseteq G$.

(e) *Definiteness and topology*: If $x \neq y$, take $G = X \setminus \{y\}$ in (d); then $\rho(x,y) > 0$. Thus ρ is a metric.
Let τ_ρ be its metric topology. Then $\tau \subseteq \tau_\rho$ by (d).
Conversely, $B_\rho(x,r) = \rho(x,\cdot)^{-1}((-\infty,r)) \in \tau$ by (c) and Proposition 6.2.2(i), so $\tau_\rho \subseteq \tau$. Hence $\tau_\rho = \tau$.

Structural Commentary: Urysohn separators form a uniformly convergent pseudometric whose local balls recover the basis topology.
Key Insight: Nested basis pairs both distinguish points and refine every open neighborhood. □

6.5 Topological Connectedness and Paths

Connectedness is an open-set obstruction to splitting a space into two visible pieces. In general topology it is most naturally phrased by separations and then transported through continuous maps.

Definition 6.5.1. *Connected Topological Spaces*
Let (X, τ) be a topological space, and let $E \subseteq X$.

(i) A set $A \subseteq X$ is *clopen* iff $A \in \tau$ and $X \setminus A \in \tau$.
(ii) A *separation* of X is a pair (U, V) with $U, V \in \tau$, $U, V \neq \emptyset$, $U \cap V = \emptyset$, and $X = U \cup V$.
(iii) X is *connected* iff no separation of X exists.
(iv) E is *connected* iff (E, τ_E) is connected, where $\tau_E := \{E \cap U : U \in \tau\}$.
Equivalently, E is disconnected iff $\exists U, V \in \tau$ with $U \cap E \neq \emptyset$, $V \cap E \neq \emptyset$, $E \subseteq U \cup V$, and $E \cap U \cap V = \emptyset$.

Key Insight: Connectedness forbids a nonempty disjoint open split.

Proposition 6.5.2. *Metric and Topological Connectedness Agree*
Let (X, d) be a metric space with its metric topology, and let $E \subseteq X$.
Then E is connected by Definition 5.1.1 iff it is connected as a topological subspace by Definition 6.5.1.

Proof.
($\Rightarrow$) Assume E is connected in the metric sense. If (U, V) separates the topological subspace E, then $U, V \neq \emptyset$ and $E = U \cup V$.
For $u \in U$, choose an open $O_u \subseteq X$ with $u \in O_u$ and $E \cap O_u \subseteq U$. Then $O_u \cap V = \emptyset$, so $u \notin \overline{V}$.
Hence $U \cap \overline{V} = \emptyset$, and similarly $\overline{U} \cap V = \emptyset$. Thus U, V are separated in the metric sense, a contradiction.
($\Leftarrow$) Assume E is connected as a topological subspace. If nonempty $A, B \subseteq E$ are separated in the metric sense and $E = A \cup B$, then $A = E \cap (X \setminus \overline{B})$ and $B = E \cap (X \setminus \overline{A})$. Thus A, B are open in E, so (A, B) separates the topological subspace E, a contradiction.

Structural Commentary: Ambient closures and relative open complements translate through subspace neighborhoods.
Key Insight: Each side avoids the opposite ambient closure exactly when it is relatively open. □

Proposition 6.5.3. *Connectedness and Clopen Sets*
Let (X, τ) be a topological space. Then X is connected iff $(\forall A \subseteq X)\,[A$ clopen $\Rightarrow (A = \emptyset \vee A = X)]$.

Proof.
($\Rightarrow$) If $A \subseteq X$ is clopen, nonempty, and proper, then $(A, X \setminus A)$ is a separation of X, impossible.
($\Leftarrow$) If (U, V) separates X, then $U = X \setminus V$ is clopen, nonempty, and proper, impossible.

Structural Commentary: Complements convert separations into clopen sets.
Key Insight: Connected means no nontrivial clopen subset. □

Proposition 6.5.4. *Continuous Images of Connected Spaces Are Connected*
Let X, Y be topological spaces and let $f : X \to Y$ be continuous. If X is connected, then $f(X)$ is connected in the subspace topology.

Proof. Let $g : X \to f(X)$ be f with codomain restricted to $f(X)$. If W is open in $f(X)$, choose O open in Y with $W = f(X) \cap O$. Then $g^{-1}(W) = f^{-1}(O)$ is open in X by Proposition 6.2.2(i), so g is continuous.
If (U, V) separates $f(X)$, then $g^{-1}(U)$, $g^{-1}(V)$ nonempty disjoint open subsets of X with union X, contrary to connectedness of X.
Structural Commentary: Restrict the codomain to make the image map surjective.
Key Insight: Separations pull back by continuity. □

Definition 6.5.5. *Intermediate Value Property*
A topological space X has the *intermediate value property* iff $(\forall f : X \to \mathbb{R})\,[f$ continuous $\Rightarrow f(X)$ is an interval$]$.

Theorem 6.5.6. *Connectedness and the Intermediate Value Property*
Let X be a topological space. Then X is connected iff X has the intermediate value property.

Proof.
($\Rightarrow$) If $f : X \to \mathbb{R}$ is continuous, then $f(X)$ is topologically connected by Proposition 6.5.4 and connected in the metric sense by Proposition 6.5.2. Hence $f(X)$ is an interval by Theorem 5.1.2.
($\Leftarrow$) We prove the contrapositive. If (U, V) separates X, define $f : X \to \mathbb{R}$ by $f|_U = 0$ and $f|_V = 1$.
For an open $O \subseteq \mathbb{R}$, $f^{-1}(O) \in \{\emptyset, U, V, X\}$, so f is continuous by Proposition 6.2.2(i). However, $f(X) = \{0, 1\}$ is not an interval.

Structural Commentary: Separations produce continuous two-valued tests.
Key Insight: Intermediate values are connectedness seen by $\mathbb{R}$. □

Proposition 6.5.7. *Unions Through a Common Point*
Let $\{C_\alpha\}_{\alpha \in A}$ be connected subsets of a topological space X with $\bigcap_{\alpha \in A} C_\alpha \neq \emptyset$. Then $C := \bigcup_{\alpha \in A} C_\alpha$ is connected.

Proof. If $A = \emptyset$, then $C = \emptyset$ is connected. Assume $A \neq \emptyset$ and choose $p \in \bigcap_{\alpha \in A} C_\alpha$.
Suppose (U, V) separates C and, after interchanging the sides if necessary, $p \in U$.
For $\alpha \in A$, the pair $(U \cap C_\alpha, V \cap C_\alpha)$ would separate C_α if $C_\alpha \cap V \neq \emptyset$.
Hence $(\forall \alpha \in A)\, C_\alpha \cap V = \emptyset$, so $V \cap C = \emptyset$, contrary to the nonemptiness of V.
Structural Commentary: Each connected piece must stay on the side containing the shared point.
Key Insight: A common point blocks separation. □

Proposition 6.5.8. *Connectedness Between a Set and Its Closure*
Let (X, τ) be a topological space and let $A \subseteq B \subseteq \overline{A}$. If A is connected, then:

(i) B is connected;
(ii) $\overline{A}$ is connected.

Proof.
(i) Suppose (P, Q) separates B. Since A is connected, $A \subseteq P$ or $A \subseteq Q$; assume $A \subseteq P$.
If $q \in Q$, choose $O \in \tau$ with $q \in O$ and $O \cap B \subseteq Q$.
Since $q \in B \subseteq \overline{A}$, $O \cap A \neq \emptyset$, contradicting $A \subseteq P$ and $P \cap Q = \emptyset$. Thus $Q = \emptyset$, contrary to the definition of a separation.
(ii) The set $\overline{A}$ is connected by (i) with $B = \overline{A}$.

Structural Commentary: Relative open separation near $\overline{A}$ must meet the connected core A.
Key Insight: Adding only closure points cannot create a new component. □

Definition 6.5.9. *Path-Connected Spaces*
A topological space X is *path-connected* iff $(\forall u, v \in X)(\exists \gamma : [0,1] \to X)\,[\gamma \text{ continuous} \wedge \gamma(0) = u \wedge \gamma(1) = v]$.

Theorem 6.5.10. *Path-Connected Spaces Are Connected*
Let X be path-connected. Then X is connected.

Proof. Suppose (U, V) separates X. Choose $u \in U$, $v \in V$, and a path $\gamma : [0,1] \to X$ from u to v.
The interval $[0,1]$ is connected in the metric sense by Theorem 5.1.2 and topologically connected by Proposition 6.5.2.
Hence $\gamma([0,1])$ is connected by Proposition 6.5.4. However, $(U \cap \gamma([0,1]), V \cap \gamma([0,1]))$ separates it, a contradiction.
Structural Commentary: A path imports interval connectedness into X.
Key Insight: Paths cannot cross a separation. □

Proposition 6.5.11. *Connected Open Sets in Euclidean Space Are Path-Connected*
Let $n \in \mathbb{N}$, and let $O \subseteq \mathbb{R}^n$ be open and connected. Then any $x, y \in O$ can be joined in O by a finite polygonal path.

Proof. Fix $x_0 \in O$. Write $a \sim b$ if $a, b \in O$ are joined in O by a finite polygonal path.
Constant paths, path reversal, and concatenation make $\sim$ an equivalence relation. Set $C := \{x \in O : x_0 \sim x\}$.
Then $x_0 \in C$. Let $x \in O$ and choose $r > 0$ with $B(x, r) \subseteq O$. Any two points of $B(x, r)$ are joined by a segment.
Thus $x \in C$ implies $B(x, r) \subseteq C$. If $x \notin C$ and $B(x, r) \cap C \neq \emptyset$, a segment from a point of C to x would imply $x \in C$.
Hence $B(x, r) \cap C = \emptyset$. Therefore C and $O \setminus C$ are open in O. Since $C \neq \emptyset$, one has $C = O$ by Proposition 6.5.3.
Thus all points of O lie in one $\sim$-equivalence class, so any two are joined by a finite polygonal path.
Structural Commentary: Polygonal reachability is both open and closed in an open set.
Key Insight: Local line segments make one component all of O. □

Counterexample 6.5.12. *Connected Need Not Mean Path-Connected*
The converse of Theorem 6.5.10 fails. Let $G := \{(x, \sin(1/x)) : 0 < x \leq 1\}$, $L := \{0\} \times [-1, 1]$, and $T := G \cup L \subseteq \mathbb{R}^2$.

(i) T is connected.
(ii) T is not path-connected.

Proof.

(i) The interval $(0, 1]$ is connected in the metric sense by Theorem 5.1.2 and topologically connected by Proposition 6.5.2.
Map $h : (0, 1] \to \mathbb{R}^2$, $h(x) := (x, \sin(1/x))$, is continuous in metric sense, hence in topological sense by Corollary 6.2.3.
Thus $G = h((0, 1])$ is connected by Proposition 6.5.4. For $y \in [-1, 1]$, choose $\theta \in [-\frac{\pi}{2}, \frac{\pi}{2}]$ with $\sin\theta = y$ and set $x_n := \frac{1}{2\pi n + \theta}$.
Then $(x_n, y) = h(x_n) \to (0, y)$, so $L \subseteq \overline{G}$ by Proposition 3.4.16. Hence $T \subseteq \overline{G}$.
Conversely, fix $p = (x, y) \in \overline{G}$ and choose $(x_n, y_n) \subseteq G$ with $(x_n, y_n) \to p$ by Proposition 3.4.16.
Then $x_n \to x$, $y_n \to y$ by Theorem 3.4.13(i). Since $(x_n) \subseteq (0, 1]$, $(y_n) \subseteq [-1, 1]$, then $x \in [0, 1]$, $y \in [-1, 1]$ by Theorem 3.4.17(ii).
If $x = 0$, then $p \in L$. If $x > 0$, then $h(x_n) \to h(x)$ by Theorem 5.1.15; hence $p = h(x) \in G$ by Theorem 3.4.6(ii).
Thus $\overline{G} \subseteq T$, so $T = \overline{G}$ and T is connected by Proposition 6.5.8(ii).

(ii) Suppose T is path-connected. Choose a path $\gamma : [0, 1] \to T$ from $(0, 0)$ to $(1, \sin 1)$ and write $\gamma(t) = (a(t), b(t))$.
The coordinate maps a, b are topologically continuous by Proposition 6.2.9 and metrically continuous by Corollary 6.2.3.
Set $Z := \{t \in [0, 1] : a(t) = 0\}$. Since $[0, 1] \setminus Z = a^{-1}(\mathbb{R} \setminus \{0\})$ is open by Proposition 6.2.2(i), Z is nonempty and closed in $[0, 1]$.
Interval $[0, 1]$ is compact in its usual topology by Theorem 4.2.5, Proposition 6.3.2; hence Z is compact by Proposition 6.3.4.
The identity on Z attains its maximum t_0 by Corollary 6.3.8. Since $a(1) = 1$, one has $t_0 < 1$.
One has $(\forall t \in (t_0, 1])\, a(t) > 0$ by $a([0, 1]) \subseteq [0, 1]$ and maximality of t_0. Set $t_j := t_0 + \frac{1 - t_0}{j+1}$.
For $j \in \mathbb{N}$, choose $N_j \in \mathbb{N}$ so large that $s_j^+ := \frac{1}{\pi/2 + 2\pi N_j} < a(t_j)$ and $s_j^- := \frac{1}{3\pi/2 + 2\pi N_j} < a(t_j)$ by Theorem 1.1.19(i).
By Theorem 5.1.43, there are $u_j^+, u_j^- \in (t_0, t_j)$ with $a(u_j^\pm) = s_j^\pm$. Since $u_j^\pm > t_0$, $\gamma(u_j^\pm) \in G$, so $b(u_j^+) = 1$ and $b(u_j^-) = -1$.
Convergence $\frac{1 - t_0}{j+1} \to 0$ follows by Theorem 2.2.10(i), Proposition 2.1.7(i), Theorem 2.1.5(ii), so $t_j \to t_0$ by Theorem 2.1.5(ii).
Hence $u_j^\pm \to t_0$ by Theorem 2.2.9 with $t_0 < u_j^\pm < t_j$. Thus $b(u_j^\pm) \to b(t_0)$ by Theorem 5.1.15.
Since $b(u_j^+) = 1$, $b(u_j^-) = -1$, uniqueness of real sequence limits by Proposition 2.1.4(i) forces $b(t_0) = 1$, $b(t_0) = -1$, contradiction.

Structural Commentary: Closure transfers connectedness from G, while the last zero forces incompatible vertical limits.
Key Insight: Infinite oscillation near $x = 0$ prevents a path from leaving L. □

Figure 151 plots the oscillatory graph G approaching the vertical segment L, the accumulation geometry behind the distinction between connectedness and path-connectedness.

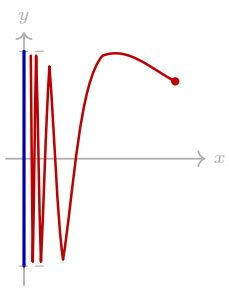

Figure 151: Topologist's sine curve: $y = \sin(1/x)$ accumulates on $\{0\} \times [-1, 1]$; connected, not path-connected.

7 Finite-Dimensional Topological Vector Spaces

7.1 Natural Topology and Continuity

Nonzero finite-dimensional real vector spaces carry a canonical topology: choose coordinates, use the standard Euclidean topology on $\mathbb{R}^n$, and then forget that coordinates were chosen. All coordinate changes are homeomorphisms. Throughout this subsection, $\mathbb{R}$ carries its usual topology and $\mathbb{R}^n$ carries its Euclidean topology.

Definition 7.1.1. *Topological Vector Space*
Let $\mathcal{V}$ be a real vector space and let $\mathcal{T}$ be a topology on its underlying set.
Define $A : \mathcal{V} \times \mathcal{V} \to \mathcal{V}$ by $A(\mathbf{u}, \mathbf{v}) := \mathbf{u} + \mathbf{v}$ and $M : \mathbb{R} \times \mathcal{V} \to \mathcal{V}$ by $M(a, \mathbf{v}) := a\mathbf{v}$.
The pair $(\mathcal{V}, \mathcal{T})$ is a *topological vector space* iff A and M are continuous, where both domains carry the product topology.

Proposition 7.1.2. *The Standard Topology on $\mathbb{R}^n$*
Let $n \in \mathbb{N}$. With the Euclidean topology, $\mathbb{R}^n$ is a topological vector space.

Proof. Fix $(\mathbf{x}, \mathbf{y}) \in \mathbb{R}^n \times \mathbb{R}^n$ and an open neighborhood O of $\mathbf{x} + \mathbf{y}$.
Choose $\varepsilon > 0$ with $B_\varepsilon(\mathbf{x} + \mathbf{y}) \subseteq O$. If $\mathbf{u} \in B_{\varepsilon/2}(\mathbf{x})$ and $\mathbf{v} \in B_{\varepsilon/2}(\mathbf{y})$, then $\|(\mathbf{u} + \mathbf{v}) - (\mathbf{x} + \mathbf{y})\|_2 \le \|\mathbf{u} - \mathbf{x}\|_2 + \|\mathbf{v} - \mathbf{y}\|_2 < \varepsilon$.
Hence $A(B_{\varepsilon/2}(\mathbf{x}) \times B_{\varepsilon/2}(\mathbf{y})) \subseteq O$, so A continuous at $(\mathbf{x}, \mathbf{y})$ by Definition 6.2.1. Fix $(a, \mathbf{x}) \in \mathbb{R} \times \mathbb{R}^n$, open neighborhood W of $a\mathbf{x}$.
Choose $\varepsilon > 0$ with $B_\varepsilon(a\mathbf{x}) \subseteq W$, and choose $\delta \in (0, 1)$ with $\delta(\|\mathbf{x}\|_2 + |a| + 1) < \varepsilon$.
If $b \in (a - \delta, a + \delta)$ and $\mathbf{y} \in B_\delta(\mathbf{x})$, then $|b| < |a| + 1$ and $\|b\mathbf{y} - a\mathbf{x}\|_2 \le |b| \, \|\mathbf{y} - \mathbf{x}\|_2 + |b - a| \, \|\mathbf{x}\|_2 < \delta(|a| + 1 + \|\mathbf{x}\|_2) < \varepsilon$.
Hence $M((a - \delta, a + \delta) \times B_\delta(\mathbf{x})) \subseteq W$, M continuous at $(a, \mathbf{x})$ by Definition 6.2.1; $\mathbb{R}^n$ is topological vector space by Definition 7.1.1.
Structural Commentary: Product neighborhoods split the output error between the input coordinates.
Key Insight: The Euclidean norm estimates both vector operations locally. □

Proposition 7.1.3. *Real Matrix Maps Are Continuous*
Let $m, n \in \mathbb{N}$, let $A = [a_{j,k}] \in \mathrm{Mat}(m, n, \mathbb{R})$, and define $T_A : \mathbb{R}^n \to \mathbb{R}^m$ by $T_A(\mathbf{x}) := A\mathbf{x}$.

(i) The map T_A is continuous for the Euclidean topologies.
(ii) If $m = n$ and A is invertible, then T_A is a homeomorphism.
(iii) $(\mathbb{R}^n)' \subseteq C(\mathbb{R}^n, \mathbb{R})$.

Proof.

(i) Fix $k \in \{1, \dots, n\}$. For $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$, $|\pi_k(\mathbf{x}) - \pi_k(\mathbf{y})| \le \|\mathbf{x} - \mathbf{y}\|_2$, so π_k is 1-Lipschitz by Definition 5.2.4.
Hence π_k is continuous by Proposition 5.2.5. Fix $j \in \{1, \dots, m\}$.
The jth coordinate $\sum_{k=1}^{n} a_{j,k}\pi_k$ of T_A is continuous by Theorem 5.1.32(i), since constant maps are continuous.
Therefore T_A is continuous in metric sense by Theorem 5.1.32(ii). It is continuous for Euclidean topologies by Corollary 6.2.3.
(ii) If A is invertible, then $(T_A)^{-1} = T_{A^{-1}}$, which is continuous by (i). Thus T_A is a homeomorphism by Definition 6.2.5.
(iii) Fix $f \in (\mathbb{R}^n)'$ and let $B \in \mathrm{Mat}(1, n, \mathbb{R})$ be its matrix. Then $f = T_B$ by Proposition 3.2.5, so f is continuous by (i).

Structural Commentary: Coordinate continuity handles matrix maps; inverse matrices, row representations handle remaining claims.
Key Insight: Matrix coordinates transfer continuity to inverses and linear functionals. □

Theorem 7.1.4. *Finite-Dimensional Linear Maps Are Lipschitz*
Let $m, n \in \mathbb{N}$ and let $A \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$.

(i) $(\forall \mathbf{x}, \mathbf{y} \in \mathbb{R}^n) \ \|A\mathbf{x} - A\mathbf{y}\|_2 \le \|A\|_{op} \|\mathbf{x} - \mathbf{y}\|_2$; hence A is $\|A\|_{op}$-Lipschitz.
(ii) If $m = n$ and A is invertible, then $(\forall \mathbf{x}, \mathbf{y} \in \mathbb{R}^n) \ \frac{1}{\|A^{-1}\|_{op}} \|\mathbf{x} - \mathbf{y}\|_2 \le \|A\mathbf{x} - A\mathbf{y}\|_2 \le \|A\|_{op} \|\mathbf{x} - \mathbf{y}\|_2$.
Hence $A : \mathbb{R}^n \to \mathbb{R}^n$ is a homeomorphism.

Proof.

(i) The bound $(\forall \mathbf{z} \in \mathbb{R}^n) \ \|A\mathbf{z}\|_2 \le \|A\|_{\mathrm{op}} \|\mathbf{z}\|_2$ holds by Definition 5.1.4. With $\mathbf{z} = \mathbf{x} - \mathbf{y}$, linearity of A proves the claim.
(ii) Since $\|A^{-1}\|_{\mathrm{op}} > 0$, $\|\mathbf{x} - \mathbf{y}\|_2 = \|A^{-1}(A\mathbf{x} - A\mathbf{y})\|_2 \le \|A^{-1}\|_{\mathrm{op}} \|A\mathbf{x} - A\mathbf{y}\|_2$ by part (i) for A^{-1}.
This inequality and part (i) are the lower and upper bounds.
The maps A and A^{-1} are continuous by part (i) and Proposition 5.2.5, so A is a homeomorphism by Definition 6.2.5.

Structural Commentary: A^{-1} converts upper control into lower control.
Key Insight: Invertible linear maps are bi-Lipschitz. □

Theorem 7.1.5. *Openness of Invertibility and Continuity of Inversion*
Let $n \in \mathbb{N}$, equip $\mathcal{L}(\mathbb{R}^n)$ with the operator-norm metric, and let Ω be its set of invertible operators.

(i) If $A \in \Omega$, $B \in \mathcal{L}(\mathbb{R}^n)$, and $\|B - A\|_{op} \|A^{-1}\|_{op} < 1$, then $B \in \Omega$.
(ii) Ω is open in $\mathcal{L}(\mathbb{R}^n)$.
(iii) The inversion map $\iota : \Omega \to \Omega$, $\iota(A) := A^{-1}$, is continuous.

Proof.

(i) Set $\alpha := \frac{1}{\|A^{-1}\|_{\mathrm{op}}}$ and $\beta := \|B - A\|_{\mathrm{op}}$; then $0 \le \beta < \alpha$.
For $\mathbf{x} \in \mathbb{R}^n$, $\alpha \|\mathbf{x}\|_2 \le \|A\mathbf{x}\|_2$ by Theorem 7.1.4(ii), while $\|A\mathbf{x}\|_2 \le \|(A - B)\mathbf{x}\|_2 + \|B\mathbf{x}\|_2 \le \beta \|\mathbf{x}\|_2 + \|B\mathbf{x}\|_2$ by Definition 5.1.4.
Hence $(\alpha - \beta) \|\mathbf{x}\|_2 \le \|B\mathbf{x}\|_2$, so $\ker B = \{\mathbf{0}\}$ and $B \in \Omega$ by Theorem 1.7.7.
For $\mathbf{y} \in \mathbb{R}^n$, set $\mathbf{x} := B^{-1}\mathbf{y}$; then $\|B^{-1}\mathbf{y}\|_2 \le \frac{1}{\alpha - \beta} \|\mathbf{y}\|_2$, so $\|B^{-1}\|_{\mathrm{op}} \le \frac{1}{\alpha - \beta}$ by Definition 5.1.4.
(ii) For $A \in \Omega$, the ball $\{B \in \mathcal{L}(\mathbb{R}^n) : \|B - A\|_{\mathrm{op}} < \frac{1}{\|A^{-1}\|_{\mathrm{op}}}\}$ lies in Ω by (i); hence Ω is open.
(iii) Fix $A \in \Omega$, let $(B_k) \subseteq \Omega$ satisfy $B_k \to A$. Set $\alpha := \frac{1}{\|A^{-1}\|_{\mathrm{op}}}$, $\beta_k := \|B_k - A\|_{\mathrm{op}}$. Eventually $\beta_k < \frac{\alpha}{2}$, so $\|B_k^{-1}\|_{\mathrm{op}} \le \frac{2}{\alpha}$ by (i).
The bound $\|B_k^{-1} - A^{-1}\|_{\mathrm{op}} \le \frac{2}{\alpha} \beta_k \|A^{-1}\|_{\mathrm{op}} \to 0$ holds by $B_k^{-1} - A^{-1} = B_k^{-1}(A - B_k)A^{-1}$ and Proposition 5.1.3(v).
Thus inversion is continuous at A by Theorem 5.1.15. Since $A \in \Omega$ was arbitrary, ι is continuous.

Structural Commentary: The lower stretch controls inverse norms; the resolvent identity transfers perturbations to inverses.
Key Insight: Uniform inverse bounds make $B^{-1}(A-B)A^{-1}$ vanish with $B-A$. □

Definition 7.1.6. *Natural Topology from a Basis*
Let $n \in \mathbb{N}$, let $\mathcal{V}$ be an n-dimensional real vector space, let β be a basis, and let $[\cdot]_\beta : \mathcal{V} \to \mathbb{R}^n$ be the coordinate isomorphism.
The *natural topology induced by* β is $\mathcal{T}_\beta := \{[\cdot]_\beta^{-1}(O) : O \subseteq \mathbb{R}^n \text{ is open}\}$. Equivalently, $(\forall U \subseteq \mathcal{V})\,[U \in \mathcal{T}_\beta \iff [\cdot]_\beta(U) \text{ is open in } \mathbb{R}^n]$.

Proposition 7.1.7. *Natural Topology Is Basis-Independent*
Let $n \in \mathbb{N}$, let $\mathcal{V}$ be an n-dimensional real vector space, and let β and γ be bases of $\mathcal{V}$. Then $\mathcal{T}_\beta = \mathcal{T}_\gamma$.

Proof. Set $H_{\gamma\leftarrow\beta} := [\cdot]_\gamma \circ [\cdot]_\beta^{-1} : \mathbb{R}^n \to \mathbb{R}^n$. The identity $H_{\gamma\leftarrow\beta}\mathbf{x} = C_{\gamma\leftarrow\beta}\mathbf{x}$ holds by Definition 3.5.1.
Matrix $C_{\gamma\leftarrow\beta}$ invertible with inverse $C_{\beta\leftarrow\gamma}$ by Theorem 3.5.2(i); $H_{\gamma\leftarrow\beta}$ is homeomorphism with inverse $H_{\beta\leftarrow\gamma}$ by Proposition 7.1.3(ii).
For $U \subseteq \mathcal{V}$, $U \in \mathcal{T}_\beta \iff [\cdot]_\beta(U)$ open $\iff H_{\gamma\leftarrow\beta}([\cdot]_\beta(U)) = [\cdot]_\gamma(U)$ open $\iff U \in \mathcal{T}_\gamma$ by Definition 7.1.6, homeomorphism property.
Structural Commentary: Basis changes are homeomorphisms.
Key Insight: The natural topology is carried by the vector-space structure, not by a preferred basis. □

Theorem 7.1.8. *Characterization of the Natural Topology*
Let $\mathcal{V}$ be a real vector space, set $n := \dim_{\mathbb{R}} \mathcal{V}$, assume $1 \le n < \infty$, let $\beta = (\mathbf{v}_1, \dots, \mathbf{v}_n)$ be a basis, and let $\mathcal{T}$ be a topology on $\mathcal{V}$.

(i) $(\mathcal{V}, \mathcal{T}_\beta)$ is a topological vector space.
(ii) $\mathcal{V}' \subseteq C((\mathcal{V}, \mathcal{T}_\beta), \mathbb{R})$.
(iii) If $(\mathcal{V}, \mathcal{T})$ is a topological vector space and $\mathcal{V}' \subseteq C((\mathcal{V}, \mathcal{T}), \mathbb{R})$, then $\mathcal{T} = \mathcal{T}_\beta$.

Proof. Put $\Phi_\beta := [\cdot]_\beta$.

(i) The map $\Phi_\beta : (\mathcal{V}, \mathcal{T}_\beta) \to \mathbb{R}^n$ is a homeomorphism by Definition 7.1.6.
The product maps $\Phi_\beta \times \Phi_\beta$ and $\mathrm{id}_{\mathbb{R}} \times \Phi_\beta$, together with their product inverses, are continuous by Propositions 6.2.9 and 6.2.2(iii).
Hence both product maps are homeomorphisms by Definition 6.2.5.
Let $A_{\mathcal{V}}, M_{\mathcal{V}}$ and $A_{\mathbb{R}^n}, M_{\mathbb{R}^n}$ denote the vector operations on $\mathcal{V}$ and $\mathbb{R}^n$, respectively.
Identity $A_{\mathcal{V}} = \Phi_\beta^{-1} \circ A_{\mathbb{R}^n} \circ (\Phi_\beta \times \Phi_\beta)$ holds by Proposition 3.2.2(i). Also, $M_{\mathcal{V}} = \Phi_\beta^{-1} \circ M_{\mathbb{R}^n} \circ (\mathrm{id}_{\mathbb{R}} \times \Phi_\beta)$ by Proposition 3.2.2(i).
The maps $A_{\mathcal{V}}$ and $M_{\mathcal{V}}$ are continuous by Propositions 7.1.2 and 6.2.2(iii).

(ii) If $\varphi \in \mathcal{V}'$, then $\varphi \circ \Phi_\beta^{-1} \in (\mathbb{R}^n)'$, continuous by Proposition 7.1.3(iii); $\varphi = (\varphi \circ \Phi_\beta^{-1}) \circ \Phi_\beta$ is continuous by Proposition 6.2.2(iii).

(iii) Suppose $(\mathcal{V}, \mathcal{T})$ is a topological vector space and $\mathcal{V}' \subseteq C((\mathcal{V}, \mathcal{T}), \mathbb{R})$.

(a) *Coordinate Functionals*: For $i \in \{1, \dots, n\}$, set $\varphi_i := \pi_i \circ \Phi_\beta \in \mathcal{V}'$. Each φ_i is continuous by the dual-continuity hypothesis.

(b) *Forward Coordinate Map*: Fix $\mathbf{v} \in \mathcal{V}$ and an open neighborhood O of $\Phi_\beta(\mathbf{v})$.
Choose $\varepsilon > 0$ with $B_\varepsilon(\Phi_\beta(\mathbf{v})) \subseteq O$, and set $I_i := \left(\varphi_i(\mathbf{v}) - \frac{\varepsilon}{\sqrt{n}}, \varphi_i(\mathbf{v}) + \frac{\varepsilon}{\sqrt{n}}\right)$ for $i \in \{1, \dots, n\}$.
The set $U := \bigcap_{i=1}^{n} \varphi_i^{-1}(I_i)$ is an open neighborhood of $\mathbf{v}$ by Definition 6.1.1 and Proposition 6.2.2(i).
For $\mathbf{u} \in U$, $\left\|\Phi_\beta(\mathbf{u}) - \Phi_\beta(\mathbf{v})\right\|_2 < \varepsilon$, so $\Phi_\beta(U) \subseteq O$. Hence $\Phi_\beta : (\mathcal{V}, \mathcal{T}) \to \mathbb{R}^n$ is continuous by Definition 6.2.1.

(c) *Coordinate Synthesis*: The inverse of Φ_β is $\Psi : \mathbb{R}^n \to \mathcal{V}$, $\Psi(\mathbf{a}) := \sum_{i=1}^{n} \pi_i(\mathbf{a})\mathbf{v}_i$, by Definition 3.2.1.
Each π_i is continuous by Proposition 7.1.3(iii). Each constant map $\mathbf{a} \mapsto \mathbf{v}_i$ is continuous by Proposition 6.2.2(i), because every open-set preimage is either $\emptyset$ or $\mathbb{R}^n$. Hence $\mathbf{a} \mapsto (\pi_i(\mathbf{a}), \mathbf{v}_i)$ is continuous by Proposition 6.2.9, and $\mathbf{a} \mapsto \pi_i(\mathbf{a})\mathbf{v}_i$ is continuous by the topological-vector-space hypothesis and Proposition 6.2.2(iii).
Finite sums of these maps continuous by same hypothesis, Proposition 6.2.9, Proposition 6.2.2(iii). Thus Ψ is continuous.

(d) *Conclusion*: The map Φ_β is a homeomorphism by (b)–(c) and Definition 6.2.5. Hence $\mathcal{T} = \mathcal{T}_\beta$ by Definition 7.1.6.

Structural Commentary: Coordinate functionals recover the forward map; vector operations recover its inverse.
Key Insight: Functionals and vector operations determine finite-dimensional coordinates topologically. □

Corollary 7.1.9. *Finite-Dimensional Linear Maps Are Continuous*
Let $\mathcal{V}$ and $\mathcal{W}$ be nonzero finite-dimensional real vector spaces with their natural topologies.

(i) $\mathcal{L}(\mathcal{V}, \mathcal{W}) \subseteq C(\mathcal{V}, \mathcal{W})$.
(ii) If $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$ is an isomorphism, then T is a homeomorphism.

Proof.

(i) Choose bases β of $\mathcal{V}$ and γ of $\mathcal{W}$, and fix $T \in \mathcal{L}(\mathcal{V}, \mathcal{W})$.
Coordinate map $[\cdot]_\gamma \circ T \circ [\cdot]_\beta^{-1}$ equals $\mathbf{x} \mapsto [T]_{\gamma\leftarrow\beta}\mathbf{x}$ by Proposition 3.2.5, and it is continuous by Proposition 7.1.3(i).
Coordinate maps $[\cdot]_\beta$, $[\cdot]_\gamma$ are homeomorphisms by Definition 7.1.6, Proposition 7.1.7; T is continuous by Proposition 6.2.2(iii).

(ii) If T is an isomorphism, then $T^{-1} \in \mathcal{L}(\mathcal{W}, \mathcal{V})$, so T^{-1} is continuous by (i); T is a homeomorphism by Definition 6.2.5.

Structural Commentary: Coordinate homeomorphisms conjugate linear maps to continuous real matrix maps.
Key Insight: Natural coordinates transfer matrix continuity back to the vector spaces. □

Perspective 7.1.10. *Finite-Dimensional Topology Is Rigid*
Natural topology is independent of coordinates by Proposition 7.1.7, recoverable from vector operations and continuous algebraic dual by Theorem 7.1.8. Every linear map is continuous and every linear isomorphism is a homeomorphism by Corollary 7.1.9.
Infinite-dimensional topological vector spaces need not share this rigidity.

Part XII
Calculus, Series, and Approximation

1 One-Variable Differentiation and Riemann Integration

1.1 Differentiation and Basic Theorems

One-variable calculus studies functions on intervals through derivatives, mean-value theorems, Riemann integration, and the FTC, then points toward vector-valued estimates and linear approximation.

Definition 1.1.1. *Derivative of a Real Function*
Let $X \subseteq \mathbb{R}$, let $f : X \to \mathbb{R}$, and let $x_0 \in X$ be a limit point of X. For $x \in X \setminus \{x_0\}$, set $\phi_{x_0}(x) := \frac{f(x)-f(x_0)}{x-x_0}$.
If $\lim_{x \to x_0} \phi_{x_0}(x)$ exists in the sense of Definition 5.1.4, denote this *derivative relative to X* by $f'(x_0)$; then f is *differentiable at x_0 relative to X*.
For $E \subseteq X$, f is *differentiable on E relative to X* iff $E \subseteq X^{\mathrm{acc}}$ and $(\forall x_0 \in E)\, f'(x_0)$ exists relative to X.

Perspective 1.1.2. *Derivative Depends on the Domain*
The punctured approach set $X \setminus \{x_0\}$ determines the derivative in Definition 1.1.1. Open-interval points correspond to two-sided derivatives, half-interval endpoints correspond to one-sided derivatives, and isolated points are excluded by the limit-point hypothesis.

Figure 152 contrasts an isolated domain point with a half-line endpoint, clarifying when punctured approach is available.

Figure 152: Domain matters: isolated points give no punctured approach; $[x_0, \infty)$ gives a right-hand one.

Figure 153 illustrates the difference quotients in Definition 1.1.1 as slopes of secant lines approaching a tangent line.

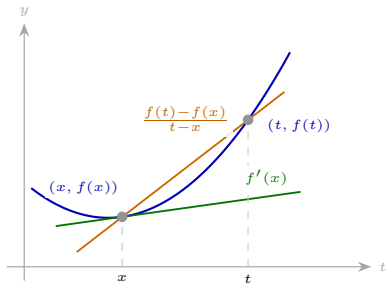

Figure 153: The derivative is the limiting slope of secant lines through $(x, f(x))$.

Proposition 1.1.3. *First-Order Approximation Form*
Let $X \subseteq \mathbb{R}$, let $x_0 \in X$ be a limit point, let $f : X \to \mathbb{R}$, and let $L \in \mathbb{R}$. Then $f'(x_0) = L$ relative to X iff $\forall \varepsilon > 0\ \exists \delta > 0$ such that $|f(x) - f(x_0) - L(x - x_0)| \le \varepsilon\,|x - x_0|$ whenever $x \in X$ and $|x - x_0| < \delta$.

Proof. For $x \neq x_0$, $\frac{|f(x)-f(x_0)-L(x-x_0)|}{|x-x_0|} = \left|\frac{f(x)-f(x_0)}{x-x_0} - L\right|$, while $x = x_0$ makes approx. estimate automatic.

(⇒) If $f'(x_0) = L$, then the displayed right-hand side is at most ε for all $x \in X \setminus \{x_0\}$ sufficiently near x_0. Multiplying by $|x - x_0|$ gives the approximation estimate.

(⇐) If the approximation estimate holds, then division by $|x - x_0|$ gives $\left|\frac{f(x)-f(x_0)}{x-x_0} - L\right| \le \varepsilon$ for all $x \in X \setminus \{x_0\}$ sufficiently near x_0. Hence $f'(x_0) = L$.

Structural Commentary: Differentiability is first-order linear approximation.
Key Insight: Multiply or divide by $|x - x_0|$. □

Theorem 1.1.4. *Differentiability Implies Continuity*
If f is differentiable at x, then f is continuous at x.

Proof. For $t \neq x$, $f(t) - f(x) = \frac{f(t)-f(x)}{t-x}(t - x)$. As $t \to x$, the difference quotient tends to $f'(x)$ and $t - x \to 0$.
By Theorem 5.1.7, $f(t) - f(x) \to 0$, so $f(t) \to f(x)$. Theorem 5.1.12 gives continuity at x.
Structural Commentary: A differentiable function has first-order control near the point.
Key Insight: The quotient stays near a finite number while $t - x$ shrinks to zero. □

Theorem 1.1.5. *Algebra Rules for Derivatives*
Let f, g be differentiable at x.

(i) $f + g$ is differentiable at x, and $(f + g)'(x) = f'(x) + g'(x)$.
(ii) fg is differentiable at x, and $(fg)'(x) = f'(x)g(x) + f(x)g'(x)$.
(iii) If $g(x) \neq 0$, then f/g is differentiable at x, and $\left(\frac{f}{g}\right)'(x) = \frac{g(x)f'(x)-g'(x)f(x)}{g(x)^2}$.

Proof.

(i) Limit algebra applied to $\frac{(f+g)(t)-(f+g)(x)}{t-x} = \frac{f(t)-f(x)}{t-x} + \frac{g(t)-g(x)}{t-x}$ gives the sum rule.

(ii) For $h = fg$, $h(t) - h(x) = f(t)(g(t) - g(x)) + g(x)(f(t) - f(x))$. Divide by $t - x$ and let $t \to x$. Theorem 1.1.4 gives $f(t) \to f(x)$, hence the product rule.

(iii) If $h = f/g$, continuity of g gives $g(t) \neq 0$ near x, and $\frac{h(t)-h(x)}{t-x} = \frac{1}{g(t)g(x)}\left[g(x)\frac{f(t)-f(x)}{t-x} - f(x)\frac{g(t)-g(x)}{t-x}\right]$. Let $t \to x$ to get the quotient rule.

Structural Commentary: Product and quotient rules are difference-quotient identities plus continuity.
Key Insight: Difference-quotient identities plus continuity give the algebra rules. □

Theorem 1.1.6. *Chain Rule*
Let f be differentiable at x and let g be differentiable at $f(x)$.
If $h = g \circ f$, then h is differentiable at x and $h'(x) = g'(f(x))f'(x)$.

Proof. Set $y = f(x)$. For $u(t) \to 0$, $f(t) - f(x) = (t - x)(f'(x) + u(t))$.
For $v(s) \to 0$, $g(s) - g(y) = (s - y)(g'(y) + v(s))$.
Since $f(t) \to y$, for $t \neq x$, $\frac{h(t)-h(x)}{t-x} = (g'(y) + v(f(t)))(f'(x) + u(t)) \to g'(y)f'(x)$.
Structural Commentary: Differentiate by composing first-order expansions.
Key Insight: First-order parts multiply; errors vanish. □

Example 1.1.7. *Oscillation at a Point*
Assuming the usual derivative of $\sin x$, define

$$f_1(x) = \begin{cases} x\sin(1/x), & x \neq 0, \\ 0, & x = 0, \end{cases} \qquad f_2(x) = \begin{cases} x^2\sin(1/x), & x \neq 0, \\ 0, & x = 0. \end{cases}$$

For f_1, the quotient at 0 is $\sin(1/t)$, so $f_1'(0)$ does not exist. For f_2, $|(f_2(t) - f_2(0))/t| \leq |t|$, so $f_2'(0) = 0$.
However, for $x \neq 0$, $f_2'(x) = 2x\sin(1/x) - \cos(1/x)$, so f_2' is not continuous at 0.

Definition 1.1.8. *Local Extrema*
Let f be a real-valued function on a metric space X. The function has a *local maximum* at $p \in X$ if there is $\delta > 0$ such that $f(q) \leq f(p)$ whenever $d(p, q) < \delta$. Local minima are defined by reversing the inequality.

Remark 1.1.9. *Local and Global Extrema*
Global extrema are local, but local extrema depend on domain: isolated points are automatic extrema. Derivative tests therefore need an interior interval point; compactness supplies global extrema (Theorem 5.1.39).

Theorem 1.1.10. *Interior Extremum Has Zero Derivative*
If f has a local extremum at $x \in (a, b)$ and $f'(x)$ exists, then $f'(x) = 0$.

Proof. For a local maximum, $f(t) \leq f(x)$ near x.
Thus the quotient $(f(t) - f(x))/(t - x)$ is nonnegative for $t < x$ and nonpositive for $t > x$. Since the two-sided limit exists, $f'(x) \geq 0$ and $f'(x) \leq 0$, so $f'(x) = 0$. For a local minimum, apply the local-maximum case to $-f$.
Since $(-f)'(x) = -f'(x)$, we get $-f'(x) = 0$, hence $f'(x) = 0$.
Structural Commentary: Interior extrema force opposite one-sided quotient signs.
Key Insight: A two-sided derivative compatible with both signs must be zero. □

Theorem 1.1.11. *Rolle's Theorem*
If $f : [a, b] \to \mathbb{R}$ continuous on $[a, b]$, differentiable on (a, b), and $f(a) = f(b)$, then $\exists x \in (a, b)$ s.t. $f'(x) = 0$.

Proof. If f is constant, any $x \in (a, b)$ works. Otherwise, by Theorem 5.1.39, f attains a nonendpoint extremum at some $x \in (a, b)$. Theorem 1.1.10 gives $f'(x) = 0$.
Structural Commentary: Equal endpoints force any nonconstant height change to turn around inside.
Key Insight: Compactness gives the extremum; differentiability makes the interior extremum stationary. □

Theorem 1.1.12. *Cauchy Mean Value Theorem*
Let f, g be continuous on $[a, b]$, differentiable on (a, b). $\exists\, x \in (a, b)$, $\big(f(b) - f(a)\big)g'(x) = \big(g(b) - g(a)\big)f'(x)$.

Proof. Set $h(t) := \big(f(b) - f(a)\big)g(t) - \big(g(b) - g(a)\big)f(t)$.
Then $h(a) = h(b)$, h is continuous on $[a, b]$, and h is differentiable on (a, b). By Theorem 1.1.11, $h'(x) = 0$ for some $x \in (a, b)$. Since $h'(x) = \big(f(b) - f(a)\big)g'(x) - \big(g(b) - g(a)\big)f'(x)$, the identity follows.
Structural Commentary: Build one auxiliary function whose endpoint values agree.
Key Insight: Equal endpoints force an interior horizontal tangent. □

Corollary 1.1.13. *Mean Value Theorem*
If f is continuous on $[a, b]$, differentiable in (a, b), then $\exists\, x \in (a, b)$ such that $f(b) - f(a) = (b - a)f'(x)$.

Proof. Let $g(t) = t$. Then $g'(x) = 1$, $g(b) - g(a) = b - a$.
Hence Theorem 1.1.12 gives $f(b) - f(a) = (b - a)f'(x)$ for some $x \in (a, b)$.
Structural Commentary: This is Cauchy's theorem with $g(t) = t$.
Key Insight: A secant slope is achieved as a tangent slope somewhere inside. □

Figure 154 depicts the geometric conclusion of Corollary 1.1.13: one interior tangent is parallel to the endpoint secant.

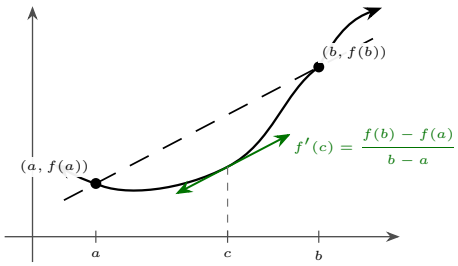

Figure 154: The Mean Value Theorem finds an interior tangent slope equal to the endpoint secant slope.

Corollary 1.1.14. *Bounded Derivative Gives Lipschitz Control*
If $f : [a, b] \to \mathbb{R}$ is continuous on $[a, b]$, differentiable on (a, b), and $|f'| \leq M$ on (a, b), then f is M-Lipschitz on $[a, b]$, hence uniformly continuous.

Proof. For $x < y$, Corollary 1.1.13 gives $f(y) - f(x) = (y - x)f'(c)$ for some $c \in (x, y)$,
so $|f(y) - f(x)| \leq M(y - x)$. Symmetry handles $x > y$, and $x = y$ is trivial.
Structural Commentary: A derivative bound controls every secant slope.
Key Insight: Local slope bounds become global Lipschitz bounds through the Mean Value Theorem. □

Theorem 1.1.15. *Derivative Sign and Monotonicity*
Suppose f is differentiable in (a, b).
(i) If $f'(x) \geq 0$ for all $x \in (a, b)$, then f is monotonically increasing.
(ii) If $f'(x) = 0$ for all $x \in (a, b)$, then f is constant.
(iii) If $f'(x) \leq 0$ for all $x \in (a, b)$, then f is monotonically decreasing.

Proof. For $x_1 < x_2$ in (a, b), Corollary 1.1.13 on $[x_1, x_2]$ gives $f(x_2) - f(x_1) = (x_2 - x_1)f'(c)$ for some $c \in (x_1, x_2)$.
(i) If $f' \geq 0$, then $f(x_2) - f(x_1) \geq 0$.
(ii) If $f' = 0$, then $f(x_2) - f(x_1) = 0$.
(iii) If $f' \leq 0$, then $f(x_2) - f(x_1) \leq 0$.
Structural Commentary: Monotonicity is a global reading of the mean-value identity.
Key Insight: The sign of every tangent slope controls every secant slope. □

Theorem 1.1.16. *Derivatives Have the Intermediate Value Property*
If f is differentiable on $[a, b]$ in the one-sided endpoint sense and $f'(a) < \lambda < f'(b)$,
Then $f'(x) = \lambda$ for some $x \in (a, b)$. The same conclusion holds when $f'(b) < \lambda < f'(a)$.

Proof. Set $g(t) = f(t) - \lambda t$. Since $g'(a) < 0 < g'(b)$, there are $t_1, t_2 \in (a, b)$ with $g(t_1) < g(a)$ and $g(t_2) < g(b)$. Hence the minimum of g on $[a, b]$ occurs at some $x \in (a, b)$. By Theorem 1.1.10, $0 = g'(x) = f'(x) - \lambda$.
Apply the same argument to $-f$ for the reversed case.
Structural Commentary: A derivative need not be continuous, but it cannot jump over values.
Key Insight: Tilt the graph by subtracting λt and force an interior extremum. □

Perspective 1.1.17. *Sliding Secants*
For fixed small $h > 0$, the secant-slope function $\sigma_h(x) := \frac{f(x+h)-f(x)}{h}$ is continuous. Thus Theorem 5.1.43 finds intermediate secant slopes, and Corollary 1.1.13 converts them to derivative values.
Key Insight: Slide secants, then apply the Mean Value Theorem.

Figure 155 illustrates the fixed-width secants used in the preceding Darboux perspective.

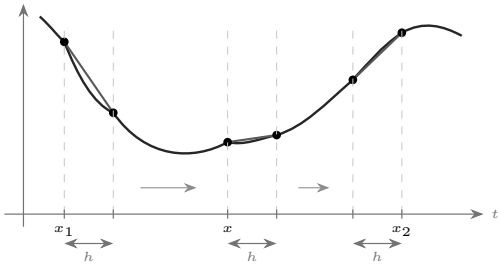

Figure 155: Sliding fixed-width secants in Darboux's theorem.

Corollary 1.1.18. *Derivatives Have No Simple Discontinuities*
If f is differentiable on $[a, b]$, then f' cannot have a simple discontinuity on $[a, b]$.

Proof. Suppose a simple discontinuity occurs at an interior point c; endpoint cases are one-sided.
If $f'(c-) \neq f'(c+)$, choose λ strictly between these limits, $\lambda \neq f'(c)$. For $x < c < y$ close to c, Theorem 1.1.16 gives $z \in (x, y)$ with $f'(z) = \lambda$, contradicting the one-sided limits. If $f'(c-) = f'(c+) = L \neq f'(c)$, choose λ between L and $f'(c)$ and apply the same theorem on a sufficiently small one-sided interval with endpoint c.
Structural Commentary: Darboux behavior rules out jump discontinuities for derivatives.
Key Insight: Derivatives may oscillate, but they do not jump. □

Theorem 1.1.19. *Derivative of an Inverse Function*
Let $f : I \to \mathbb{R}$ be one-to-one on an open interval I, let $x_0 \in I$, and put $y_0 = f(x_0)$. Suppose f is differentiable at x_0, $f'(x_0) \neq 0$, and $g = f^{-1} : f(I) \to I$ is continuous at y_0. Then g is differentiable at y_0 and $g'(y_0) = \frac{1}{f'(x_0)}$.

Proof. For $y \in f(I)$ with $y \neq y_0$, write $x = g(y)$. Then $x \neq x_0$ and $\frac{g(y)-g(y_0)}{y-y_0} = \frac{x-x_0}{f(x)-f(x_0)} = \left(\frac{f(x)-f(x_0)}{x-x_0}\right)^{-1}$.
As $y \to y_0$, the assumed continuity of g gives $x = g(y) \to x_0$.
The difference quotient for f tends to $f'(x_0) \neq 0$, so the reciprocal tends to $1/f'(x_0)$ by Theorem 5.1.7.
Structural Commentary: Matched inverse quotients are reciprocal.
Key Insight: Continuity of the inverse converts the limit $y \to y_0$ back into $x \to x_0$. □

Corollary 1.1.20. *One-Dimensional Inverse Function Theorem*
If $f : (a, b) \to (c, d)$ is a differentiable bijection and $f' \neq 0$,
then f is a homeomorphism and f^{-1} is differentiable, with $(f^{-1})'(y) = \frac{1}{f'(f^{-1}(y))}$.

Proof. By Theorem 1.1.16, f' has constant sign. Corollary 1.1.13 makes f strictly monotone, hence its continuous interval inverse is continuous. Apply Theorem 1.1.19 pointwise.
Structural Commentary: Darboux gives constant sign; the inverse derivative formula is local.
Key Insight: Nonvanishing derivative is the one-dimensional obstruction to differentiating the inverse. □

Theorem 1.1.21. *L'Hospital's Rule*
Let $-\infty \leq a < b \leq +\infty$, let f, g be differentiable on (a, b), assume $g' \neq 0$, and suppose $\frac{f'}{g'} \to A \in \overline{\mathbb{R}}$ as $x \to a^+$.

(i) If $f, g \to 0$ as $x \to a^+$, then $\frac{f}{g} \to A$ as $x \to a^+$.

(ii) If $|g| \to \infty$ as $x \to a^+$, then $\frac{f}{g} \to A$ as $x \to a^+$.

The analogous statements hold as $x \to b^-$.

Proof. For $a < r < s < b$, Theorem 1.1.12 gives $t \in (r, s)$ with $\frac{f(s)-f(r)}{g(s)-g(r)} = \frac{f'(t)}{g'(t)}$, so eventual bounds on $\frac{f'}{g'}$ near a transfer to these difference quotients.

(i) Fix s and let $r \to a^+$; since $f(r), g(r) \to 0$, the same bounds hold for $\frac{f(s)}{g(s)}$.

(ii) Fix s near a and use $\frac{f(r)}{g(r)} = \frac{f(r)-f(s)}{g(r)-g(s)}\frac{g(r)-g(s)}{g(r)} + \frac{f(s)}{g(r)}$.
As $r \to a^+$, the second factor tends to 1 and the last term to 0, so the same bounds hold for $\frac{f(r)}{g(r)}$.

In both cases, the transferred eventual bounds force $\frac{f}{g} \to A$.
Structural Commentary: CMVT transfers derivative-quotient bounds to function quotients.
Key Insight: Bounds on f'/g' force the same limit for f/g. □

Definition 1.1.22. *Higher Derivatives*
If f has derivative f' on an interval and f' is differentiable, then $(f')'$ is denoted f'' and called the *second derivative*. Continuing recursively gives $f^{(n)}$, the derivative of order n.

Definition 1.1.23. *Smoothness Classes*
On an interval, C^0 means continuous, C^r means $f^{(r)}$ exists and continuous, C^∞ means C^r for every finite r.

Theorem 1.1.24. *Higher-Order Leibniz Product Rule*
Let $r \geq 1$, and $f, g : (a, b) \to \mathbb{R}$ be r times differentiable. Then $\forall x \in (a, b)$, $(fg)^{(r)}(x) = \sum_{k=0}^{r} \binom{r}{k} f^{(k)}(x) g^{(r-k)}(x)$.

Proof. Induct on r. For $r = 1$, this is the product rule in Theorem 1.1.5. Assume the formula holds at order r.
If f, g are $(r + 1)$ times differentiable, differentiating gives $(fg)^{(r+1)} = \sum_{k=0}^{r} \binom{r}{k} f^{(k+1)} g^{(r-k)} + \sum_{k=0}^{r} \binom{r}{k} f^{(k)} g^{(r-k+1)}$.
Reindex the first sum by $j = k + 1$; the coefficient of $f^{(j)} g^{(r+1-j)}$ is $\binom{r}{j-1} + \binom{r}{j} = \binom{r+1}{j}$, with the endpoint terms $j = 0, r + 1$ equal to 1.
Structural Commentary: Differentiating shifts one derivative from the total count onto f or g.
Key Insight: Pascal's identity produces the binomial coefficients. □

Theorem 1.1.25. *Taylor's Theorem with Lagrange Remainder*
Let $f : [a, b] \to \mathbb{R}$, let $n \geq 1$, suppose $f^{(n-1)}$ is continuous on $[a, b]$, and suppose $f^{(n)}$ exists on (a, b).
For distinct $\alpha, \beta \in [a, b]$, set $P(t) := \sum_{k=0}^{n-1} \frac{f^{(k)}(\alpha)}{k!}(t - \alpha)^k$.
Then for some x between α and β, $f(\beta) = P(\beta) + \frac{f^{(n)}(x)}{n!}(\beta - \alpha)^n$.

Proof. Choose M so that $f(\beta) = P(\beta) + M(\beta - \alpha)^n$, and set $G(t) := f(t) - P(t) - M(t - \alpha)^n$.
Then $G(\alpha) = G'(\alpha) = \cdots = G^{(n-1)}(\alpha) = G(\beta) = 0$. Repeated applications of Corollary 1.1.13 give $G^{(n)}(x) = 0$ for some x between α and β. Since $G^{(n)}(x) = f^{(n)}(x) - n!M$, the formula follows.
Structural Commentary: The auxiliary error vanishes at β and to order $n - 1$ at α.
Key Insight: Repeated Rolle-style arguments turn endpoint cancellation into a precise remainder. □

Definition 1.1.26. *Vector-Valued Derivative*
For $\mathbf{f} : [a, b] \to \mathbb{R}^k$, set $\mathbf{f}'(x) = \mathbf{L}$ when $\lim_{t \to x} \left\| \frac{\mathbf{f}(t)-\mathbf{f}(x)}{t-x} - \mathbf{L} \right\|_2 = 0$.
For $\mathbf{f} = (f_1, \ldots, f_k)$, this is equivalent to componentwise differentiability, with $\mathbf{f}'(x) = (f_1'(x), \ldots, f_k'(x))$.

Theorem 1.1.27. *Vector-Valued Mean Value Inequality*
If $\mathbf{f} : [a, b] \to \mathbb{R}^k$ is continuous on $[a, b]$ and differentiable on (a, b).
Then for some $x \in (a, b)$, $\|\mathbf{f}(b) - \mathbf{f}(a)\|_2 \leq (b - a) \|\mathbf{f}'(x)\|_2$.

Proof. Set $\mathbf{z} := \mathbf{f}(b) - \mathbf{f}(a)$ and $\varphi(t) := \mathbf{z} \cdot \mathbf{f}(t)$.
Corollary 1.1.13 gives $\varphi(b) - \varphi(a) = (b-a)\varphi'(x) = (b-a)\mathbf{z} \cdot \mathbf{f}'(x)$ for some $x \in (a,b)$. Since $\varphi(b) - \varphi(a) = \|\mathbf{z}\|_2^2$, Theorem 1.1.13 gives $\|\mathbf{z}\|_2^2 \le (b-a)\,\|\mathbf{z}\|_2\,\|\mathbf{f}'(x)\|_2$, and the result follows by cancellation, with $\mathbf{z} = 0$ trivial.
Structural Commentary: A scalar projection yields the vector norm bound.
Key Insight: Project onto the displacement vector, then use Schwarz to return to norms. □

Method 1.1.28. *Differentiation Proof Patterns*

(i) *Domain*: require x_0 to be a limit point of X; isolated points have no derivative.
(ii) *Definition*: factor $f(t) - f(x) = (t-x)Q_x(t)$ and take $Q_x(t) \to f'(x)$.
(iii) *Approximation*: use Proposition 1.1.3 to replace quotient limits by first-order error bounds.
(iv) *Algebra*: prove quotient identities first; use continuity to pass to limits.
(v) *Mean values*: choose h with equal endpoint values and apply Theorem 1.1.10.
(vi) *Taylor*: set $G = f - P - M(t-\alpha)^n$ and iterate the mean value theorem.

Key Insight: Difference quotients and auxiliary functions drive one-variable differentiation.

1.2 Riemann Integration

Ordinary Riemann integration is organized by Darboux envelopes and tagged sums. The Riemann–Stieltjes generalization and the fundamental theorems follow in the next section.

Definition 1.2.1. *Partitions and Riemann Upper/Lower Sums*

(i) A *partition* of $[a,b]$ is $\Pi = \{x_0, \dots, x_n\}$ with $a = x_0 \le x_1 \le \cdots \le x_n = b$.
Set $\Delta x_i := x_i - x_{i-1}$ for $1 \le i \le n$.
(ii) For bounded $f : [a,b] \to \mathbb{R}$, set $M_i := \sup_{x \in [x_{i-1}, x_i]} f(x)$ and $m_i := \inf_{x \in [x_{i-1}, x_i]} f(x)$.
(iii) The *upper* and *lower Darboux sums* are $U(\Pi, f) := \sum_{i=1}^{n} M_i \Delta x_i$ and $L(\Pi, f) := \sum_{i=1}^{n} m_i \Delta x_i$.
(iv) The *upper* and *lower Darboux integrals* are $\overline{\int_a^b f\,dx} := \inf_\Pi U(\Pi, f)$ and $\underline{\int_a^b f\,dx} := \sup_\Pi L(\Pi, f)$, where Π ranges over all partitions of $[a,b]$.
(v) If $\underline{\int_a^b f\,dx} = \overline{\int_a^b f\,dx}$, then f is *Riemann integrable* on $[a,b]$; $f \in \mathcal{R}[a,b]$, $\int_a^b f\,dx := \overline{\int_a^b f\,dx} = \underline{\int_a^b f\,dx}$.

If $m \le f(x) \le M$ for $x \in [a,b]$, then $m(b-a) \le L(\Pi, f) \le U(\Pi, f) \le M(b-a)$ for every partition Π.
Hence the upper and lower Darboux integrals are finite for bounded f.
Key Insight: Riemann integrability means least upper Darboux area equals greatest lower Darboux area.

Figure 156 illustrates how a partition produces lower and upper step envelopes for the same bounded function.

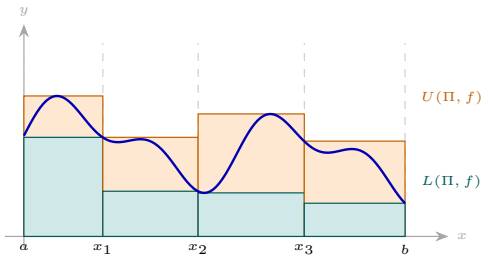

Figure 156: Upper and lower sums record the oscillation of f on each partition interval.

Definition 1.2.2. *Tagged Partitions and Riemann Sums*
Let $\Pi = \{x_0, \dots, x_n\}$ be a partition of $[a,b]$, and set $\Delta x_i := x_i - x_{i-1}$.

(i) A *tagging* of Π is $c = (c_1, \dots, c_n)$ with $c_i \in [x_{i-1}, x_i]$ for $1 \le i \le n$; the pair (Π, c) is a *tagged partition*.
(ii) For $f : [a,b] \to \mathbb{R}$, the associated *Riemann sum* is $R(f, \Pi, c) := \sum_{i=1}^{n} f(c_i)\Delta x_i$.
(iii) If f is bounded, then $L(\Pi, f) \le R(f, \Pi, c) \le U(\Pi, f)$.

Figure 157 shows how each tag c_i selects the rectangle height on its partition interval.

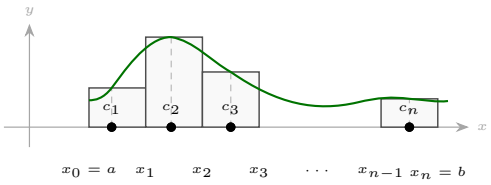

Figure 157: A tagged Riemann sum uses one sample value $f(c_i)$ on each subinterval $[x_{i-1}, x_i]$.

Perspective 1.2.3. *Tagged Sums and Gauges*
Gauge integration keeps tagged sums but replaces one mesh bound δ with a local bound $\delta(c_i)$.
Thus fineness may vary by tag, giving a stronger framework for FTC-type results.

2 Riemann-Stieltjes and Improper Integration

2.1 Riemann-Stieltjes Integrability

Definition 2.1.1. *Riemann–Stieltjes Integral*
Let $\alpha : [a,b] \to \mathbb{R}$ be increasing, let $\Pi = \{x_0, \dots, x_n\}$ be a partition of $[a,b]$, and let $f : [a,b] \to \mathbb{R}$ be bounded. Set $M_i := \sup_{x \in [x_{i-1}, x_i]} f(x)$ and $m_i := \inf_{x \in [x_{i-1}, x_i]} f(x)$.

(i) The Stieltjes increment on $[x_{i-1}, x_i]$ is $\Delta\alpha_i := \alpha(x_i) - \alpha(x_{i-1}) \geq 0$ for $1 \leq i \leq n$.

(ii) The *upper* and *lower Riemann–Stieltjes sums* are $U(\Pi, f, \alpha) := \sum_{i=1}^{n} M_i \Delta\alpha_i$ and $L(\Pi, f, \alpha) := \sum_{i=1}^{n} m_i \Delta\alpha_i$.

(iii) The *upper* and *lower Riemann–Stieltjes integrals* are $\overline{\int_a^b f \, d\alpha} := \inf_{\Pi} U(\Pi, f, \alpha)$ and $\underline{\int_a^b f \, d\alpha} := \sup_{\Pi} L(\Pi, f, \alpha)$, where the infimum and supremum range over all partitions of $[a,b]$.

(iv) If $\overline{\int_a^b f \, d\alpha} = \underline{\int_a^b f \, d\alpha}$, then f is *Riemann integrable with respect to* α, written $f \in \mathcal{R}(\alpha)$, and $\int_a^b f \, d\alpha := \overline{\int_a^b f \, d\alpha} = \underline{\int_a^b f \, d\alpha}$, also written $\int_a^b f(x) \, d\alpha(x)$.

For $\alpha(x) = x$, this is the ordinary Riemann integral.

Definition 2.1.2. *Refinements*
Let Π, Π^*, Π_1, Π_2 be partitions of $[a,b]$.

(i) Π^* is a *refinement* of Π iff $\Pi \subseteq \Pi^*$.

(ii) The *common refinement* of Π_1 and Π_2 is $\Pi_1 \cup \Pi_2$.

Theorem 2.1.3. *Refinement Monotonicity*
If Π^* is a refinement of Π, then $L(\Pi, f, \alpha) \leq L(\Pi^*, f, \alpha)$ and $U(\Pi^*, f, \alpha) \leq U(\Pi, f, \alpha)$.

Proof. It suffices to add one point $x^* \in (x_{i-1}, x_i)$. If w_1, w_2 are infima on $[x_{i-1}, x^*]$ and $[x^*, x_i]$, then $w_1, w_2 \geq m_i$ and $L(\Pi^*, f, \alpha) - L(\Pi, f, \alpha) = (w_1 - m_i)\big[\alpha(x^*) - \alpha(x_{i-1})\big] + (w_2 - m_i)\big[\alpha(x_i) - \alpha(x^*)\big] \geq 0$.
Iterate for additional points. The upper-sum inequality is the same argument with suprema.
Structural Commentary: Refinement raises lower sums and lowers upper sums.
Key Insight: Splitting an interval tightens the local oscillation bounds. □

Perspective 2.1.4. *Piecewise-Constant Envelopes*
A partition Π gives lower and upper step envelopes with values m_i and M_i; their integrals are exactly $L(\Pi, f)$ and $U(\Pi, f)$. Common refinements make these envelope sums compatible across partitions.

Theorem 2.1.5. *Lower Integral Below Upper Integral*
For every bounded real f and increasing α on $[a,b]$, $\underline{\int_a^b f \, d\alpha} \leq \overline{\int_a^b f \, d\alpha}$.

Proof. Given partitions Π_1, Π_2, let $\Pi^* = \Pi_1 \cup \Pi_2$.
By Theorem 2.1.3, $L(\Pi_1, f, \alpha) \leq L(\Pi^*, f, \alpha) \leq U(\Pi^*, f, \alpha) \leq U(\Pi_2, f, \alpha)$.
Take the supremum over Π_1 and then the infimum over Π_2.
Structural Commentary: Common refinements compare sums from different partitions.
Key Insight: The lower envelope never rises above the upper envelope. □

Theorem 2.1.6. *Upper–Lower Criterion*
A bounded real f is in $\mathcal{R}(\alpha)$ on $[a,b]$ if and only if $\forall \varepsilon > 0$ $\exists$ a partition Π with $U(\Pi, f, \alpha) - L(\Pi, f, \alpha) < \varepsilon$.

Proof.

(⇒) If $f \in \mathcal{R}(\alpha)$, choose Π_1, Π_2 whose lower and upper sums are within $\varepsilon/2$ of $\int_a^b f \, d\alpha$. Their common refinement Π satisfies the displayed inequality by Theorem 2.1.3.

(⇐) If such Π exist, then $L(\Pi, f, \alpha) \leq \underline{\int_a^b f \, d\alpha} \leq \overline{\int_a^b f \, d\alpha} \leq U(\Pi, f, \alpha)$ forces upper and lower integrals to agree.

Structural Commentary: Integrability is exactly the ability to make one partition squeeze the oscillation.
Key Insight: The gap $U - L$ is the quantitative defect of integrability. □

Perspective 2.1.7. *Darboux Gaps and Riemann Sums*
For $\alpha(x) = x$, a small Darboux gap $U(\Pi, f) - L(\Pi, f)$ traps every tagged sum for Π near the integral. This is the local reason the Darboux definition above and the tagged Riemann-sum definition give the same number. The same estimate works with Stieltjes weights $\Delta\alpha_i$ whenever the upper–lower gap is small.

Theorem 2.1.8. *Tagged Sums*
Let $\Pi = \{x_0, \dots, x_n\}$ satisfy $U(\Pi, f, \alpha) - L(\Pi, f, \alpha) < \varepsilon$, and choose tags $t_i \in [x_{i-1}, x_i]$.

(i) If $s_i, t_i \in [x_{i-1}, x_i]$, then $\sum_{i=1}^{n} |f(s_i) - f(t_i)| \, \Delta\alpha_i < \varepsilon$.

(ii) If $f \in \mathcal{R}(\alpha)$, then $\left| \sum_{i=1}^{n} f(t_i) \Delta\alpha_i - \int_a^b f \, d\alpha \right| < \varepsilon$.

Proof.

(i) Since $|f(s_i) - f(t_i)| \leq M_i - m_i$, summing gives $\sum_{i=1}^{n} |f(s_i) - f(t_i)| \, \Delta\alpha_i \leq U(\Pi, f, \alpha) - L(\Pi, f, \alpha) < \varepsilon$.

(ii) The tagged sum and $\int_a^b f \, d\alpha$ both lie between $L(\Pi, f, \alpha)$ and $U(\Pi, f, \alpha)$, so their distance is $< \varepsilon$.

Structural Commentary: A small Darboux gap makes tags and the integral close.
Key Insight: Tags are harmless after oscillation has been controlled. □

Theorem 2.1.9. *Continuous Functions Are Riemann–Stieltjes Integrable*
If f is continuous on $[a,b]$ and α is increasing on $[a,b]$, then $f \in \mathcal{R}(\alpha)$.

Proof. If $\alpha(b) = \alpha(a)$, the Darboux gap is zero.
Otherwise choose $\eta > 0$ with $\eta[\alpha(b) - \alpha(a)] < \varepsilon$. Uniform continuity gives partition Π with $M_i - m_i \le \eta\ \forall i$, so $U(\Pi, f, \alpha) - L(\Pi, f, \alpha) = \sum_{i=1}^{n} (M_i - m_i)\Delta\alpha_i \le \eta[\alpha(b) - \alpha(a)] < \varepsilon$. Apply Theorem 2.1.6.
Structural Commentary: Uniform continuity controls oscillation uniformly across the partition.
Key Insight: Continuity turns local small intervals into a small total Darboux gap. □

Theorem 2.1.10. *Monotone Functions and Continuous Integrators*
If f is monotone on $[a, b]$ and α is continuous and increasing on $[a, b]$, then $f \in \mathcal{R}(\alpha)$.

Proof. Assume first that f is increasing. If $\alpha(b) = \alpha(a)$, then every $\Delta\alpha_i = 0$, so $U(\Pi, f, \alpha) = L(\Pi, f, \alpha) = 0$ for every partition Π. Choose n and a partition Π such that $\Delta\alpha_i = [\alpha(b) - \alpha(a)]/n$ for all i.
Existence follows from continuity of α and Theorem 5.1.43.
Then $U(\Pi, f, \alpha) - L(\Pi, f, \alpha) = \frac{\alpha(b)-\alpha(a)}{n} \sum_{i=1}^{n} \big(f(x_i) - f(x_{i-1})\big) = \frac{\alpha(b)-\alpha(a)}{n} \big(f(b) - f(a)\big) < \varepsilon$ for n large.
If f is decreasing, use the same partition. Then the suprema and infima on $[x_{i-1}, x_i]$ are $f(x_{i-1})$ and $f(x_i)$, so the same computation gives $U(\Pi, f, \alpha) - L(\Pi, f, \alpha) = \frac{\alpha(b)-\alpha(a)}{n} \big(f(a) - f(b)\big)$, which is $< \varepsilon$ for large n.
Structural Commentary: Equal α-increments convert the monotone oscillations into a telescoping sum.
Key Insight: A monotone function's total oscillation is finite and can be spread thinly. □

Theorem 2.1.11. *Finitely Many Discontinuities*
Suppose f is bounded on $[a, b]$, the discontinuity set $E := \{x \in [a, b] : f \text{ is discontinuous at } x\}$ is finite, and α is continuous at each point of E. Then $f \in \mathcal{R}(\alpha)$.

Proof. Let $M = \sup_{[a,b]} |f|$ and let $\eta > 0$. By continuity of α on the finite set E, choose disjoint intervals $I_j = [u_j, v_j]$ covering E, with each point of $E \cap (a, b)$ in some (u_j, v_j), such that $\sum_j \big(\alpha(v_j) - \alpha(u_j)\big) < \eta$.
Set $K = [a, b] \setminus \bigcup_j (u_j, v_j)$. Then $f|_K$ is uniformly continuous by Theorem 5.2.6.
Choose a partition Π containing all u_j, v_j, with no points inside the intervals (u_j, v_j), and fine enough on K that $M_i - m_i \le \eta$ whenever $[x_{i-1}, x_i] \subset K$.
Hence $U(\Pi, f, \alpha) - L(\Pi, f, \alpha) \le \eta\big[\alpha(b) - \alpha(a)\big] + 2M \sum_j \big(\alpha(v_j) - \alpha(u_j)\big) < \eta\big[\alpha(b) - \alpha(a) + 2M\big]$.
Since η is arbitrary, Theorem 2.1.6 applies.
Structural Commentary: Isolate bad points in small α-intervals; use uniform continuity elsewhere.
Key Insight: Finitely many discontinuities do not matter unless α also jumps there. □

Figure 158 illustrates the proof mechanism in Theorem 2.1.11: isolate each discontinuity in a short interval and use compact control on the complement.

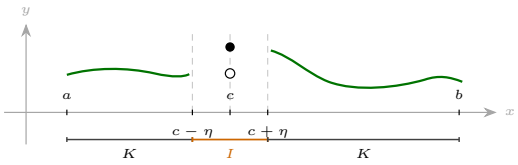

Figure 158: Isolate the discontinuity in a short interval; control the compact pieces outside it.

Example 2.1.12. *Dirichlet's Function Is Not Riemann Integrable*
Let $g = \mathbf{1}_{\mathbb{Q}}$ on $[0, 1]$. Every nondegenerate subinterval contains rationals and irrationals by Corollary 1.1.20, so for every partition Π, $M_i = 1$ and $m_i = 0$ on each nonzero-width subinterval.
Thus $U(\Pi, g) = 1$ and $L(\Pi, g) = 0$, hence $g \notin \mathcal{R}$.

Theorem 2.1.13. *Continuous Composition Preserves Integrability*
Let α be increasing on $[a, b]$. Suppose $f \in \mathcal{R}(\alpha)$, $m \le f(x) \le M$ on $[a, b]$, and $\phi : [m, M] \to \mathbb{R}$ is continuous. Define $h : [a, b] \to \mathbb{R}$ by $h(x) := \phi(f(x))$. Then $h \in \mathcal{R}(\alpha)$.

Proof. Let $C := \sup_{y\in[m,M]} |\phi(y)|$ and let $\varepsilon > 0$. Choose $\eta > 0$ such that $\eta[\alpha(b) - \alpha(a) + 2C] < \varepsilon$. Since ϕ is uniformly continuous on $[m, M]$, choose $\gamma > 0$ such that $|s - t| < \gamma \implies |\phi(s) - \phi(t)| < \eta$ $(s, t \in [m, M])$.
Choose a partition $\Pi = \{x_0, \dots, x_n\}$ with $U(\Pi, f, \alpha) - L(\Pi, f, \alpha) < \gamma\eta$.
Let M_i, m_i denote upper and lower values for f on $[x_{i-1}, x_i]$, M_i^h, m_i^h denote corresponding values for h.
Split $A := \{i : M_i - m_i < \gamma\}$, $B := \{i : M_i - m_i \ge \gamma\}$. For $i \in A$, $M_i^h - m_i^h \le \eta$; for $i \in B$, $M_i^h - m_i^h \le 2C$.
Also $\gamma \sum_{i\in B} \Delta\alpha_i \le \sum_{i\in B} (M_i - m_i)\Delta\alpha_i \le U(\Pi, f, \alpha) - L(\Pi, f, \alpha) < \gamma\eta$, so $\sum_{i\in B} \Delta\alpha_i < \eta$.
$U(\Pi, h, \alpha) - L(\Pi, h, \alpha) \le \eta \sum_{i\in A} \Delta\alpha_i + 2C \sum_{i\in B} \Delta\alpha_i < \eta[\alpha(b) - \alpha(a) + 2C] < \varepsilon$. Theorem 2.1.6 gives $h \in \mathcal{R}(\alpha)$.
Structural Commentary: Integrability survives continuous remeasurement of the values of f.
Key Insight: Large oscillation intervals have small total α-weight. □

Theorem 2.1.14. *Basic Properties of the Integral*
Let all functions be bounded and real on $[a, b]$, and let all integrators be increasing.

(i) If $f_1, f_2 \in \mathcal{R}(\alpha)$, $c \in \mathbb{R}$, then $f_1 + f_2, cf_1 \in \mathcal{R}(\alpha)$, and $\int_a^b (f_1 + f_2)\, d\alpha = \int_a^b f_1\, d\alpha + \int_a^b f_2\, d\alpha$; $\int_a^b cf_1\, d\alpha = c\int_a^b f_1\, d\alpha$.

(ii) If $f_1 \le f_2$ and both functions are in $\mathcal{R}(\alpha)$, then $\int_a^b f_1\, d\alpha \le \int_a^b f_2\, d\alpha$.

(iii) If $f \in \mathcal{R}(\alpha)$ and $a < c < b$, then f is integrable on $[a, c]$ and $[c, b]$, and $\int_a^c f\, d\alpha + \int_c^b f\, d\alpha = \int_a^b f\, d\alpha$.

(iv) *If $f \in \mathcal{R}(\alpha)$ and $|f| \le M$, then $\left|\int_a^b f\,d\alpha\right| \le M[\alpha(b)-\alpha(a)]$*

(v) *If $f \in \mathcal{R}(\alpha_1)$ and $f \in \mathcal{R}(\alpha_2)$, then $f \in \mathcal{R}(\alpha_1+\alpha_2)$ and $\int_a^b f\,d(\alpha_1+\alpha_2) = \int_a^b f\,d\alpha_1 + \int_a^b f\,d\alpha_2$.*
If $c>0$ and $f \in \mathcal{R}(\alpha)$, then $f \in \mathcal{R}(c\alpha)$ and $\int_a^b f\,d(c\alpha) = c\int_a^b f\,d\alpha$.

Proof.

(i) $L(\Pi,f_1,\alpha)+L(\Pi,f_2,\alpha) \le L(\Pi,f_1+f_2,\alpha) \le U(\Pi,f_1+f_2,\alpha) \le U(\Pi,f_1,\alpha)+U(\Pi,f_2,\alpha)$,
where Π is common refinement, and Theorem 2.1.6; scalar multiplication is the same estimate with signs handled by swapping upper and lower sums when $c<0$.
(ii) If $f_1 \le f_2$, then $L(\Pi,f_2-f_1,\alpha) \ge 0$ for every Π; apply (i) to f_2-f_1.
(iii) Refine so that $c \in \Pi$. Then the lower and upper sums split into the sums over $[a,c]$ and $[c,b]$.
(iv) Apply (ii) to $-M \le f \le M$ and use the integrals of the constant functions $\pm M$.
(v) Since $\Delta(\alpha_1+\alpha_2)_i = \Delta\alpha_{1,i}+\Delta\alpha_{2,i}$ and $\Delta(c\alpha)_i = c\,\Delta\alpha_i$, corresponding lower and upper sums split exactly.

Structural Commentary: The algebra of integrals is inherited from the algebra of upper and lower sums.
Key Insight: Common refinements let several integrable functions be approximated by the same partition. □

Theorem 2.1.15. *Products and Absolute Values*
If $f,g \in \mathcal{R}(\alpha)$ on $[a,b]$, then $fg \in \mathcal{R}(\alpha)$, $|f| \in \mathcal{R}(\alpha)$, and $\left|\int_a^b f\,d\alpha\right| \le \int_a^b |f|\,d\alpha$.

Proof. By Theorem 2.1.14, $f \pm g \in \mathcal{R}(\alpha)$. Applying Theorem 2.1.13 to $\phi(t)=t^2$ gives $(f\pm g)^2 \in \mathcal{R}(\alpha)$, hence $fg \in \mathcal{R}(\alpha)$ from $4fg = (f+g)^2-(f-g)^2$.
Applying the same theorem to $\phi(t)=|t|$ gives $|f| \in \mathcal{R}(\alpha)$, and $-|f| \le f \le |f|$ gives the inequality.
Structural Commentary: Products reduce to squares; absolute values to composition.
Key Insight: Once continuous composition is available, the usual algebra closes. □

2.2 Fundamental Theorems of Calculus

Theorem 2.2.1. *Integral Functions*
Let $f \in \mathcal{R}$ on $[a,b]$ and define $F(x) := \int_a^x f(t)\,dt$. Then F is continuous.
If f is continuous at x_0, then $F'(x_0) = f(x_0)$, with one-sided derivatives at endpoints.

Proof. Let $|f| \le M$. For $x<y$, Theorem 2.1.14 gives $|F(y)-F(x)| = \left|\int_x^y f(t)\,dt\right| \le M(y-x)$ so F continuous.
If f continuous at x_0, for $x \ne x_0$ near x_0, $\left|\frac{F(x)-F(x_0)}{x-x_0} - f(x_0)\right| \le \sup_{u\in[x,x_0]} |f(u)-f(x_0)| \to 0$. $F'(x_0)=f(x_0)$.

Structural Commentary: Boundedness controls increments; local continuity gives the derivative.
Key Insight: Averaging a continuous function over shrinking intervals returns its value. □

Theorem 2.2.2. *Fundamental Theorem of Calculus*
If $f \in \mathcal{R}$ on $[a,b]$ and $\exists$ a differentiable function F on $[a,b]$ such that $F'=f$, then $\int_a^b f(x)\,dx = F(b)-F(a)$.

Proof. Choose $\Pi = \{x_0,\dots,x_n\}$ with $U(\Pi,f)-L(\Pi,f)<\varepsilon$.
By MVT, choose $t_i \in [x_{i-1},x_i]$ so that $F(b)-F(a) = \sum_i \big(F(x_i)-F(x_{i-1})\big) = \sum_i f(t_i)\Delta x_i$.

Theorem 2.1.8 puts this tagged sum within ε of $\int_a^b f$. Let $\varepsilon \to 0$.
Structural Commentary: Mean-value increments convert antiderivatives into tagged Riemann sums.
Key Insight: The integral is the common limit of all sufficiently fine tagged sums. □

Theorem 2.2.3. *Integration by Parts*
Suppose F,G are differentiable on $[a,b]$, $F'=f \in \mathcal{R}$, and $G'=g \in \mathcal{R}$.
Then $\int_a^b F(x)g(x)\,dx = F(b)G(b)-F(a)G(a)-\int_a^b f(x)G(x)\,dx$.

Proof. Set $H := FG$. Since F,G are continuous, $F,G \in \mathcal{R}$; hence $Fg, fG \in \mathcal{R}$ by Theorem 2.1.15.
Thus $H' = Fg+fG \in \mathcal{R}$, and Theorem 2.2.2 gives $F(b)G(b)-F(a)G(a) = H(b)-H(a) = \int_a^b Fg + \int_a^b fG$.
Structural Commentary: Integration by parts is the product rule integrated over the interval.
Key Insight: Move one derivative from G onto F by applying the fundamental theorem to FG. □

2.3 Step Integrators and Change of Variable

Definition 2.3.1. *Unit Step Function*
The *unit step function* I is $I(x) = \begin{cases} 0, & x \le 0, \\ 1, & x > 0. \end{cases}$

Theorem 2.3.2. *Single Jump Integrator*
If $a<s<b$, f is bounded on $[a,b]$ and continuous at s, and $\alpha(x) = I(x-s)$, then $\int_a^b f\,d\alpha = f(s)$.

Proof. Use partitions $\Pi = \{a,s,x_2,b\}$ with $s<x_2<b$. The only nonzero $\Delta\alpha_i$ occurs on $[s,x_2]$, so $L(\Pi,f,\alpha)$ and $U(\Pi,f,\alpha)$ are the infimum and supremum of f on $[s,x_2]$. As $x_2 \downarrow s$, continuity at s squeezes both to $f(s)$.
Structural Commentary: A jump of α makes the integral sample f at the jump.
Key Insight: Stieltjes integration includes point masses without changing the Darboux framework. □

Remark 2.3.3. *Stieltjes Increments as α-Lengths*
Stieltjes sums replace ordinary length Δx_i by $\Delta\alpha_i$, the length measured by α.
Thus $\alpha(x)=x$ gives Riemann sums, while jumps of α place point mass as in Theorem 2.3.2.

Theorem 2.3.4. *Pure Step Integrators Give Series*
Suppose $c_n \ge 0$, $\sum c_n$ converges, and (s_n) is a sequence of distinct points in (a,b).
Define $\alpha(x) := \sum_{n=1}^{\infty} c_n I(x-s_n)$. If f is continuous on $[a,b]$, then $\int_a^b f\,d\alpha = \sum_{n=1}^{\infty} c_n f(s_n)$.

Proof. By comparison, α is increasing. For $N \in \mathbb{N}$, put $\alpha_N(x) := \sum_{n=1}^{N} c_n I(x - s_n)$ and $\beta_N := \alpha - \alpha_N$..

Theorems 2.3.2 and 2.1.14 give $\int_a^b f\, d\alpha_N = \sum_{n=1}^{N} c_n f(s_n)$. Also $f \in \mathcal{R}(\beta_N)$ by Theorem 2.1.9.

If $|f| \le M$, then Theorem 2.1.14 gives $\left|\int_a^b f\, d\beta_N\right| \le M[\beta_N(b) - \beta_N(a)] = M \sum_{n>N} c_n$.

Letting $N \to \infty$ and using additivity in the integrator gives the formula.

Structural Commentary: Finite step integrators sum point samples; summable tails vanish by the integral bound.

Key Insight: A Stieltjes integral can be an ordinary series in disguise. □

Figure 159 illustrates the pure-step integrator in Theorem 2.3.4: each jump c_i at s_i contributes the point sample $c_i f(s_i)$.

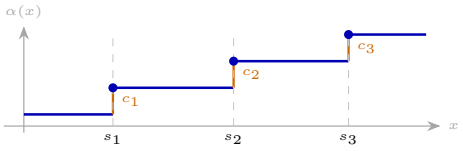

Figure 159: A step integrator concentrates mass at jumps: $\int f\, d\alpha = \sum_i c_i f(s_i)$.

Theorem 2.3.5. *Differentiable Integrators Reduce to Riemann Integrals*
Assume α increases monotonically, $\alpha' \in \mathcal{R}$ on $[a,b]$, and f is bounded and real on $[a,b]$.
Then $f \in \mathcal{R}(\alpha) \iff f\alpha' \in \mathcal{R}$, and in that case $\int_a^b f\, d\alpha = \int_a^b f(x)\alpha'(x)\, dx$.

Proof. Let $M = \sup_{[a,b]} |f|$. Choose Π with $U(\Pi, \alpha') - L(\Pi, \alpha') < \varepsilon$.
For any refinement and any tags $s_i \in [x_{i-1}, x_i]$, MVT gives points $t_i \in [x_{i-1}, x_i]$ with $\Delta\alpha_i = \alpha'(t_i)\Delta x_i$.
Hence $\left|\sum_i f(s_i)\Delta\alpha_i - \sum_i f(s_i)\alpha'(s_i)\Delta x_i\right| \le M \sum_i |\alpha'(t_i) - \alpha'(s_i)|\, \Delta x_i \le M\varepsilon$. Thus every tagged Stieltjes sum for $f\, d\alpha$ is within $M\varepsilon$ of the corresponding tagged Riemann sum for $f\alpha'\, dx$, and conversely. By the tagged-sum criterion, one family has a limit exactly when the other does, and the two limits are equal.

Structural Commentary: The increment $d\alpha$ is replaced by $\alpha'(x)\, dx$ when α' is Riemann integrable.

Key Insight: The mean value theorem turns Stieltjes increments into ordinary Riemann weights. □

Theorem 2.3.6. *Change of Variable*
Let $\varphi : [A,B] \to [a,b]$ be strictly increasing, continuous, and onto.
Let α be increasing on $[a,b]$, $f \in \mathcal{R}(\alpha)$, and set $\beta(y) := \alpha(\varphi(y))$ and $g(y) := f(\varphi(y))$.
Then $g \in \mathcal{R}(\beta)$ and $\int_A^B g\, d\beta = \int_a^b f\, d\alpha$. If also $\alpha(x) = x$ and $\varphi' \in \mathcal{R}$, then $\int_a^b f(x)\, dx = \int_A^B f(\varphi(y))\varphi'(y)\, dy$.

Proof. Partitions $Q = \{y_i\}$ of $[A,B]$ correspond to partitions $\Pi = \{\varphi(y_i)\}$ of $[a,b]$. On corresponding intervals, g has same range as f and $\Delta\beta_i = \Delta\alpha_i$, so $U(Q, g, \beta) = U(\Pi, f, \alpha)$ and $L(Q, g, \beta) = L(\Pi, f, \alpha)$. The upper–lower criterion gives the Stieltjes formula. If $\alpha(x) = x$, then $\beta = \varphi$; apply Theorem 2.3.5 to the left side.

Structural Commentary: A monotone change of variable relabels the same partition intervals.

Key Insight: Stieltjes change of variable is equality of Darboux sums under reparametrization. □

2.4 Improper Integrals

Definition 2.4.1. *Improper Riemann Integrals*
Let $f \in \mathcal{R}$ on every compact subinterval of its domain.
Set $\int_a^b f(x)\, dx := \lim_{d \to b^-} \int_a^d f(x)\, dx$ at a right endpoint, and $\int_a^b f(x)\, dx := \lim_{c \to a^+} \int_c^b f(x)\, dx$ at a left endpoint.
If both endpoints are improper, choose $\xi \in (a,b)$ and set $\int_a^b f(x)\, dx := \int_a^\xi f(x)\, dx + \int_\xi^b f(x)\, dx$, provided both one-sided integrals exist and the sum is not indeterminate.
A finite value means the improper integral *converges*; otherwise it diverges to $+\infty$ or $-\infty$.

Figure 160 illustrates the endpoint truncations in Definition 2.4.1, both toward a finite singular endpoint and toward infinity.

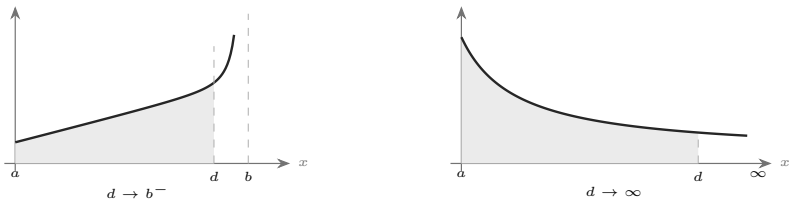

Figure 160: Improper integrals are limits of ordinary integrals over compact truncations.

Theorem 2.4.2. *Nonnegative Improper Integrals*
Let $f \ge 0$ and $f \in \mathcal{R}$ on every $[a,d]$, $a < d < b$. Then $\int_a^b f(x)\, dx = \sup\left\{\int_a^d f(x)\, dx : a < d < b\right\}$.
Thus $\int_a^b f$ exists in $[0, +\infty]$ and converges exactly when this supremum is finite.

Proof. For $a < d_1 < d_2 < b$, $\int_a^{d_2} f - \int_a^{d_1} f = \int_{d_1}^{d_2} f \ge 0$.
Hence $d \mapsto \int_a^d f$ is increasing, so its extended limit exists and equals its supremum.

Structural Commentary: Nonnegative area can only accumulate.

Key Insight: Improper convergence for $f \ge 0$ is boundedness of all finite truncations. □

Perspective 2.4.3. *Principal Value Is Different*
Improper integrals over $(-\infty,\infty)$ require separate one-sided limits.
A symmetric limit such as $\lim_{A\to\infty}\int_{-A}^{A}\sin x\,dx$ may still exist (Cauchy principal value, not Definition 2.4.1).

Definition 2.4.4. *Improper Riemann–Stieltjes Integrals on $\mathbb{R}$*
Let $\alpha:\mathbb{R}\to\mathbb{R}$ be increasing and $f\in\mathcal{R}(\alpha)$ on every finite interval.
Define, when the limits exist, $\int_0^\infty f\,d\alpha := \lim_{b\to\infty}\int_0^b f\,d\alpha$; and $\int_{-\infty}^0 f\,d\alpha := \lim_{a\to-\infty}\int_a^0 f\,d\alpha$.
If their sum is not indeterminate, set $\int_{-\infty}^\infty f\,d\alpha := \int_{-\infty}^0 f\,d\alpha + \int_0^\infty f\,d\alpha$.
Finite value means f is *α-integrable on $\mathbb{R}$*. Write $\alpha(\pm\infty) := \lim_{t\to\pm\infty}\alpha(t)$ when these extended limits are used.

Theorem 2.4.5. *Nonnegative and Bounded-Mass Stieltjes Integrals*
Let $\alpha:\mathbb{R}\to\mathbb{R}$ be increasing, and suppose $f\in\mathcal{R}(\alpha)$ on every finite interval.
(i) If $f\ge 0$, then either f is α-integrable on $\mathbb{R}$ or $\int_{-\infty}^\infty f\,d\alpha=+\infty$.
(ii) If $-\infty<\alpha(-\infty)<\alpha(\infty)<+\infty$ and f is bounded, then f is α-integrable on $\mathbb{R}$.

Proof.
(i) By additivity and order preservation, $\int_0^b f\,d\alpha$ and $\int_a^0 f\,d\alpha$ are monotone under outward truncation. Hence both extended one-sided limits exist, so their sum is finite or $+\infty$.
(ii) Let $|f|\le M$. For finite $a<b$, Theorem 2.1.14 gives $\left|\int_a^b f\,d\alpha\right|\le M\left[\alpha(b)-\alpha(a)\right]$. Since $\alpha(\infty)$ and $\alpha(-\infty)$ are finite, the right and left tails have vanishing α-increment. Thus the one-sided truncations are Cauchy and have finite limits.
Structural Commentary: Positivity gives monotone limits; finite mass bounds tails.
Key Insight: A bounded increasing integrator behaves like finite total mass. □

2.5 Vector-Valued Integrals and Curves

Definition 2.5.1. *Vector-Valued Riemann–Stieltjes Integral*
For $\mathbf{f}=(f_1,\dots,f_k):[a,b]\to\mathbb{R}^k$, define $\mathbf{f}\in\mathcal{R}(\alpha)$ iff $f_j\in\mathcal{R}(\alpha)$ $\forall j$, and set $\int_a^b\mathbf{f}\,d\alpha := \left(\int_a^b f_1\,d\alpha,\dots,\int_a^b f_k\,d\alpha\right)$.

Theorem 2.5.2. *Vector-Valued Integral Results*
(i) If $\mathbf{f},\mathbf{F}:[a,b]\to\mathbb{R}^k$, $\mathbf{f}\in\mathcal{R}$, and $\mathbf{F}'=\mathbf{f}$, then $\int_a^b\mathbf{f}(t)\,dt=\mathbf{F}(b)-\mathbf{F}(a)$.
(ii) If $\mathbf{f}:[a,b]\to\mathbb{R}^k$ and $\mathbf{f}\in\mathcal{R}(\alpha)$, then $\|\mathbf{f}\|\in\mathcal{R}(\alpha)$ and $\left\|\int_a^b\mathbf{f}\,d\alpha\right\|\le\int_a^b\|\mathbf{f}\|\,d\alpha$

Proof.
(i) Write $\mathbf{f}=(f_1,\dots,f_k)$ and $\mathbf{F}=(F_1,\dots,F_k)$. For each j, Theorem 2.2.2 gives $\int_a^b f_j(t)\,dt=F_j(b)-F_j(a)$. The vector identity follows componentwise.
(ii) Write $\mathbf{f}=(f_1,\dots,f_k)$. Since $\|\mathbf{f}\|=(f_1^2+\cdots+f_k^2)^{1/2}$, Theorems 2.1.15 and 2.1.13 give $\|\mathbf{f}\|\in\mathcal{R}(\alpha)$.
Let $\mathbf{y}:=\int_a^b\mathbf{f}\,d\alpha$. If $\mathbf{y}=0$, the inequality is immediate.
Otherwise, $\|\mathbf{y}\|^2=\sum_{j=1}^k y_j\int_a^b f_j\,d\alpha=\int_a^b\sum_{j=1}^k y_jf_j\,d\alpha\le\int_a^b\|\mathbf{y}\|\,\|\mathbf{f}\|\,d\alpha=\|\mathbf{y}\|\int_a^b\|\mathbf{f}\|\,d\alpha$, by Theorem 1.1.13 and order preservation.
Divide by $\|\mathbf{y}\|$.
Structural Commentary: Coordinatewise integration; Schwarz controls norms.
Key Insight: Integrate the projection of $\mathbf{f}$ onto the resulting vector. □

Definition 2.5.3. *Curves and Rectifiability*
A *curve* in $\mathbb{R}^k$ is a continuous map $\gamma:[a,b]\to\mathbb{R}^k$; it is an *arc* if one-to-one and a *closed curve* if $\gamma(a)=\gamma(b)$.
Curves are maps, not just ranges. For a partition $\Pi=\{x_0,\dots,x_n\}$, set $\ell(\Pi,\gamma):=\sum_{i=1}^n\|\gamma(x_i)-\gamma(x_{i-1})\|$.
The *length* is $\ell(\gamma):=\sup_\Pi\ell(\Pi,\gamma)$; if $\ell(\gamma)<\infty$, γ is *rectifiable*.

Perspective 2.5.4. *Length Is Not Just Shape*
Length is a supremum over partitions of one curve. Passing lengths through curve limits needs more than positional convergence; Theorem 2.5.5 uses C^1 speed control.

Figure 161 contrasts staircase curves approaching the diagonal in position with their constant polygonal length.

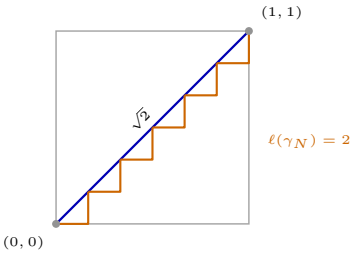

Figure 161: A staircase path can approach the diagonal in position while its polygonal length stays 2, not $\sqrt{2}$.

Theorem 2.5.5. *Length of a Continuously Differentiable Curve*
If $\gamma':[a,b]\to\mathbb{R}^k$ is continuous, then γ is rectifiable and $\ell(\gamma)=\int_a^b\|\gamma'(t)\|\,dt$.

Proof. For $\Pi = \{x_0, \dots, x_n\}$, Theorem 2.5.2(i) gives $\|\gamma(x_i) - \gamma(x_{i-1})\| = \left\|\int_{x_{i-1}}^{x_i} \gamma'(t)\,dt\right\| \le \int_{x_{i-1}}^{x_i} \|\gamma'(t)\|\,dt$.
Hence $\ell(\Pi,\gamma) \le \int_a^b \|\gamma'\|$. Conversely, choose Π so fine that $\|\gamma'(s) - \gamma'(t)\| < \varepsilon$ on each subinterval.
Choose $t_i \in [x_{i-1}, x_i]$. Then $\int_{x_{i-1}}^{x_i} \|\gamma'(t)\|\,dt \le \|\gamma'(t_i)\|\,\Delta x_i + \varepsilon \Delta x_i$.
Also $\gamma(x_i) - \gamma(x_{i-1}) = \int_{x_{i-1}}^{x_i} \gamma'(t)\,dt$, so $\|\gamma'(t_i)\|\,\Delta x_i \le \|\gamma(x_i) - \gamma(x_{i-1})\| + \varepsilon \Delta x_i$.
Thus $\int_{x_{i-1}}^{x_i} \|\gamma'(t)\|\,dt \le \|\gamma(x_i) - \gamma(x_{i-1})\| + 2\varepsilon \Delta x_i$.
Summing gives $\int_a^b \|\gamma'\| \le \ell(\gamma) + 2\varepsilon(b-a)$; let $\varepsilon \downarrow 0$.
Structural Commentary: Upper bounds are immediate; uniform continuity gives matching lower bounds.
Key Insight: For C^1 curves, length is accumulated speed. □

2.6 Further Topics in Integration

Method 2.6.1. *Integration Proof Patterns*

(i) *Definitions*: fix $\Pi = \{x_i\}_{i=0}^n$ before defining $M_i, m_i, \Delta x_i, \Delta\alpha_i$.
(ii) *Refinement*: prove the one-point insertion case; iterate.
(iii) *Integrability*: find Π with $U(\Pi, f, \alpha) - L(\Pi, f, \alpha) < \varepsilon$.
(iv) *Bad sets*: cover E by $I_j = [u_j, v_j]$ with $\sum_j [\alpha(v_j) - \alpha(u_j)] < \varepsilon$; control $K = [a,b] \setminus \bigcup_j (u_j, v_j)$ uniformly.
(v) *Properties*: pass to a common refinement before comparing sums.
(vi) *Calculus*: use the mean value theorem to form tagged sums, then apply Theorem 2.1.8.
(vii) *Improper integrals*: truncate endpoints; use monotonicity or tail bounds.

Key Insight: Riemann–Stieltjes integration is Darboux approximation plus a choice of interval weights $\Delta\alpha_i$.

3 Several-Variable Differentiation

3.1 Partial and Total Derivatives

Several-variable differentiation studies best linear approximations and local geometry, using linear maps, operator norms, determinants, invertibility, and metric estimates.

Definition 3.1.1. *Total Derivative*
Let $E \subseteq \mathbb{R}^n$ be open, $\mathbf{f} : E \to \mathbb{R}^m$, $\mathbf{x} \in E$, and $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ denote space of linear maps (Definition 1.5.1).
If $\exists A \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ s.t. $\lim_{\mathbf{h}\to\mathbf{0}} \frac{\|\mathbf{f}(\mathbf{x}+\mathbf{h}) - \mathbf{f}(\mathbf{x}) - A\mathbf{h}\|_2}{\|\mathbf{h}\|_2} = 0$, then $\mathbf{f}$ is *differentiable at* $\mathbf{x}$, and A denoted $D\mathbf{f}(\mathbf{x})$ or $\mathbf{f}'(\mathbf{x})$.
Equivalently, $\mathbf{f}(\mathbf{x}+\mathbf{h}) - \mathbf{f}(\mathbf{x}) = D\mathbf{f}(\mathbf{x})\mathbf{h} + \mathbf{r}(\mathbf{h})$, and $\frac{\|\mathbf{r}(\mathbf{h})\|_2}{\|\mathbf{h}\|_2} \to 0$.
If this holds for every $\mathbf{x} \in E$, then $\mathbf{f}$ is differentiable on E.

Perspective 3.1.2. *Derivative First, Matrix Second*
The total derivative is a linear map first; the Jacobian is its matrix in chosen bases. This keeps coordinate formulas subordinate to the intrinsic estimate $\|A\mathbf{h}\|_2 \le \|A\|_{\mathrm{op}} \|\mathbf{h}\|_2$ from Definition 5.1.4.

Figure 162 separates the input increment $\mathbf{h}$, its linear image $D\mathbf{f}(\mathbf{x})\mathbf{h}$, and the smaller remainder $\mathbf{r}(\mathbf{h})$.

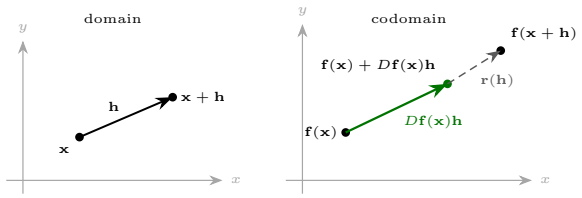

Figure 162: $D\mathbf{f}(\mathbf{x})\mathbf{h}$ is the linear part; $\mathbf{r}(\mathbf{h}) = o(\|\mathbf{h}\|_2)$ is the error.

Theorem 3.1.3. *Basic Consequences of Total Differentiability*
If $\mathbf{f} : E \to \mathbb{R}^m$ is differentiable at $\mathbf{x} \in E$, then $D\mathbf{f}(\mathbf{x})$ is unique and $\mathbf{f}$ is continuous at $\mathbf{x}$.

Proof. If A_1, A_2 both satisfy Definition 3.1.1, set $B = A_1 - A_2$. Then $\|B\mathbf{h}\|_2 / \|\mathbf{h}\|_2 \to 0$ as $\mathbf{h} \to \mathbf{0}$.
For fixed $\mathbf{h} \neq \mathbf{0}$, applying this to $t\mathbf{h}$ and using linearity makes the quotient independent of t, so $B\mathbf{h} = \mathbf{0}$.
Hence $B = 0$. For continuity, write $\mathbf{f}(\mathbf{x}+\mathbf{h}) - \mathbf{f}(\mathbf{x}) = D\mathbf{f}(\mathbf{x})\mathbf{h} + \mathbf{r}(\mathbf{h})$.
The operator-norm estimate gives $\|D\mathbf{f}(\mathbf{x})\mathbf{h}\|_2 \le \|D\mathbf{f}(\mathbf{x})\|_{\mathrm{op}} \|\mathbf{h}\|_2$, and remainder is $o(\|\mathbf{h}\|_2)$, so $\mathbf{f}(\mathbf{x}+\mathbf{h}) \to \mathbf{f}(\mathbf{x})$.
Structural Commentary: The derivative is a rigid first-order linear part.
Key Insight: A remainder smaller than $\|\mathbf{h}\|$ cannot hide a second linear map. □

Example 3.1.4. *Derivative of a Linear Map*
If $A \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ and $\mathbf{f}(\mathbf{x}) = A\mathbf{x}$, then $D\mathbf{f}(\mathbf{x}) = A$ for every $\mathbf{x} \in \mathbb{R}^n$.
The remainder in Definition 3.1.1 is identically zero.

Theorem 3.1.5. *Chain Rule*
If $\mathbf{f} : E \subseteq \mathbb{R}^n \to \mathbb{R}^m$ is differentiable at $\mathbf{x}_0$, $\mathbf{g} : G \subseteq \mathbb{R}^m \to \mathbb{R}^k$ is differentiable at $\mathbf{f}(\mathbf{x}_0)$, and $\mathbf{f}(E) \subseteq G$, then $\mathbf{g} \circ \mathbf{f}$ is differentiable at $\mathbf{x}_0$ and $D(\mathbf{g} \circ \mathbf{f})(\mathbf{x}_0) = D\mathbf{g}(\mathbf{f}(\mathbf{x}_0))\, D\mathbf{f}(\mathbf{x}_0)$.

Proof. Let $A = D\mathbf{f}(\mathbf{x}_0)$, $B = D\mathbf{g}(\mathbf{f}(\mathbf{x}_0))$, $\mathbf{u}(\mathbf{h}) = \mathbf{f}(\mathbf{x}_0 + \mathbf{h}) - \mathbf{f}(\mathbf{x}_0) - A\mathbf{h}$, and $\mathbf{v}(\mathbf{k}) = \mathbf{g}(\mathbf{f}(\mathbf{x}_0) + \mathbf{k}) - \mathbf{g}(\mathbf{f}(\mathbf{x}_0)) - B\mathbf{k}$.
For $\mathbf{k} = \mathbf{f}(\mathbf{x}_0 + \mathbf{h}) - \mathbf{f}(\mathbf{x}_0)$, differentiability of $\mathbf{f}$ gives $\mathbf{k} \to \mathbf{0}$ and $(\mathbf{g} \circ \mathbf{f})(\mathbf{x}_0 + \mathbf{h}) - (\mathbf{g} \circ \mathbf{f})(\mathbf{x}_0) - BA\mathbf{h} = B\mathbf{u}(\mathbf{h}) + \mathbf{v}(\mathbf{k})$, where $\|\mathbf{u}(\mathbf{h})\|_2 = o(\|\mathbf{h}\|_2)$ and $\|\mathbf{v}(\mathbf{k})\|_2 = o(\|\mathbf{k}\|_2) = o(\|\mathbf{h}\|_2)$. Divide by $\|\mathbf{h}\|_2$.
Structural Commentary: The first-order parts compose as linear maps.
Key Insight: The output increment of $\mathbf{f}$ is small enough to feed into the remainder estimate for $\mathbf{g}$. □

Theorem 3.1.6. *Componentwise Differentiability*
Let $\mathbf{f} = (f_1, \dots, f_m) : E \subseteq \mathbb{R}^n \to \mathbb{R}^m$ and let $\pi_i : \mathbb{R}^m \to \mathbb{R}$ be the ith coordinate projection. Then $\mathbf{f}$ is differentiable at $\mathbf{x} \in E$ iff each f_i is differentiable at $\mathbf{x}$, and $Df_i(\mathbf{x}) = \pi_i \circ D\mathbf{f}(\mathbf{x})$ when these derivatives exist.

Proof.
($\Rightarrow$) If $\mathbf{f}$ is differentiable, write $\mathbf{f}(\mathbf{x}+\mathbf{h}) - \mathbf{f}(\mathbf{x}) = D\mathbf{f}(\mathbf{x})\mathbf{h} + \mathbf{r}(\mathbf{h})$ with $\|\mathbf{r}(\mathbf{h})\|_2 = o(\|\mathbf{h}\|_2)$.
Applying π_i gives $f_i(\mathbf{x}+\mathbf{h}) - f_i(\mathbf{x}) = \pi_i(D\mathbf{f}(\mathbf{x})\mathbf{h}) + \pi_i(\mathbf{r}(\mathbf{h}))$ and $|\pi_i(\mathbf{r}(\mathbf{h}))| \le \|\mathbf{r}(\mathbf{h})\|_2 = o(\|\mathbf{h}\|_2)$.
Thus $Df_i(\mathbf{x}) = \pi_i \circ D\mathbf{f}(\mathbf{x})$.
($\Leftarrow$) Suppose $Df_i(\mathbf{x}) = A_i \in \mathcal{L}(\mathbb{R}^n, \mathbb{R})$ for each i. Define $A \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ by $A\mathbf{h} = (A_1\mathbf{h}, \dots, A_m\mathbf{h})$.
With $r_i(\mathbf{h}) = f_i(\mathbf{x}+\mathbf{h}) - f_i(\mathbf{x}) - A_i\mathbf{h}$, each $r_i(\mathbf{h}) = o(\|\mathbf{h}\|_2)$.
So $\mathbf{r}(\mathbf{h}) = (r_1(\mathbf{h}), \dots, r_m(\mathbf{h}))$ satisfies $\|\mathbf{r}(\mathbf{h})\|_2 \le \sum_i |r_i(\mathbf{h})| = o(\|\mathbf{h}\|_2)$. Definition 3.1.1 gives $D\mathbf{f}(\mathbf{x}) = A$.
Structural Commentary: Component derivatives assemble into one linear map.
Key Insight: Components test the derivative; the total derivative packages the tests together. □

Definition 3.1.7. *Partial, Gradient, and Directional Derivatives*
Let $E \subseteq \mathbb{R}^n$ be open, $\mathbf{f} = (f_1, \dots, f_m) : E \to \mathbb{R}^m$, $\mathbf{x} \in E$, and let $\mathbf{e}_1, \dots, \mathbf{e}_n$ be the standard basis of $\mathbb{R}^n$.
(i) For $1 \le i \le m$ and $1 \le j \le n$, the *partial derivative* of f_i in coordinate j at $\mathbf{x}$ is $(D_j f_i)(\mathbf{x}) := \lim_{t\to 0} \frac{f_i(\mathbf{x}+t\mathbf{e}_j) - f_i(\mathbf{x})}{t}$, when this limit exists.
(ii) For $\mathbf{u} \in \mathbb{R}^n$, the *directional derivative* of $\mathbf{f}$ at $\mathbf{x}$ in direction $\mathbf{u}$ is $(D_{\mathbf{u}}\mathbf{f})(\mathbf{x}) := \lim_{t\to 0} \frac{\mathbf{f}(\mathbf{x}+t\mathbf{u}) - \mathbf{f}(\mathbf{x})}{t}$, when this limit exists; if only direction matters, take $\|\mathbf{u}\|_2 = 1$.
(iii) If $m = 1$, write $f = f_1$; if all $(D_j f)(\mathbf{x})$ exist, the *gradient* of f at $\mathbf{x}$ is $(\nabla f)(\mathbf{x}) := \sum_{j=1}^{n} (D_j f)(\mathbf{x})\mathbf{e}_j$.

Perspective 3.1.8. *Partials Are Coordinate Tests*
Partials and directional derivatives test selected lines; the total derivative controls all small increments by one linear map. Theorem 3.1.9 extracts partials, and Theorem 3.2.4 gives a continuity-based converse.

Theorem 3.1.9. *Matrix of the Total Derivative*
If $\mathbf{f} : E \to \mathbb{R}^m$ is differentiable at $\mathbf{x}$, then every $(D_j f_i)(\mathbf{x})$ exists and, in standard bases,

$$[D\mathbf{f}(\mathbf{x})] = \begin{bmatrix} (D_1 f_1)(\mathbf{x}) & \cdots & (D_n f_1)(\mathbf{x}) \\ \vdots & & \vdots \\ (D_1 f_m)(\mathbf{x}) & \cdots & (D_n f_m)(\mathbf{x}) \end{bmatrix}$$

If $m = 1$ and f is differentiable at $\mathbf{x}$, then $(D_{\mathbf{u}} f)(\mathbf{x}) = (\nabla f)(\mathbf{x}) \cdot \mathbf{u}$ for every $\mathbf{u} \in \mathbb{R}^n$.

Proof. Set $\mathbf{h} = t\mathbf{e}_j$ in Definition 3.1.1; limit is $D\mathbf{f}(\mathbf{x})\mathbf{e}_j$, so components form column j (Proposition 3.2.5).
For $m = 1$, set $\mathbf{h} = t\mathbf{u}$, identify linear functional with dot product against $\nabla f(\mathbf{x})$ (Theorem 1.6.1).
Structural Commentary: Partials are coordinate columns of $D\mathbf{f}(\mathbf{x})$.
Key Insight: Differentiability controls all directions at once; partial derivatives record its coordinate columns. □

Remark 3.1.10. *Row and Column Conventions*
With the coordinate-column convention from Proposition 3.2.5, the Jacobian matrix above is the standard-basis matrix of the linear map $D\mathbf{f}(\mathbf{x})$, and its jth column is $D\mathbf{f}(\mathbf{x})\mathbf{e}_j$.

Definition 3.1.11. *Jacobian*
Let $E \subseteq \mathbb{R}^n$, let $\mathbf{f} = (y_1, \dots, y_n) : E \to \mathbb{R}^n$, and suppose $\mathbf{f}$ is differentiable at $\mathbf{x} \in E$.
The *Jacobian determinant* is $J_{\mathbf{f}}(\mathbf{x}) := \det D\mathbf{f}(\mathbf{x}) = \frac{\partial(y_1,\dots,y_n)}{\partial(x_1,\dots,x_n)}(\mathbf{x})$.
Then $D\mathbf{f}(\mathbf{x})$ is invertible iff $J_{\mathbf{f}}(\mathbf{x}) \neq 0$. Interpretation: $|J_{\mathbf{f}}(\mathbf{x})|$ is the infinitesimal volume-scaling factor.

3.2 Differentiability and Linear Approximation

Theorem 3.2.1. *Mean-Value Inequality on Convex Sets*
Let $E \subseteq \mathbb{R}^n$ be open and convex, and let $\mathbf{f} : E \to \mathbb{R}^m$ be differentiable.
(i) If $M \ge 0$ and $\|D\mathbf{f}(\mathbf{x})\|_{op} \le M$ for all $\mathbf{x} \in E$, then $\|\mathbf{f}(\mathbf{b}) - \mathbf{f}(\mathbf{a})\|_2 \le M\|\mathbf{b} - \mathbf{a}\|_2$ for all $\mathbf{a}, \mathbf{b} \in E$.
(ii) If $D\mathbf{f}(\mathbf{x}) = 0$ for all $\mathbf{x} \in E$, then $\mathbf{f}$ is constant on E.

Proof.
(i) Fix $\mathbf{a}, \mathbf{b} \in E$, set $\gamma(t) := (1-t)\mathbf{a} + t\mathbf{b}$, and put $\mathbf{g} := \mathbf{f} \circ \gamma$. Convexity gives $\gamma([0,1]) \subseteq E$, and the chain rule gives $\mathbf{g}'(t) = D\mathbf{f}(\gamma(t))(\mathbf{b} - \mathbf{a})$, so $\|\mathbf{g}'(t)\|_2 \le M\|\mathbf{b} - \mathbf{a}\|_2$.
Theorem 1.1.27 gives $\|\mathbf{f}(\mathbf{b}) - \mathbf{f}(\mathbf{a})\|_2 = \|\mathbf{g}(1) - \mathbf{g}(0)\|_2 \le M\|\mathbf{b} - \mathbf{a}\|_2$.
(ii) If $D\mathbf{f}(\mathbf{x}) = 0$ on E, apply (i) with $M = 0$: for all $\mathbf{a}, \mathbf{b} \in E$, $\|\mathbf{f}(\mathbf{b}) - \mathbf{f}(\mathbf{a})\|_2 = 0$, hence $\mathbf{f}(\mathbf{a}) = \mathbf{f}(\mathbf{b})$.
Structural Commentary: Line restriction gives a one-variable estimate.
Key Insight: Derivative bounds control secants. □

Definition 3.2.2. *C^1 Mapping*
Let $E \subseteq \mathbb{R}^n$ be open. A differentiable map $\mathbf{f} : E \to \mathbb{R}^m$ is *continuously differentiable*, or C^1, if $\mathbf{x} \mapsto D\mathbf{f}(\mathbf{x})$ is continuous from E into $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ in operator norm.

Perspective 3.2.3. *C^1 Uses the Operator-Norm Metric*
C^1 continuity measures $\mathbf{x} \mapsto D\mathbf{f}(\mathbf{x})$ in operator norm. In coordinates this is spectral-norm continuity, equivalent here to continuity of the derivative matrix entries.

Figure 163 decomposes $\mathbf{h}$ into successive coordinate increments, the path used to telescope from $\mathbf{x}$ to $\mathbf{x}+\mathbf{h}$ in the coordinate criterion.

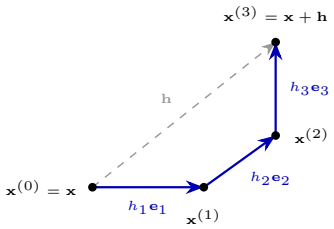

Figure 163: Coordinate increments telescope $\mathbf{x}$ to $\mathbf{x}+\mathbf{h}$.

Theorem 3.2.4. *C^1 Means Continuous Partials*
Let $E \subseteq \mathbb{R}^n$ be open and let $\mathbf{f} = (f_1, \dots, f_m) : E \to \mathbb{R}^m$.
Then $\mathbf{f}$ is C^1 on E iff each $D_j f_i$ exists and is continuous on E, for $1 \le i \le m$ and $1 \le j \le n$.

Proof.

($\Rightarrow$) If $\mathbf{f}$ is C^1, then $D\mathbf{f} : E \to \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ is continuous. By Theorem 3.1.9, $(D_j f_i)(\mathbf{x})$ is the (i,j) matrix entry of $D\mathbf{f}(\mathbf{x})$; matrix-entry projections are continuous, so each $D_j f_i$ is continuous on E.

($\Leftarrow$) By Theorem 3.1.6, it suffices to treat $m = 1$. Fix $\mathbf{x} \in E$ and small $\mathbf{h}$ with coordinate polygon in E.

Set $\mathbf{x}^{(0)} := \mathbf{x}$ and $\mathbf{x}^{(j)} := \mathbf{x} + \sum_{k=1}^{j} h_k \mathbf{e}_k$. Telescoping and the one-variable MVT give

$f(\mathbf{x}+\mathbf{h}) - f(\mathbf{x}) = \sum_{j=1}^{n} h_j (D_j f)(\xi_j)$ for some $\xi_j \in [\mathbf{x}^{(j-1)}, \mathbf{x}^{(j)}]$. Let $A_{\mathbf{x}}\mathbf{h} := \sum_{j=1}^{n} h_j (D_j f)(\mathbf{x})$.

Since $\xi_j \to \mathbf{x}$ as $\mathbf{h} \to \mathbf{0}$, $|f(\mathbf{x}+\mathbf{h}) - f(\mathbf{x}) - A_{\mathbf{x}}\mathbf{h}| \le \sum_{j=1}^{n} |h_j|\,|(D_j f)(\xi_j) - (D_j f)(\mathbf{x})| = o(\|\mathbf{h}\|_2)$.

Thus $Df(\mathbf{x}) = A_{\mathbf{x}}$, i.e. $Df(\mathbf{x}) = [(D_1 f)(\mathbf{x}) \ \cdots \ (D_n f)(\mathbf{x})]$, and continuity of the entries gives $\mathbf{f} \in C^1$.

Structural Commentary: Continuous partials form the derivative matrix.
Key Insight: Coordinate telescoping gives the linear approximation. □

Higher derivatives repeat the same idea: once $D\mathbf{f}$ is itself a map into the finite-dimensional vector space $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$, we differentiate it again. The linear-algebra viewpoint matters here because the second derivative is naturally bilinear, not merely an array of second partial derivatives.

Definition 3.2.5. *Higher Derivatives and C^r*
Let $E \subseteq \mathbb{R}^n$ be open, $\mathbf{f} : E \to \mathbb{R}^m$, $r \ge 1$, and let $\mathcal{L}^r(\mathbb{R}^n, \mathbb{R}^m)$ denote the space of r-linear maps $(\mathbb{R}^n)^r \to \mathbb{R}^m$.

(i) The *rth derivative* is recursive: $D^1\mathbf{f} := D\mathbf{f}$.
For $r \ge 2$, if $D^{r-1}\mathbf{f}$ is differentiable at $\mathbf{x}$, then $D^r\mathbf{f}(\mathbf{x})(\mathbf{v}_1, \dots, \mathbf{v}_r) := \big(D(D^{r-1}\mathbf{f})(\mathbf{x})\mathbf{v}_1\big)(\mathbf{v}_2, \dots, \mathbf{v}_r)$.
(ii) For real-valued $f : E \to \mathbb{R}$, the mixed second partial is $D_{ij} f := D_i(D_j f)$ where defined.
(iii) $\mathbf{f}$ is C^r on E iff $D^r\mathbf{f} : E \to \mathcal{L}^r(\mathbb{R}^n, \mathbb{R}^m)$ exists and is continuous; $\mathbf{f}$ is C^∞ iff $\mathbf{f}$ is C^r for every $r \ge 1$.

Theorem 3.2.6. *Second Derivatives and Second Partials*
Let $\mathbf{f} = (f_1, \dots, f_m) : E \subseteq \mathbb{R}^n \to \mathbb{R}^m$ and $p \in E$.

(i) If $D^2\mathbf{f}(p)$ exists, then each $D_{ij} f_\ell(p)$ exists and $D^2 f_\ell(p)(\mathbf{e}_i, \mathbf{e}_j) = D_{ij} f_\ell(p)$.
(ii) If all $D_{ij} f_\ell$ exist near p and are continuous at p, then $D^2\mathbf{f}(p)$ exists.

Proof.

(i) Apply Theorem 3.1.6 to $D\mathbf{f} : E \to \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$. The entries of $D\mathbf{f}$ are $D_j f_\ell$ by Theorem 3.1.9; differentiating the (ℓ, j) entry in the $\mathbf{e}_i$ direction gives $D_{ij} f_\ell(p)$ and the displayed formula.

(ii) Matrix entries of $D\mathbf{f}$ are functions $D_j f_\ell$. Since first partials $D_i(D_j f_\ell) = D_{ij} f_\ell$ exist near p and are continuous at p, coordinate criterion at p gives differentiability of $D\mathbf{f}$ there. Hence $D^2\mathbf{f}(p)$ exists.

Structural Commentary: Second partials are matrix entries of the derivative of the first-derivative matrix.
Key Insight: Continuous second partials make the first-derivative matrix differentiable. □

Figure 164 illustrates the symmetry of the signed four-vertex difference used below: exchanging $\mathbf{v}$ and $\mathbf{w}$ preserves its vertices and signs.

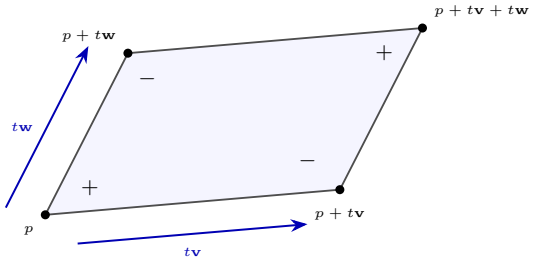

Figure 164: The signed vertex sum on a small parallelogram is symmetric in $\mathbf{v}$ and $\mathbf{w}$.

Theorem 3.2.7. *Symmetry of the Second Derivative*
If $D^2\mathbf{f}(p)$ exists, then $D^2\mathbf{f}(p)(\mathbf{v}, \mathbf{w}) = D^2\mathbf{f}(p)(\mathbf{w}, \mathbf{v})$ for all $\mathbf{v}, \mathbf{w} \in \mathbb{R}^n$.

Proof. Reduce to scalar f by Theorem 3.1.6.
For small t, set $\Delta(t,\mathbf{v},\mathbf{w}) := f(p+t\mathbf{v}+t\mathbf{w}) - f(p+t\mathbf{v}) - f(p+t\mathbf{w}) + f(p)$.
Then $\Delta(t,\mathbf{v},\mathbf{w}) = \Delta(t,\mathbf{w},\mathbf{v})$. The one-variable mean value theorem and differentiability of Df at p give $D^2f(p)(\mathbf{v},\mathbf{w}) = \lim_{t\to 0} \frac{\Delta(t,\mathbf{v},\mathbf{w})}{t^2}$.
The same formula with $\mathbf{v},\mathbf{w}$ reversed proves symmetry.
Structural Commentary: A pointwise second derivative is already forced to be a symmetric bilinear form.
Key Insight: The parallelogram difference is symmetric in the two directions. □

Corollary 3.2.8. *Mixed Partials from D^2*
If $D^2\mathbf{f}(p)$ exists, then $D_{ij}f_\ell(p) = D_{ji}f_\ell(p)$ for all components and all i,j.

Proof. By Theorem 3.2.6, $D_{ij}f_\ell(p) = D^2f_\ell(p)(\mathbf{e}_i,\mathbf{e}_j)$; and $D_{ji}f_\ell(p) = D^2f_\ell(p)(\mathbf{e}_j,\mathbf{e}_i)$.
Theorem 3.2.7 makes the two right-hand sides equal.
Structural Commentary: Mixed partials are coordinate values of one bilinear map.
Key Insight: Symmetry of $D^2f_\ell(p)$ gives equality of mixed entries. □

Corollary 3.2.9. *Symmetry of Higher Derivatives*
Let $E \subseteq \mathbb{R}^n$ be open, $\mathbf{f}: E \to \mathbb{R}^m$, $p \in E$, and $r \geq 2$.
If $D^r\mathbf{f}(p)$ exists, then for every $\sigma \in S_r$ and $\mathbf{v}_1,\dots,\mathbf{v}_r \in \mathbb{R}^n$, $D^r\mathbf{f}(p)(\mathbf{v}_{\sigma(1)},\dots,\mathbf{v}_{\sigma(r)}) = D^r\mathbf{f}(p)(\mathbf{v}_1,\dots,\mathbf{v}_r)$.

Proof. Induct on r; $r=2$ is Theorem 3.2.7. For $r>2$, the induction hypothesis gives symmetry in slots $2,\dots,r$ of $D^r\mathbf{f}(p)$. Applying Theorem 3.2.7 to $D^{r-2}\mathbf{f}: E \to \mathcal{L}^{r-2}(\mathbb{R}^n,\mathbb{R}^m)$ and evaluating at $\mathbf{v}_3,\dots,\mathbf{v}_r$ gives symmetry in slots $1,2$. Hence every adjacent transposition fixes $D^r\mathbf{f}(p)$, so every $\sigma \in S_r$ fixes it.
Structural Commentary: Symmetry propagates from D^2.
Key Insight: Adjacent swaps generate S_r. □

The next rectangle argument is the classical coordinate route to equality of mixed partials. It is weaker in hypothesis than global C^2, but it proves the same compatibility of coordinate second derivatives.

Theorem 3.2.10. *Rectangle Mean Value Formula*
Let $E \subseteq \mathbb{R}^2$ be open, let $f: E \to \mathbb{R}$, and assume D_1f and $D_{21}f = D_2(D_1f)$ exist on E. Let $h,k \neq 0$, let $Q \subseteq E$ be the closed coordinate rectangle with opposite vertices (a,b) and $(a+h,b+k)$, and set $\Delta(f,Q) := f(a+h,b+k) - f(a+h,b) - f(a,b+k) + f(a,b)$. Then there exists $(x,y) \in \operatorname{int} Q$ such that $\Delta(f,Q) = hk(D_{21}f)(x,y)$.

Proof. Let I,J be the open intervals with endpoints $a, a+h$ and $b, b+k$. Set $u(t) := f(t,b+k) - f(t,b)$.
By Corollary 1.1.13, $\Delta(f,Q) = u(a+h) - u(a) = h[(D_1f)(x,b+k) - (D_1f)(x,b)]$ for some $x \in I$. Applying the same result to $s \mapsto (D_1f)(x,s)$ gives $(D_1f)(x,b+k) - (D_1f)(x,b) = k(D_{21}f)(x,y)$ for some $y \in J$.
Thus $(x,y) \in I \times J = \operatorname{int} Q$ and $\Delta(f,Q) = hk(D_{21}f)(x,y)$.
Structural Commentary: Two MVT steps factor the rectangle increment.
Key Insight: $D_{21}f$ tracks vertical change of D_1f. □

Theorem 3.2.11. *Equality of Mixed Partials*
Let (a,b) lie in an open set $E \subseteq \mathbb{R}^2$. If D_1f, D_2f, and $D_{21}f$ exist on E, and $D_{21}f$ is continuous at (a,b), then $D_{12}f(a,b)$ exists and $(D_{12}f)(a,b) = (D_{21}f)(a,b)$. Hence $D_{12}f = D_{21}f$ when $f \in C^2(E)$.

Proof. Let $A = (D_{21}f)(a,b)$, $\varepsilon > 0$.
Continuity of $D_{21}f$, Theorem 3.2.10 gives $\forall$ small $h,k \neq 0$, $\left|\frac{\Delta(f,Q)}{hk} - A\right| < \varepsilon$.
Fix such an h and let $k \to 0$. Since D_2f exists at $(a+h,b)$ and (a,b), $\frac{\Delta(f,Q)}{hk} \to \frac{(D_2f)(a+h,b)-(D_2f)(a,b)}{h}$.
Thus this last quotient differs from A by at most ε $\forall$ sufficiently small $h \neq 0$.
Since ε was arbitrary, the quotient tends to A as $h \to 0$, so $D_{12}f(a,b)$ exists and equals A.
Structural Commentary: Continuity of $D_{21}f$ controls local rectangle quotients.
Key Insight: The missing mixed partial is recovered by taking the two one-variable limits in the reverse order. □

Perspective 3.2.12. *Mixed Partials Need Hypotheses*
$D_{12}f$ and $D_{21}f$ are different iterated limits. Theorems 3.2.7 and 3.2.11 give hypotheses for equality.

4 Inverse, Implicit, and Rank Theorems

4.1 Inverse Function Theorem

Perspective 4.1.1. *Linear Inverse Estimate*
For invertible $A \in \mathcal{L}(\mathbb{R}^n)$, Theorem 7.1.4 gives $c\|\mathbf{h}\|_2 \leq \|A\mathbf{h}\|_2 \leq \|A\|_{\text{op}}\|\mathbf{h}\|_2$; and $c := \frac{1}{\|A^{-1}\|_{\text{op}}}$.
The inverse function theorem preserves this lower stretch under small derivative changes.

Figure 165 illustrates the positive lower stretch c: the image $A(S^{n-1})$ stays uniformly separated from the origin.

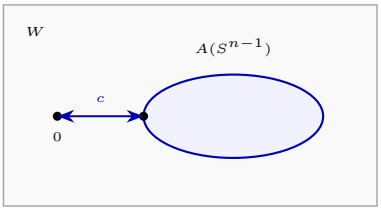

Figure 165: Invertibility keeps $A(S^{n-1})$ a positive distance from 0.

Theorem 4.1.2. *Inverse Function Theorem*
Let $E \subseteq \mathbb{R}^n$ be open, let $\mathbf{f} : E \to \mathbb{R}^n$ be C^1, let $\mathbf{a} \in E$, put $\mathbf{b} := \mathbf{f}(\mathbf{a})$, and assume $A := D\mathbf{f}(\mathbf{a})$ is invertible. Then there exist open neighborhoods U of $\mathbf{a}$ and V of $\mathbf{b}$ such that:

(i) $\mathbf{f}|_U : U \to V$ *is bijective; write* $\mathbf{g} := (\mathbf{f}|_U)^{-1} : V \to U$.
(ii) $\mathbf{g}$ *is differentiable on* V *and* $D\mathbf{g}(\mathbf{y}) = \big(D\mathbf{f}(\mathbf{g}(\mathbf{y}))\big)^{-1}$ *for all* $\mathbf{y} \in V$.
(iii) $\mathbf{g} \in C^1(V, \mathbb{R}^n)$*; equivalently,* $\mathbf{f}|_U$ *is a* C^1 *diffeomorphism.*

Proof. Choose $0 < \theta < 1$ and $r > 0$ so that $\overline{B}_r(\mathbf{a}) \subset E$ and $\big\|I - A^{-1}D\mathbf{f}(\mathbf{x})\big\|_{\mathrm{op}} \le \theta$ on $\overline{B}_r(\mathbf{a})$.
Let $V := \{\mathbf{y} : \big\|A^{-1}(\mathbf{y} - \mathbf{b})\big\|_2 < (1-\theta)r\}$.

(i) For $\mathbf{y} \in V$, set $\varphi_{\mathbf{y}}(\mathbf{x}) := \mathbf{x} + A^{-1}(\mathbf{y} - \mathbf{f}(\mathbf{x}))$. Theorem 3.2.1 gives $\|\varphi_{\mathbf{y}}(\mathbf{x}) - \varphi_{\mathbf{y}}(\mathbf{z})\|_2 \le \theta \|\mathbf{x} - \mathbf{z}\|_2$ on $\overline{B}_r(\mathbf{a})$, and $\|\varphi_{\mathbf{y}}(\mathbf{x}) - \mathbf{a}\|_2 \le \theta r + \big\|A^{-1}(\mathbf{y} - \mathbf{b})\big\|_2 < r$. Since $\overline{B}_r(\mathbf{a})$ is complete, Theorem 4.5.3 gives a unique fixed point $\mathbf{x} \in \overline{B}_r(\mathbf{a})$, equivalently $\mathbf{f}(\mathbf{x}) = \mathbf{y}$. With $U := B_r(\mathbf{a}) \cap \mathbf{f}^{-1}(V)$, $\mathbf{f}|_U : U \to V$ is bijective.

(ii) Let $\mathbf{y} = \mathbf{f}(\mathbf{x})$ and $\mathbf{y} + \mathbf{k} = \mathbf{f}(\mathbf{x} + \mathbf{h})$ lie in V. The derivative bound gives $\big\|\mathbf{h} - A^{-1}\mathbf{k}\big\|_2 \le \theta \|\mathbf{h}\|_2$, hence $\|\mathbf{h}\|_2 \le C \|\mathbf{k}\|_2$ locally. Since $\big\|I - A^{-1}D\mathbf{f}(\mathbf{x})\big\|_{\mathrm{op}} < 1$, $D\mathbf{f}(\mathbf{x})$ is invertible, and
$\mathbf{g}(\mathbf{y} + \mathbf{k}) - \mathbf{g}(\mathbf{y}) - \big(D\mathbf{f}(\mathbf{x})\big)^{-1}\mathbf{k} = -\big(D\mathbf{f}(\mathbf{x})\big)^{-1}[\mathbf{f}(\mathbf{x} + \mathbf{h}) - \mathbf{f}(\mathbf{x}) - D\mathbf{f}(\mathbf{x})\mathbf{h}]$.
Since $\mathbf{f}$ is differentiable at $\mathbf{x}$, division by $\|\mathbf{k}\|_2$ gives $D\mathbf{g}(\mathbf{y}) = \big(D\mathbf{f}(\mathbf{x})\big)^{-1}$.

(iii) The estimate in (ii) makes $\mathbf{g}$ continuous. Since $D\mathbf{g}(\mathbf{y}) = \big(D\mathbf{f}(\mathbf{g}(\mathbf{y}))\big)^{-1}$, continuity of $D\mathbf{g}$ follows from continuity of $D\mathbf{f}$, $\mathbf{g}$, and Theorem 7.1.5.

Structural Commentary: A^{-1} turns solving $\mathbf{f}(\mathbf{x}) = \mathbf{y}$ into a contraction.
Key Insight: Small derivative variation preserves invertibility locally. □

Corollary 4.1.3. *Local Diffeomorphisms Are Open*
If $\mathbf{f} : E \subseteq \mathbb{R}^n \to \mathbb{R}^n$ is C^1 and $D\mathbf{f}$ is everywhere invertible, then $\mathbf{f}$ is an open map (locally one-to-one).

Proof. Let $W \subseteq E$ be open and let $\mathbf{y} \in \mathbf{f}(W)$. Choose $\mathbf{x} \in W$ with $\mathbf{f}(\mathbf{x}) = \mathbf{y}$. Applying Theorem 4.1.2 to $\mathbf{f}|_W$ at $\mathbf{x}$ gives open neighborhoods $U \subseteq W$ of $\mathbf{x}$ and V of $\mathbf{y}$ with $\mathbf{f}(U) = V$. Hence $V \subseteq \mathbf{f}(W)$, so $\mathbf{y}$ is interior to $\mathbf{f}(W)$. Since $\mathbf{y}$ was arbitrary, $\mathbf{f}(W)$ is open. Local one-to-one-ness is the same theorem applied pointwise.
Structural Commentary: Openness is checked one image point at a time.
Key Insight: A local inverse turns nearby domain points into a full image neighborhood. □

4.2 Implicit Function Theorem

Definition 4.2.1. *Block Splitting of a Linear Map*
For $A \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n)$ and $(\mathbf{h}, \mathbf{k}) \in \mathbb{R}^n \times \mathbb{R}^m$, define $A_x\mathbf{h} := A(\mathbf{h}, \mathbf{0})$ and $A_y\mathbf{k} := A(\mathbf{0}, \mathbf{k})$.
Then $A_x \in \mathcal{L}(\mathbb{R}^n)$, $A_y \in \mathcal{L}(\mathbb{R}^m, \mathbb{R}^n)$, and $A(\mathbf{h}, \mathbf{k}) = A_x\mathbf{h} + A_y\mathbf{k}$.

Theorem 4.2.2. *Linear Implicit Function Theorem*
If $A \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n)$, A_x invertible, then $\forall \mathbf{k} \in \mathbb{R}^m$ $\exists$ unique $\mathbf{h} \in \mathbb{R}^n$ s.t. $A(\mathbf{h}, \mathbf{k}) = 0$, that $\mathbf{h} = -(A_x)^{-1}A_y\mathbf{k}$.

Proof. Fix $\mathbf{k} \in \mathbb{R}^m$ and set $\mathbf{h}_0 := -(A_x)^{-1}A_y\mathbf{k}$.
By Definition 4.2.1, $A(\mathbf{h}_0, \mathbf{k}) = A_x\mathbf{h}_0 + A_y\mathbf{k} = -A_y\mathbf{k} + A_y\mathbf{k} = 0$, so a solution exists.
If $\mathbf{h} \in \mathbb{R}^n$ also satisfies $A(\mathbf{h}, \mathbf{k}) = 0$, then $A_x\mathbf{h} + A_y\mathbf{k} = 0$, hence $A_x\mathbf{h} = -A_y\mathbf{k}$.
Applying $(A_x)^{-1}$ gives $\mathbf{h} = -(A_x)^{-1}A_y\mathbf{k} = \mathbf{h}_0$. Thus the solution exists and is unique.
Structural Commentary: Splitting A separates the unknown variable from the parameter.
Key Insight: Invertibility of A_x turns constraint $A(\mathbf{h}, \mathbf{k}) = 0$ into a uniquely solvable linear equation for $\mathbf{h}$. □

The implicit theorem below is the nonlinear counterpart of the block equation theorem. The invertible block is the set of variables one can solve for, just as in Theorem 4.2.2.
Figure 166 depicts the local graph form: writing the solved variable as $\mathbf{x} = \mathbf{g}(\mathbf{y})$ and marking the parameter value $\mathbf{b}$, the zero locus is parameterized by $\mathbf{y} \mapsto (\mathbf{g}(\mathbf{y}), \mathbf{y})$ near $(\mathbf{g}(\mathbf{b}), \mathbf{b})$.

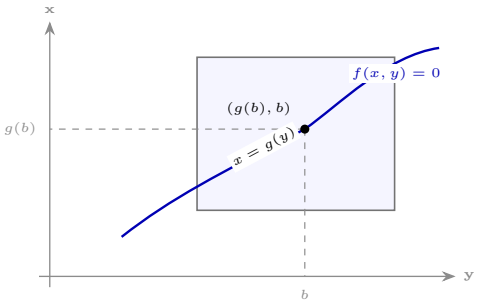

Figure 166: Near a regular point, the zero locus is the graph of an implicit function.

Theorem 4.2.3. *Implicit Function Theorem*
Let $E \subseteq \mathbb{R}^{n+m}$ be open, $\mathbf{f} \in C^1(E, \mathbb{R}^n)$, $(\mathbf{a}, \mathbf{b}) \in E$, and $\mathbf{f}(\mathbf{a}, \mathbf{b}) = \mathbf{0}$.
Put $A := D\mathbf{f}(\mathbf{a}, \mathbf{b})$ and write $A(\mathbf{h}, \mathbf{k}) = A_x\mathbf{h} + A_y\mathbf{k}$; assume A_x is invertible.
Then there exist open neighborhoods U of $\mathbf{a}$ and V of $\mathbf{b}$, and a unique map $\mathbf{g} : V \to U$, such that:

(i) $\{(\mathbf{x}, \mathbf{y}) \in U \times V : \mathbf{f}(\mathbf{x}, \mathbf{y}) = \mathbf{0}\} = \{(\mathbf{g}(\mathbf{y}), \mathbf{y}) : \mathbf{y} \in V\}$ *and* $\mathbf{g}(\mathbf{b}) = \mathbf{a}$.
(ii) $\mathbf{g} \in C^1(V, \mathbb{R}^n)$ *and* $D\mathbf{g}(\mathbf{y}) = -\big(D_1\mathbf{f}(\mathbf{g}(\mathbf{y}), \mathbf{y})\big)^{-1} D_2\mathbf{f}(\mathbf{g}(\mathbf{y}), \mathbf{y})$ *for* $\mathbf{y} \in V$*; in particular,* $D\mathbf{g}(\mathbf{b}) = -(A_x)^{-1}A_y$.

Proof. Let $\Phi(\mathbf{x},\mathbf{y}) := (\mathbf{f}(\mathbf{x},\mathbf{y}),\mathbf{y})$. Since $D\Phi(\mathbf{a},\mathbf{b})(\mathbf{h},\mathbf{k}) = (A_x\mathbf{h} + A_y\mathbf{k},\mathbf{k})$, $\ker D\Phi(\mathbf{a},\mathbf{b}) = \{\mathbf{0}\}$; by Theorems 1.7.7 and 4.1.2, $\Phi : W \to Z$ is a local C^1 diffeomorphism. Shrink product neighborhoods $U \times V \subseteq W$ so that $\{\mathbf{0}\} \times V \subseteq Z$, $\Phi^{-1}(\{\mathbf{0}\} \times V) \subseteq U \times V$, and $D_1\mathbf{f}$ is invertible on $U \times V$.

(i) Define $\mathbf{g}(\mathbf{y})$ by $\Phi^{-1}(\mathbf{0},\mathbf{y}) = (\mathbf{g}(\mathbf{y}),\mathbf{y})$. Since $\Phi(\mathbf{x},\mathbf{y}) = (\mathbf{0},\mathbf{y})$ iff $\mathbf{f}(\mathbf{x},\mathbf{y}) = \mathbf{0}$, the zero set in $U \times V$ is exactly the graph of $\mathbf{g}$, and $\mathbf{g}(\mathbf{b}) = \mathbf{a}$.

(ii) The map $\mathbf{g}$ is C^1 as a component of $\Phi^{-1}(\mathbf{0},\mathbf{y})$.
Differentiating $\mathbf{f}(\mathbf{g}(\mathbf{y}),\mathbf{y}) = \mathbf{0}$ gives $D_1\mathbf{f}(\mathbf{g}(\mathbf{y}),\mathbf{y})D\mathbf{g}(\mathbf{y}) + D_2\mathbf{f}(\mathbf{g}(\mathbf{y}),\mathbf{y}) = 0$, hence the formula.

Structural Commentary: Add $\mathbf{y}$ as a coordinate, then invert.
Key Insight: Invertible $D_x\mathbf{f}$ solves locally for $\mathbf{x}$. □

4.3 Rank Theorem

Perspective 4.3.1. *Rank Theorem Linear Model*
Theorem 2.2.12 reduces a linear map to its kernel–range split.
The constant-rank theorem is the local C^1 analogue after coordinate changes.

Theorem 4.3.2. *Rank Theorem*
Let $E \subseteq \mathbb{R}^n$ be open, let $\mathbf{F} \in C^1(E,\mathbb{R}^m)$ have constant rank r, and fix $\mathbf{a} \in E$. Set $A := D\mathbf{F}(\mathbf{a})$, $Y := \operatorname{range} A$, and let $P : \mathbb{R}^m \to Y$ be the orthogonal projection. Then for some $\mathbf{x}_0 \in \mathbb{R}^n$, neighborhoods $V_0 \ni \mathbf{x}_0$ and $U \ni \mathbf{a}$, and C^1 diffeomorphism $H : V_0 \to U$, there exists $\varphi \in C^1(A(V_0), \ker P)$ such that $\mathbf{F} \circ H = A + \varphi \circ A$ on V_0.

Proof. If $r = 0$, Theorem 3.2.1 makes $\mathbf{F}$ locally constant; take $H = I$ and $\varphi(0) = \mathbf{F}(\mathbf{a})$.
Assume $r > 0$. Choose $S : Y \to \mathbb{R}^n$ with $AS = I_Y$ and set $G := I + SP(\mathbf{F} - A)$. Since $DG(\mathbf{a}) = I$, Theorem 4.1.2 gives a local C^1 diffeomorphism $G : U \to V_0$ with inverse H; shrink V_0 convex and put $\mathbf{x}_0 := G(\mathbf{a})$.
Let $\Psi := \mathbf{F} \circ H$. From $AG = P\mathbf{F}$, $P\Psi = A$ and $PD\Psi = A$.
Since $\operatorname{rank} D\Psi = \operatorname{rank} A = \operatorname{rank} PD\Psi = r$, P is injective on range $D\Psi$; hence $A\mathbf{v} = 0$ implies $D\Psi(\mathbf{x})\mathbf{v} = 0$.
By Theorem 3.2.1, Ψ is constant on each convex fiber $V_0 \cap (\mathbf{x} + \ker A)$.
Define $\varphi(A\mathbf{x}) := (I - P)\Psi(\mathbf{x})$. Fiber constancy makes φ well-defined, $\varphi(A\mathbf{x}) \in \ker P$, and $\Psi = A + \varphi \circ A$. After shrinking V_0 so $\sigma(\mathbf{u}) := \mathbf{x}_0 + S(\mathbf{u} - A\mathbf{x}_0)$ lies in V_0 for $\mathbf{u} \in A(V_0)$, $\varphi = (I - P)\Psi \circ \sigma$ is C^1.
Structural Commentary: Constant rank gives projection-plus-graph normal form.
Key Insight: Constant rank kills variation along A-fibers. □

Rank-nullity (Theorem 1.7.3) says that the domain directions split into rank directions and fiber directions. The rank theorem says a constant-rank map has, locally, the same split after C^1 changes of coordinates.
Figure 167 contrasts the original curved fibers and image with the straight $\ker A$-fibers and projection image in local normal-form coordinates.

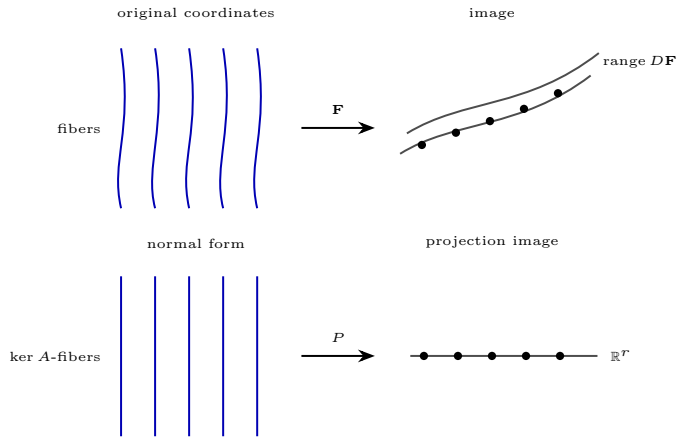

Figure 167: After local coordinate changes, a constant-rank map looks like projection onto the rank directions.

Theorem 4.3.3. *One-Constraint Lagrange Multiplier*
Let $E \subseteq \mathbb{R}^n$ be open, $f, g : E \to \mathbb{R}$ be C^1, and $S = \{\mathbf{x} : g(\mathbf{x}) = c\}$.
If $p \in S$, $\nabla g(p) \neq \mathbf{0}$, and $f|_S$ has a local extremum at p, then $\exists \lambda \in \mathbb{R}$ with $\nabla f(p) = \lambda \nabla g(p)$.

Proof. If $Df(p) = 0$, take $\lambda = 0$. Otherwise suppose $Df(p)$ is not a multiple of $Dg(p)$.
Complete $Dg(p), Df(p)$ to a dual basis $Dg(p)$, $Df(p)$, $\ell_3, \dots, \ell_n$ by Theorem 4.1.4,
and set $\Phi(\mathbf{x}) = \big(g(\mathbf{x}) - c,\ f(\mathbf{x}) - f(p),\ \ell_3(\mathbf{x} - p), \dots, \ell_n(\mathbf{x} - p)\big)$.
Then $D\Phi(p)$ is invertible, so Theorem 4.1.2 makes Φ locally invertible. In these coordinates, S is locally the slice with first coordinate 0, while the second coordinate is $f - f(p)$. Local invertibility gives nearby points of S with this second coordinate of both signs, contradicting extremality.
Hence $Df(p) = \lambda Dg(p)$; Riesz representation, Theorem 1.6.1, gives the gradient form.
Structural Commentary: The constraint kills first-order variation along S.
Key Insight: If Df were independent of Dg, f would be a free constraint coordinate. □

4.4 Further Topics in Local Differential Theory

Method 4.4.1. *Several-Variable Differentiation Proof Patterns*

(i) *Linear approximation*: write $\mathbf{f}(\mathbf{x} + \mathbf{h}) - \mathbf{f}(\mathbf{x}) = D\mathbf{f}(\mathbf{x})\mathbf{h} + \mathbf{r}(\mathbf{h})$ with $\|\mathbf{r}(\mathbf{h})\|_2 = o(\|\mathbf{h}\|_2)$.

(ii) *Norm estimates*: use $\|A\mathbf{h}\|_2 \le \|A\|_{\mathrm{op}} \|\mathbf{h}\|_2$ and the product estimate from Proposition 5.1.3.

(iii) *Coordinates*: read partial derivatives as the entries of the matrix of $D\mathbf{f}(\mathbf{x})$, using Theorem 3.1.9.
(iv) *Line-segment reduction*: on convex sets, restrict to $\gamma(t) = (1-t)\mathbf{a} + t\mathbf{b}$ and apply one-variable results.
(v) *Higher derivatives*: regard $D^r\mathbf{f}(p)$ as an r-linear map; recover coordinate partials via Theorem 3.2.6.
(vi) *Local inversion*: if $A = D\mathbf{f}(\mathbf{a})$ is invertible, write $D\mathbf{f}(\mathbf{x}) = A + E_{\mathbf{x}}$ with $\|E_{\mathbf{x}}\|_{\text{op}}$ small and solve by contraction (Theorem 4.5.3); linear block equations use Theorem 4.2.2.
(vii) *Rank normal forms*: for $A = D\mathbf{F}(\mathbf{a})$, split domain by $\ker A$ and image by $\operatorname{range} A$; use the quotient-by-kernel picture from Theorem 2.2.12 and project with $P_{\operatorname{range} A}$.

Key Insight: Several-variable calculus is one-variable limiting plus finite-dimensional linear algebra.

5 Differential Forms and Stokes Theory

5.1 Multiple Integration and Change of Variables

This subsection develops Euclidean-region integration and change of variables as the foundation for differential forms, pullbacks, and oriented parametrized surfaces.

Theorem 5.1.1. *Linear Maps Scale Volume by $|\det T|$*
Let $T \in \mathcal{L}(\mathbb{R}^n)$ and let $\Omega \subseteq \mathbb{R}^n$ be bounded Jordan measurable.

(i) *$T(\Omega)$ is Jordan measurable.*
(ii) $\operatorname{vol}(T(\Omega)) = |\det T| \operatorname{vol}(\Omega)$.

Proof. If T invertible, let $T = SP$ with S orthogonal, $P = \operatorname{diag}(\lambda_1, \dots, \lambda_n)$, $\lambda_j > 0$, in orthonormal coordinates.

(i) If T is invertible, P and S preserve Jordan measurability, so $T(\Omega)$ is Jordan measurable.
If T is singular, $T(\Omega) \subseteq W$ for a proper affine subspace W, hence $T(\Omega)$ is Jordan null.
(ii) If T is invertible, rectangle scaling gives $\operatorname{vol}(P\Omega) = (\det P)\operatorname{vol}(\Omega)$ by Jordan approximation.
Hhence $\operatorname{vol}(T\Omega) = \operatorname{vol}(P\Omega) = |\det T| \operatorname{vol}(\Omega)$. If T is singular, (i) gives $\operatorname{vol}(T\Omega) = 0 = |\det T| \operatorname{vol}(\Omega)$.

Structural Commentary: Polar decomposition leaves only diagonal stretching.
Key Insight: $|\det T|$ is total coordinate stretch. □

Figure 168 compares a region Ω with its image $T(\Omega)$, whose volume is scaled by $|\det T|$.

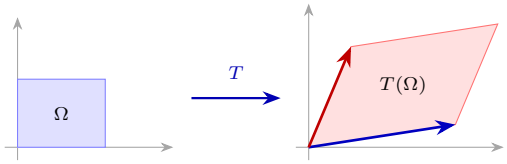

Figure 168: A linear map scales volume by $|\det T|$.

Definition 5.1.2. *k-Cells and Multiple Integrals*
Let $a_i \le b_i$.

(i) Set $I^j := \prod_{i=1}^{j} [a_i, b_i] \subseteq \mathbb{R}^j$ for $0 \le j \le k$, with I^0 a point. The *k-cell* is I^k.
(ii) For $f \in C(I^k)$, set $f_k := f$ and $f_{j-1}(x_1, \dots, x_{j-1}) := \int_{a_j}^{b_j} f_j(x_1, \dots, x_j)\, dx_j$, $j = k, \dots, 1$.
The *multiple integral* is $\int_{I^k} f(\mathbf{x})\, d\mathbf{x} := f_0$, also written $\int_{I^k} f$.

For bounded functions on rectangles, the Darboux picture from Definition 1.2.1 generalizes by replacing intervals with grid rectangles.

Definition 5.1.3. *Rectangular Grids and Riemann Sums*
Let $R = [a, b] \times [c, d] \subseteq \mathbb{R}^2$, let $P : a = x_0 < \cdots < x_m = b$, let $Q : c = y_0 < \cdots < y_n = d$, and set $G := P \times Q$.

(i) The *grid rectangles* are $R_{ij} := [x_{i-1}, x_i] \times [y_{j-1}, y_j]$, with $|R_{ij}| := (x_i - x_{i-1})(y_j - y_{j-1})$.
(ii) For tags $S = \{(s_{ij}, t_{ij}) \in R_{ij}\}$, the *Riemann sum* is $R(f, G, S) := \sum_{i=1}^{m} \sum_{j=1}^{n} f(s_{ij}, t_{ij})\, |R_{ij}|$.
(iii) For bounded $f : R \to \mathbb{R}$, set $(m_{ij}, M_{ij}) := (\inf_{R_{ij}} f, \sup_{R_{ij}} f)$ and $(L(f, G), U(f, G)) := \sum_{i,j} (m_{ij}, M_{ij})\, |R_{ij}|$.
(iv) The *lower* and *upper integrals* are $\underline{\int_R} f := \sup_G L(f, G)$ and $\overline{\int_R} f := \inf_G U(f, G)$.
If they agree, f is Riemann integrable on R, and $\int_R f$ denotes the common value.

Figure 169 identifies a grid rectangle R_{ij} and its tag (s_{ij}, t_{ij}), the local data used in the Riemann sum.

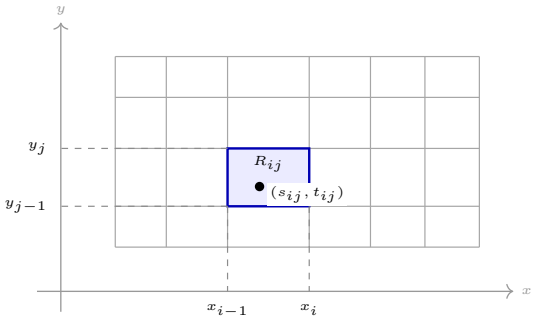

Figure 169: A grid rectangle R_{ij} and sample point (s_{ij}, t_{ij}).

Theorem 5.1.4. *Fubini on a Rectangle, Darboux Form*
Let $R = [a,b] \times [c,d]$, let $f : R \to \mathbb{R}$ be Riemann integrable, and set $f_y(x) := f(x,y)$.
For $y \in [c,d]$, define $\underline{F}(y) := \sup_P L(P, f_y)$ and $\overline{F}(y) := \inf_P U(P, f_y)$, with P ranging over partitions of $[a,b]$.

(i) $\underline{F}, \overline{F}$ are Riemann integrable on $[c,d]$.
(ii) $\int_R f = \int_c^d \underline{F}(y)\,dy = \int_c^d \overline{F}(y)\,dy$.

If $\int_a^b f(x,y)\,dx$ exists for every y, then $\underline{F}(y) = \overline{F}(y) = \int_a^b f(x,y)\,dx$.

Proof.

(i) For $G = P \times Q$, horizontal slice sums give $L(f,G) \le L(Q,\underline{F}) \le U(Q,\overline{F}) \le U(f,G)$.
Since f is integrable on R, choose G with $U(f,G) - L(f,G) < \varepsilon$; hence $U(Q,\overline{F}) - L(Q,\underline{F}) < \varepsilon$.
Thus $\underline{F}$ and $\overline{F}$ are integrable and have the same integral by Theorem 2.1.6.

(ii) The same inequalities give $L(f,G) \le \int_c^d \underline{F} \le \int_c^d \overline{F} \le U(f,G)$.
Letting $U(f,G) - L(f,G) \to 0$ gives both integrals equal to $\int_R f$.

Structural Commentary: Product grids become slice sums.
Key Insight: Fubini is a Darboux squeeze. □

Theorem 5.1.5. *Order Independence on Cells*
For $f \in C(I^k)$, all iterated orders defining $\int_{I^k} f$ give the same value.

Proof. Let L, L' be two iterated orders. For $h(\mathbf{x}) = h_1(x_1)\cdots h_k(x_k)$, $L(h) = L'(h) = \prod_{i=1}^k \int_{a_i}^{b_i} h_i(x_i)\,dx_i$, so $L(g) = L'(g)$ for every finite sum g of such products. These sums are dense in $C(I^k)$ by Theorem 9.2.8.

Choose g with $\|f - g\|_\infty < \varepsilon/V$, where $V = \prod_{i=1}^k (b_i - a_i)$.

Since $|L(r)|, |L'(r)| \le V \|r\|_\infty$, then $|L(f) - L'(f)| \le |L(f-g)| + |L'(f-g)| < 2\varepsilon$.
Structural Commentary: Product functions plus uniform approximation prove order independence.
Key Insight: Fubini-type order independence is first an algebraic fact, then a uniform approximation fact. □

Perspective 5.1.6. *Order Interchange Requires Hypotheses*
Finite sums are order-free; limiting processes are not.
Theorems 5.1.4 and 5.1.5 give hypotheses for interchanging integral order.

Definition 5.1.7. *Support and Simplex Integrals*
For $f : \mathbb{R}^k \to \mathbb{R}$ or $\mathbb{C}$, define $\operatorname{supp} f := \overline{\{\mathbf{x} \in \mathbb{R}^k : f(\mathbf{x}) \neq 0\}}$.

(i) For $f \in C_c(\mathbb{R}^k)$ and any cell $I^k \supseteq \operatorname{supp} f$, define $\int_{\mathbb{R}^k} f := \int_{I^k} f$; this is independent of I^k.

(ii) The *standard k-simplex* is $Q^k := \{\mathbf{x} \in \mathbb{R}^k : x_i \ge 0,\ \sum_{i=1}^k x_i \le 1\}$.
For $f \in C(Q^k)$, extend f by 0 to $[0,1]^k$ and define $\int_{Q^k} f$ as the corresponding multiple integral.

Definition 5.1.8. *Primitive Mappings and Flips*
Let $E \subseteq \mathbb{R}^n$ be open.

(i) $G : E \to \mathbb{R}^n$ is *primitive in coordinate m* if $G(\mathbf{x}) = (x_1, \ldots, x_{m-1}, g(\mathbf{x}), x_{m+1}, \ldots, x_n)$.
(ii) If g is differentiable at $\mathbf{a} \in E$, then $DG(\mathbf{a})$ is I_n except row m is $\nabla g(\mathbf{a})$, and $J_G(\mathbf{a}) = (D_m g)(\mathbf{a})$.
(iii) A *flip* is a linear map $B : \mathbb{R}^n \to \mathbb{R}^n$ with $B\mathbf{e}_p = \mathbf{e}_q$, $B\mathbf{e}_q = \mathbf{e}_p$, and $B\mathbf{e}_i = \mathbf{e}_i$ for $i \notin \{p,q\}$, $p \neq q$.

Theorem 5.1.9. *Local Decomposition into Primitive Mappings*
Let $E \subseteq \mathbb{R}^n$ be open, let $\mathbf{F} \in C^1(E, \mathbb{R}^n)$, let $\mathbf{0} \in E$, and assume $\mathbf{F}(\mathbf{0}) = \mathbf{0}$ and $D\mathbf{F}(\mathbf{0})$ is invertible. Then there exist a neighborhood U of $\mathbf{0}$, primitive C^1 maps $G_1, \ldots, G_n$ near $\mathbf{0}$, and maps $B_1, \ldots, B_{n-1}$ such that:

(i) $G_i(\mathbf{0}) = \mathbf{0}$, $DG_i(\mathbf{0})$ is invertible, and each B_i is a flip or I.
(ii) $\mathbf{F} = B_1 \cdots B_{n-1} G_n \circ \cdots \circ G_1$ on U.

Proof. Let $P_m \mathbf{x} := \sum_{i=1}^m x_i \mathbf{e}_i$ and set $\mathbf{F}_1 := \mathbf{F}$.

(i) Suppose $P_{m-1}\mathbf{F}_m = P_{m-1}$, $\mathbf{F}_m(\mathbf{0}) = \mathbf{0}$, and $D\mathbf{F}_m(\mathbf{0})$ invertible, and write $\mathbf{F}_m = P_{m-1} + \sum_{i=m}^n \alpha_i \mathbf{e}_i$.
Choose $k \ge m$ with $(D_m \alpha_k)(\mathbf{0}) \neq 0$, let B_m swap m, k (or $B_m = I$), set $G_m(\mathbf{x}) := \mathbf{x} + (\alpha_k(\mathbf{x}) - x_m)\mathbf{e}_m$.
Then G_m is primitive, $G_m(\mathbf{0}) = \mathbf{0}$, $J_{G_m}(\mathbf{0}) \neq 0$, and G_m is locally invertible.

With $\mathbf{F}_{m+1} := B_m \mathbf{F}_m \circ G_m^{-1}$, one has $P_m \mathbf{F}_{m+1} = P_m$, $\mathbf{F}_{m+1}(\mathbf{0}) = \mathbf{0}$, and $D\mathbf{F}_{m+1}(\mathbf{0})$ invertible.
Iterate for $m = 1, \dots, n-1$ and set $G_n := \mathbf{F}_n$.

(ii) From $\mathbf{F}_{m+1} = B_m \mathbf{F}_m \circ G_m^{-1}$ and $B_m^2 = I$, $\mathbf{F}_m = B_m \mathbf{F}_{m+1} \circ G_m$.
Iteration gives $\mathbf{F} = \mathbf{F}_1 = B_1 \cdots B_{n-1} G_n \circ G_{n-1} \circ \cdots \circ G_1$ near $\mathbf{0}$.

Structural Commentary: Local diffeomorphisms factor by coordinate elimination.
Key Insight: Nonlinear elimination follows $D\mathbf{F}(\mathbf{0})$. □

Theorem 5.1.10. *Partition of Unity on a Compact Set*
Let $K \subseteq \mathbb{R}^n$ be compact and let $\{V_\alpha\}$ cover K by open sets. Then there are $\psi_1, \dots, \psi_s \in C^1(\mathbb{R}^n)$ such that

(i) $0 \le \psi_i \le 1$ for all i;
(ii) $\operatorname{supp}(\psi_i) \subseteq V_\alpha$ for some α;
(iii) $\sum_{i=1}^s \psi_i = 1$ on K.

If $f \in C(\mathbb{R}^n)$ and $\operatorname{supp}(f) \subseteq K$, then $f = \sum_{i=1}^s \psi_i f$, with each summand supported in one member of the cover.

Proof.

(i) For each $\mathbf{x} \in K$, choose balls with $\overline{B(\mathbf{x})} \subseteq W(\mathbf{x}) \subseteq \overline{W(\mathbf{x})} \subseteq V_{\alpha(\mathbf{x})}$.
By compactness, Definition 4.1.1, finitely many $B(\mathbf{x}_i)$ cover K.

(ii) Choose $\varphi_i \in C^1(\mathbb{R}^n)$ with $\varphi_i = 1$ on $B(\mathbf{x}_i)$ and $\operatorname{supp}(\varphi_i) \subseteq W(\mathbf{x}_i)$. Set $\psi_i = (1-\varphi_1)\cdots(1-\varphi_{i-1})\varphi_i$.

(iii) Then $0 \le \psi_i \le 1$, each ψ_i is supported in some V_α, and $\sum_{i=1}^{s} \psi_i = 1 - \prod_{i=1}^{s} (1-\varphi_i)$, which equals 1 on K.
Multiplying by f gives the final assertion.

Structural Commentary: Compactness finite; product cutoffs sum to one.
Key Insight: A partition of unity turns local change-of-variable information into a global formula. □

The nonlinear change-of-variables theorem is the local volume-scaling formula from Theorem 5.1.1 applied cell by cell after a fine grid in a domain U has been warped by a C^1 diffeomorphism $T : U \to T(U)$. Figure 170 compares that grid with its curvilinear image, where $|J_T|$ records the local volume factor.

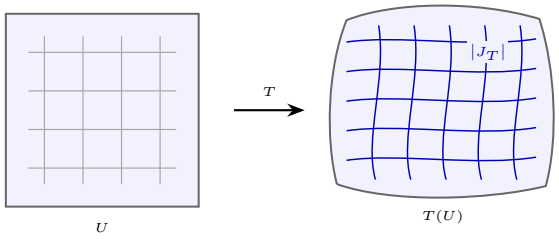

Figure 170: A C^1 change of variables turns a fine grid into curvilinear cells; $|J_T|$ records local volume scaling.

Theorem 5.1.11. *Change of Variables in $\mathbb{R}^k$*
Let $T : E \to \mathbb{R}^k$ be one-to-one and C^1 on open $E \subseteq \mathbb{R}^k$, with $J_T \neq 0$ on E.
If $f \in C(\mathbb{R}^k)$ and $\operatorname{supp}(f)$ is compact in $T(E)$, then $\int_{\mathbb{R}^k} f(\mathbf{y})\, d\mathbf{y} = \int_{\mathbb{R}^k} f(T(\mathbf{x}))\, |J_T(\mathbf{x})|\, d\mathbf{x}$.

Proof. Let $\mathcal{C}$ be the class of maps for which formula holds for all continuous functions with compact support in the image. Primitive maps lie in $\mathcal{C}$ by one-variable substitution, and flips lie in $\mathcal{C}$ by Theorem 5.1.5.
If $P, Q \in \mathcal{C}$, then $P \circ Q \in \mathcal{C}$, since Theorems 3.1.5 and 3.8.2 give $J_{P\circ Q}(\mathbf{x}) = J_P(Q(\mathbf{x}))J_Q(\mathbf{x})$.
After translating coordinates, Theorem 5.1.9 therefore gives the formula on a neighborhood of each point of E. By Theorem 4.1.2, these neighborhoods have open images covering $\operatorname{supp}(f)$.
Choose a partition of unity from Theorem 5.1.10, write $f = \sum_i \psi_i f$ with each $\psi_i f$ supported in one such image, apply the local formula to each summand, and sum.
Structural Commentary: Model cases plus partitions of unity prove the theorem.
Key Insight: The absolute Jacobian is local volume scaling, globalized by compact support. □

Method 5.1.12. *Change-of-Variables Jacobian Method*
For a differentiable map $\sigma : \Omega \subseteq \mathbb{R}^n \to \mathbb{R}^n$:

(i) compute the derivative matrix $D\sigma(\mathbf{x})$;
(ii) compute the local volume factor $|\det D\sigma(\mathbf{x})|$;
(iii) replace $d\mathbf{y}$ by $|\det D\sigma(\mathbf{x})|\, d\mathbf{x}$ when $\mathbf{y} = \sigma(\mathbf{x})$;
(iv) transform the domain bounds in the new coordinates.

Example 5.1.13. *Polar and Spherical Jacobian Factors*
For polar coordinates $\sigma(r,\theta) = (r\cos\theta, r\sin\theta)$, $D\sigma(r,\theta) = \begin{bmatrix} \cos\theta & -r\sin\theta \\ \sin\theta & r\cos\theta \end{bmatrix}$, and $|\det D\sigma(r,\theta)| = r$.
Thus area integrals acquire the factor $r\, dr\, d\theta$.
For spherical coordinates $\sigma(\rho,\varphi,\theta) = (\rho\sin\varphi\cos\theta, \rho\sin\varphi\sin\theta, \rho\cos\varphi)$, and $|\det D\sigma(\rho,\varphi,\theta)| = \rho^2\sin\varphi$.
Thus volume integrals acquire the factor $\rho^2 \sin\varphi\, d\rho\, d\varphi\, d\theta$.

Method 5.1.14. *Multiple-Integration Proof Patterns*
For a multiple-integration identity:

(i) *Products*: prove product cases, then pass by uniform approximation;
(ii) *Grids*: compare product-grid upper and lower sums with one-variable slice sums;
(iii) *Support*: enclose compact support in a cell and check cell-independence;
(iv) *Local form*: reduce C^1 coordinate changes to primitive maps and flips;
(v) *Determinants*: use multiplicativity and Theorem 3.8.2;

(vi) *Globalize*: apply the partition of unity, Theorem 5.1.10.

Key Insight: Change of variables is local determinant geometry plus compactness.

5.2 Differential Forms and Manifolds

Differential forms package oriented integration on parametrized cells. They use determinant sign and laws (Definition 3.8.1, Theorems 3.8.2, 1.2.5) and change of variables (Theorem 5.1.11); conceptually, forms test oriented cells.

Perspective 5.2.1. *Forms as Functionals*
The notation $\int f\,dx$ treats dx as directed coordinate variation. Differential forms make this precise: a 1-form such as $f\,dx+g\,dy$ assigns a number to an oriented path; dx records net x-variation, and $f\,dx$ weights it by f.

Figure 171 contrasts oriented paths C and C' from p to q, showing how the sign of y changes the contribution of $y\,dx$.

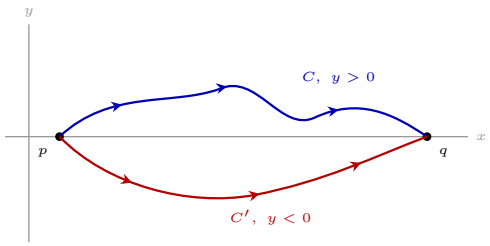

Figure 171: $y\,dx$ records signed, y-weighted x-variation.

Definition 5.2.2. *k-Surfaces and Differential Forms*
Let $E\subseteq\mathbb{R}^n$ be open.

(i) A compact *parameter domain* $D\subseteq\mathbb{R}^k$ is a k-cell or $Q^k=\{\mathbf{u}\in\mathbb{R}^k : u_i\geq 0,\ \sum_i u_i\leq 1\}$.

For compact D, $C^r(D)$ means extendable as C^r to an open neighborhood of D.

(ii) A *k-surface* in E is a C^1 map $\Phi: D\to E$ from a compact parameter domain $D\subseteq\mathbb{R}^k$.

(iii) For $k\geq 1$, a *k-form* on E is $\omega=\sum_I a_I(\mathbf{x})\,dx_{i_1}\wedge\cdots\wedge dx_{i_k}$, where $I=(i_1,\dots,i_k)$ and $a_I\in C(E,\mathbb{R})$.

(iv) For an increasing k-index $I=(i_1<\cdots<i_k)$, set $dx_I:=dx_{i_1}\wedge\cdots\wedge dx_{i_k}$.
A *standard presentation* is $\omega=\sum_I b_I(\mathbf{x})\,dx_I$, with I increasing.

(v) For a k-surface $\Phi: D\to E$, define $\int_\Phi\omega:=\int_D\sum_I a_I(\Phi(\mathbf{u}))J_I\Phi(\mathbf{u})\,d\mathbf{u}$, where $J_I\Phi:=\frac{\partial(x_{i_1},\dots,x_{i_k})}{\partial(u_1,\dots,u_k)}$.

(vi) A 0-form is a continuous function on E; a form is C^r iff all coefficients a_I are C^r.

Remark 5.2.3. *Parametrized Cells, Not Just Images*
Parametrizations may fail to be injective or regular. Forms therefore act on parametrized cells, not just images; this matters for orientation, multiplicity, and cancellation.

Proposition 5.2.4. *Basic Forms and Standard Presentation*

(i) Swapping neighboring factors in $dx_{i_1}\wedge\cdots\wedge dx_{i_k}$ changes sign; repeated indices give 0.
(ii) Every k-form has a unique standard presentation.

Proof.

(i) For $\Phi(\mathbf{u})=(x_{i_1},\dots,x_{i_k})$, the coefficient of $dx_{i_1}\wedge\cdots\wedge dx_{i_k}$ is the determinant of the corresponding $k\times k$ Jacobian minor. Row swaps change its sign and repeated rows make it 0.

(ii) By (i), each term either vanishes or sorts to an increasing index, giving existence.
For uniqueness, let $\omega=\sum_I b_I(\mathbf{x})\,dx_I$ be zero in standard presentation.

If $b_J(\mathbf{v})\neq 0$ for increasing $J=(j_1,\dots,j_k)$, choose $D=[-h,h]^k$ so $b_J(\Phi(\mathbf{u}))$ has constant nonzero sign for $\Phi(\mathbf{u})=\mathbf{v}+\sum_{r=1}^k u_r\mathbf{e}_{j_r}$.

Then the J-Jacobian is 1 and all other standard Jacobians are 0, so $0=\int_\Phi\omega=\int_D b_J(\Phi(\mathbf{u}))\,d\mathbf{u}$, a contradiction. Hence all $b_I=0$.

Structural Commentary: Wedge signs are determinant signs.
Key Insight: Standard form sorts indices once. □

Theorem 5.2.5. *Naturality Under Reparametrization*
Let $\Phi: D\to E\subseteq\mathbb{R}^n$ be a C^1 k-surface, and let $R: D'\to D$ be a C^1 diffeomorphism with $\epsilon:=\operatorname{sgn}\det DR$ constant on D'. For every k-form ω on E, $\int_{\Phi\circ R}\omega=\epsilon\int_\Phi\omega$.

Proof. By linearity, take $\omega=f\,dx_I$. Cauchy-Binet gives $J_I(\Phi\circ R)(\mathbf{u})=J_I\Phi(R(\mathbf{u}))\det DR(\mathbf{u})$.
Thus $\int_{\Phi\circ R}\omega=\int_{D'}f(\Phi(R\mathbf{u}))J_I\Phi(R\mathbf{u})\det DR(\mathbf{u})\,d\mathbf{u}=\epsilon\int_D f(\Phi(\mathbf{v}))J_I\Phi(\mathbf{v})\,d\mathbf{v}$ by change of variables.
Structural Commentary: Reparametrization changes coordinates only.
Key Insight: Orientation contributes $\operatorname{sgn}\det DR$. □

Definition 5.2.6. *Product and Exterior Derivative*
For basic forms, $dx_I\wedge dx_J$ is obtained by concatenating I,J; it is 0 if an index repeats, and otherwise $\operatorname{sgn}(\sigma)dx_K$, where K is the increasing rearrangement and σ is the sorting permutation. Extend bilinearly.

(i) For $f\in C^1(E)$, define $df:=\sum_{i=1}^n(D_if)(\mathbf{x})\,dx_i$.

(ii) For a C^1 k-form $\omega=\sum_I b_I(\mathbf{x})\,dx_I$, define $d\omega:=\sum_I(db_I)\wedge dx_I$.

Theorem 5.2.7. *Exterior Derivative Laws*
If ω, λ are C^1 forms in E and ω is a k-form, then $d(\omega \wedge \lambda) = (d\omega) \wedge \lambda + (-1)^k \omega \wedge d\lambda$. If ω is C^2, then $d^2\omega = 0$.

Proof. By bilinearity, it suffices to take $\omega = f\,dx_I$ and $\lambda = g\,dx_J$.
The ordinary product rule gives $d(fg) = f\,dg + g\,df$; moving dg past k factors in dx_I gives the displayed sign.
For a C^2 0-form f, $d^2 f = \sum_{i,j} (D_{ij} f)(\mathbf{x})\,dx_i \wedge dx_j = 0$, by Theorem 3.2.11 and antisymmetry.
The general case follows from $\omega = \sum_I b_I\,dx_I$ and the product rule just proved.
Structural Commentary: The exterior derivative is built to make mixed partial cancellation visible.
Key Insight: Symmetric second derivatives meet antisymmetric wedge products, so $d^2 = 0$. □

Definition 5.2.8. *Change of Variables for Forms*
Let $E \subseteq \mathbb{R}^n$, $V \subseteq \mathbb{R}^m$, let $T = (t_1, \dots, t_m) : E \to V$ be C^1, and let $\omega = \sum_I b_I(\mathbf{y})\,dy_I$ be a k-form on V.

(i) Set $dt_i := \sum_{j=1}^{n} (D_j t_i)(\mathbf{x})\,dx_j$ for $1 \le i \le m$.
(ii) The *pullback* of ω by T is $T^*\omega := \omega_T := \sum_I b_I(T(\mathbf{x}))\,dt_{i_1} \wedge \cdots \wedge dt_{i_k}$.

Pullback is the differential-form analogue of the dual map in Definition 4.2.4: cells move forward by composition with T, while forms move backward so they can be evaluated before or after that forward motion. Figure 172 writes the forward cell as $T_*\varphi = T \circ \varphi$ and displays the resulting integral identity.

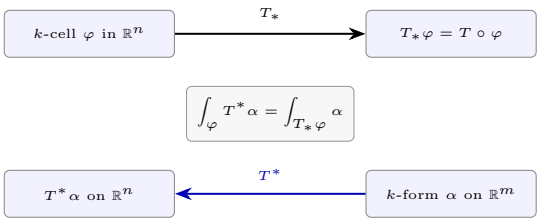

Figure 172: Cells push forward with T; forms pull back with T^*, so $T^*\alpha(\varphi) = \alpha(T_*\varphi)$.

Theorem 5.2.9. *Pullback Commutes with the Basic Operations*
Let $T = (t_1, \dots, t_m) : E \subseteq \mathbb{R}^n \to V \subseteq \mathbb{R}^m$ be C^1, and let $\omega_T := T^*\omega$.
(i) $(\omega + \lambda)_T = \omega_T + \lambda_T$ for forms of the same order;
(ii) $(\omega \wedge \lambda)_T = \omega_T \wedge \lambda_T$;
(iii) $d(\omega_T) = (d\omega)_T$ when ω is C^1 and T is C^2;
(iv) if $S : V \to W$ is C^1, then $(\omega_S)_T = \omega_{S \circ T}$.
Moreover, if Φ is a k-surface in E and ω is a k-form in V, then $\int_{T\circ\Phi} \omega = \int_\Phi \omega_T$.

Proof.
(i) Addition follows termwise from $b_I \mapsto b_I \circ T$ and $dy_i \mapsto dt_i$.
(ii) Pullback replaces each dy_i by dt_i; bilinearity gives $(\omega \wedge \lambda)_T = \omega_T \wedge \lambda_T$.
(iii) Let $\omega = \sum_I b_I\,dy_I$. Since $d(b_I \circ T) = (db_I)_T$ (Theorem 3.1.5) and $d(dt_i) = d^2 t_i = 0$, $d(\omega_T) = (d\omega)_T$.
(iv) If $S = (s_1, \dots, s_p)$, both $(\omega_S)_T$ and $\omega_{S\circ T}$ replace dz_q by $d(s_q \circ T)$, by the chain rule.
For the integral identity, expand over D and use Cauchy-Binet on $D(T \circ \Phi) = DT(\Phi)D\Phi$.
Structural Commentary: Pullback translates forms before integration.
Key Insight: Forms are defined so that composition of parameterizations becomes an algebraic substitution. □

5.3 Stokes Theory

Stokes theory relates exterior differentiation to oriented boundary, with Green's theorem, classical Stokes, and divergence as special cases.

Definition 5.3.1. *Chains and Boundaries*
Let $\mathbf{p}_0, \dots, \mathbf{p}_k \in \mathbb{R}^n$.

(i) The oriented affine *k-simplex* $[\mathbf{p}_0, \dots, \mathbf{p}_k]$ is the k-surface $\sigma : Q^k \to \mathbb{R}^n$, $\sigma(\mathbf{u}) := \mathbf{p}_0 + \sum_{i=1}^{k} u_i(\mathbf{p}_i - \mathbf{p}_0)$.
(ii) For a permutation π, $[\mathbf{p}_{\pi(0)}, \dots, \mathbf{p}_{\pi(k)}] := \operatorname{sgn}(\pi)[\mathbf{p}_0, \dots, \mathbf{p}_k]$.
(iii) An *affine k-chain* is $C = \sum_\ell c_\ell \sigma_\ell$; integration is linear: $\int_C \omega := \sum_\ell c_\ell \int_{\sigma_\ell} \omega$.
(iv) For $k \ge 1$, $\partial_{\mathrm{ch}}[\mathbf{p}_0, \dots, \mathbf{p}_k] := \sum_{j=0}^{k} (-1)^j [\mathbf{p}_0, \dots, \mathbf{p}_{j-1}, \mathbf{p}_{j+1}, \dots, \mathbf{p}_k]$, extended linearly.
If $\Phi = T \circ \sigma$ is a C^2 oriented simplex, set $\partial_{\mathrm{ch}}\Phi := T(\partial_{\mathrm{ch}}\sigma)$, extended linearly to chains.

Theorem 5.3.2. *Stokes' Theorem*
Let $V \subseteq \mathbb{R}^m$ be open, let Ψ be a C^2 k-chain in V, and let ω be a C^1 $(k-1)$-form on V. Then $\int_\Psi d\omega = \int_{\partial_{\mathrm{ch}}\Psi} \omega$.

Proof.
(i) *Linearity Reduction*: By linearity, take $\Psi = \Phi = T \circ \sigma$, where σ is the standard oriented k-simplex.
(ii) *Pullback*: By Theorem 5.2.9, $\int_\Phi d\omega = \int_\sigma d(\omega_T)$ and $\int_{\partial_{\mathrm{ch}}\Phi} \omega = \int_{\partial_{\mathrm{ch}}\sigma} \omega_T$; it remains to prove the formula on σ.
(iii) *Coordinate Form*: By linearity, reduce to $\lambda = f\,dx_1 \wedge \cdots \wedge \widehat{dx_r} \wedge \cdots \wedge dx_k$.
(iv) *Boundary Faces*: For $\partial_{\mathrm{ch}}\sigma = \sum_{j=0}^{k} (-1)^j \sigma_j$, all faces vanish except the two with varying x_r endpoints.

(v) *Conclusion*: The remaining equality is the one-variable FTC in the x_r integral.

Structural Commentary: Pullback reduces Stokes to the standard simplex.
Key Insight: Boundary signs match the missing wedge factor. □

Definition 5.3.3. *Closed and Exact Forms*
Let $E \subseteq \mathbb{R}^n$ be open and let ω be a k-form on E.

(i) ω is *exact* if $\omega = d\lambda$ for some $(k-1)$-form λ on E.
(ii) ω is *closed* if $\omega \in C^1$ and $d\omega = 0$.

Perspective 5.3.4. *Closed Is Local, Exact Is Global*
Exact $\Rightarrow$ closed is just $d^2 = 0$; the converse depends on the domain.
On $\mathbb{R}^2 \setminus \{\mathbf{0}\}$ the standard warning example is $\omega = \frac{-y}{x^2+y^2}\,dx + \frac{x}{x^2+y^2}\,dy$, which is closed but not exact.
Holes can obstruct global antiderivatives even when local derivative tests vanish.

Theorem 5.3.5. *Poincare Lemma on Convex Sets*
Let $k \geq 1$.

(i) If $E \subseteq \mathbb{R}^n$ is open and convex, then every closed C^1 k-form on E is exact.
(ii) The same conclusion holds on any open set C^2-diffeomorphic to a convex open set.

Proof.

(i) Fix $\mathbf{a} \in E$ and set $H_t(\mathbf{x}) := \mathbf{a} + t(\mathbf{x} - \mathbf{a})$, $0 \leq t \leq 1$.
For a k-form ω, define $(K\omega)_{\mathbf{x}}(\mathbf{v}_1, \dots, \mathbf{v}_{k-1}) := \int_0^1 t^{k-1} \omega_{H_t(\mathbf{x})}(\mathbf{x} - \mathbf{a}, \mathbf{v}_1, \dots, \mathbf{v}_{k-1})\,dt$.
Differentiating under the integral gives $\omega - H_0^*\omega = dK\omega + Kd\omega$.
Since $H_0^*\omega = 0$ for $k \geq 1$, $d\omega = 0$ implies $\omega = d(K\omega)$.
(ii) Let $\Phi : C \to E$ be a C^2 diffeomorphism from convex open C. If $d\omega = 0$, then $d(\Phi^*\omega) = \Phi^*(d\omega) = 0$.
By (i), $\Phi^*\omega = d\eta$ on C, hence $\omega = (\Phi^{-1})^* d\eta = d((\Phi^{-1})^*\eta)$ on E.

Structural Commentary: Convex contraction gives a homotopy operator.
Key Insight: Closed forms become derivatives along the contraction. □

Theorem 5.3.6. *Vector Analysis Dictionary in $\mathbb{R}^3$*
Let $E \subseteq \mathbb{R}^3$ be open and let $\mathbf{F} = F_1\mathbf{e}_1 + F_2\mathbf{e}_2 + F_3\mathbf{e}_3 \in C^1(E, \mathbb{R}^3)$.
Set $\lambda_{\mathbf{F}} := F_1\,dx + F_2\,dy + F_3\,dz$ and $\omega_{\mathbf{F}} := F_1\,dy \wedge dz + F_2\,dz \wedge dx + F_3\,dx \wedge dy$.

(i) For $u \in C^1(E)$, $\mathbf{F} = \nabla u$ iff $\lambda_{\mathbf{F}} = du$.
(ii) $d\lambda_{\mathbf{F}} = \omega_{\nabla \times \mathbf{F}}$.
(iii) $\nabla \times \mathbf{F} = 0$ iff $d\lambda_{\mathbf{F}} = 0$.
(iv) For $\mathbf{G} \in C^1(E, \mathbb{R}^3)$, $\mathbf{F} = \nabla \times \mathbf{G}$ iff $\omega_{\mathbf{F}} = d\lambda_{\mathbf{G}}$.
(v) $d\omega_{\mathbf{F}} = (\nabla \cdot \mathbf{F})\,dx \wedge dy \wedge dz$.
(vi) $\nabla \cdot \mathbf{F} = 0$ iff $d\omega_{\mathbf{F}} = 0$.
(vii) If E is C^2-diffeomorphic to a convex open set and $\nabla \times \mathbf{F} = 0$, then $\exists u \in C^1(E) : \mathbf{F} = \nabla u$.
(viii) If E is C^2-diffeomorphic to a convex open set and $\nabla \cdot \mathbf{F} = 0$, then $\exists \mathbf{G} \in C^1(E, \mathbb{R}^3) : \mathbf{F} = \nabla \times \mathbf{G}$.

Proof.

(i) ($\Rightarrow$) If $\mathbf{F} = \nabla u$, then $\lambda_{\mathbf{F}} = (D_1 u)\,dx + (D_2 u)\,dy + (D_3 u)\,dz = du$.
(i) ($\Leftarrow$) If $\lambda_{\mathbf{F}} = du$, then $\mathbf{F} = \nabla u$ by equality of the dx, dy, dz coefficients.
(ii) $d\lambda_{\mathbf{F}} = (D_2F_3 - D_3F_2)\,dy \wedge dz + (D_3F_1 - D_1F_3)\,dz \wedge dx + (D_1F_2 - D_2F_1)\,dx \wedge dy = \omega_{\nabla \times \mathbf{F}}$ by direct expansion.
(iii) ($\Rightarrow$) If $\nabla \times \mathbf{F} = 0$, then $d\lambda_{\mathbf{F}} = \omega_{\nabla \times \mathbf{F}} = 0$ by (ii).
(iii) ($\Leftarrow$) If $d\lambda_{\mathbf{F}} = 0$, then $\omega_{\nabla \times \mathbf{F}} = 0$ by (ii), so $\nabla \times \mathbf{F} = 0$ by injectivity of $\mathbf{H} \mapsto \omega_{\mathbf{H}}$.
(iv) ($\Rightarrow$) If $\mathbf{F} = \nabla \times \mathbf{G}$, then $\omega_{\mathbf{F}} = \omega_{\nabla \times \mathbf{G}} = d\lambda_{\mathbf{G}}$ by (ii).
(iv) ($\Leftarrow$) If $\omega_{\mathbf{F}} = d\lambda_{\mathbf{G}}$, then $\omega_{\mathbf{F}} = \omega_{\nabla \times \mathbf{G}}$ by (ii), so $\mathbf{F} = \nabla \times \mathbf{G}$ by injectivity of $\mathbf{H} \mapsto \omega_{\mathbf{H}}$.
(v) $d\omega_{\mathbf{F}} = (D_1F_1 + D_2F_2 + D_3F_3)\,dx \wedge dy \wedge dz = (\nabla \cdot \mathbf{F})\,dx \wedge dy \wedge dz$ by direct expansion.
(vi) ($\Rightarrow$) If $\nabla \cdot \mathbf{F} = 0$, then $d\omega_{\mathbf{F}} = 0$ by (v).
(vi) ($\Leftarrow$) If $d\omega_{\mathbf{F}} = 0$, then $\nabla \cdot \mathbf{F} = 0$ by (v) and equality of the $dx \wedge dy \wedge dz$ coefficient.
(vii) If $\nabla \times \mathbf{F} = 0$, then $d\lambda_{\mathbf{F}} = 0$ by (iii). Thus $\lambda_{\mathbf{F}} = du$ for some $u \in C^1(E)$ by Theorem 5.3.5(ii), and $\mathbf{F} = \nabla u$ by (i).
(viii) If $\nabla \cdot \mathbf{F} = 0$, then $d\omega_{\mathbf{F}} = 0$ by (vi). Thus $\omega_{\mathbf{F}} = d\eta$ for some 1-form η by Theorem 5.3.5(ii). Write $\eta = \lambda_{\mathbf{G}}$; then $\mathbf{F} = \nabla \times \mathbf{G}$ by (iv).

Structural Commentary: Exterior derivative is grad–curl–div.
Key Insight: Vector identities are $d^2 = 0$ in $\mathbb{R}^3$. □

Theorem 5.3.7. *Green, Classical Stokes, and Divergence*
With the indicated positive orientations:

(i) For $\Omega \subseteq \mathbb{R}^2$ with positively oriented $\operatorname{bd}\Omega$ and $\alpha, \beta \in C^1$ near Ω, $\int_{\operatorname{bd}\Omega}(\alpha\,dx + \beta\,dy) = \int_\Omega (D_1\beta - D_2\alpha)\,dA$.
(ii) If Φ is a C^2 oriented 2-surface in $\mathbb{R}^3$ and $\mathbf{F} \in C^1$ near Φ, then $\int_{\partial_{\mathrm{ch}}\Phi} \mathbf{F} \cdot \mathbf{t}\,ds = \int_\Phi (\nabla \times \mathbf{F}) \cdot \mathbf{n}\,dA$.
(iii) If $\Omega \subseteq \mathbb{R}^3$ has positively oriented boundary and $\mathbf{F} \in C^1$ near Ω, then $\int_{\operatorname{bd}\Omega} \mathbf{F} \cdot \mathbf{n}\,dA = \int_\Omega (\nabla \cdot \mathbf{F})\,dV$.

Proof. Use the form Stokes identity $\int_\Psi d\eta = \int_{\partial_{\mathrm{ch}}\Psi} \eta$.

(i) For $\lambda := \alpha\,dx + \beta\,dy$, $d\lambda = (D_1\beta - D_2\alpha)\,dx \wedge dy$; hence $\int_{\operatorname{bd}\Omega} \lambda = \int_\Omega d\lambda$ gives Green's formula.
(ii) For $\lambda := \lambda_{\mathbf{F}}$, $d\lambda = \omega_{\nabla \times \mathbf{F}}$; hence $\int_{\partial_{\mathrm{ch}}\Phi} \lambda = \int_\Phi d\lambda$ gives the classical Stokes formula.
(iii) For $\omega := \omega_{\mathbf{F}}$, $d\omega = (\nabla \cdot \mathbf{F})\,dx \wedge dy \wedge dz$; hence $\int_{\operatorname{bd}\Omega} \omega = \int_\Omega d\omega$ gives the divergence formula.

Structural Commentary: One form identity yields the three vector formulas.
Key Insight: Boundary plus d is invariant; notation changes. □

5.4 Further Topics in Differential Forms and Stokes Theory

Method 5.4.1. *Differential-Forms Proof Patterns*

(i) *Signs*: compute wedge signs by determinant swaps and permutation parity.
(ii) *Standard presentation*: remove repeated indices and sort the rest.
(iii) *Pullback*: substitute dt_i for dy_i and apply the chain rule.
(iv) *Stokes*: pull back to the standard simplex, prove the coordinate case, extend linearly.
(v) *Closed versus exact*: use $d^2 = 0$ for necessity; use convexity or C^2-equivalence for primitives.
(vi) *Vector analysis*: translate fields to forms, apply Stokes, translate back.

Key Insight: Forms package signs, orientation, and parameter changes.

6 Infinite Series and Summability

6.1 Series Tests

Series are sequences of partial sums. Comparison, condensation, root and ratio tests, rearrangements, products, and double sums all refine that viewpoint.

Definition 6.1.1. *Series and Partial Sums*
Let $(a_n)_{n\geq 1} \subseteq \mathbb{C}$. Summation indices are bound variables and may be renamed within unchanged scope.

(i) For integers $1 \leq p \leq q$, $\sum_{n=p}^{q} a_n := a_p + a_{p+1} + \cdots + a_q$.

(ii) The *series* $\sum_{n=1}^{\infty} a_n$ is the *partial-sum sequence* (s_N), where $s_N := \sum_{n=1}^{N} a_n$.

(iii) The series *converges to* s, written $\sum_{n=1}^{\infty} a_n = s$, iff $s_N \to s$; otherwise it *diverges*. Also for $n = 0$.

Key Insight: A series is a sequence first; its sum is a limit when that limit exists.

Definition 6.1.2. *Absolute and Nonabsolute Convergence*
The series $\sum a_n$ *converges absolutely* if $\sum |a_n|$ converges.
If $\sum a_n$ converges but $\sum |a_n|$ diverges, then $\sum a_n$ converges *nonabsolutely*.

Motivation 6.1.3. *Partial Sums Remember Order*
An infinite sum is a limit of partial sums. For alternating harmonic series, odd and even partial sums approach the same value from opposite sides; see Corollary 6.1.25 and Theorem 6.1.34.

Perspective 6.1.4. *Formal Algebra Needs Convergence*
Finite sums are algebraic; infinite sums are partial-sum limits. Algebraic manipulations are justified only by convergence control, as in Theorem 6.1.5, Corollary 6.1.6, and Theorems 6.1.31, 6.1.34.
Key Insight: The symbol $\sum_{n=1}^{\infty}$ is a limit claim before it is an algebraic object.

Theorem 6.1.5. *Cauchy Criterion for Series*
The series $\sum a_n$ converges if and only if $\forall \varepsilon > 0$ $\exists$ an integer N s.t. $m \geq n \geq N$ implies $\left|\sum_{k=n}^{m} a_k\right| \leq \varepsilon$.

Proof.
($\Rightarrow$) If $s_n := \sum_{k=1}^{n} a_k$ converges, then (s_n) is Cauchy. Thus, for $m \geq n$ large enough, $\left|\sum_{k=n}^{m} a_k\right| = |s_m - s_{n-1}| \leq \varepsilon$.
($\Leftarrow$) The tail condition gives, for $m > n$ large enough, $|s_m - s_n| = \left|\sum_{k=n+1}^{m} a_k\right| \leq \varepsilon$.
Hence (s_n) is Cauchy in $\mathbb{C} \cong \mathbb{R}^2$ and converges by Corollary 4.2.8.
Structural Commentary: A series converges exactly when all sufficiently late finite tails are small.
Key Insight: The Cauchy test measures tails, not the eventual value of the sum. □

Corollary 6.1.6. *Terms of a Convergent Series Tend to Zero*
If $\sum a_n$ converges, then $a_n \to 0$.

Proof. Let $\varepsilon > 0$. By Theorem 6.1.5, there is N such that $m \geq n \geq N$ implies $\left|\sum_{k=n}^{m} a_k\right| \leq \varepsilon$.
Taking $m = n$ gives $|a_n| \leq \varepsilon$ for all $n \geq N$, hence $a_n \to 0$.
Structural Commentary: A single term is the shortest possible tail.
Key Insight: The condition $a_n \to 0$ is necessary, but not sufficient for convergence. □

Theorem 6.1.7. *Nonnegative Series and Bounded Partial Sums*
A series of nonnegative real terms converges if and only if its partial sums form a bounded sequence.

Proof.
($\Rightarrow$) Every convergent sequence is bounded, so the partial sums are bounded.
($\Leftarrow$) Since $a_n \geq 0$, $s_n = \sum_{k=1}^{n} a_k$ increases; if bounded, it converges by Theorem 2.1.11.
Structural Commentary: Nonnegative series replace cancellation by monotonicity.
Key Insight: For nonnegative terms, convergence is exactly bounded accumulation. □

Theorem 6.1.8. *Comparison Test*
(i) If $|a_n| \leq c_n$ for $n \geq N_0$, and if $\sum c_n$ converges, then $\sum a_n$ converges.
(ii) If $a_n \geq d_n \geq 0$ for $n \geq N_0$, and if $\sum d_n$ diverges, then $\sum a_n$ diverges.

Proof.

(i) Given $\varepsilon > 0$, choose $N \geq N_0$ so that $m \geq n \geq N$ implies $\sum_{k=n}^{m} c_k \leq \varepsilon$.
Then $\left|\sum_{k=n}^{m} a_k\right| \leq \sum_{k=n}^{m} |a_k| \leq \sum_{k=n}^{m} c_k \leq \varepsilon$, so Theorem 6.1.5 applies.

(ii) If $\sum a_n$ converged, then (i) applied to $d_n \leq a_n$ would force $\sum d_n$ to converge, a contradiction.

Structural Commentary: Absolute tail domination transfers Cauchy convergence.
Key Insight: Comparison is a tail test; finitely many early terms do not matter. □

Theorem 6.1.9. *Geometric Series*

(i) If $0 \leq x < 1$, then $\sum_{n=0}^{\infty} x^n = \frac{1}{1-x}$.
(ii) If $x \geq 1$, the series diverges.

Proof.

(i) For $0 \leq x < 1$, $\sum_{k=0}^{n} x^k = \frac{1-x^{n+1}}{1-x}$ and $x^{n+1} \to 0$ by Theorem 2.2.10.

(ii) If $x = 1$, the partial sums are $n+1$, so they diverge. If $x > 1$, then $x^n \not\to 0$, so the series diverges by Corollary 6.1.6.

Structural Commentary: The finite geometric identity converts convergence into the limit of x^{n+1}.
Key Insight: The geometric series is the model comparison series for ratio-like decay. □

Figure 173 represents the case $x = \frac{2}{3}$ by adjacent strip widths whose total length is 3.

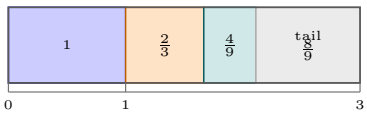

Figure 173: At $x = 2/3$, the strip widths sum to $1 + \frac{2}{3} + \frac{4}{9} + \cdots = 3$.

Definition 6.1.10. *Real Decimals as Series*
For digits $b_N, \ldots, b_0, a_1, a_2, \ldots \in \{0, \ldots, 9\}$, with $b_N \neq 0$ unless the integer part is 0,
$b_N \cdots b_0.a_1a_2\cdots := \sum_{i=0}^{N} b_i 10^i + \sum_{j=1}^{\infty} a_j 10^{-j}$. The fractional series converges absolutely since $0 \leq a_j 10^{-j} \leq 9 \cdot 10^{-j}$ and $\sum 9 \cdot 10^{-j}$ is geometric. A minus sign denotes the negative of this value.

Proposition 6.1.11. *Terminal Nines Are Nonunique*
The same real number can have two decimal representations: $1.000\ldots = 0.999\ldots$.

Proof. $1.000\ldots = 1 + \sum_{j=1}^{\infty} 0 \cdot 10^{-j} = 1$, while $0.999\ldots = \sum_{j=1}^{\infty} 9 \cdot 10^{-j} = 9 \cdot \frac{10^{-1}}{1-10^{-1}} = 1$.
Structural Commentary: The two digit strings have the same partial-sum limit.
Key Insight: Uniqueness requires excluding terminal 9 tails. □

Perspective 6.1.12. *Decimal Expansions Are Series*
Proposition 2.2.11 gives decimal truncations that converge to a real number, while Definition 6.1.10 interprets the infinite digit string as a series. Proposition 6.1.11 explains the standard terminal-9 ambiguity.

Theorem 6.1.13. *Cauchy Condensation Test*
Let $(a_n)_{n\geq 1}$ satisfy $a_1 \geq a_2 \geq \cdots \geq 0$. Then $\sum_{n=1}^{\infty} a_n$ converges iff $\sum_{k=0}^{\infty} 2^k a_{2^k}$ converges.

Proof. Let $s_n := \sum_{j=1}^{n} a_j$ and $t_k := \sum_{j=0}^{k} 2^j a_{2^j}$. Both partial-sum sequences are nondecreasing.

($\Rightarrow$) If (s_n) is bounded, then $t_m \leq 2 \sum_{j=1}^{2^m} a_j = 2s_{2^m}$, so (t_m) is bounded and the condensed series converges.

($\Leftarrow$) If (t_k) is bounded, then for $2^m \leq n < 2^{m+1}$, $s_n \leq \sum_{j=0}^{m} 2^j a_{2^j} = t_m$; hence (s_n) is bounded, QED.

Structural Commentary: Dyadic blocks compare to endpoint terms.
Key Insight: Monotone tails are detected on dyadic scales. □

Corollary 6.1.14. *p-Series Test*
For $p \in \mathbb{R}$:

(i) If $p > 1$, then $\sum_{n=1}^{\infty} n^{-p}$ converges.
(ii) If $p \leq 1$, then $\sum_{n=1}^{\infty} n^{-p}$ diverges.

Proof.

(i) If $p > 1$, condensation reduces to $\sum_{k=0}^{\infty} 2^k (2^k)^{-p} = \sum_{k=0}^{\infty} 2^{(1-p)k}$, a geometric series with ratio $2^{1-p} < 1$.

(ii) If $p \leq 0$, then $n^{-p} \not\to 0$; if $0 < p \leq 1$, condensation gives a geometric series with ratio $2^{1-p} \geq 1$.

Structural Commentary: Condensation turns n-powers into a geometric series.
Key Insight: The threshold is the ratio $2^{1-p} = 1$. □

Theorem 6.1.15. *Integral Test*
Let $N \in \mathbb{N}$ and let $f : [N, \infty) \to [0, \infty)$ be decreasing and Riemann integrable on compact subintervals.

(i) For $M \geq N$, $\int_N^{M+1} f(x)\,dx \leq \sum_{k=N}^{M} f(k) \leq f(N) + \int_N^M f(x)\,dx$.

(ii) $\sum_{k=N}^{\infty} f(k)$ converges iff $\int_N^{\infty} f(x)\,dx$ converges.

Proof.

(i) For $x \in [k, k+1]$, $f(x) \leq f(k)$, so $\int_N^{M+1} f \leq \sum_{k=N}^{M} f(k)$.

For $k \geq N+1$ and $x \in [k-1, k]$, $f(k) \leq f(x)$, so $\sum_{k=N}^{M} f(k) \leq f(N) + \int_N^M f$.

(ii) ($\Rightarrow$) If $\sum_{k=N}^{\infty} f(k)$ converges, its partial sums are bounded. The nondecreasing truncations $\int_N^{M+1} f$ are bounded by (i), so $\int_N^{\infty} f$ converges.

(ii) ($\Leftarrow$) If $\int_N^{\infty} f$ converges, its truncations are bounded. The partial sums $\sum_{k=N}^{M} f(k)$ are bounded by (i), so the series converges by Theorem 6.1.7.

Structural Commentary: Unit intervals compare samples to area.
Key Insight: Same monotone tail, same boundedness. □

Figure 174 compares the graph of decreasing f with left- and right-endpoint rectangles that produce the bounds in Theorem 6.1.15(i).

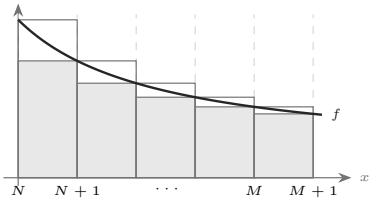

Figure 174: Left and right endpoint estimates for decreasing $f \geq 0$.

Definition 6.1.16. *The Number e*
Define $e := \sum_{n=0}^{\infty} \frac{1}{n!}$, where $0! := 1$; convergence follows by comparison with the geometric series.

Theorem 6.1.17. *A Limit Formula for e*
The limit formula is $\lim_{n\to\infty} \left(1 + \frac{1}{n}\right)^n = e$.

Proof. Let $s_m := \sum_{k=0}^{m} \frac{1}{k!}$ and $t_n := (1 + \frac{1}{n})^n$. The binomial theorem gives $t_n \leq s_n$, hence $\limsup t_n \leq e$.
For fixed $m \leq n$, first m binomial terms give $t_n \geq 1 + 1 + \frac{1}{2!}\left(1 - \frac{1}{n}\right) + \cdots + \frac{1}{m!}\left(1 - \frac{1}{n}\right)\cdots\left(1 - \frac{m-1}{n}\right)$.
Letting $n \to \infty$ with m fixed gives $\liminf t_n \geq s_m$, and then $m \to \infty$ gives $e \leq \liminf t_n$.
Structural Commentary: Bound above by the factorial series; bound below by fixed binomial terms.
Key Insight: Limsup and liminf squeeze the binomial limit to the series definition. □

Proposition 6.1.18. *Remainder Bound for the Series of e*
If $n \geq 1$ and $s_n = \sum_{k=0}^{n} 1/k!$, then $0 < e - s_n < \frac{1}{n!\,n}$.

Proof. Tail is $e - s_n = \frac{1}{(n+1)!} + \frac{1}{(n+2)!} + \cdots < \frac{1}{(n+1)!}\left(1 + \frac{1}{n+1} + \frac{1}{(n+1)^2} + \cdots\right) = \frac{1}{n!\,n}$
Structural Commentary: The factorial tail is bounded by a geometric tail.
Key Insight: Rapid convergence of $\sum \frac{1}{n!}$ gives arithmetic control of e. □

Theorem 6.1.19. *e Is Irrational*
The number e is irrational.

Proof. Suppose $e = p/q$ with p, q positive integers. By Proposition 6.1.18, $0 < q!(e - s_q) < \frac{1}{q}$.
But $q!e$ and $q!s_q$ are integers, so $q!(e - s_q)$ is an integer strictly between 0 and 1, impossible.
Structural Commentary: The sharp tail bound turns rationality into an impossible integer.
Key Insight: A positive integer cannot be smaller than 1. □

Theorem 6.1.20. *Root Test*
For a series $\sum a_n$, put $\alpha := \limsup_{n\to\infty} \sqrt[n]{|a_n|}$. Then:

(i) if $\alpha < 1$, then $\sum a_n$ converges absolutely;
(ii) if $\alpha > 1$, then $\sum a_n$ diverges;
(iii) if $\alpha = 1$, the test gives no information.

Proof.

(i) Choose $\alpha < \beta < 1$. Eventually $|a_n| < \beta^n$, so $\sum |a_n|$ converges by comparison with $\sum \beta^n$.
(ii) Since $\alpha > 1$, $|a_n| > 1$ for infinitely many n, so $a_n \not\to 0$; use Corollary 6.1.6.

(iii) $\sum 1/n$ and $\sum 1/n^2$ both have $\alpha = 1$, but behave differently by Corollary 6.1.14.

Structural Commentary: The root test compares term size directly to geometric decay.
Key Insight: Values below 1 force absolute convergence; values above 1 prevent terms from tending to 0. □

Theorem 6.1.21. *Ratio Test*
Assume $a_n \neq 0$ for all sufficiently large n.

(i) If $\limsup_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| < 1$, then $\sum a_n$ converges absolutely.
(ii) If $\liminf_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| > 1$, then $\sum a_n$ diverges.
(iii) In the remaining cases, the test gives no information.

Proof.

(i) Choose $\beta < 1$ with $|a_{n+1}/a_n| < \beta$ eventually.
Then $|a_n| = O(\beta^n)$, so $\sum |a_n|$ converges by comparison with a geometric series.
(ii) Choose $\beta > 1$ with $|a_{n+1}/a_n| > \beta$ eventually.
Then the tail $|a_n|$ is eventually increasing and bounded away from 0, so $a_n \not\to 0$.
(iii) The series $\sum 1/n$ and $\sum 1/n^2$ both have ratio limit 1, but behave differently by Corollary 6.1.14.

Structural Commentary: Ratios turn successive terms into a geometric majorant.
Key Insight: Ratios below 1 force geometric decay; ratios above 1 prevent terms from tending to zero. □

Theorem 6.1.22. *Root and Ratio Test Comparison*
For any sequence (c_n) of positive numbers:

(i) $\liminf_{n\to\infty} \frac{c_{n+1}}{c_n} \leq \liminf_{n\to\infty} \sqrt[n]{c_n}$;
(ii) $\liminf_{n\to\infty} \sqrt[n]{c_n} \leq \limsup_{n\to\infty} \sqrt[n]{c_n}$;
(iii) $\limsup_{n\to\infty} \sqrt[n]{c_n} \leq \limsup_{n\to\infty} \frac{c_{n+1}}{c_n}$.

Proof.

(i) Let $\ell = \liminf c_{n+1}/c_n$. If $\ell = 0$, the inequality is automatic. If $\gamma < \ell$ with $\gamma > 0$, then eventually $c_{n+1} \geq \gamma c_n$, hence $c_n \geq c_N \gamma^{n-N}$ for all large n. After taking nth roots, $\liminf \sqrt[n]{c_n} \geq \gamma$; let $\gamma \uparrow \ell$.
(ii) This is the general fact that $\liminf a_n \leq \limsup a_n$.
(iii) Let $\alpha = \limsup c_{n+1}/c_n$. If $\alpha < +\infty$ and $\beta > \alpha$, then eventually $c_{n+1} \leq \beta c_n$, hence $c_n \leq c_N \beta^{n-N}$ for all large n. After taking nth roots, $\limsup \sqrt[n]{c_n} \leq \beta$; let $\beta \downarrow \alpha$. If $\alpha = +\infty$, the inequality is automatic.

Structural Commentary: A tail ratio bound multiplies into a root bound.
Key Insight: Whenever the ratio test proves convergence, the root test does too. □

Theorem 6.1.23. *Summation by Parts*
Given two sequences (a_n) and (b_n), put $A_n := \sum_{k=0}^{n} a_k$ and $A_{-1} := 0$.

If $0 \leq p \leq q$, then $\sum_{n=p}^{q} a_n b_n = \sum_{n=p}^{q-1} A_n(b_n - b_{n+1}) + A_q b_q - A_{p-1} b_p$.

Proof. Since $a_n = A_n - A_{n-1}$, $\sum_{n=p}^{q} a_n b_n = \sum_{n=p}^{q} A_n b_n - \sum_{n=p}^{q} A_{n-1} b_n = \sum_{n=p}^{q} A_n b_n - \sum_{n=p-1}^{q-1} A_n b_{n+1}$.
Structural Commentary: This is the discrete analogue of integration by parts.
Key Insight: Move the difference from a_n onto b_n by rewriting $a_n = A_n - A_{n-1}$. □

Theorem 6.1.24. *Dirichlet Test*
If the partial sums A_n of $\sum a_n$ are bounded, $b_n \downarrow 0$, and $b_n \geq 0$, then $\sum a_n b_n$ converges.

Proof. Choose M with $|A_n| \leq M$. If $M = 0$, the result is immediate. Otherwise choose N with $b_N \leq \varepsilon/(2M)$.
For $N \leq p \leq q$, $\left|\sum_{n=p}^{q} a_n b_n\right| \leq M\left(\sum_{n=p}^{q-1} (b_n - b_{n+1}) + b_q + b_p\right) = 2Mb_p \leq 2Mb_N \leq \varepsilon$. Theorem 6.1.5 applies.
Structural Commentary: Bounded oscillation in A_n is damped by a monotone scalar tending to 0.
Key Insight: Summation by parts converts cancellation into a total variation estimate for b_n. □

Corollary 6.1.25. *Alternating Series Test*
Suppose $|c_1| \geq |c_2| \geq |c_3| \geq \cdots$, the signs alternate, and $c_n \to 0$. Then $\sum c_n$ converges.

Proof. After shifting indices to start at 0 if desired, apply Theorem 6.1.24 with $a_n = (-1)^{n+1}$ and $b_n = |c_n|$.
Structural Commentary: Alternation gives bounded sums; decreasing magnitudes damp them.
Key Insight: Alternating convergence is Dirichlet convergence in its simplest form. □

Perspective 6.1.26. *Alternating Partial Sums as Nested Control*
Set $a_n := |c_n|$. Figure 175 depicts the disjoint intervals $I_j = [a_{2j}, a_{2j-1}]$ whose lengths form the paired terms in the even partial sums. The interval picture explains the boundedness in Corollary 6.1.25: the even partial sums collect disjoint lengths inside a fixed interval, while the odd partial sums differ from the even ones by the next term, which tends to 0.

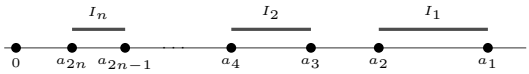

Figure 175: The intervals $I_j = [a_{2j}, a_{2j-1}]$ are disjoint inside $(0, a_1)$.

Figure 176 plots the dimensionless partial sums $s_n = \sum_{k=1}^{n} (-1)^{k+1}/k$ vertically against the integer index n horizontally for $1 \le n \le 10$, with dashed reference level $\log 2$.

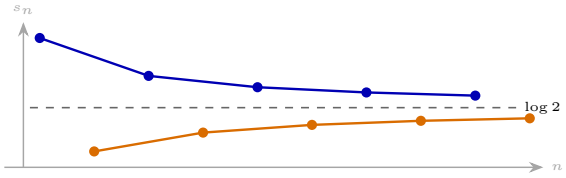

Figure 176: Odd partial sums (blue) decrease and even partial sums (orange) increase toward $\log 2$.

Theorem 6.1.27. *Absolute Convergence Implies Convergence*
If $\sum a_n$ converges absolutely, then $\sum a_n$ converges.

Proof. For $m \ge n$, $\left|\sum_{k=n}^{m} a_k\right| \le \sum_{k=n}^{m} |a_k|$. Apply Theorem 6.1.5 to $\sum |a_n|$.
Structural Commentary: Absolute convergence removes cancellation from the convergence question.
Key Insight: Small absolute tails force small signed or complex tails. □

Theorem 6.1.28. *Addition and Scalar Multiplication of Series*
(i) If $\sum a_n = A$ and $\sum b_n = B$, then $\sum (a_n + b_n) = A + B$.
(ii) If $\sum a_n = A$, then $\sum ca_n = cA$ for every fixed scalar c.

Proof.
(i) The sums of the corresponding partial sums converge to $A + B$ by Theorem 2.1.5.
(ii) The scalar multiples of the corresponding partial sums converge to cA by Theorem 2.1.5.
Structural Commentary: Linearity of convergent series is just limit algebra for partial sums.
Key Insight: Add series by adding their partial-sum sequences. □

Definition 6.1.29. *Cauchy Product*
Given $\sum a_n$, $\sum b_n$, define $c_n := \sum_{k=0}^{n} a_k b_{n-k}$, $(n = 0, 1, 2, \ldots)$. Series $\sum c_n$ is *Cauchy product* of given series.

Figure 177 groups the array entries $a_i b_j$ by diagonals $i + j = n$, matching the definition of each coefficient c_n.

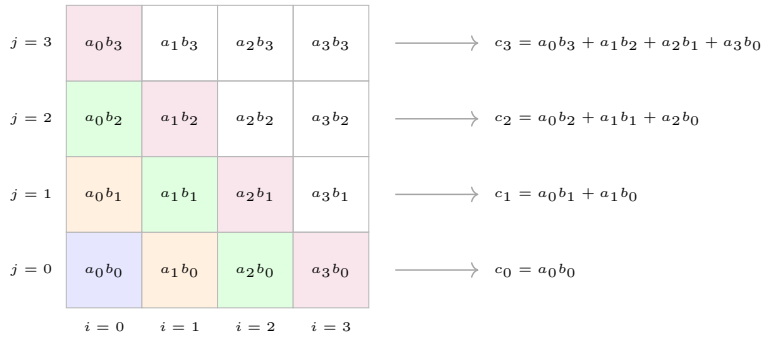

Figure 177: Diagonal sums of $(a_i b_j)$ form the Cauchy product; finite rectangular sums are order-free.

Perspective 6.1.30. *Diagonal Ordering in a Product*
c_n is the diagonal sum of the products $a_i b_j$ with $i + j = n$. Absolute convergence, as in Theorems 6.1.31 and 6.1.34, keeps the value independent of the accumulation order.

Theorem 6.1.31. *Mertens' Theorem for Cauchy Products*
Suppose $\sum a_n$ converges absolutely, $\sum a_n = A$, $\sum b_n = B$, and $c_n = \sum_{k=0}^{n} a_k b_{n-k}$. Then $\sum_{n=0}^{\infty} c_n = AB$.

Proof.
(i) *Setup*: Let A_n, B_n, C_n be the partial sums and set $\beta_n := B_n - B$.
(ii) *Error Decomposition*: Then $C_n = A_n B + \gamma_n$, and $\gamma_n := a_0\beta_n + a_1\beta_{n-1} + \cdots + a_n\beta_0$. Since $A_n B \to AB$, it suffices to show $\gamma_n \to 0$.
(iii) *Tail Estimate*: Put $\alpha := \sum |a_n|$. If $|\beta_j| \le \varepsilon$ for $j \ge N$, then $|\gamma_n| \le |\beta_0 a_n + \cdots + \beta_N a_{n-N}| + \varepsilon\alpha$.
(iv) *Conclusion*: Let $n \to \infty$ with N fixed. The first term tends to 0, so $\limsup |\gamma_n| \le \varepsilon\alpha$; let $\varepsilon \downarrow 0$.
Structural Commentary: Absolute convergence of one factor controls the convolution error.
Key Insight: One absolute factor makes the Cauchy product converge to AB. □

Definition 6.1.32. *Rearrangement of a Series*
If (k_n) lists each positive integer exactly once and $a'_n := a_{k_n}$, then $\sum a'_n$ is a *rearrangement* of $\sum a_n$.

Theorem 6.1.33. *Riemann Rearrangement Theorem*
Let $\sum a_n$ be a real series converging but not absolutely, and let $\alpha, \beta \in [-\infty, \infty]$ with $\alpha \le \beta$.
Then there exists a bijection $\pi : \mathbb{N} \to \mathbb{N}$ such that, for $s'_N := \sum_{n=1}^{N} a_{\pi(n)}$:

(i) π rearranges every term of $\sum a_n$ exactly once.
(ii) $\liminf_{N\to\infty} s'_N = \alpha$.
(iii) $\limsup_{N\to\infty} s'_N = \beta$.

Proof. Write $a_n = p_n - q_n$, where $p_n := \max(a_n, 0)$ and $q_n := \max(-a_n, 0)$. Then $\sum p_n = \sum q_n = +\infty$ and $p_n, q_n \to 0$. List the nonzero p_n as $P_1, P_2, \ldots$ and the nonzero q_n as $Q_1, Q_2, \ldots$, preserving order.
Choose finite targets $\ell_N < u_N$ with $\ell_N \to \alpha$, $u_N \to \beta$, and $\ell_N < u_{N+1}$.

(i) Alternately add unused P terms until $s' > u_N$, then unused $-Q$ terms until $s' < \ell_N$.
Since $\sum P_j = \sum Q_j = +\infty$, all stops are finite and every nonzero term is used; insert zeros anywhere.
(ii) At the Nth down-crossing, $\ell_N - Q_j \le s'_k < \ell_N$ with $Q_j \to 0$. Thus lower crossing subsequences tend to α, and later sums stay above later ℓ_N up to $o(1)$; hence $\liminf s'_N = \alpha$.
(iii) At the Nth up-crossing, $u_N < s'_k \le u_N + P_j$ with $P_j \to 0$. Thus upper crossing subsequences tend to β, and later sums stay below later u_N up to $o(1)$; hence $\limsup s'_N = \beta$.

Structural Commentary: Divergent one-sided masses steer the partial sums.
Key Insight: Vanishing terms make the overshoot vanish. □

Theorem 6.1.34. *Absolutely Convergent Series Are Rearrangement-Invariant*
Every rearrangement of an absolutely convergent complex series converges to the same sum.

Proof. Let s_n, s'_n be the original and rearranged partial sums.
Given $\varepsilon > 0$, choose N so that $\sum_{i=N}^{m} |a_i| \le \varepsilon$ for $m \ge N$, then choose p so $a_1, \ldots, a_N$ occur among $a'_1, \ldots, a'_p$.
For $n > p$, $s_n - s'_n$ uses only tail terms, hence $|s_n - s'_n| \le \varepsilon$. Thus s'_n has the same limit as s_n.
Structural Commentary: Absolute tails control any finite reordering of the remaining terms.
Key Insight: Absolute convergence is exactly the protection needed against rearrangement. □

Definition 6.1.35. *Absolute Summation over Countable Sets*
Let X be countable, $f : X \to \mathbb{C}$, and $g : \mathbb{N} \to X$ be a bijection, $g_n := g(n)$.
If $\sum_{n=1}^{\infty} |f(g_n)| < \infty$, then $\sum_{x\in X} f(x)$ is *absolutely convergent*, and $\sum_{x\in X} f(x) := \sum_{n=1}^{\infty} f(g_n)$.

Theorem 6.1.36. *Countable Sums Are Order-Free Under Absolute Convergence*
Let X, Y be countable, let $f : X \to \mathbb{C}$ be absolutely summable, and let $h : Y \to X$ be a bijection.

(i) $f \circ h : Y \to \mathbb{C}$ is absolutely summable.
(ii) $\sum_{y\in Y} f(h(y)) = \sum_{x\in X} f(x)$.
(iii) Countable absolutely convergent sums are independent of enumeration.

Proof. Let $g : \mathbb{N} \to X$ and $k : \mathbb{N} \to Y$ be enumerations, and set $\sigma := g^{-1} \circ h \circ k : \mathbb{N} \to \mathbb{N}$.

(i) As σ is bijection, $h(k_n) = g_{\sigma(n)}$; $\sum_{n=1}^{\infty} |f(h(k_n))| = \sum_{n=1}^{\infty} \left|f(g_{\sigma(n)})\right| < \infty$ by absolute rearrangement invariance.
(ii) The same invariance gives $\sum_{y\in Y} f(h(y)) = \sum_{n=1}^{\infty} f(g_{\sigma(n)}) = \sum_{n=1}^{\infty} f(g_n) = \sum_{x\in X} f(x)$.
(iii) Take $Y = \mathbb{N}$ and let h be any enumeration of X.

Structural Commentary: Bijections only reorder an absolutely summable list.
Key Insight: Absolute tails make enumeration irrelevant. □

Theorem 6.1.37. *Fubini for Absolutely Summable Arrays*
Let $(a_{mn})_{m,n\ge1} \subseteq \mathbb{C}$ and $L := \sum_{(m,n)\in\mathbb{N}^2} |a_{mn}| < \infty$. Define $S := \sum_{(m,n)\in\mathbb{N}^2} a_{mn}$ when summed absolutely over $\mathbb{N}^2$.

(i) Each row $\sum_{n=1}^{\infty} a_{mn}$ and column $\sum_{m=1}^{\infty} a_{mn}$ converges absolutely.
(ii) With $r_m := \sum_{n=1}^{\infty} a_{mn}$ and $c_n := \sum_{m=1}^{\infty} a_{mn}$, $\sum_m |r_m| \le L$ and $\sum_n |c_n| \le L$.
(iii) $\sum_{m=1}^{\infty} r_m = S = \sum_{n=1}^{\infty} c_n$.

Proof.

(i) For fixed m, N, $\sum_{n=1}^{N} |a_{mn}| \le L$; similarly $\sum_{m=1}^{M} |a_{mn}| \le L$. Hence every row, column absolutely summable.
(ii) For $M \ge 1$, $\sum_{m=1}^{M} |r_m| \le \sum_{m=1}^{M} \sum_{n=1}^{\infty} |a_{mn}| \le L$; let $M \to \infty$. The column estimate is identical.
(iii) Given $\varepsilon > 0$, choose finite $F \subseteq \mathbb{N}^2$ with $\sum_{\mathbb{N}^2\setminus F} |a_{mn}| < \varepsilon$, then $R = \{1, \ldots, M\} \times \{1, \ldots, N\} \supseteq F$.
Each of S, $\sum_m r_m$, and $\sum_n c_n$ differs from $S_R := \sum_{(m,n)\in R} a_{mn}$ by at most $\sum_{\mathbb{N}^2\setminus R} |a_{mn}| \le \varepsilon$. Let $\varepsilon \downarrow 0$.

Structural Commentary: Rectangles plus absolute tails justify Fubini.
Key Insight: Absolute summability makes order irrelevant. □

Method 6.1.38. *Series Proof Patterns*

(i) *Partial sums*: translate every assertion about $\sum a_n$ into an assertion about $s_n = \sum_{k=1}^{n} a_k$.
(ii) *Cauchy tails*: prove convergence by estimating $\left|\sum_{k=n}^{m} a_k\right|$ for $m \geq n$.
(iii) *Nonnegative terms*: replace convergence by boundedness of partial sums.
(iv) *Comparison*: dominate only the tail; finitely many early terms are irrelevant.
(v) *Absolute convergence*: use $\sum |a_n|$ when cancellation should not matter.
(vi) *Countable index sets*: choose a bijection $g : \mathbb{N} \to X$; use Theorem 6.1.36 so $\sum_{x \in X} a_x$ is independent of g.
(vii) *Double sums*: prove identities on $R_{M,N} := \{1, \ldots, M\} \times \{1, \ldots, N\}$; pass to ∞ arrays (Theorem 6.1.37).
(viii) *Conditional convergence*: order matters; use summation by parts or rearrangements.

Key Insight: Series arguments are sequence arguments with special notation for tails.

7 Uniform Convergence

7.1 Uniform Limits

Uniform convergence asks when limits of functions preserve structure. The key distinction is whether N may depend on x, which controls continuity, integration, differentiation, and the supremum metric.

Perspective 7.1.1. *Function Limits Before Function-Sequence Limits*
$\lim_{t \to x} f(t)$ denotes the metric-space function limit of Definition 5.1.4.
Uniform convergence is the hypothesis that lets the limits in n and t commute.

Definition 7.1.2. *Pointwise Limits of Functions*
Let $f_n : E \to (Y, d_Y)$.

(i) $f_n \to f$ *pointwise* on E if $d_Y(f_n(x), f(x)) \to 0$ for every $x \in E$.
(ii) If Y is scalar, $\sum f_n \to f$ *pointwise* on E if $s_N(x) := \sum_{n=1}^{N} f_n(x) \to f(x)$ for every $x \in E$.

No metric on E is required; topology matters only for preserving continuity, limits, or integrals.

Example 7.1.3. *Pointwise Limits Can Lose Structure*

(i) $s_{m,n} := m/(m+n)$ gives $\lim_n \lim_m s_{m,n} = 1$ but $\lim_m \lim_n s_{m,n} = 0$.
(ii) For $f_n(x) = x^2/(1+x^2)^n$, $\sum_{n=0}^{\infty} f_n$ equals 0 at 0 and $1 + x^2$ otherwise, by Theorem 6.1.9.
(iii) $f_n(x) = \sin(nx)/\sqrt{n}$ satisfies $f_n \to 0$ pointwise but $f_n'(0) = \sqrt{n} \to +\infty$.
(iv) $f_n(x) = n^2 x(1-x^2)^n$ on $[0,1]$ satisfies $f_n \to 0$ pointwise, while $\int_0^1 f_n \, dx = n^2/(2n+2) \to +\infty$.

Key Insight: Pointwise control can miss global spikes and oscillations.

Definition 7.1.4. *Uniform Convergence*
For $f_n, f : E \to (Y, d_Y)$, $f_n \rightrightarrows f$ on E if $\forall \varepsilon > 0 \; \exists \; N \in \mathbb{N}$ such that $n \geq N, \; x \in E \implies d_Y(f_n(x), f(x)) \leq \varepsilon$.
In the scalar-valued case, take $d_Y(u, v) = |u - v|$; $\sum f_n$ converges uniformly on E if its partial sums do.

Perspective 7.1.5. *One Tail, All Points*
Pointwise convergence lets N depend on x; uniform convergence uses one N for all x.
Equivalently, late graphs lie in one ε-strip around f, as illustrated in Figure 178.

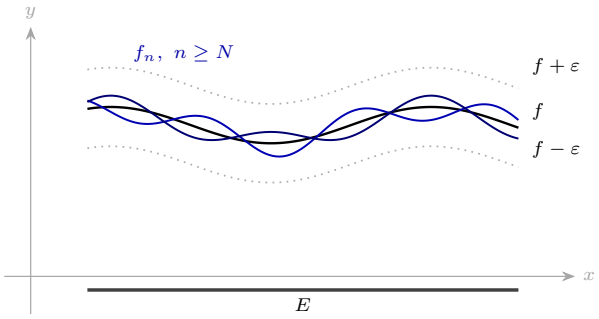

Figure 178: One index N puts all later graphs inside the same ε-strip around f on E.

Example 7.1.6. *x^n Converges Pointwise But Not Uniformly*
On $[0,1]$, let $g_n(x) = x^n$. Then $g_n \to g$ pointwise, where $g(x) = \begin{cases} 0, & 0 \leq x < 1, \\ 1, & x = 1. \end{cases}$
The convergence is not uniform: for each n, some $x < 1$ has $|x^n - g(x)| = x^n > 1/2$. Figure 179 plots the dimensionless functions x, x^2, x^4, x^8 vertically against $x \in [0,1]$ horizontally, showing the persistent endpoint transition.

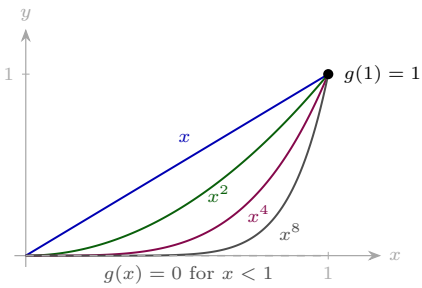

Figure 179: $x^n \to 0$ pointwise on $[0,1)$, but the endpoint prevents uniform convergence on $[0,1]$.

Theorem 7.1.7. *Cauchy Criterion for Uniform Convergence*
For complex-valued $f_n : E \to \mathbb{C}$, f_n converges uniformly on E if and only if

$$\forall \varepsilon > 0 \ \exists N \in \mathbb{N} : \quad m, n \geq N, \ x \in E \Longrightarrow |f_n(x) - f_m(x)| \leq \varepsilon$$

Proof.
($\Rightarrow$) If $f_n \rightrightarrows f$, choose N so that $|f_k(x) - f(x)| \leq \varepsilon/2$ for $k \geq N$ and $x \in E$. Then $|f_n(x) - f_m(x)| \leq \varepsilon$.
($\Leftarrow$) For each x, $(f_n(x))$ is Cauchy in $\mathbb{C}$, so define $f(x) := \lim f_n(x)$.
Fix $n \geq N$ and let $m \to \infty$ in the criterion; then $|f_n(x) - f(x)| \leq \varepsilon$ for all $x \in E$, hence $f_n \rightrightarrows f$.
Structural Commentary: The same N gives Cauchy control simultaneously for every $x \in E$.
Key Insight: Uniform Cauchy tails are exactly uniform convergence. □

Theorem 7.1.8. *Supremum Test for Uniform Convergence*
Suppose $f_n(x) \to f(x)$ $\forall x \in E$, and $M_n := \sup_{x \in E} |f_n(x) - f(x)|$. Then $f_n \rightrightarrows f$ on E if and only if $M_n \to 0$.

Proof.
($\Rightarrow$) If $f_n \rightrightarrows f$, then $\forall \varepsilon > 0$ $\exists$ N such that $n \geq N$ implies $|f_n(x) - f(x)| \leq \varepsilon$ for all $x \in E$. Hence $M_n \leq \varepsilon$.
($\Leftarrow$) If $M_n \to 0$, then $\forall \varepsilon > 0$ $\exists$ N such that $n \geq N$ implies $M_n \leq \varepsilon$. Hence $|f_n(x) - f(x)| \leq \varepsilon$ for all $x \in E$.
Structural Commentary: Uniform convergence is convergence in the supremum error.
Key Insight: The pointwise errors must vanish as one global quantity. □

Theorem 7.1.9. *Weierstrass M-Test*
Let f_n be functions on E and suppose $|f_n(x)| \leq M_n$ for every $x \in E$.
If $\sum M_n$ converges, then $\sum f_n$ converges uniformly on E.

Proof. For $m \geq n$ and $x \in E$, $\left| \sum_{k=n}^{m} f_k(x) \right| \leq \sum_{k=n}^{m} M_k$.
Since $\sum M_k$ converges, Theorem 6.1.5 makes the right-hand side $< \varepsilon$ for all large m, n.
Thus the partial sums of $\sum f_k$ are uniformly Cauchy, so Theorem 7.1.7 applies.
Structural Commentary: Absolute numerical tails dominate functional tails.
Key Insight: A summable uniform majorant gives uniform convergence of a function series. □

Theorem 7.1.10. *Uniform Convergence Interchanges Limits*
Let E lie in a metric space, let x be a limit point of E, and suppose $f_n \rightrightarrows f$ on E.
If $A_n := \lim_{t \to x} f_n(t)$ exists for every n, then:

(i) (A_n) *converges;*
(ii) $\lim_{t \to x} f(t) = \lim_{n \to \infty} A_n$.

Proof.
(i) By Theorem 7.1.7, $\forall \varepsilon > 0$ $\exists$ N such that $m, n \geq N$ and $t \in E$ imply $|f_n(t) - f_m(t)| \leq \varepsilon$. Letting $t \to x$, $|A_n - A_m| \leq \varepsilon$, hence $A_n \to A$ for some $A \in \mathbb{C}$.
(ii) For any n, $|f(t) - A| \leq |f(t) - f_n(t)| + |f_n(t) - A_n| + |A_n - A|$. Given $\varepsilon > 0$, choose n so $|f(t) - f_n(t)| < \varepsilon/3$ for all $t \in E$ and $|A_n - A| < \varepsilon/3$; then take t sufficiently close to x so $|f_n(t) - A_n| < \varepsilon/3$. Thus $\lim_{t \to x} f(t) = A$.
Structural Commentary: Uniform convergence controls the outer two terms in the three-term estimate.
Key Insight: Uniformity is precisely what allows the $n \to \infty$ limit to move past the $t \to x$ limit. □

Theorem 7.1.11. *Uniform Limits Preserve Continuity*
If (f_n) is a sequence of continuous functions on E and $f_n \rightrightarrows f$ on E, then f is continuous on E.

Proof. Let $x \in E$. If x is isolated, f is continuous at x.
If x is a limit point, then $\lim_{t \to x} f_n(t) = f_n(x)$ for all n, so Theorem 7.1.10 gives $\lim_{t \to x} f(t) = \lim_{n \to \infty} f_n(x) = f(x)$.
Structural Commentary: Uniform convergence passes continuity to the limit.
Key Insight: Uniform convergence protects continuity from the failure modes in Example 7.1.3. □

Theorem 7.1.12. *Dini's Monotone Uniform Convergence Theorem*
Let K be compact and let $f_n, f : K \to \mathbb{R}$ be continuous. If $f_n(x) \downarrow f(x)$ for every $x \in K$, then $f_n \rightrightarrows f$ on K.

Proof. Set $g_n := f_n - f$. Then g_n is continuous, $g_n \downarrow 0$, and $g_n \geq 0$. Given $\varepsilon > 0$, let $K_n := \{x \in K : g_n(x) \geq \varepsilon\}$. Then (K_n) is nested compact and $\bigcap_n K_n = \emptyset$, so Corollary 4.1.10 gives $K_N = \emptyset$ for some N.
Thus $0 \leq f_n(x) - f(x) < \varepsilon$ for all $x \in K$ and $n \geq N$.
Structural Commentary: Monotone convergence turns the bad sets into a nested compact sequence.
Key Insight: Compactness turns pointwise eventual escape from every bad set into a uniform escape. □

Definition 7.1.13. *The Supremum Metric on Bounded Continuous Functions*
Let X be a metric space.

(i) $C_b(X)$ is the set of bounded continuous maps $X \to \mathbb{C}$.
(ii) For $f \in C_b(X)$, $\|f\|_\infty := \sup_{x \in X} |f(x)|$.
(iii) The *supremum metric* on $C_b(X)$ is $d_\infty(f,g) := \|f-g\|_\infty$.
(iv) $f_n \to f$ in d_∞ iff $\|f_n - f\|_\infty \to 0$, i.e. iff $f_n \rightrightarrows f$ on X.

Key Insight: Uniform convergence is metric convergence in $C_b(X)$.

Perspective 7.1.14. *A Metric Space Whose Points Are Functions*
Uniform convergence is sequence convergence in the metric space $C_b(X)$.

Perspective 7.1.15. *Four Limit Notions*
The four limit notions are sequence limits, function limits, pointwise function limits, and uniform function limits. By Theorem 7.1.8, the last is ordinary sequence convergence in the supremum metric.

7.2 Interchange of Limits

Theorem 7.2.1. *Uniform Convergence and Riemann–Stieltjes Integration*
Let α be increasing on $[a,b]$. If $f_n \in \mathcal{R}(\alpha)$ on $[a,b]$ and $f_n \rightrightarrows f$, then:
(i) $f \in \mathcal{R}(\alpha)$;
(ii) $\int_a^b f\,d\alpha = \lim_{n\to\infty} \int_a^b f_n\,d\alpha$.

Proof.
(i) Put $\varepsilon_n := \sup_{a\le x\le b} |f_n(x) - f(x)|$. Then $\varepsilon_n \to 0$ by Theorem 7.1.8, and $f_n - \varepsilon_n \le f \le f_n + \varepsilon_n$. Upper and lower integrals of f are therefore squeezed between corresponding integrals of $f_n \pm \varepsilon_n$, and the gap is at most $2\varepsilon_n[\alpha(b)-\alpha(a)]$. Thus $f \in \mathcal{R}(\alpha)$.
(ii) $\left|\int_a^b f\,d\alpha - \int_a^b f_n\,d\alpha\right| \le \varepsilon_n[\alpha(b)-\alpha(a)] \to 0$ by the same estimate.

Structural Commentary: Uniform error becomes an integral error multiplied by the total α-variation.
Key Insight: Uniform convergence is strong enough to pass limits through the Riemann–Stieltjes integral. □

Corollary 7.2.2. *Termwise Integration of Uniformly Convergent Series*
If $f_n \in \mathcal{R}(\alpha)$ on $[a,b]$ and $\sum f_n$ converges uniformly to f, then $\int_a^b f\,d\alpha = \sum_{n=1}^{\infty} \int_a^b f_n\,d\alpha$.

Proof. Let $s_N := \sum_{n=1}^N f_n$. By linearity, $s_N \in \mathcal{R}(\alpha)$ and $\int_a^b s_N\,d\alpha = \sum_{n=1}^N \int_a^b f_n\,d\alpha$.
Since $s_N \rightrightarrows f$, Theorem 7.2.1 gives $\int_a^b f\,d\alpha = \lim_{N\to\infty} \int_a^b s_N\,d\alpha = \sum_{n=1}^{\infty} \int_a^b f_n\,d\alpha$.

Structural Commentary: Reduce the series to its uniformly convergent partial sums.
Key Insight: Uniform convergence lets integration be performed term by term. □

Theorem 7.2.3. *Differentiation Under a Riemann–Stieltjes Integral*
Let $\alpha : [a,b] \to \mathbb{R}$ be increasing, let $\varphi : [a,b] \times [c,d] \to \mathbb{R}$, write $\varphi^t(x) := \varphi(x,t)$, and fix $s \in (c,d)$.
Assume $\varphi^t \in \mathcal{R}(\alpha)$ for every $t \in [c,d]$, and for some $\eta > 0$ with $(s-\eta, s+\eta) \subseteq (c,d)$, $D_2\varphi$ exists on $[a,b] \times (s-\eta, s+\eta)$ and $(D_2\varphi)^t \rightrightarrows (D_2\varphi)^s$ on $[a,b]$ as $t \to s$.
If $F(t) := \int_a^b \varphi(x,t)\,d\alpha(x)$, then:
(i) $(D_2\varphi)^s \in \mathcal{R}(\alpha)$;
(ii) $F'(s) = \int_a^b (D_2\varphi)(x,s)\,d\alpha(x)$.

Proof. For $t \ne s$, set $\psi_t := (\varphi^t - \varphi^s)/(t-s) \in \mathcal{R}(\alpha)$.
By Corollary 1.1.13, $\psi_t(x) = D_2\varphi(x, \tau_x(t))$ for some $\tau_x(t)$ between s and t; hence $\psi_t \rightrightarrows (D_2\varphi)^s$.

(i) $(D_2\varphi)^s \in \mathcal{R}(\alpha)$ by Theorem 7.2.1(i).
(ii) By Theorem 7.2.1(ii), $\frac{F(t)-F(s)}{t-s} = \int_a^b \psi_t\,d\alpha \to \int_a^b (D_2\varphi)^s\,d\alpha$, so $F'(s) = \int_a^b (D_2\varphi)(x,s)\,d\alpha(x)$.

Structural Commentary: Integrable difference quotients converge uniformly.
Key Insight: Uniform convergence permits $D_t \int = \int D_t$. □

Theorem 7.2.4. *Uniform Convergence and Differentiation*
Let f_n be differentiable on $[a,b]$, suppose $f_n(x_0)$ converges for some $x_0 \in [a,b]$, and suppose $f_n' \rightrightarrows g$ on $[a,b]$. Then:
(i) $f_n \rightrightarrows f$ for some f;
(ii) $f' = g$ on $[a,b]$ (one-sided at endpoints).

Proof.
(i) For m,n, $|f_n(x) - f_m(x)| \le |f_n(x_0) - f_m(x_0)| + (b-a) \sup_{t\in[a,b]} |f_n'(t) - f_m'(t)|$ by Corollary 1.1.13. Thus (f_n) is uniformly Cauchy, so $f_n \rightrightarrows f$.
(ii) Fix x and set $\phi_n(t) := \frac{f_n(t)-f_n(x)}{t-x}$, $\phi(t) := \frac{f(t)-f(x)}{t-x}$. For $t \ne x$, $|\phi_n(t) - \phi_m(t)| \le \|f_n' - f_m'\|_\infty$ by the same estimate, hence $\phi_n \rightrightarrows \phi$. By Theorem 7.1.10, $f'(x) = \lim_{t\to x} \phi(t) = \lim_{n\to\infty} f_n'(x) = g(x)$.

Structural Commentary: Derivative control anchors functions, then quotients.
Key Insight: Uniform derivative convergence plus one anchor passes derivatives to the limit. □

7.3 Further Topics in Uniform Convergence

Method 7.3.1. *Uniform Convergence Proof Patterns*

(i) *Pointwise*: fix x, then choose $N = N(x, \varepsilon)$.
(ii) *Uniform*: choose $N = N(\varepsilon)$; equivalently $\sup_E |f_n - f| \to 0$.
(iii) *Uniform Cauchy*: prove $\sup_E |f_n - f_m| \to 0$ as $m, n \to \infty$.
(iv) *Preservation*: use a three-term estimate and choose the uniform index first.
(v) *Series of functions*: apply Weierstrass M-test when numerical absolute tails dominate all functional tails.
(vi) *Termwise operations*: require $f_n \to f$ locally uniformly, i.e. $\sup_{x\in K} |f_n - f| \to 0$ for each compact K, before $\lim_n \int_K f_n = \int_K f$; for derivatives, require $f_n' \to g$ locally uniformly and get $(\lim_n f_n)' = g$.

Key Insight: Uniformity means N is chosen before x.

8 Function-Space Compactness

8.1 Equicontinuity

Function-space compactness treats functions as points. Supremum metrics preview Banach spaces, Baire category describes generic behavior, and equicontinuity leads to Arzela–Ascoli.

Theorem 8.1.1. *Completeness of the Supremum Metric*
The metric space $C_b(X)$ with metric $d(f, g) = \|f - g\|_\infty$ is complete.

Proof. Let (f_n) be Cauchy in $C_b(X)$. Then Theorem 7.1.7 gives a function f with $f_n \rightrightarrows f$. By Theorem 7.1.11, f is continuous. For some n, $\|f - f_n\|_\infty < 1$, hence f_n is bounded, thus $f \in C_b(X)$ and $\|f_n - f\|_\infty \to 0$.
Structural Commentary: Uniform Cauchy convergence builds the limit inside the same function space.
Key Insight: Completeness of $\mathbb{C}$ plus uniform convergence makes $C_b(X)$ complete. □

Definition 8.1.2. *Bounded Target Metric for All Functions*
For metric spaces (X, d_X) and (Y, d_Y), let $\mathcal{F} = Y^X$ and set $\rho(y, z) := \frac{d_Y(y,z)}{1+d_Y(y,z)}$ and $d_\rho(f, g) := \sup_{x\in X} \rho(f(x), g(x))$.
Then $\rho < 1$, so d_ρ is finite on all of $\mathcal{F}$; d_ρ-convergence is uniform convergence measured by d_Y.

Theorem 8.1.3. *Completeness and Closed Subspaces for d_ρ*
If the target metric space (Y, d_Y) is complete, then:

(i) $(\mathcal{F}, d_\rho)$ is complete;
(ii) $\mathcal{F}_b := \{f \in \mathcal{F} : f(X)$ is d_Y-bounded$\}$ is closed in $\mathcal{F}$;
(iii) $C(X, Y)$ is closed in $\mathcal{F}$.

Proof.

(i) Let (f_n) be d_ρ-Cauchy. For each $x \in X$, $(f_n(x))$ is Cauchy in Y; define $f(x) := \lim_n f_n(x)$.
Given $\varepsilon > 0$, choose N with $d_\rho(f_n, f_m) < \varepsilon$ for $m, n \geq N$. Letting $m \to \infty$ gives $d_\rho(f_n, f) \leq \varepsilon$ for $n \geq N$.
(ii) If $f_n \in \mathcal{F}_b$ and $d_\rho(f_n, f) \to 0$, choose N with $d_\rho(f_N, f) < 1/2$.
Then $d_Y(f_N(x), f(x)) < 1$ for all x. Since $f_N(X)$ is bounded, so is $f(X)$.
(iii) If $f_n \in C(X, Y)$ and $d_\rho(f_n, f) \to 0$, then $f_n \to f$ uniformly in d_Y.
Given $x_0 \in X$ and $\varepsilon > 0$, choose N with $d_Y(f_N(x), f(x)) < \varepsilon/3$ for all x, then use continuity of f_N at x_0 and the triangle inequality. Thus f is continuous.

Structural Commentary: Compress the target metric; then close the useful subspaces.
Key Insight: Completeness and uniform control make boundedness and continuity closed. □

Definition 8.1.4. *Boundedness and Equicontinuity of Function Families*
Let $\mathcal{F}$ be a family of functions from E into a metric space (Y, d_Y); in scalar cases, take $d_Y(u, v) = |u - v|$.

(i) (f_n) is *pointwise bounded* on E if $(f_n(x))$ is bounded in Y for each $x \in E$.
(ii) A scalar sequence (f_n) is *uniformly bounded* on E if $\exists M$ such that $|f_n(x)| < M$ for all $x \in E, n \in \mathbb{N}$.
(iii) If E lies in a metric space (X, d_X), then $\mathcal{F}$ is *equicontinuous* on E if $\forall \varepsilon > 0\ \exists \delta > 0$, such that $d_X(x, y) < \delta,\ x, y \in E,\ f \in \mathcal{F} \Longrightarrow d_Y(f(x), f(y)) < \varepsilon$.
(iv) The family is *pointwise equicontinuous* if for every $p \in E$ and $\varepsilon > 0$ there is $\delta = \delta(p, \varepsilon) > 0$ such that $d_X(p, y) < \delta,\ y \in E,\ f \in \mathcal{F}$ implies $d_Y(f(p), f(y)) < \varepsilon$.

Figure 180 depicts the defining common scale: one δ about p controls every $f \in \mathcal{F}$ at tolerance ε.

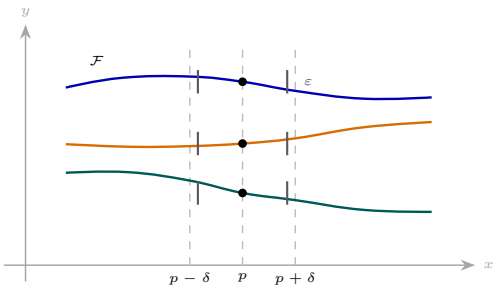

Figure 180: One input scale δ controls every curve in $\mathcal{F}$ within tolerance ε.

Theorem 8.1.5. *Pointwise Equicontinuity Becomes Uniform on Compact Sets*
Every pointwise equicontinuous family $\mathcal{F} \subset C(K, \mathbb{C})$ on compact K is equicontinuous.

Proof. Otherwise, choose $\varepsilon > 0$, $f_n \in \mathcal{F}$, and $x_n, t_n \in K$ with $d(x_n, t_n) < 1/n$ but $|f_n(x_n) - f_n(t_n)| \geq \varepsilon$.
By Theorem 4.1.13, pass to $x_n \to x_0$; then $t_n \to x_0$ too.
Pointwise equicontinuity at x_0 gives $|f_n(x_n) - f_n(t_n)| < \varepsilon$ for large n, a contradiction.
Structural Commentary: Compactness turns moving counterexamples into one base point.
Key Insight: The local $\delta(x, \varepsilon)$ becomes one uniform δ only after compactness prevents escape. □

Theorem 8.1.6. *Uniform Convergence Implies Equicontinuity on Compact Sets*
If K is compact, $f_n \in C_b(K)$, and $f_n \rightrightarrows f$ on K, then $\{f_n : n \in \mathbb{N}\}$ is equicontinuous.

Proof.

(i) *Tail Anchor*: Choose N so $\|f_n - f_N\|_\infty < \varepsilon$ for $n > N$.
(ii) *Finite Initial Family*: By Theorem 5.2.6, choose one $\delta > 0$ giving ε-control for $f_1, \ldots, f_N$.
(iii) *Tail Estimate*: If $n > N$, $d(x, y) < \delta$, then $|f_n(x) - f_n(y)| \leq |f_n(x) - f_N(x)| + |f_N(x) - f_N(y)| + |f_N(y) - f_n(y)| < 3\varepsilon$.
(iv) *Conclusion*: Together with the finite initial family, $\{f_n\}$ is equicontinuous.

Structural Commentary: A uniformly convergent tail stays close to one uniformly continuous function.
Key Insight: Compactness handles finitely many functions; uniform convergence handles the tail. □

Example 8.1.7. *Uniform Boundedness Alone Is Not Enough*
On $[0, 1]$, let $f_n(x) := \frac{x^2}{x^2 + (1 - nx)^2}$. Then $|f_n| \leq 1$ and $f_n \to 0$ pointwise, but $f_n(1/n) = 1$; hence no uniformly convergent subsequence.
The missing hypothesis is equicontinuity.

Theorem 8.1.8. *Diagonal Selection on a Countable Set*
Every pointwise bounded sequence (f_n) on countable E has a subsequence converging pointwise on E.

Proof. List $E = \{x_1, x_2, \ldots\}$. Inductively choose nested subsequences S_i so that $S_i(x_i)$ converges.
The diagonal subsequence is eventually contained in each S_i, hence converges at every x_i.
Structural Commentary: The diagonal keeps the ith convergence property after the ith step.
Key Insight: Countability permits diagonal convergence. □

8.2 Arzela-Ascoli-Type Compactness

Theorem 8.2.1. *Arzela–Ascoli Selection Theorem*
Let K be a compact metric space and let $(f_n) \subset C_b(K)$.
If $\sup_n |f_n(x)| < \infty$ for each $x \in K$ and (f_n) is equicontinuous on K, then:

(i) (f_n) is uniformly bounded on K;
(ii) (f_n) contains a uniformly convergent subsequence.

Proof.

(i) Choose $\delta > 0$ so $d(x, y) < \delta \Rightarrow |f_n(x) - f_n(y)| < 1$ $\forall n$. Let $K \subseteq \bigcup_{j=1}^{r} B_\delta(p_j)$, $M_j := \sup_n |f_n(p_j)| < \infty$.
If $x \in B_\delta(p_j)$, then $|f_n(x)| < 1 + M_j$; hence $\sup_{n, x \in K} |f_n(x)| \leq 1 + \max_j M_j$.
(ii) Let $E \subset K$ be countable dense, obtained from finite $1/m$-nets. A subsequence (g_i) converging pointwise on E exists by Theorem 8.1.8. Given $\varepsilon > 0$, choose $\delta > 0$ for equicontinuity with tolerance $\varepsilon/3$ and $x_1, \ldots, x_r \in E$ with $K \subseteq \bigcup_s B_\delta(x_s)$. For large i, j, $|g_i(x_s) - g_j(x_s)| < \varepsilon/3$ $\forall s$.
If $d(x, x_s) < \delta$, then $|g_i(x) - g_j(x)| < \varepsilon$, so (g_i) is uniformly Cauchy and converges uniformly by Theorem 8.1.1.

Structural Commentary: Dense convergence plus equicontinuity becomes uniform convergence.
Key Insight: Equicontinuity turns finite sampling into uniform control. □

Figure 181 illustrates conclusion (ii) of Theorem 8.2.1: the selected functions f_{n_k} converge uniformly to f.

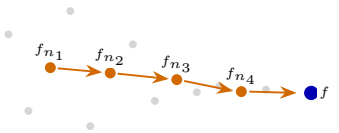

Figure 181: Arzela–Ascoli selects a uniformly convergent subsequence.

Theorem 8.2.2. *Compact Subsets of $C(K)$*
Let K be a compact metric space and let $C(K, \mathbb{R})$ carry the supremum metric.
For $\mathcal{F} \subseteq C(K, \mathbb{R})$, the following are equivalent:

(i) $\mathcal{F}$ is compact.
(ii) $\mathcal{F}$ is closed, uniformly bounded, and equicontinuous.

Proof.

(i) $\Rightarrow$ (ii) Compactness gives closedness and total boundedness in $\|\cdot\|_\infty$. If $\mathcal{F} \neq \emptyset$, choose $g \in \mathcal{F}$; boundedness follows from $\|f\|_\infty \leq \|f - g\|_\infty + \|g\|_\infty$. Given $\varepsilon > 0$, take a finite $\varepsilon/3$-net $g_1, \ldots, g_r \in \mathcal{F}$.
For $d(x, y) < \delta$, chosen so $|g_i(x) - g_i(y)| < \frac{\varepsilon}{3}$ $\forall i$, any f with $\|f - g_i\|_\infty < \frac{\varepsilon}{3}$ satisfies $|f(x) - f(y)| < \varepsilon$.
(ii) $\Rightarrow$ (i) Closedness makes $\mathcal{F}$ complete. For total boundedness, fix $\varepsilon > 0$, choose δ from equicontinuity at $\varepsilon/3$, and a finite δ-net $x_1, \ldots, x_r \subset K$. With $|f| \leq M$ on K for $f \in \mathcal{F}$, partition $[-M, M]$ into intervals of length $< \varepsilon/3$ and classify f by the interval data of $(f(x_1), \ldots, f(x_r))$. For one representative g per class and $d(x, x_i) < \delta$, $|f(x) - g(x)| \leq |f(x) - f(x_i)| + |f(x_i) - g(x_i)| + |g(x_i) - g(x)| < \varepsilon$. Hence $\mathcal{F}$ is totally bounded, so complete plus totally bounded implies compact.

Structural Commentary: Compactness in $C(K)$ is finite-resolution control plus closedness.
Key Insight: Equicontinuity lets finitely many sample values control whole functions. □

Example 8.2.3. *Hölder Balls Have Compact Closure*
For $0 < \alpha \le 1$, define $[f]_\alpha := \sup_{x \neq y} \frac{|f(x)-f(y)|}{|x-y|^\alpha}$ when finite.
Set $\mathcal{H}_\alpha := \{f \in C([0,1],\mathbb{R}) : \|f\|_\infty + [f]_\alpha \le 1\}$, with closure taken in $C([0,1],\mathbb{R})$.

(i) If $f \in \mathcal{H}_\alpha$, then $\|f\|_\infty \le 1$.
(ii) If $f \in \mathcal{H}_\alpha$, then $|f(x) - f(y)| \le |x-y|^\alpha$, so $\mathcal{H}_\alpha$ is equicontinuous.
(iii) Uniform limits preserve $\|f\|_\infty \le 1$ and $|f(x) - f(y)| \le |x-y|^\alpha$.

Thus $\overline{\mathcal{H}_\alpha}$ is closed, uniformly bounded, and equicontinuous; hence it is compact.

Definition 8.2.4. *σ-Compact Metric Space*
A metric space X is *σ-compact* if $X = \bigcup_{j=1}^{\infty} K_j$ for compact subsets $K_j \subseteq X$.

Theorem 8.2.5. *Arzela–Ascoli on σ-Compact Spaces*
Let X be a σ-compact metric space, Y a metric space, $f_n : X \to Y$ pointwise equicontinuous. If $\overline{\{f_n(x) : n \in \mathbb{N}\}}$ is compact in Y $\forall x \in X$, then some subsequence (g_m) converges uniformly on every compact $K \subseteq X$.

Proof. Choose an increasing compact exhaustion $X = \bigcup_j K_j$.

(i) On each K_j, the restrictions $(f_n|_{K_j})$ are uniformly equicontinuous and pointwise relatively compact in Y.
(ii) Choose subsequences successively so the jth one converges uniformly on K_j.
The diagonal g_m satisfies $g_m|_{K_j} \rightrightarrows g|_{K_j}$ for every j.
(iii) For compact $K \subseteq X$, $(g_m|_K)$ is uniformly equicontinuous and $g_m \to g$ pointwise.
Given $\varepsilon > 0$, take a finite δ-net $E \subset K$ with equicontinuity tolerance $\varepsilon/3$.
Convergence on E gives $\sup_{x \in K} d_Y(g_m(x), g_n(x)) < \varepsilon$ for large m, n, hence $g_m \rightrightarrows g$ on K.

Structural Commentary: Exhaust, select, diagonalize.
Key Insight: Compact-local control gives compact-local uniform convergence. □

Corollary 8.2.6. *Real-Line Local Uniform Subsequence*
Let $f_n : \mathbb{R} \to \mathbb{R}$ be pointwise equicontinuous and suppose $\sup_n |f_n(x_0)| < \infty$ for some $x_0 \in \mathbb{R}$.
Then some subsequence converges uniformly on every compact $K \subseteq \mathbb{R}$.

Proof. For $x \in \mathbb{R}$, take compact $I \supset \{x_0, x\}$. The restrictions $(f_n|_I)$ are uniformly equicontinuous by Theorem 8.1.5; choose $\delta > 0$ with step-size tolerance 1.
Choose a finite δ-chain $x_0 = t_0, \dots, t_m = x$; then $|f_n(x)| \le |f_n(x_0)| + m$ for all n.
Thus each orbit $\{f_n(x) : n \in \mathbb{N}\}$ has compact closure in $\mathbb{R}$, and the desired subsequence exists by Theorem 8.2.5.
Structural Commentary: One bounded orbit propagates by finite chains.
Key Insight: Equicontinuity turns one anchor into compact-local control. □

8.3 Further Topics in Function-Space Compactness

Method 8.3.1. *Function-Space Compactness Proof Patterns*

(i) *Completeness*: prove a function sequence is uniformly Cauchy, build the pointwise limit, and use uniform convergence to keep continuity or boundedness; compare Theorem 8.1.1.
(ii) *Baire category*: show a desired property contains a countable intersection of dense open subsets of a complete function space; compare Method 4.3.13.
(iii) *Compactness/equicontinuity*: pass from finite nets to all of K; compare Theorems 8.2.1 and 8.2.2.
(iv) *Diagonal selection*: get pointwise convergence on a countable dense set, then upgrade using equicontinuity; compare Theorem 8.1.8.
(v) *Locally uniform*: exhaust a σ-compact domain by compact sets and diagonalize; compare Theorem 8.2.5.

Key Insight: Compactness in function spaces is finite-net control plus equicontinuity.

9 Power Series and Approximation

9.1 Power Series

Power series are controlled infinite polynomials, and approximation is uniform closure. This section covers radii, Taylor structure, Abel behavior, elementary analytic functions, the gamma function, Weierstrass approximation, and Stone–Weierstrass.

Definition 9.1.1. *Core Objects: Power Series, Approximation, and Gamma*

(i) A real *power series about a* is $\sum_{n=0}^{\infty} c_n (x-a)^n$; a local representation of f by one makes f *analytic* at a.
(ii) A *polynomial approximant* to f on a compact set K is a polynomial P chosen so that $\|f - P\|_{\infty,K}$ is small.
(iii) For $x > 0$, the *gamma function* is $\Gamma(x) := \int_0^\infty t^{x-1} e^{-t}\, dt$ when the improper integral converges.

Key Insight: Power series are local analytic objects; approximation theorems turn algebraic families into dense function families; Γ extends factorials by integration.

Definition 9.1.2. *Power Series and Radius of Convergence*
Let $(c_n)_{n \ge 0} \subseteq \mathbb{C}$ and $\alpha := \limsup_{n \to \infty} \sqrt[n]{|c_n|} \in [0, +\infty]$.

(i) The series $\sum_{n=0}^{\infty} c_n z^n$ is a *power series*.
(ii) The *radius of convergence* is $R := \alpha^{-1} \in [0, +\infty]$, with $0^{-1} = +\infty$ and $(+\infty)^{-1} = 0$.

Theorem 9.1.3. *Convergence Inside the Circle*
For a power series $\sum c_n z^n$ with radius R:
(i) the series converges if $|z| < R$;

(ii) the series diverges if $|z| > R$.

Proof. For $a_n = c_n z^n$, $\limsup_{n\to\infty} \sqrt[n]{|a_n|} = |z| \limsup_{n\to\infty} \sqrt[n]{|c_n|} = \frac{|z|}{R}$, with extended meaning if $R = 0$ or $R = +\infty$.

(i) If $|z| < R$, this value is < 1, so the series converges by Theorem 6.1.20.
(ii) If $|z| > R$, this value is > 1, so the series diverges by Theorem 6.1.20.

Structural Commentary: Radius controls the interior and exterior, not the boundary.
Key Insight: The root test is the radius-of-convergence theorem in disguise. □

Theorem 9.1.4. *A Boundary Test for Power Series*
If $\sum c_n z^n$ has radius 1, $c_n \downarrow 0$, and $c_n \geq 0$, then it converges for $|z| = 1$, except possibly at $z = 1$.

Proof. For $|z| = 1$ and $z \neq 1$, put $a_n = z^n$ and $b_n = c_n$.
The partial sums of $\sum z^n$ are bounded because $\left|\sum_{m=0}^{n} z^m\right| = \left|\frac{1-z^{n+1}}{1-z}\right| \leq \frac{2}{|1-z|}$. Theorem 6.1.24 applies.

Structural Commentary: Boundary convergence away from $z = 1$ comes from bounded geometric partial sums.
Key Insight: Monotone coefficients can give conditional boundary convergence. □

Theorem 9.1.5. *Abel's Endpoint Theorem*
Let $s_n := \sum_{k=0}^{n} c_k \to s$. For $|x| < 1$, set $f(x) := \sum_{n\geq 0} c_n x^n$. Then $\lim_{x\to 1^-} f(x) = s$.

Proof.

(i) *Abel Identity*: Set $s_{-1} := 0$. Since $c_n = s_n - s_{n-1}$, for $|x| < 1$, $f(x) = \sum_{n\geq 0} (s_n - s_{n-1})x^n = (1-x)\sum_{n\geq 0} s_n x^n$.

(ii) *Error Split*: Thus $f(x) - s = (1-x)\sum_{n\geq 0} (s_n - s)x^n$. Given $\varepsilon > 0$, choose N with $|s_n - s| < \varepsilon/2$ for $n > N$.

(iii) *Estimate*: For $0 < x < 1$, $|f(x) - s| \leq (1-x)\sum_{n=0}^{N} |s_n - s|\, x^n + \frac{\varepsilon}{2}(1-x)\sum_{n>N} x^n$.

(iv) *Limit*: The first term tends to 0 as $x \to 1^-$, and the second is $\leq \varepsilon/2$; hence $f(x) \to s$.

Structural Commentary: Endpoint convergence is one-sided Abel continuity.
Key Insight: $(1-x)\sum s_n x^n$ is a geometric average of partial sums. □

Theorem 9.1.6. *Abel Product Theorem for Cauchy Products*
Let $\sum a_n = A$ and $\sum b_n = B$. Define $c_n := \sum_{k=0}^{n} a_k b_{n-k}$, and suppose $\sum c_n = C$. Then $C = AB$.

Proof. For $|x| < 1$, set $f(x) := \sum_{n\geq 0} a_n x^n$, $g(x) := \sum_{n\geq 0} b_n x^n$, and $h(x) := \sum_{n\geq 0} c_n x^n$. Since $(a_n), (b_n), (c_n)$ are bounded, these series converge absolutely on $|x| < 1$. Hence $f(x)g(x) = \sum_{n\geq 0} \big(\sum_{k=0}^{n} a_k b_{n-k}\big)x^n = \sum_{n\geq 0} c_n x^n = h(x)$.
By Abel's endpoint thm, $f(x) \to A$, $g(x) \to B$, $h(x) \to C$ as $x \to 1^-$;$C = \lim_{x\to 1^-} h(x) = \lim_{x\to 1^-} f(x)g(x) = AB$.

Structural Commentary: Regularize by x, multiply inside, pass to $x = 1$.
Key Insight: Abel moves the safe product identity to the endpoint. □

Perspective 9.1.7. *Centered Series Are Translated Series*
$\sum c_n(x-a)^n$ is $\sum c_n y^n$ with $y = x - a$ and radius R: absolute convergence for $|x-a| < R$, divergence for $|x-a| > R$, and separate endpoint tests for $|x-a| = R$.

Figure 182 marks the convergence interval centered at a and, for $0 < \rho < R$, the compact subinterval $[a-\rho, a+\rho]$ used for locally uniform estimates.

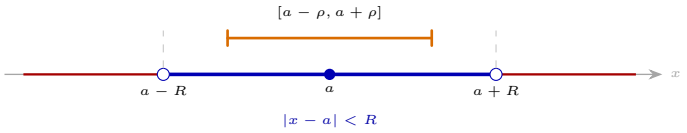

Figure 182: Inside $|x-a| < R$: absolute and locally uniform; outside divergence; endpoints undecided.

Definition 9.1.8. *Real Analytic at a Point*
Let $E \subseteq \mathbb{R}$, $f : E \to \mathbb{R}$, $a \in \operatorname{int} E$. The function f is *real analytic at a* if $\exists r > 0$ and $(c_n)_{n\geq 0} \subseteq \mathbb{R}$ such that:

(i) $(a-r, a+r) \subseteq E$.
(ii) The power series $\sum c_n(x-a)^n$ has radius of convergence $\geq r$.
(iii) $f(x) = \sum_{n=0}^{\infty} c_n(x-a)^n$ for all $x \in (a-r, a+r)$.

If E is open and f is real analytic at every $a \in E$, then f is *real analytic on E*. Analytic functions form the class C^ω.

Theorem 9.1.9. *Power Series May Be Differentiated Term by Term*
Let $f(x) = \sum_{n\geq 0} c_n x^n$ have radius $R > 0$, and set $I_R := (-R, R)$, $K_\rho := [-\rho, \rho]$ for $0 < \rho < R$.

(i) $\sum c_n x^n$ converges uniformly on each K_ρ.
(ii) The function f lies in $C^\infty(I_R)$, and for $k \geq 1$ and $x \in I_R$, $f^{(k)}(x) = \sum_{n\geq k} \frac{n!}{(n-k)!} c_n x^{n-k}$; in particular, $f^{(k)}(0) = k! c_k$.

Proof.

(i) If $0 < \rho < R$, then $\sum |c_n|\,\rho^n < \infty$; hence $|c_n x^n| \le |c_n|\,\rho^n$ on K_ρ, so $\sum c_n x^n$ converges uniformly there.

(ii) For fixed k, $\frac{n!}{(n-k)!} \sim n^k$, so $\limsup \sqrt[n]{\left|\frac{n!}{(n-k)!}c_n\right|} = \limsup \sqrt[n]{|c_n|}$.

Hence every derivative series has radius R and converges uniformly on each K_ρ.
Iterating termwise differentiation gives the formula and $f^{(k)}(0) = k!c_k$.

Structural Commentary: Work on $K_\rho \Subset I_R$ to justify termwise operations.
Key Insight: Polynomial coefficient growth does not change the radius. □

Corollary 9.1.10. *Termwise Calculus for Centered Power Series*
Let $f(x) = \sum_{n=0}^{\infty} c_n(x-a)^n$ *have radius* $R > 0$.

(i) The series converges locally uniformly on $(a-R, a+R)$ *and defines a continuous function.*

(ii) For $|x-a| < R$, $f'(x) = \sum_{n=1}^{\infty} nc_n(x-a)^{n-1}$, *locally uniformly.*

(iii) If $[y,z] \subset (a-R, a+R)$, *then* $\int_y^z f(x)\,dx = \sum_{n=0}^{\infty} c_n \frac{(z-a)^{n+1}-(y-a)^{n+1}}{n+1}$.

Proof. Set $g(u) := \sum c_n u^n$ and $T(x) := x - a$, so $f = g \circ T$ on $(a-R, a+R)$.

(i) Local uniform convergence of $\sum c_n u^n$ on $(-R, R)$ implies local uniform convergence of $\sum c_n (Tx)^n$ on $(a-R, a+R)$; continuity follows from uniform limits.

(ii) Since $T'(x) = 1$, $f'(x) = g'(Tx) = \sum_{n=1}^{\infty} nc_n(Tx)^{n-1}$, with local uniform convergence.

(iii) If $[y,z] \subset (a-R, a+R)$, choose $\rho < R$ with $[y,z] \subset [a-\rho, a+\rho]$.

Uniform convergence on $[a-\rho, a+\rho]$ gives $\int_y^z f = \lim_N \int_y^z \sum_{n=0}^{N} c_n(Tx)^n\,dx$, yielding the stated formula.

Structural Commentary: Work on compact intervals strictly inside the radius.
Key Insight: Translation reduces centered series to ordinary power series. □

Corollary 9.1.11. *Analytic Functions Are Their Taylor Series*
Suppose $f(x) = \sum_{n=0}^{\infty} c_n(x-a)^n$ *for* $|x-a| < r$, *with* $r > 0$.

(i) $f \in C^\infty(a-r, a+r)$.
(ii) $c_k = f^{(k)}(a)/k!$ *for every* $k \ge 0$.
(iii) The power-series expansion of f *about* a *is unique.*
(iv) $f(x) = \sum_{n=0}^{\infty} \frac{f^{(n)}(a)}{n!}(x-a)^n$ *for* $|x-a| < r$.

Proof.

(i) Termwise differentiation gives $f \in C^\infty(a-r, a+r)$.
(ii) For $k \ge 0$, $f^{(k)}(x) = \sum_{n \ge k} \frac{n!}{(n-k)!}c_n(x-a)^{n-k}$; at $x = a$, $f^{(k)}(a) = k!c_k$.
(iii) If $f = \sum b_n(x-a)^n$ also, then $b_k = f^{(k)}(a)/k! = c_k$ for all k.
(iv) Replace c_n by $f^{(n)}(a)/n!$ in $f(x) = \sum c_n(x-a)^n$.

Structural Commentary: Derivatives determine every coefficient.
Key Insight: Analytic representation forces its own Taylor series. □

Theorem 9.1.12. *Re-Expansion and Identity for Power Series*
Let $f(x) = \sum_{n \ge 0} c_n x^n$ *have radius* $R > 0$, *and set* $S = (-R, R)$.

(i) If $a \in S$, *then* $f(x) = \sum_{m \ge 0} \frac{f^{(m)}(a)}{m!}(x-a)^m$ *for* $|x-a| < R - |a|$.

(ii) Let $F(x) = \sum_{n \ge 0} a_n x^n$ *and* $G(x) = \sum_{n \ge 0} b_n x^n$ *converge on* S.
If $\mathcal{Z}_{F,G} := \{x \in S : F(x) = G(x)\}$ *has a limit point in* S, *then* $a_n = b_n$ *for all* $n \ge 0$, *hence* $F = G$ *on* S.

Proof.

(i) Put $\rho := |x-a| + |a| < R$. Since $\sum_{n \ge 0} |c_n|\,\rho^n < \infty$, the binomial double sum is absolutely rearrangeable:

$f(x) = \sum_{m \ge 0} A_m(x-a)^m$, where $A_m := \sum_{n \ge m} \binom{n}{m} c_n a^{n-m}$. Also $f^{(m)}(a) = \sum_{n \ge m} \frac{n!}{(n-m)!}c_n a^{n-m} = m!A_m$.

(ii) Set $H := F - G = \sum_{n \ge 0} d_n x^n$, $d_n := a_n - b_n$, $Z := \{x \in S : H(x) = 0\}$, and $A := Z' \cap S$.

For $x_0 \in A$, (i) gives $H(x) = \sum e_n(x-x_0)^n$ near x_0.
If $k = \min\{n : e_n \ne 0\}$ existed, then $H = (x-x_0)^k g$ with $g(x_0) = e_k \ne 0$, so x_0 would be isolated in Z, contradiction. Thus all $e_n = 0$, so $H = 0$ near x_0 and A is open. Since $S \setminus A$ is open, $A \ne \emptyset$, and S is connected, $A = S$. As Z is closed in S, $Z = S$; hence $d_n = H^{(n)}(0)/n! = 0$.

Structural Commentary: Re-expand locally; connectedness propagates zeros.
Key Insight: Accumulating zeros force every local coefficient to vanish. □

Perspective 9.1.13. *Regularity Hierarchy*
The inclusions are $C^\omega \subseteq C^\infty \subseteq \cdots \subseteq C^2 \subseteq C^1 \subseteq C^0$.
The inclusions follow from Theorem 9.1.9 and Definition 1.1.23; they are generally proper.
Key Insight: Higher regularity is extra structure, not just a different notation for continuity.

Example 9.1.14. *Smooth but Not Analytic*
Define $e(x) = \begin{cases} e^{-1/x}, & x > 0, \\ 0, & x \le 0. \end{cases}$. By repeated L'Hospital, Theorem 1.1.21, $e \in C^\infty$ and $e^{(r)}(0) = 0$ for all r.
Its Taylor series at 0 is zero, but $e(x) > 0$ for $x > 0$, so e is not analytic at 0 (Definition 9.1.8).
Key Insight: A function can be infinitely tangent to the x-axis without being locally equal to its Taylor series.

Perspective 9.1.15. *Taylor Coefficients Are Only the First Half*
Power-series coefficients are forced by derivatives (Corollary 9.1.11); for a function not already known to be analytic, proving the Taylor series represents the function needs a remainder estimate (Theorem 1.1.25).

Theorem 9.1.16. *Exponential and Logarithm from the Power Series*
Define $\mathsf{E}(z) := \sum_{n=0}^{\infty} \frac{z^n}{n!}$ *for* $z \in \mathbb{C}$.

(i) $\mathsf{E}(z+w) = \mathsf{E}(z)\mathsf{E}(w)$ *for* $z, w \in \mathbb{C}$.
(ii) On $\mathbb{R}$, $\mathsf{E} > 0$, $\mathsf{E}' = \mathsf{E}$, $\mathsf{E}(x) = e^x$, *and* E *is strictly increasing.*
(iii) The inverse $\mathsf{L} := \mathsf{E}^{-1} : (0,\infty) \to \mathbb{R}$ *satisfies* $\mathsf{L}'(y) = 1/y$ *and* $\mathsf{L}(uv) = \mathsf{L}(u) + \mathsf{L}(v)$ *for* $u, v > 0$.
(iv) For $x > 0$ *and* $\alpha \in \mathbb{R}$, *set* $x^\alpha := \mathsf{E}(\alpha \mathsf{L}(x))$; *then* $(x^\alpha)' = \alpha x^{\alpha-1}$.

Proof. The ratio test gives convergence for all $z \in \mathbb{C}$.

(i) Absolute convergence gives $\mathsf{E}(z)\mathsf{E}(w) = \sum_{n\ge 0} \sum_{j=0}^{n} \frac{z^j w^{n-j}}{j!(n-j)!} = \sum_{n\ge 0} \frac{(z+w)^n}{n!} = \mathsf{E}(z+w)$.
(ii) Termwise differentiation gives $\mathsf{E}' = \mathsf{E}$ on $\mathbb{R}$. By (i), $\mathsf{E}(x)\mathsf{E}(-x) = 1$, so continuity and $\mathsf{E}(0) = 1$ give $\mathsf{E} > 0$; hence $\mathsf{E}' = \mathsf{E} > 0$. Since $\mathsf{E}(1) = e$, (i) gives $\mathsf{E}(p) = e^p$ for $p \in \mathbb{Q}$, and continuity gives $\mathsf{E}(x) = e^x$.
(iii) For $y = \mathsf{E}(x)$, differentiating $\mathsf{L}(\mathsf{E}(x)) = x$ gives $\mathsf{L}'(y) = 1/\mathsf{E}'(x) = 1/y$.
If $u = \mathsf{E}(s)$ and $v = \mathsf{E}(t)$, then $\mathsf{L}(uv) = \mathsf{L}(\mathsf{E}(s+t)) = s + t = \mathsf{L}(u) + \mathsf{L}(v)$.
(iv) $\frac{d}{dx}\mathsf{E}(\alpha\mathsf{L}(x)) = \mathsf{E}(\alpha\mathsf{L}(x))\alpha\mathsf{L}'(x) = x^\alpha \alpha/x = \alpha x^{\alpha-1}$.

Structural Commentary: Addition, inversion, powers.
Key Insight: $\mathsf{E}(z+w) = \mathsf{E}(z)\mathsf{E}(w)$ creates the logarithm law. □

Perspective 9.1.17. *Real Powers by Rational Approximation*
One route defines x^α for $x > 0$ by choosing $q_n \in \mathbb{Q}$ with $q_n \to \alpha$ and setting $x^\alpha = \lim_{n\to\infty} x^{q_n}$ after proving existence and independence of (q_n). The power-series construction sets $x^\alpha = \mathsf{E}(\alpha\mathsf{L}(x))$; both routes must agree with rational powers and be choice-independent.

Perspective 9.1.18. *Logarithmic Integral Route*
With the Riemann integral, set $L(y) := \int_1^y \frac{1}{t}\,dt$ for $y > 0$. Theorem 2.2.1 gives $L'(y) = 1/y$; endpoint limits make L invertible, and Theorem 1.1.6 then recovers $E' = E$ and the product laws.

Theorem 9.1.19. *Trigonometric Functions from the Exponential*
For $x \in \mathbb{R}$, *set* $\mathsf{C}(x) := \frac{\mathsf{E}(ix)+\mathsf{E}(-ix)}{2}$, $\mathsf{S}(x) := \frac{\mathsf{E}(ix)-\mathsf{E}(-ix)}{2i}$, *and* $\gamma(t) := \mathsf{E}(it)$.

(i) $\mathsf{E}(ix) = \mathsf{C}(x) + i\mathsf{S}(x)$, $\mathsf{C}^2 + \mathsf{S}^2 = 1$, $\mathsf{C}' = -\mathsf{S}$, *and* $\mathsf{S}' = \mathsf{C}$.
(ii) $x_0 := \min\{x > 0 : \mathsf{C}(x) = 0\}$ *exists; with* $\pi := 2x_0$, $\mathsf{E}(\pi i) = -1$, $\mathsf{E}(2\pi i) = 1$, $\mathsf{E}(z + 2\pi i) = \mathsf{E}(z)$ *for* $z \in \mathbb{C}$.
(iii) C, S *are* 2π*-periodic,* $\gamma([0, 2\pi]) = \{\zeta \in \mathbb{C} : |\zeta| = 1\}$, *and* γ *is injective on* $[0, 2\pi)$.

Proof.

(i) Real coefficients give $\overline{\mathsf{E}(ix)} = \mathsf{E}(-ix)$, so $\mathsf{E}(ix) = \mathsf{C} + i\mathsf{S}$ and $|\mathsf{E}(ix)|^2 = \mathsf{E}(ix)\mathsf{E}(-ix) = 1$.
Thus $\mathsf{C}^2 + \mathsf{S}^2 = 1$; differentiating the definitions gives $\mathsf{C}' = -\mathsf{S}$ and $\mathsf{S}' = \mathsf{C}$.
(ii) If C has no positive zero, then $\mathsf{C} > 0$ on $(0,\infty)$, hence $\mathsf{S}' > 0$ and $\mathsf{S}(x) > 0$ for $x > 0$.
For $0 < x < y$, $\mathsf{S}(x)(y-x) < \int_x^y \mathsf{S}(t)\,dt = \mathsf{C}(x) - \mathsf{C}(y) \le 2$, impossible as $y \to \infty$; continuity gives the first zero x_0. On $(0, x_0)$, $\mathsf{C} > 0$, so S increases from 0 to $\mathsf{S}(x_0) = 1$.
Since $x_0 = \pi/2$, $\mathsf{E}(\pi i/2) = i$, and $\mathsf{E}(z+w) = \mathsf{E}(z)\mathsf{E}(w)$ gives $\mathsf{E}(\pi i) = -1$, $\mathsf{E}(2\pi i) = 1$, and $\mathsf{E}(z + 2\pi i) = \mathsf{E}(z)$.
(iii) Periodicity of C, S follows from (ii). On $[0, \pi/2]$, C decreases from 1 to 0 and S increases from 0 to 1, so γ traverses the first quadrant once. Since $\gamma(t + m\pi/2) = \gamma(t)i^m$ for $m = 0, 1, 2, 3$, the four quadrants give $\gamma([0, 2\pi]) = \{\zeta : |\zeta| = 1\}$ and injectivity on $[0, 2\pi)$.

Structural Commentary: $\mathsf{E}(it)$ supplies trigonometry.
Key Insight: $\mathsf{E}(it)\mathsf{E}(-it) = 1$ puts the path on the unit circle. □

Figure 183 depicts the path $\gamma(t) = \mathsf{E}(it)$ and its coordinate projections $\mathsf{C}(t)$ and $\mathsf{S}(t)$ from Theorem 9.1.19.

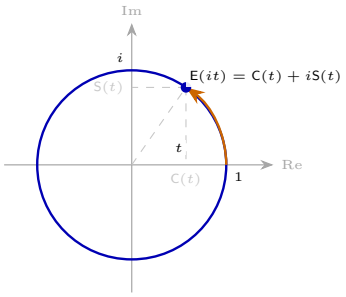

Figure 183: $\mathsf{E}(it) = \mathsf{C}(t) + i\mathsf{S}(t)$ traces the unit circle, defining sine and cosine analytically.

Theorem 9.1.20. *Algebraic Completeness of* $\mathbb{C}$
If $P \in \mathbb{C}[z]$ *and* $\deg P \ge 1$, *then* $\exists z_0 \in \mathbb{C}$ *such that* $P(z_0) = 0$.

Proof.

(i) *Minimum Setup*: Write $P(z)=\sum_{j=0}^{n} a_j z^j$, $n\ge 1$, $a_n=1$. Since $|P(z)|\to\infty$ as $|z|\to\infty$, choose z_0 with $\mu:=|P(z_0)|=\min_{\mathbb{C}}|P|$. If $\mu=0$, done.

(ii) *Normalized Expansion*: Assume $\mu>0$ and set $Q(w):=P(z_0+w)/P(z_0)$. Then $Q(0)=1$ and $|Q(w)|\ge 1$ for all w. Write $Q(w)=1+b_k w^k+w^{k+1}H(w)$ with $k\ge 1$, $b_k\neq 0$, and H polynomial.

(iii) *Decreasing Direction*: Choose $\theta\in\mathbb{R}$ with $b_k e^{ik\theta}=-|b_k|$. For $r>0$, $Q(re^{i\theta})=1-r^k A(r)$, where $A(r):=|b_k|-rH(re^{i\theta})$. For small r, $\Re A(r)>|b_k|/2$, hence $\left|1-r^k A(r)\right|^2=1-2r^k\Re A(r)+r^{2k}|A(r)|^2<1$, contradicting $|Q|\ge 1$.

Structural Commentary: Minimize $|P|$, translate, perturb.
Key Insight: A phase choice makes the first nonzero term decrease $|Q|$. □

Perspective 9.1.21. *From Exponentials to Factorials*
Theorems 9.1.16, 2.2.3 supply real-power laws and integration-by-parts pattern used for Γ in Theorem 9.1.22.

Theorem 9.1.22. *Gamma Function, Beta Function, and Stirling Skeleton*
For $x>0$, set $\Gamma(x):=\int_0^\infty t^{x-1}e^{-t}\,dt$; for $x,y>0$, set $\mathrm{B}(x,y):=\int_0^1 t^{x-1}(1-t)^{y-1}\,dt$.

(i) $\Gamma(x+1)=x\Gamma(x)$ *for* $x>0$, $\Gamma(n+1)=n!$ *for* $n\in\mathbb{N}$, *and* $\log\Gamma$ *is convex on* $(0,\infty)$.
(ii) Γ *is the unique* $f:(0,\infty)\to(0,\infty)$ *with* $f(1)=1$, $f(x+1)=xf(x)$, *and* $\log f$ *convex.*
(iii) $\mathrm{B}(x,y)=\frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}$ *for* $x,y>0$.
(iv) $\Gamma\left(\frac12\right)=\sqrt{\pi}$, $\int_{-\infty}^{\infty}e^{-s^2}\,ds=\sqrt{\pi}$, $\Gamma(x)=\frac{2^{x-1}}{\sqrt{\pi}}\Gamma\left(\frac{x}{2}\right)\Gamma\left(\frac{x+1}{2}\right)$, *and* $\lim_{x\to\infty}\frac{\Gamma(x+1)}{(x/e)^x\sqrt{2\pi x}}=1$.

Proof.

(i) Integration by parts gives $\Gamma(x+1)=\int_0^\infty t^x e^{-t}\,dt=x\Gamma(x)$; $\Gamma(1)=1$ gives $\Gamma(n+1)=n!$.
For $0<\lambda<1$, Holder gives $\Gamma(\lambda x+(1-\lambda)y)\le\Gamma(x)^\lambda\Gamma(y)^{1-\lambda}$, hence $\log\Gamma$ is convex.

(ii) Let $\varphi=\log f$. For $0<x<1$ and $n\ge 1$, convexity with $\varphi(t+1)=\varphi(t)+\log t$ gives
$0\le\varphi(x)-\log\frac{n!\,n^x}{x(x+1)\cdots(x+n)}\le x\log(1+\frac1n)$. Letting $n\to\infty$ fixes φ on $(0,1)$; recurrence fixes φ on $(0,\infty)$.

(iii) Fix $y>0$ and set $F_y(x):=\frac{\Gamma(x+y)}{\Gamma(y)}\mathrm{B}(x,y)$. Since $\mathrm{B}(1,y)=1/y$ and $\mathrm{B}(x+1,y)=\frac{x}{x+y}\mathrm{B}(x,y)$, $F_y(1)=1$ and $F_y(x+1)=xF_y(x)$; Holder gives log-convexity. Thus (ii) gives $F_y=\Gamma$.

(iv) $t=\sin^2\theta$ gives $\mathrm{B}(\frac12,\frac12)=\pi$, hence $\Gamma(\frac12)=\sqrt{\pi}$ by (iii). Then $t=s^2$ gives $\Gamma(\frac12)=\int_{-\infty}^{\infty}e^{-s^2}\,ds$.
Beta duplication gives the duplication formula, and $t=x(1+u)$ with Laplace asymptotics gives Stirling.

Structural Commentary: Recurrence plus log-convexity gives uniqueness.
Key Insight: Bohr–Mollerup turns beta identities into gamma identities. □

Method 9.1.23. *Gamma Function Proof Pattern*

(i) *Gamma function*: use $\Gamma(x+1)=x\Gamma(x)$, $\Gamma(1)=1$, and log-convexity for uniqueness.

9.2 Approximation Methods

Figure 184 motivates uniform approximation: the polygonal interpolants P_2 and P_8 approach $f(x)=\sqrt{1-x}$ on $[0,1]$, while Theorem 9.2.1 replaces polygonal interpolants by polynomials.

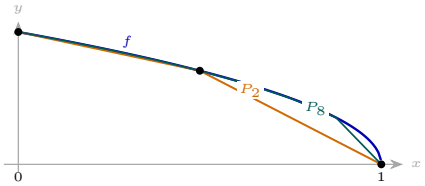

Figure 184: The polygonal interpolants P_2 and P_8 approach $f(x)=\sqrt{1-x}$ uniformly on $[0,1]$.

Theorem 9.2.1. *Weierstrass Polynomial Approximation*
Let $a<b$ and $f\in C([a,b],\mathbb{C})$. Then:

(i) $\exists(P_n)\subset\mathbb{C}[x]$ *with* $P_n\rightrightarrows f$ *on* $[a,b]$;
(ii) if $f([a,b])\subset\mathbb{R}$, *then* (P_n) *may be chosen in* $\mathbb{R}[x]$.

Proof.

(i) By affine change and subtraction of the endpoint interpolant, reduce to $[0,1]$ with $f(0)=f(1)=0$.
Extend $f=0$ off $[0,1]$; then f is uniformly continuous on $[-1,2]$. Choose $c_n>0$ so $Q_n(t):=c_n(1-t^2)^n$ satisfies $\int_{-1}^{1}Q_n=1$.
Use $c_n<\sqrt{n}$ and $Q_n(t)\le\sqrt{n}(1-\delta^2)^n$ for $0<\delta\le|t|\le 1$. Set $P_n(x):=\int_{-1}^{1}f(x+t)Q_n(t)\,dt$.
Since $P_n(x)=\int_0^1 f(u)Q_n(u-x)\,du$, $P_n\in\mathbb{C}[x]$.
Given $\varepsilon>0$, choose $0<\delta\le 1$ with $|u-v|<\delta\Rightarrow|f(u)-f(v)|<\varepsilon/2$ on $[-1,2]$, and set $M=\sup_{[-1,2]}|f|$.
For $x\in[0,1]$, $Q_n\ge 0$, $\int_{-1}^{1}Q_n=1$ give $|P_n(x)-f(x)|\le\int_{-1}^{1}|f(x+t)-f(x)|\,Q_n(t)\,dt\le\frac{\varepsilon}{2}+4M\sqrt{n}(1-\delta^2)^n$.
Thus $\|P_n-f\|_\infty\to 0$ on $[0,1]$; undo the reductions.

(ii) If f is real-valued, then the same construction has $P_n\in\mathbb{R}[x]$.

Structural Commentary: Polynomial kernels approximate the identity.
Key Insight: Uniform continuity handles near mass; kernel concentration removes far mass. □

Figure 185 shows the proof's concentration mechanism: for $n > m$, the solid Q_n is narrower than the dashed Q_m, while the shaded interval has width 2δ and each kernel retains integral 1.

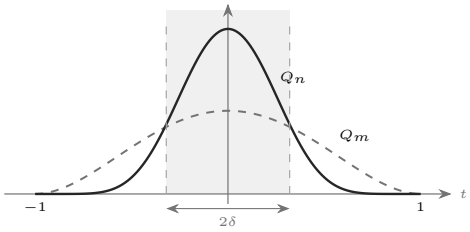

Figure 185: The normalized kernels $Q_k(t) = c_k(1-t^2)^k$ concentrate near 0: for $n > m$, the solid Q_n is narrower than the dashed Q_m, and the central window is $[-\delta, \delta]$.

Corollary 9.2.2. *Polynomial Approximation of $|x|$*
Let $a > 0$. There exists $(P_n) \subset \mathbb{R}[x]$ such that $P_n(0) = 0$ and $P_n \rightrightarrows |x|$ on $[-a, a]$.

Proof. By Theorem 9.2.1, choose $Q_n \in \mathbb{R}[x]$ with $Q_n \rightrightarrows |x|$ on $[-a, a]$. Set $P_n(x) := Q_n(x) - Q_n(0)$.
Then $P_n \in \mathbb{R}[x]$, $P_n(0) = 0$, and $Q_n(0) \to 0$, so $\|P_n - |x|\|_\infty \le \|Q_n - |x|\|_\infty + |Q_n(0)| \to 0$.
Structural Commentary: Normalize at 0.
Key Insight: The constant correction vanishes uniformly. □

Definition 9.2.3. *Algebras and Uniform Closure*
Let $\mathcal{A}$ be a family of complex-valued functions on a set E.

(i) $\mathcal{A}$ is an *algebra* if it is closed under $+$, products, and scalar multiplication (real scalars in the real case).
(ii) $\mathcal{A}$ is *uniformly closed* if $f_n \in \mathcal{A}$ and $f_n \rightrightarrows f$ on E imply $f \in \mathcal{A}$.
(iii) The *uniform closure* of $\mathcal{A}$ is $\{f : f_n \in \mathcal{A},\ f_n \rightrightarrows f \text{ on } E\}$.

Theorem 9.2.4. *Uniform Closures Are Closed Algebras*
Let $\mathcal{A}$ be an algebra of bounded functions and let $\mathcal{B}$ be its uniform closure. Then:

(i) $\mathcal{B}$ is an algebra;
(ii) $\mathcal{B}$ is uniformly closed.

Proof.

(i) If $f, g \in \mathcal{B}$, choose $f_n, g_n \in \mathcal{A}$ with $f_n \rightrightarrows f$ and $g_n \rightrightarrows g$.
Boundedness and uniform convergence give $f_n + g_n \rightrightarrows f + g$; $f_n g_n \rightrightarrows fg$; and $cf_n \rightrightarrows cf$. Thus $\mathcal{B}$ is an algebra.
(ii) If $h_n \in \mathcal{B}$ and $h_n \rightrightarrows h$, approximate each h_n uniformly by some $a_n \in \mathcal{A}$ within $1/n$; then $a_n \rightrightarrows h$, so $h \in \mathcal{B}$.

Structural Commentary: Uniform limits preserve algebraic operations for bounded functions.
Key Insight: The uniform closure of an algebra has already absorbed all further uniform limits. □

Definition 9.2.5. *Separation, Nonvanishing, and Self-Adjointness*
Let $\mathcal{A}$ be a family of functions on E.

(i) $\mathcal{A}$ *separates points* on E if for every distinct $x_1, x_2 \in E$ there is $f \in \mathcal{A}$ with $f(x_1) \neq f(x_2)$.
(ii) $\mathcal{A}$ *vanishes at no point* of E if for every $x \in E$ there is $g \in \mathcal{A}$ with $g(x) \neq 0$.
(iii) A complex algebra $\mathcal{A}$ is *self-adjoint* if $f \in \mathcal{A}$ implies $\overline{f} \in \mathcal{A}$, where $\overline{f}(x) := \overline{f(x)}$.

Theorem 9.2.6. *Two-Point Interpolation in a Separating Algebra*
Let $\mathcal{A}$ be a scalar algebra on E that separates points and vanishes nowhere.
For $x_1 \neq x_2$ in E and scalars c_1, c_2, $\exists f \in \mathcal{A}$ such that $f(x_i) = c_i$, $i = 1, 2$.

Proof. Choose $g, h, k \in \mathcal{A}$ with $g(x_1) \neq g(x_2)$, $h(x_1) \neq 0$, $k(x_2) \neq 0$. Set $u := gk - g(x_1)k$ and $v := gh - g(x_2)h$.
Then $u(x_1) = v(x_2) = 0$, while $u(x_2) = (g(x_2) - g(x_1))k(x_2) \neq 0$ and $v(x_1) = (g(x_1) - g(x_2))h(x_1) \neq 0$.
Hence $f := \frac{c_1 v}{v(x_1)} + \frac{c_2 u}{u(x_2)} \in \mathcal{A}$ and $f(x_i) = c_i$, $i = 1, 2$.
Structural Commentary: Build point-isolating functions.
Key Insight: Isolation reduces interpolation to linear combination. □

Perspective 9.2.7. *Interpolation Is Linear Algebra*
The two-point interpolation step can also be written as a 2×2 linear system. Its invertibility is exactly the finite-dimensional criterion from Theorem 1.7.7, with the determinant test supplied by Theorem 3.8.2. The proof above chooses explicit point-isolating functions instead of reopening the calculation.

Theorem 9.2.8. *Stone–Weierstrass Theorem, Real Form*
Let K be compact Hausdorff; $\mathcal{A} \subset C(K, \mathbb{R})$ point-separating, nowhere-vanishing real algebra. $\overline{\mathcal{A}}^{\|\cdot\|_\infty} = C(K, \mathbb{R})$.

Proof.

(i) *Closure and Lattice Operations*: Put $\mathcal{B} := \overline{\mathcal{A}}^{\|\cdot\|_\infty}$. By Theorem 9.2.4, $\mathcal{B}$ is a uniformly closed algebra and inherits separation/non-vanishing. For $r \in \mathcal{B}$, if $a = \|r\|_\infty > 0$, Corollary 9.2.2 gives $p_n(0) = 0$ with $p_n \rightrightarrows |t|$ on $[-a, a]$, hence $p_n(r) \rightrightarrows |r|$. The case $a = 0$ is trivial. Thus $|r| \in \mathcal{B}$, so for $r, s \in \mathcal{B}$, $r \vee s = \frac{r+s+|r-s|}{2}$ and $r \wedge s = \frac{r+s-|r-s|}{2}$ lie in $\mathcal{B}$.
(ii) *Pointwise Interpolation*: Fix $f \in C(K, \mathbb{R})$ and $\varepsilon > 0$. For $x, y \in K$, choose $h_{x,y} \in \mathcal{B}$ with $h_{x,y}(x) = f(x)$, $h_{x,y}(y) = f(y)$, using Theorem 9.2.6 if $x \neq y$ and $f(x)q/q(x)$ with $q \in \mathcal{B}$, $q(x) \neq 0$, if $x = y$. For fixed x, set $V_y := \{h_{x,y} > f - \varepsilon\}$.
(iii) *Lower Approximation*: Since $y \in V_y$, choose y_i with $K = \bigcup_i V_{y_i}$ and put $g_x := \bigvee_i h_{x,y_i} \in \mathcal{B}$. Then $f - \varepsilon < g_x$ and $g_x(x) = f(x)$.
(iv) *Uniform Approximation*: Set $U_x := \{g_x < f + \varepsilon\}$. Since $x \in U_x$, choose x_j with $K = \bigcup_j U_{x_j}$ and put $h := \bigwedge_j g_{x_j} \in \mathcal{B}$. Then $f - \varepsilon < h < f + \varepsilon$, so $\|h - f\|_\infty < \varepsilon$. Since $\mathcal{B}$ is uniformly closed, $f \in \mathcal{B}$.

Structural Commentary: Finite joins/meets globalize interpolation.
Key Insight: Compactness upgrades pointwise to uniform. □

Theorem 9.2.9. *Stone–Weierstrass Theorem, Complex Form*
Let K be compact Hausdorff and let $\mathcal{A} \subset C(K,\mathbb{C})$ be a self-adjoint, point-separating, nowhere-vanishing complex algebra. Then $\overline{\mathcal{A}}^{\|\cdot\|_\infty} = C(K,\mathbb{C})$.

Proof. Set $\mathcal{A}_\mathbb{R} := \mathcal{A} \cap C(K,\mathbb{R})$. Self-adjointness gives $\operatorname{Re} f, \operatorname{Im} f \in \mathcal{A}_\mathbb{R}$ for all $f \in \mathcal{A}$. If $f(x) \neq f(y)$ or $f(x) \neq 0$, then one of $\operatorname{Re} f, \operatorname{Im} f$ witnesses the same condition; hence $\mathcal{A}_\mathbb{R}$ is point-separating and nowhere-vanishing.
By Theorem 9.2.8, $\overline{\mathcal{A}_\mathbb{R}} = C(K,\mathbb{R})$. For $F = u + iv \in C(K,\mathbb{C})$, take $u_n, v_n \in \mathcal{A}_\mathbb{R}$ with $u_n \rightrightarrows u$, $v_n \rightrightarrows v$.
Then $u_n + iv_n \in \mathcal{A}$ and $u_n + iv_n \rightrightarrows F$.
Structural Commentary: Self-adjointness yields a real subalgebra.
Key Insight: Approximate real and imaginary parts. □

Theorem 9.2.10. *Riesz Separability Criterion for $C(K)$*
Let K be a compact Hausdorff space. Then $(C(K,\mathbb{R}), \|\cdot\|_\infty)$ is separable iff K is metrizable.

Proof.
(⇒) Let $\{g_n\}$ be dense in $C(K,\mathbb{R})$ and $O_n := \{g_n > 1/2\}$. Each O_n is open. For open $O \ni x$, Urysohn gives $g \in C(K,\mathbb{R})$ with $0 \le g \le 1$, $g(x) = 1$, and $g|_{K\setminus O} = 0$. Pick n with $\|g - g_n\|_\infty < 1/3$; then $x \in O_n \subseteq O$.
Thus $\{O_n\}$ is a countable basis, so Theorem 6.4.26 makes K metrizable.
(⇐) Let d metrize K and choose dense $\{x_n : n \ge 1\} \subset K$. Put $f_0 = 1$ and $f_n(x) = d(x, x_n)$.
If $x \neq y$, choose x_n with $d(x,x_n) < d(x,y)/3$; then $f_n(x) \neq f_n(y)$. Hence $\{f_n : n \ge 0\}$ separates points and vanishes nowhere, so Theorem 9.2.8 makes $\operatorname{alg}(f_n : n \ge 0)$ dense in $C(K,\mathbb{R})$.
Its rational polynomial subalgebra is countable and dense.

Structural Commentary: Dense functions give a base; dense points give generators.
Key Insight: Countability moves between K and $C(K)$. □

Theorem 9.2.11. *A Continuous Nowhere Differentiable Function Exists*
There exists a real continuous function on $\mathbb{R}$ which is nowhere differentiable.

Proof.
(i) *Construction and Continuity*: Let φ be the 2-periodic extension of $|x|$ on $[-1,1]$. Then $0 \le \varphi \le 1$ and $|\varphi(s) - \varphi(t)| \le |s-t|$. Define $f(x) := \sum_{n=0}^{\infty} \left(\frac{3}{4}\right)^n \varphi(4^n x)$, converges uniformly (Theorem 7.1.9); hence f is continuous (Theorem 7.1.11).
(ii) *Scale Choice*: Fix x and $m \in \mathbb{N}$. Choose $\delta_m = \pm\frac{1}{2}4^{-m}$ so that no integer lies between $4^m x$ and $4^m(x+\delta_m)$. Set $\gamma_{n,m} := \frac{\varphi(4^n(x+\delta_m)) - \varphi(4^n x)}{\delta_m}$.
(iii) *Difference Quotient Bound*: If $n > m$, then $4^n\delta_m$ is an even integer, so $\gamma_{n,m} = 0$. If $0 \le n \le m$, then $|\gamma_{n,m}| \le 4^n$, and the choice of δ_m gives $|\gamma_{m,m}| = 4^m$. Hence $\left|\frac{f(x+\delta_m) - f(x)}{\delta_m}\right| = \left|\sum_{n=0}^{m} \left(\frac{3}{4}\right)^n \gamma_{n,m}\right| \ge 3^m - \sum_{n=0}^{m-1} 3^n = \frac{1}{2}(3^m + 1)$.
(iv) *Conclusion*: Since $\delta_m \to 0$, the difference quotients are unbounded near x; since x was arbitrary, f is nowhere differentiable.

Structural Commentary: Uniform sums give continuity; scaled cusps force unbounded quotients.
Key Insight: Uniform convergence preserves continuity, not differentiability. □

Figure 186 plots the first three summands $\sigma_k(x) := (3/4)^k \varphi(4^k x)$: their amplitudes decrease while their oscillation frequencies and slopes increase.

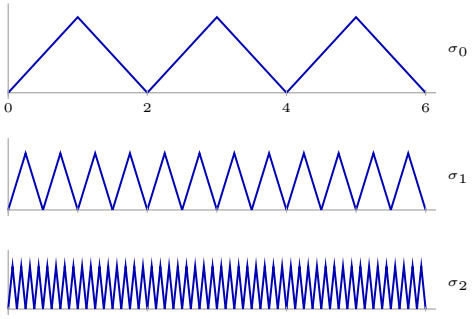

Figure 186: The first compressed sawtooth terms $\sigma_k(x) = (3/4)^k \varphi(4^k x)$: heights shrink, slopes grow.

Perspective 9.2.12. *Explicit Versus Generic Pathology*
The sawtooth series proves existence; Baire category shows nowhere differentiability is residual in $C([a,b],\mathbb{R})$.

Theorem 9.2.13. *Generic Nowhere Differentiability on Compact Intervals*
Let $a < b$, and let $C = C([a,b],\mathbb{R})$ with the supremum metric. There exists a residual set $\mathcal{G} \subseteq C$ such that:
(i) no $f \in \mathcal{G}$ has an available one-sided derivative at any point of $[a,b]$;
(ii) no $f \in \mathcal{G}$ is monotone on any nondegenerate subinterval of $[a,b]$;
(iii) the set $\{f \in C : f$ is differentiable at some point of $[a,b]\}$ is first category.

Proof. Write $\Delta_h f(x) := f(x+h) - f(x)$, and choose N_0 with $1/N_0 < b - a$. For $n \geq N_0$, define

$$R_n := \left\{ f \in C : \forall x \in [a, b - 1/n] \ \exists h > 0 \text{ with } \left| \frac{\Delta_h f(x)}{h} \right| > n \right\},$$

$$L_n := \left\{ f \in C : \forall x \in [a + 1/n, b] \ \exists h < 0 \text{ with } \left| \frac{\Delta_h f(x)}{h} \right| > n \right\},$$

$$G_n := \{ f \in C : f \text{ is nonmonotone on every subinterval of length } 1/n \}.$$

Each R_n, L_n, G_n is open and dense in C (Weierstrass Approximation Theorem 9.2.1), plus small high-slope sawtooth perturbation; openness follows from compactness and uniform perturbation estimates. Set $\mathcal{G} := \bigcap_{n \geq N_0} (R_n \cap L_n \cap G_n)$. By Definition 4.3.6, $\mathcal{G}$ is residual.

(i) If $f \in \mathcal{G}$, then the R_n and L_n conditions give one-sided difference quotients of arbitrarily large absolute value; since f is bounded, the corresponding increments tend to 0. Thus no available one-sided derivative exists.
(ii) Let $f \in \mathcal{G}$. Every nondegenerate subinterval contains a subinterval of length $1/n$ for all sufficiently large n, so the G_n conditions make f nonmonotone on every nondegenerate subinterval.
(iii) If f is differentiable somewhere, then $f \notin \mathcal{G}$; hence the differentiable-somewhere set lies in $C \setminus \mathcal{G}$, which is first category.

Structural Commentary: Baire category turns dense sawtooth perturbability into a generic regularity failure.
Key Insight: The explicit construction shows existence; the category proof shows typicality. □

Method 9.2.14. *Power-Series and Approximation Proof Patterns*

(i) *Power series*: work on $K_\rho \Subset I_R$; use uniform convergence before termwise limits or derivatives.
(ii) *Endpoint theorems*: prove identities inside the radius and pass to endpoints with Abel-type control.
(iii) *Approximate identities*: use kernels $Q_n \geq 0$, $\int Q_n = 1$, with tails $\to 0$ off 0.
(iv) *Uniform closure*: show $a_n \in \mathcal{A}$ and $a_n \rightrightarrows f$.
(v) *Lattice closure*: derive $|f|$, then $\max, \min$ from algebraic formulas.
(vi) *Stone–Weierstrass*: interpolate locally; use compactness and finite max/min to globalize.

Key Insight: Uniform convergence and compactness are what make infinite algebra behave like finite algebra.

9.3 The Umbral Calculus

The umbral calculus is the formal linear algebra of polynomial sequences. It identifies a formal power series with three related objects: an algebra element, a linear functional on $\mathbb{C}[x]$, and an operator on $\mathbb{C}[x]$. Refines duality of Definition 4.2.4 and polynomial operator calculus of Definition 1.1.2, without invoking convergence.

Definition 9.3.1. *Formal Power Series and Order*
Let $\mathscr{F} := \mathbb{C}[[t]]$.

(i) $f \in \mathscr{F}$ are *formal power series* $f(t) = \sum_{k \geq 0} a_k t^k$, w. coefficientwise addition, Cauchy product multiplication.
(ii) The *order* of f is $o(f) := \min\{k : a_k \neq 0\}$, where $o(0) := +\infty$.
(iii) A series is *invertible* if it has a multiplicative inverse in $\mathscr{F}$, and is a *delta series* if $o(f) = 1$.
(iv) If $o(f) = 1$, its *compositional inverse* is denoted $\overline{f}$ and satisfies $f(\overline{f}(t)) = \overline{f}(f(t)) = t$.
(v) The *lower factorial polynomials* are $(x)_0 := 1$ and $(x)_n := x(x-1)\cdots(x-n+1)$, for $n \geq 1$.

Proposition 9.3.2. *Formal Order Calculus*
For $f, g \in \mathscr{F}$:

(i) $f \in \mathscr{F}^\times \iff o(f) = 0$;
(ii) $o(fg) = o(f) + o(g)$ *and* $o(f+g) \geq \min\{o(f), o(g)\}$;
(iii) if $g(t) = \sum_{k \geq 0} b_k t^k$ *and* $o(f) \geq 1$, *then* $g \circ f := g(f(t)) := \sum_{k \geq 0} b_k f(t)^k \in \mathscr{F}$;
(iv) if $o(f) \geq 1$ *and* $g \neq 0$, *then* $o(g \circ f) = o(g) o(f)$;
(v) if $o(f) = 1$, *then for every* $g \in \mathscr{F}$ *there are unique* $c_k \in \mathbb{C}$ *such that* $g(t) = \sum_{k \geq 0} c_k f(t)^k$.

Proof.

(i) ($\Rightarrow$) If $f \in \mathscr{F}^\times$, then $[t^0]f \in \mathbb{C}^\times$, hence $o(f) = 0$.
(i) ($\Leftarrow$) If $o(f) = 0$, then $[t^0]f \in \mathbb{C}^\times$, hence $f \in \mathscr{F}^\times$.
(ii) Let $r = o(f)$ and $s = o(g)$. Then $[t^{r+s}]fg = [t^r]f\,[t^s]g \neq 0$, and all lower coefficients vanish; hence $o(fg) = r + s$. Also $[t^m](f+g) = 0$ for $m < \min\{r, s\}$, giving the stated lower bound.
(iii) Since $o(f) \geq 1$, $o(f^k) \to \infty$; hence $\forall n$, coefficient $[t^n] \sum_{k \geq 0} b_k f^k$ has only finitely many nonzero terms.
(iv) Let $s = o(g)$. Then $g \circ f = f^s \left(b_s + \sum_{k > s} b_k f^{k-s} \right)$, where second factor has order 0; hence $o(g \circ f) = s\, o(f)$.
(v) If $o(f) = 1$ and $f(t) = a_1 t + \cdots$ with $a_1 \neq 0$, then $f^k = a_1^k t^k +$ higher terms. Thus $\{t^k\}_{k \geq 0} \mapsto \{f^k\}_{k \geq 0}$ is triangular with nonzero diagonal, so existence and uniqueness follow by recursive coefficient matching.

Structural Commentary: Delta series behave like a formal change of coordinate at $t = 0$.
Key Insight: Order replaces convergence as the bookkeeping device. □

Definition 9.3.3. *Derivation*
Let $\mathcal{A}$ be an algebra over a field. Linear operator $\partial : \mathcal{A} \to \mathcal{A}$ is a *derivation* if $\partial(ab) = (\partial a)b + a(\partial b)$ $\forall a, b \in \mathcal{A}$.

Proposition 9.3.4. *Formal Differentiation*
Define $\partial_t : \mathscr{F} \to \mathscr{F}$ *by* $\partial_t \left(\sum_{k \geq 0} a_k t^k \right) := \sum_{k \geq 1} k a_k t^{k-1}$. *Then:*

(i) ∂_t *is* $\mathbb{C}$*-linear.*
(ii) $\partial_t(fg) = (\partial_t f)g + f(\partial_t g)$ *for all* $f, g \in \mathscr{F}$; *hence* $\partial_t \in \mathrm{Der}_{\mathbb{C}}(\mathscr{F})$.

Proof.

(i) Let $f=\sum a_k t^k$, $g=\sum b_k t^k$, and $\alpha,\beta\in\mathbb{C}$. Then $\partial_t(\alpha f+\beta g)=\sum_{k\ge 1} k(\alpha a_k+\beta b_k)t^{k-1}=\alpha\partial_t f+\beta\partial_t g$.

(ii) Let $f(t)=\sum_{k\ge 0} a_k t^k$ and $g(t)=\sum_{k\ge 0} b_k t^k$. For $n\ge 0$, $[t^n]\partial_t(fg)=(n+1)\sum_{j=0}^{n+1} a_j b_{n+1-j}$.

Also $[t^n]\big((\partial_t f)g+f(\partial_t g)\big)=\sum_{j=1}^{n+1} j a_j b_{n+1-j}+\sum_{j=0}^{n}(n+1-j)a_j b_{n+1-j}$, equals preceding coefficient.

Structural Commentary: Formal differentiation is the canonical derivation of $\mathbb{C}[[t]]$.
Key Insight: Leibniz is a Cauchy-product coefficient identity. □

Definition 9.3.5. *The Umbral Algebra*

(i) *Polynomial algebra*: set $\mathscr{P}:=\mathbb{C}[x]$ and let $\mathscr{P}':=\mathrm{Hom}_{\mathbb{C}}(\mathscr{P},\mathbb{C})$.
(ii) *Umbral pairing*: for $L\in\mathscr{P}'$ and $p(x)\in\mathscr{P}$, write $\langle L\mid p(x)\rangle:=L(p(x))$.
(iii) *Exponential normalization*: write each $f\in\mathscr{F}$ as $f(t)=\sum_{k\ge 0}\frac{a_k}{k!}t^k$.
(iv) *Associated functional*: set $\langle f(t)\mid x^n\rangle:=a_n$ for $n\ge 0$, extending $\mathbb{C}$-linearly.

Theorem 9.3.6. *Formal Series Represent All Algebraic Functionals*
Define $\Phi:\mathscr{P}'\to\mathscr{F}$ *by* $\Phi(L):=\sum_{k\ge 0}\frac{\langle L|x^k\rangle}{k!}t^k$. *Then:*

(i) Φ *is a* $\mathbb{C}$*-linear isomorphism with inverse* $\Phi^{-1}\left(\sum_{k\ge 0}\frac{a_k}{k!}t^k\right)\left(\sum_{k=0}^{d}c_k x^k\right):=\sum_{k=0}^{d}c_k a_k$.

(ii) $\langle t^k\mid x^n\rangle=n!\delta_{n,k}$ *and* $\langle t^k\mid p\rangle=p^{(k)}(0)$ *for* $p\in\mathscr{P}$*; hence* $t^0=\mathrm{ev}_0$ *and* $t^k=D^k|_0$.

Proof.

(i) Let $T:\mathscr{P}'\to\mathbb{C}^{\mathbb{N}}$ be $T(L)=(a_k)_{k\ge 0}$, $a_k=\langle L\mid x^k\rangle$.

Since $\{x^k\}_{k\ge 0}$ is a Hamel basis, T is a $\mathbb{C}$-linear bijection with $T^{-1}(a)\left(\sum_{k=0}^{d}c_k x^k\right)=\sum_{k=0}^{d}c_k a_k$.

The map $E:\mathbb{C}^{\mathbb{N}}\to\mathscr{F}$, $E(a)=\sum_{k\ge 0}\frac{a_k}{k!}t^k$, is a $\mathbb{C}$-linear bijection, hence $\Phi=E\circ T$ and $\Phi^{-1}=T^{-1}\circ E^{-1}$.

(ii) As $t^k=k!\,\frac{t^k}{k!}$, coefficient sequence is $(n!\delta_{n,k})_{n\ge 0}$. For $p=\sum_{n=0}^{d}c_n x^n$, by linearity, $\langle t^k\mid p\rangle=k!c_k=p^{(k)}(0)$.

Structural Commentary: Functionals are monomial-coordinate sequences.
Key Insight: Exponential normalization makes t^k equal $D^k|_0$. □

Definition 9.3.7. *Delta and Invertible Functionals*
Under the identification $\mathscr{F}\simeq\mathscr{P}'$:

(i) *Delta functional*: a functional represented by $f\in\mathscr{F}$ with $o(f)=1$.
(ii) *Invertible functional*: a functional represented by $f\in\mathscr{F}^{\times}$, equivalently $o(f)=0$.

Proposition 9.3.8. *Basic Umbral Identities*
For $f,g\in\mathscr{F}$, $p\in\mathscr{P}$, *and* $n\ge 0$*:*

(i) $f(t)=\sum_{k\ge 0}\frac{\langle f(t)\mid x^k\rangle}{k!}t^k$;

(ii) $p(x)=\sum_{k=0}^{\deg p}\frac{\langle t^k\mid p\rangle}{k!}x^k$;

(iii) $\langle fg\mid x^n\rangle=\sum_{k=0}^{n}\binom{n}{k}\langle f\mid x^k\rangle\langle g\mid x^{n-k}\rangle$;

(iv) if $o(f)>\deg p$, *then* $\langle f\mid p\rangle=0$;

(v) if $o(f_k)=k$ *for all* $k\ge 0$, *then* $\left\langle\sum_{k\ge 0}a_k f_k\middle| p\right\rangle=\sum_{k=0}^{\deg p}a_k\langle f_k\mid p\rangle$, *with* $\sum_{k\ge 0}a_k f_k$ *well-defined in* $\mathscr{F}$.

Proof.

(i) If $f(t)=\sum_{k\ge 0}a_k t^k/k!$, then $a_k=\langle f\mid x^k\rangle$ by definition.

(ii) Since $\langle t^k\mid p\rangle=p^{(k)}(0)$, this is Taylor's formula for the polynomial p.

(iii) Write $f=\sum a_k t^k/k!$ and $g=\sum b_k t^k/k!$.

The Cauchy product is $fg=\sum_{n\ge 0}\left(\sum_{k=0}^{n}\binom{n}{k}a_k b_{n-k}\right)\frac{t^n}{n!}$, and $a_k=\langle f\mid x^k\rangle$, $b_k=\langle g\mid x^k\rangle$.

(iv) If $p=\sum_{j=0}^{d}c_j x^j$ and $o(f)>d$, then $\langle f\mid x^j\rangle=0$ for $0\le j\le d$.

(v) Since $o(f_k)=k$, each coefficient of $\sum_{k\ge 0}a_k f_k$ has only finitely many contributions.

With $d=\deg p$, $\langle f_k\mid p\rangle=0$ for $k>d$ by (iv), proving the finite formula.

Structural Commentary: The umbral pairing dualizes coefficient calculus.
Key Insight: Order makes infinite formal sums act finitely on each polynomial. □

Theorem 9.3.9. *Multiplication by* x *Moves to Formal Differentiation*
Let $M_x:\mathscr{P}\to\mathscr{P}$ *be* $M_x p=xp$, *and let* $\partial_t:\mathscr{F}\to\mathscr{F}$ *be formal differentiation. Then:*

(i) $\langle f\mid M_x p\rangle=\langle\partial_t f\mid p\rangle$ *for all* $f\in\mathscr{F}$ *and* $p\in\mathscr{P}$.

(ii) $M_x^* = \partial_t$ *under the umbral pairing.*

Proof.

(i) By linearity in p, take $p = x^n$.
For $f = \sum_{k\geq 0} \frac{a_k}{k!} t^k$, $\partial_t f = \sum_{k\geq 0} \frac{a_{k+1}}{k!} t^k$, hence $\langle \partial_t f \mid x^n \rangle = a_{n+1} = \langle f \mid x^{n+1} \rangle = \langle f \mid M_x x^n \rangle$.

(ii) For $f \in \mathscr{F}$, the adjoint satisfies $\langle M_x^* f \mid p \rangle = \langle f \mid M_x p \rangle$ for all $p \in \mathscr{P}$.
By (i), $\langle M_x^* f \mid p \rangle = \langle \partial_t f \mid p \rangle$ for all p, so $M_x^* f = \partial_t f$ by nondegeneracy. Hence $M_x^* = \partial_t$.

Structural Commentary: M_x and ∂_t are adjoint under the umbral pairing.
Key Insight: Exponential normalization makes multiplication by x a coefficient shift. □

Definition 9.3.10. *Basic Umbral Functionals*
For $a \in \mathbb{C}$ and $p \in \mathscr{P}$:

(i) *Evaluation*: $\epsilon_a = e^{at}$ and $\langle e^{at} \mid p \rangle = p(a)$; hence $\epsilon_a \epsilon_b = \epsilon_{a+b}$.
(ii) *Forward difference*: $\Delta_a = e^{at} - 1$ and $\langle \Delta_a \mid p \rangle = p(a) - p(0)$.
(iii) *Abel functional*: te^{at} and $\langle te^{at} \mid p \rangle = p'(a)$.
(iv) *Gamma functional*: $(1-t)^{-1}$ and $\langle (1-t)^{-1} | p \rangle = \int_0^\infty p(u) e^{-u}\, du$.
(v) *Integral functional*: $\left\langle \frac{e^{at}-1}{t} \middle| p \right\rangle = \int_0^a p(u)\, du$
(vi) *Bernoulli numbers*: for $a = 1$, $B_n = \left\langle \frac{t}{e^t - 1} \middle| x^n \right\rangle$.

Definition 9.3.11. *Formal Series as Polynomial Operators*
For $f(t) = \sum_{k\geq 0} a_k t^k / k! \in \mathscr{F}$:

(i) *Operator action*: define $f(t) \in \mathrm{End}_{\mathbb{C}}(\mathscr{P})$ by $f(t)p(x) := \sum_{k\geq 0} \frac{a_k}{k!} p^{(k)}(x)$, a finite sum for each $p \in \mathscr{P}$.

(ii) *Monomial action*: for $n \geq 0$, $f(t)x^n = \sum_{k=0}^{n} \binom{n}{k} a_k x^{n-k}$.

Theorem 9.3.12. *Functional-Operator Compatibility*
For $f, g \in \mathscr{F}$ and $p \in \mathscr{P}$:

(i) $\langle fg \mid p \rangle = \langle f \mid g(t)p \rangle$.
(ii) $\langle f \mid p \rangle = \langle t^0 \mid f(t)p \rangle$.

Proof.

(i) By linearity in p, take $p = x^n$. Write $f = \sum_i \frac{a_i}{i!} t^i$ and $g = \sum_j \frac{b_j}{j!} t^j$.

Then $\langle fg \mid x^n \rangle = \sum_{j=0}^{n} \binom{n}{j} a_{n-j} b_j = \left\langle f \middle| \sum_{j=0}^{n} \binom{n}{j} b_j x^{n-j} \right\rangle = \langle f \mid g(t) x^n \rangle$.

(ii) In (i), set $(f, g) = (t^0, F)$ with $F \in \mathscr{F}$. Since $t^0 F = F$ in $\mathscr{F}$, $\langle F \mid p \rangle = \langle t^0 F \mid p \rangle = \langle t^0 \mid F(t)p \rangle$.

Structural Commentary: Multiplication is adjoint to action.
Key Insight: One finite coefficient sum appears on both sides. □

Definition 9.3.13. *Basic Umbral Operators*
For $a \in \mathbb{C}$ and $p \in \mathscr{P}$:

(i) *Translation*: $e^{at} p(x) = p(x + a)$.
(ii) *Forward difference*: $(e^{at} - 1)p(x) = p(x + a) - p(x)$.
(iii) *Abel operator*: $te^{at} p(x) = p'(x + a)$.
(iv) *Gamma operator*: $(1-t)^{-1} p(x) = \int_0^\infty p(x + u) e^{-u}\, du$
(v) *Integral operator*: $\frac{e^{at}-1}{t} p(x) = \int_x^{x+a} p(u)\, du$

Theorem 9.3.14. *Shift-Invariant Operators*
For $T \in \mathrm{End}_{\mathbb{C}}(\mathscr{P})$, the following are equivalent:

(i) $T = f(t)$ *for some* $f \in \mathscr{F}$;
(ii) $[T, t] = 0$;
(iii) $[T, h(t)] = 0$ *for every delta series* h;
(iv) $[T, e^{at}] = 0$ *for all* $a \in \mathbb{C}$.

Proof.

(i) $\Rightarrow$ *(ii)* If $T = f(t)$, then $[T, t] = [f(t), t] = 0$, since $\mathscr{F}$ is commutative.

(ii) $\Rightarrow$ *(iii)* Set $g(t) := \sum_{k\geq 0} \frac{\langle t^0 | T x^k \rangle}{k!} t^k$ and $a_k := \langle t^0 \mid T x^k \rangle$.

Since $[T, t] = 0$, for $m, k \geq 0$, $\langle t^m \mid T x^k \rangle = \langle t^0 \mid t^m T x^k \rangle = \langle t^0 \mid T t^m x^k \rangle = (k)_m a_{k-m}$, with $a_{k-m} = 0$ if $m > k$. Also, $g(t) = \sum_{r\geq 0} \frac{a_r}{r!} t^r$ and $t^r x^k = (k)_r x^{k-r}$.

Then $\langle t^m \mid g(t) x^k \rangle = \sum_{r=0}^{k} \binom{k}{r} a_r \langle t^m \mid x^{k-r} \rangle = (k)_m a_{k-m}$.

Thus $\langle t^m \mid T x^k - g(t) x^k \rangle = 0$ for all m, k. Since $\{t^m : m \geq 0\}$ separates $\mathscr{P}$, $T = g(t)$, so $[T, h(t)] = 0$ for every delta series h.

(iii) $\Rightarrow$ *(iv)* For $a \neq 0$, $e^{at} - 1$ is a delta series, so $[T, e^{at}] = [T, e^{at} - 1] = 0$; for $a = 0$, the commutator vanishes trivially.

(iv) $\Rightarrow$ *(i)* For each $p \in \mathscr{P}$, $0 = [a^1]\,[T, e^{at}]p = [T, t]p$, so $[T, t] = 0$. The construction in *(ii)* $\Rightarrow$ *(iii)* then identifies $T = g(t)$ for some $g \in \mathscr{F}$.

Structural Commentary: The commutant of t on $\mathscr{P}$ is $\mathscr{F}$.
Key Insight: The derivative is enough to recover every coefficient of the operator. □

Definition 9.3.15. *Sheffer, Associated, and Appell Sequences*
Let f be a delta series, g an invertible series, and $\deg s_n = n$.

(i) *Sheffer sequence*: $(s_n)_{n\geq 0}$ is Sheffer for (g,f) if $\langle g(t)f(t)^k \mid s_n(x)\rangle = n!\delta_{n,k}$ for $n,k \geq 0$.
(ii) *Associated sequence*: a Sheffer sequence for $(1,f)$.
(iii) *Appell sequence*: a Sheffer sequence for (g,t).

Theorem 9.3.16. *Existence and Expansion Theorems*
Let f be a delta series, g an invertible series, and $q_k := g(t)f(t)^k$.

(i) There is a unique sequence $(s_n)_{n\geq 0}$ with $\deg s_n = n$ and $\langle q_k \mid s_n\rangle = n!\delta_{n,k}$.
(ii) If $p_n := g(t)s_n$, then (s_n) is Sheffer for (g,f) iff (p_n) is associated with f.
(iii) For all $h \in \mathscr{F}$, $h = \sum_{k\geq 0} \frac{\langle h \mid s_k\rangle}{k!} q_k$.
(iv) For all $p \in \mathscr{P}$, $p = \sum_{k=0}^{\deg p} \frac{\langle q_k \mid p\rangle}{k!} s_k$.

Proof.

(i) Since $o(q_k) = k$, the matrix $A_n = (\langle q_i \mid x^j\rangle)_{0\leq i,j\leq n}$ is triangular with nonzero diagonal.
Hence the equations $\langle q_k \mid s_n\rangle = n!\delta_{n,k}$ have a unique solution $s_n \in \mathscr{P}_{\leq n}$, necessarily with $\deg s_n = n$.
(ii) ($\Rightarrow$) If (s_n) is Sheffer for (g,f), then $\langle f(t)^k \mid p_n\rangle = \langle f(t)^k \mid g(t)s_n\rangle = \langle q_k \mid s_n\rangle = n!\delta_{n,k}$ by Theorem 9.3.12, so (p_n) is associated with f.
(ii) ($\Leftarrow$) If (p_n) is associated with f, then $\langle q_k \mid s_n\rangle = \langle f(t)^k \mid g(t)s_n\rangle = \langle f(t)^k \mid p_n\rangle = n!\delta_{n,k}$ by Theorem 9.3.12, so (s_n) is Sheffer for (g,f).
(iii) Since $o(q_k) = k$, every $h \in \mathscr{F}$ has a unique expansion $h = \sum c_k q_k$.
Pairing with s_n, $\langle h \mid s_n\rangle = c_n n!$, so $c_n = \langle h \mid s_n\rangle/n!$.
(iv) Let $d = \deg p$ and $r := p - \sum_{k=0}^{d} \langle q_k \mid p\rangle s_k/k!$.
Then $\langle q_j \mid r\rangle = 0$ for all $j \leq d$, and also for $j > d$ by $o(q_j) > d$. Since the q_j separate $\mathscr{P}$, $r = 0$.

Structural Commentary: (s_n) is dual to $q_k = gf^k$.
Key Insight: The order filtration makes the orthogonality equations triangular. □

Theorem 9.3.17. *Generating and Operator Characterizations*
Let f be a delta series with compositional inverse $\overline{f}$, let $g \in \mathscr{F}^\times$, and let $(p_n), (s_n)$ be polynomial sequences with $\deg p_n = \deg s_n = n$. Set $P(y,u) := \sum_{n\geq 0} \frac{p_n(y)}{n!}u^n$ and $S(y,u) := \sum_{n\geq 0} \frac{s_n(y)}{n!}u^n$.

(i) (p_n) is associated with f iff $P(y,u) = e^{y\overline{f}(u)}$
(ii) (s_n) is Sheffer for (g,f) iff $S(y,u) = g(\overline{f}(u))^{-1}e^{y\overline{f}(u)}$
(iii) (p_n) is associated with f iff $p_n(0) = \delta_{n,0}$, $f(t)p_n = np_{n-1}$, where $p_{-1} := 0$.
(iv) (s_n) is Sheffer for (γ,f) for some $\gamma \in \mathscr{F}^\times$ iff $f(t)s_n = ns_{n-1}$, where $s_{-1} := 0$.
(v) If (p_n) is associated with f, then $p_n(x) = \sum_{k=0}^{n} \frac{\langle \overline{f}(t)^k \mid x^n\rangle}{k!} x^k$
(vi) If (s_n) is Sheffer for (g,f), then $s_n(x) = \sum_{k=0}^{n} \frac{1}{k!} \left\langle g(\overline{f}(t))^{-1}\overline{f}(t)^k \middle| x^n \right\rangle x^k$.

Proof.

(i) ($\Rightarrow$) By Theorem 9.3.16, $e^{yt} = \sum_{n\geq 0} \frac{p_n(y)}{n!} f(t)^n$. Substitute $t = \overline{f}(u)$ to obtain $P(y,u) = e^{y\overline{f}(u)}$.
(i) ($\Leftarrow$) If $P(x,u) = e^{x\overline{f}(u)}$, then for all $k \geq 0$, $\sum_{n\geq 0} \frac{\langle f(t)^k \mid p_n\rangle}{n!}u^n = \langle f(t)^k \mid P(x,u)\rangle = f(\overline{f}(u))^k = u^k$.
Thus $\langle f(t)^k \mid p_n\rangle = n!\delta_{n,k}$.
(ii) ($\Rightarrow$) By Theorem 9.3.16, $e^{yt} = \sum_{n\geq 0} \frac{s_n(y)}{n!} g(t)f(t)^n$. Substitute $t = \overline{f}(u)$ and divide by $g(\overline{f}(u))$.
(ii) ($\Leftarrow$) If $S(x,u) = g(\overline{f}(u))^{-1}e^{x\overline{f}(u)}$, then $\sum_{n\geq 0} \frac{\langle g(t)f(t)^k \mid s_n\rangle}{n!}u^n = \langle g(t)f(t)^k \mid S(x,u)\rangle = u^k$,
so $\langle g(t)f(t)^k \mid s_n\rangle = n!\delta_{n,k}$.
(iii) ($\Rightarrow$) If (p_n) is associated, then $p_n(0) = \langle 1 \mid p_n\rangle = \delta_{n,0}$ and, for all k, $\langle f(t)^k \mid f(t)p_n - np_{n-1}\rangle = 0$.
Since $\{f(t)^k : k \geq 0\}$ separates $\mathscr{P}$, $f(t)p_n = np_{n-1}$.
(iii) ($\Leftarrow$) By the lowering relation, $f(t)^k p_n = (n)_k p_{n-k}$.
Hence $\langle f(t)^k \mid p_n\rangle = \langle 1 \mid f(t)^k p_n\rangle = (n)_k p_{n-k}(0) = n!\delta_{n,k}$.
(iv) ($\Rightarrow$) If (s_n) is Sheffer for (γ,f), then for all k, $\langle \gamma(t)f(t)^k \mid f(t)s_n - ns_{n-1}\rangle = 0$.
Since $\{\gamma(t)f(t)^k : k \geq 0\}$ separates $\mathscr{P}$, $f(t)s_n = ns_{n-1}$.
(iv) ($\Leftarrow$) Define $L \in \mathscr{P}'$ by $L(s_0) = 1$ and $L(s_n) = 0$ for $n > 0$, and put $\gamma := \Phi(L)$. Then $\langle \gamma \mid 1\rangle = L(1) \neq 0$, so $\gamma \in \mathscr{F}^\times$, and $\langle \gamma(t)f(t)^k \mid s_n\rangle = \langle \gamma(t) \mid f(t)^k s_n\rangle = (n)_k L(s_{n-k}) = n!\delta_{n,k}$.
(v) From (i), $e^{x\overline{f}(u)} = \sum_{k\geq 0} \frac{\overline{f}(u)^k}{k!} x^k$. The stated formula for p_n follows after extracting $n![u^n]$.
(vi) From (ii), $g(\overline{f}(u))^{-1}e^{x\overline{f}(u)} = \sum_{k\geq 0} \frac{g(\overline{f}(u))^{-1}\overline{f}(u)^k}{k!} x^k$. The stated formula for s_n follows after extracting $n![u^n]$.

Structural Commentary: $\overline{f}$ converts f-lowering to exponential generating functions.
Key Insight: Generating functions package the whole triangular duality into one formal identity. □

Definition 9.3.18. *Binomial Type and Sheffer Identity*
Let (p_n) and (s_n) be polynomial sequences.

(i) *Binomial type*: (p_n) is of binomial type if $p_n(x+y) = \sum_{k=0}^{n} \binom{n}{k} p_k(y)p_{n-k}(x)$.

(ii) *Sheffer identity*: (s_n) satisfies the Sheffer identity relative to (p_n) if $s_n(x+y) = \sum_{k=0}^{n} \binom{n}{k} p_k(y) s_{n-k}(x)$.

Theorem 9.3.19. *Action and Binomial Identities*
Let (s_n) be Sheffer for (g,f), let (p_n) be associated with f, and write $E_y := e^{yt}$. Then:

(i) for $h \in \mathscr{F}$ and $n \geq 0$, $h(t)s_n = \sum_{k=0}^{n} \binom{n}{k} \langle h \mid s_k \rangle p_{n-k}$;
(ii) (p_n) is associated with a delta series iff (p_n) is of binomial type;
(iii) (s_n) is Sheffer for some $g \in \mathscr{F}^\times$ and same f iff (s_n) satisfies the Sheffer identity relative to (p_n).

Proof.

(*i*) By Theorem 9.3.16, $h = \sum_{k \geq 0} \frac{\langle h | s_k \rangle}{k!} g(t) f(t)^k$.
Since $g(t)s_n = p_n$ and $f(t)^k p_n = (n)_k p_{n-k}$, $h(t)s_n = \sum_{k=0}^{n} \frac{\langle h|s_k\rangle}{k!} (n)_k p_{n-k}$.

(*ii*) ($\Rightarrow$) If (p_n) is associated, the formula in (i) holds with $s_n = p_n$, $g = 1$, and $h = E_y$.
Since $\langle E_y \mid p_k \rangle = p_k(y)$ and $E_y p_n(x) = p_n(x+y)$, (p_n) is of binomial type.

(*ii*) ($\Leftarrow$) If (p_n) is of binomial type, then $p_n(0) = \delta_{n,0}$. Define $Qp_n := np_{n-1}$. Then $QE_y p_n = E_y Q p_n$ for all n, y by the binomial identity, so $[Q, E_y] = 0$. By Theorem 9.3.14, $Q = f(t)$ for some $f \in \mathscr{F}$.
Since Q lowers degree by one, $o(f) = 1$; (p_n) is associated with f by Theorem 9.3.17.

(*iii*) ($\Rightarrow$) If (s_n) is Sheffer for (g,f), the formula in (i) holds with $h = E_y$.
Since $\langle E_y \mid s_k \rangle = s_k(y)$ and $E_y s_n(x) = s_n(x+y)$, $s_n(x+y) = \sum_{k=0}^{n} \binom{n}{k} s_k(y) p_{n-k}(x)$.
Relabel and swap x, y to get the Sheffer identity relative to (p_n).

(*iii*) ($\Leftarrow$) If the Sheffer identity holds, apply $f(t)$ in the y-variable and set $y = 0$.
Since $f(t)p_k(y)|_{y=0} = kp_{k-1}(0) = k\delta_{k,1}$, $f(t)s_n = ns_{n-1}$.
By Theorem 9.3.17, (s_n) is Sheffer for (g,f) for some $g \in \mathscr{F}^\times$.

Structural Commentary: Translation turns the operator formula into addition laws for polynomial sequences.
Key Insight: Binomial identities are the visible polynomial shadow of a delta operator. □

Example 9.3.20. *Standard Sheffer Examples*

(i) *Monomials*: $p_n(x) = x^n$ is associated with $f(t) = t$; the binomial identity is the usual binomial theorem.
(ii) *Lower factorials*: $(x)_n$ is associated with $f(t) = e^t - 1$, with $(1+t)^y = e^{y\log(1+t)} = \sum_{k \geq 0} \frac{(y)_k}{k!} t^k$,
and Vandermonde identity $(x+y)_n = \sum_{k=0}^{n} \binom{n}{k} (x)_k (y)_{n-k}$.
(iii) *Abel polynomials*: associated with $f(t) = te^{at}$, $A_n(x;a) = x(x-an)^{n-1}$.
(iv) *Hermite polynomials*: for $g(t) = e^{t^2/2}$, the polynomial is $H_n(x) = e^{-t^2/2} x^n$, where $e^{yt - t^2/2} = \sum_{k \geq 0} \frac{H_k(y)}{k!} t^k$.
(v) *Laguerre polynomials*: order α, Sheffer for $g(t) = (1-t)^{-\alpha-1}$, $f(t) = \frac{t}{t-1}$, $\frac{1}{(1-t)^{\alpha+1}} e^{yt/(t-1)} = \sum_{k \geq 0} \frac{L_k^{(\alpha)}(y)}{k!} t^k$.

Definition 9.3.21. *Umbral Operators and Shifts*
Let (s_n) be Sheffer for (g,f), and let (p_n) be associated with f.

(i) *Sheffer operator*: $\lambda_{g,f} \in \mathcal{L}(\mathscr{P})$ is defined by $\lambda_{g,f}(x^n) = s_n(x)$.
(ii) *Umbral operator*: $\lambda_f \in \mathcal{L}(\mathscr{P})$ is defined by $\lambda_f(x^n) = p_n(x)$.
(iii) *Sheffer/umbral shift*: $\theta_{g,f} s_n = s_{n+1}$; in the associated case, $\theta_f p_n = p_{n+1}$.

Definition 9.3.22. *Continuous Operators on the Umbral Algebra*
An operator $T \in \mathcal{L}(\mathscr{F})$ is *continuous* iff $o(f_k) \to \infty$ implies $o(Tf_k) \to \infty$.
Equivalently, for every defined formal sum with $o(f_k) \to \infty$, $T\left(\sum_{k \geq 0} a_k f_k\right) = \sum_{k \geq 0} a_k T(f_k)$.

Definition 9.3.23. *Algebraic Adjoints on the Umbral Algebra*
For $\tau \in \mathcal{L}(\mathscr{P})$, its *algebraic adjoint* $\tau^\times \in \mathcal{L}(\mathscr{F})$ is defined by $\langle \tau^\times h \mid p \rangle = \langle h \mid \tau p \rangle$ for $h \in \mathscr{F}$ and $p \in \mathscr{P}$. This is the dual-map adjoint of Definition 4.2.4, not an inner-product adjoint.

Theorem 9.3.24. *Continuous Operators Are Exactly Operator Adjoints*
Let $\mathcal{L}_{\mathrm{cont}}(\mathscr{F})$ denote the continuous linear operators on $\mathscr{F}$.
Then $(-)^\times : \mathcal{L}(\mathscr{P}) \xrightarrow{\sim} \mathcal{L}_{\mathrm{cont}}(\mathscr{F})$, $\tau \longmapsto \tau^\times$ is a vector-space isomorphism.

Proof.

(i) *Well-Definedness and Injectivity*: Let $\tau \in \mathcal{L}(\mathscr{P})$ and $o(h_j) \to \infty$. For fixed n, $\tau x^n \in \mathscr{P}$, hence $\langle \tau^\times h_j \mid x^n \rangle = \langle h_j \mid \tau x^n \rangle = 0$ for all sufficiently large j. Thus $o(\tau^\times h_j) \to \infty$, so $\tau^\times \in \mathcal{L}_{\mathrm{cont}}(\mathscr{F})$.
If $\tau^\times = 0$, then $\langle h \mid \tau p \rangle = 0$ for all h, p, hence $\tau = 0$; the map is injective.

(ii) *Surjectivity*: Let $T \in \mathcal{L}_{\mathrm{cont}}(\mathscr{F})$. Define $\tau_T x^n := \sum_{k \geq 0} \frac{\langle Tt^k | x^n \rangle}{k!} x^k$. Since $o(Tt^k) \to \infty$, the sum is finite for each n.
For all m, n, $\langle \tau_T^\times t^m \mid x^n \rangle = \langle t^m \mid \tau_T x^n \rangle = \langle Tt^m \mid x^n \rangle$. Thus $\tau_T^\times t^m = Tt^m$ for every m.
By continuity, $\tau_T^\times = T$, so the map is surjective.

Structural Commentary: Continuity is the finiteness condition for dualising polynomial operators.
Key Insight: Finiteness on each polynomial degree is the hidden topology. □

Theorem 9.3.25. *Umbral Operators and Adjoint Automorphisms*
Let f be a delta series, let $\overline{f}$ be its compositional inverse, let (p_n) be associated with f, and set $\lambda_f(x^n) = p_n(x)$. For $C_{\overline{f}}(h) := h(\overline{f})$ and $\lambda \in \mathcal{L}(\mathscr{P})$:

(i) $\lambda = \lambda_f$ iff $\lambda^\times = C_{\overline{f}}$; in this case $\lambda_f^\times f = t$.
(ii) λ is umbral iff $\lambda^\times \in \mathrm{Aut}_{\mathbb{C}\text{-}alg}(\mathscr{F})$.

Proof.

(i) ($\Rightarrow$) If $\lambda = \lambda_f$, then $\langle \lambda^\times f^k \mid x^n\rangle = \langle f^k \mid p_n\rangle = n!\delta_{n,k} = \langle t^k \mid x^n\rangle$, so $\lambda^\times f^k = t^k$. For $h \in \mathscr{F}$, put $q := h(\overline{f})$, so $h = q(f)$. Then $\lambda^\times h = q(t) = h(\overline{f}) = C_{\overline{f}}h$ by continuity. Hence $\lambda^\times = C_{\overline{f}}$ and $\lambda_f^\times f = t$.
(i) ($\Leftarrow$) If $\lambda^\times = C_{\overline{f}}$, set $r_n := \lambda x^n$. Then $\langle f^k \mid r_n\rangle = \langle \lambda^\times f^k \mid x^n\rangle = \langle t^k \mid x^n\rangle = n!\delta_{n,k}$.
Thus (r_n) is associated with f, so $r_n = p_n$ and $\lambda = \lambda_f$.
(ii) ($\Rightarrow$) If λ is umbral, then $\lambda = \lambda_u$ for some delta series u. By (i), $\lambda^\times = C_{\overline{u}} \in \mathrm{Aut}_{\mathbb{C}\text{-alg}}(\mathscr{F})$.
(ii) ($\Leftarrow$) Let $A := \lambda^\times \in \mathrm{Aut}_{\mathbb{C}\text{-alg}}(\mathscr{F})$ and set $u := A^{-1}t$. Since $A^{-1}((t)) = (t)$ and $A^{-1}((t)^2) = (t)^2$, $u \in (t) \setminus (t)^2$, so $o(u) = 1$. With $r_n := \lambda x^n$, $\langle u^k \mid r_n\rangle = \langle Au^k \mid x^n\rangle = \langle t^k \mid x^n\rangle = n!\delta_{n,k}$.
Hence (r_n) is associated with u, so $\lambda = \lambda_u$ is umbral.

Structural Commentary: Umbral adjoints are substitutions.
Key Insight: The delta series is $A^{-1}t$. □

Definition 9.3.26. *Umbral Composition*

For polynomial sequences (p_n) and (q_n) with $p_n(x) = \sum_{k=0}^n p_{n,k}x^k$, define $(p \circ_U q)_n(x) := \sum_{k=0}^n p_{n,k}q_k(x)$.

Theorem 9.3.27. *Group Law for Umbral Operators*
Let f, g be delta series, and let (p_n) and (q_n) be associated with f and g. Then:

(i) $\lambda_g\lambda_f = \lambda_{f\circ g}$.
(ii) $\lambda_f^{-1} = \lambda_{\overline{f}}$.
(iii) $(p \circ_U q)_n = (\lambda_g\lambda_f)x^n$; hence associated sequences form a group under $\circ_U$.

Proof.

(i) By $(AB)^\times = B^\times A^\times$ and Theorem 9.3.25, for $h \in \mathscr{F}$, $(\lambda_g\lambda_f)^\times h = \lambda_f^\times \lambda_g^\times h = h(\overline{g}(\overline{f})) = h(\overline{f \circ g})$. QED.
(ii) Put $g = \overline{f}$ in (i). Then $\lambda_{\overline{f}}\lambda_f = \lambda_t = I$ and $\lambda_f\lambda_{\overline{f}} = \lambda_t = I$, so $\lambda_f^{-1} = \lambda_{\overline{f}}$.
(iii) If $p_n = \sum_{k=0}^n p_{n,k}x^k$, then $(\lambda_g\lambda_f)x^n = \lambda_g p_n = \sum_{k=0}^n p_{n,k}q_k = (p \circ_U q)_n$.
By (i) and (ii), the operation inherits associativity, identity, and inverses from operator composition.

Structural Commentary: Umbral composition is substitution of delta series.
Key Insight: Adjoints reverse the operator composition. □

Proposition 9.3.28. *Sheffer Operators*
Let f, k be delta series, $g, h \in \mathscr{F}^\times$, (s_n) Sheffer for (g, f), and (p_n) associated with f. Then:

(i) $s_n = g(t)^{-1}p_n$ and $\lambda_{g,f} = g(t)^{-1}\lambda_f$.
(ii) $\lambda_{g,f}\lambda_{h,k} = \lambda_{g(h\circ f),\, k\circ f}$.
(iii) $\lambda_{g,f}^{-1} = \lambda_{g^{-1}(\overline{f}),\, \overline{f}}$.

Proof.

(i) $g(t)s_n = p_n$ by Theorem 9.3.16, hence $s_n = g(t)^{-1}p_n$ and $\lambda_{g,f} = g(t)^{-1}\lambda_f$.
(ii) For $a \in \mathscr{F}$, $\lambda_f a(t) = a(f(t))\lambda_f$ by Theorem 9.3.25.
Thus $\lambda_{g,f}\lambda_{h,k} = g(t)^{-1}\lambda_f h(t)^{-1}\lambda_k = g(t)^{-1}h(f(t))^{-1}\lambda_{k\circ f} = \lambda_{g(h\circ f),\, k\circ f}$.
(iii) In (ii), take $(h, k) = (g^{-1}(\overline{f}), \overline{f})$ to get $\lambda_{g,f}\lambda_{g^{-1}(\overline{f}),\,\overline{f}} = \lambda_{1,t} = I$.
Reversing the factors, $\lambda_{g^{-1}(\overline{f}),\,\overline{f}}\lambda_{g,f} = \lambda_{g^{-1}(\overline{f})(g\circ\overline{f}),\, f\circ\overline{f}} = \lambda_{1,t} = I$.

Structural Commentary: Weight then umbral substitution.
Key Insight: $(g, f)(h, k) = (g(h \circ f), k \circ f)$. □

Theorem 9.3.29. *Umbral Shift Derivations*
Let f be a delta series and let θ_f be its umbral shift. Define the continuous derivation $\partial_f : \mathscr{F} \to \mathscr{F}$ by $\partial_f(f^k) = kf^{k-1}$, $k \geq 0$. Then:

(i) $\theta_f^\times = \partial_f$.
(ii) $\partial_f f = 1$.
(iii) If g is a delta series, then $\partial_g = (\partial_g f)\partial_f$.

Proof.

(i) Let (p_n) be associated with f.
For $k, n \geq 0$, $\langle \theta_f^\times f^k \mid p_n\rangle = \langle f^k \mid p_{n+1}\rangle = (n+1)!\delta_{n+1,k} = \langle kf^{k-1} \mid p_n\rangle$.
Hence $\theta_f^\times f^k = kf^{k-1}$ for all k, so $\theta_f^\times = \partial_f$ by continuity.
(ii) By definition of ∂_f, $\partial_f f = \partial_f(f^1) = 1 \cdot f^0 = 1$.
(iii) It suffices by continuity to test on f^k: $(\partial_g f)\partial_f(f^k) = k(\partial_g f)f^{k-1} = \partial_g(f^k)$.

Structural Commentary: Umbral shift is delta-coordinate differentiation.
Key Insight: The associated basis turns shifts into derivatives. □

Theorem 9.3.30. *Umbral Shifts and Surjective Derivations*
For $\theta \in \mathcal{L}(\mathscr{P})$, θ is an umbral shift $\iff$ $\theta^\times$ is a surjective derivation of $\mathscr{F}$.

Proof.

($\Rightarrow$) If $\theta = \theta_f$, then $\theta^\times = \partial_f$ by Theorem 9.3.29. Since $\partial_f\left(\frac{f^{k+1}}{k+1}\right) = f^k$, $k \geq 0$, ∂_f is a surjective derivation.

($\Leftarrow$) Let $D := \theta^\times$ be a surjective derivation. Choose $u \in \mathscr{F}$ with $Du = 1$ and set $f := u - [t^0]u$.
Then $Df = 1$ and, since D lowers order by one, $o(f) = 1$. Let (p_n) be associated with f.
For $k, n \geq 0$, $\langle f^k \mid \theta p_n\rangle = \langle Df^k \mid p_n\rangle = \langle kf^{k-1} \mid p_n\rangle = \langle f^k \mid p_{n+1}\rangle$.
The functionals f^k separate $\mathscr{P}$, so $\theta p_n = p_{n+1}$ and $\theta = \theta_f$.

Structural Commentary: Surjective derivations are derivatives in delta coordinates.
Key Insight: Surjectivity chooses the coordinate whose derivative is 1. □

Figure 187 summarizes the adjoint correspondences established by Theorems 9.3.25 and 9.3.30: umbral operators correspond to algebra automorphisms, while umbral shifts correspond to surjective derivations.

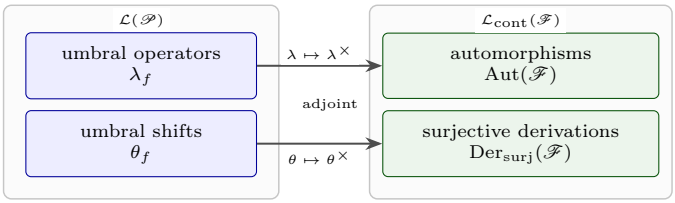

Figure 187: Adjoints identify $\mathcal{L}(\mathscr{P})$ with $\mathcal{L}_{\mathrm{cont}}(\mathscr{F})$ and map the umbral classes shown.

9.4 Umbral Recurrences and Variants

Lemma 9.4.1. *Pincherle Commutator*
For $a(t) \in \mathscr{F}$, $xa(t) = a(t)x - a'(t)$ as operators on $\mathscr{P}$.

Proof. Since t acts as differentiation and x as multiplication, $tx = xt + 1$. By induction on k, $xt^k = t^k x - kt^{k-1}$ for $k \geq 0$. For $a(t) = \sum_{k\geq 0} a_k t^k/k!$, the operator sum is finite on each polynomial, so $xa(t) = a(t)x - a'(t)$.
Structural Commentary: The basic commutator extends coefficientwise from monomials to formal series.
Key Insight: The relation $tx - xt = 1$ differentiates operator series. □

Theorem 9.4.2. *Recurrence and Transfer Formulas*
Let (p_n) be associated with the delta series f, and set $u(t) := f(t)/t \in \mathscr{F}^\times$. Then:
(i) $p_{n+1} = x[f'(t)]^{-1}p_n$ for $n \geq 0$.
(ii) $p_n = f'(t)u(t)^{-n-1}x^n = xu(t)^{-n}x^{n-1}$ for $n \geq 1$.

Proof.
(i) By Theorem 9.3.29, $\theta_t = (\partial_t f)\theta_f = f'(t)\theta_f$. Since $\theta_t = x$ and $\theta_f p_n = p_{n+1}$, $p_{n+1} = x[f'(t)]^{-1}p_n$.
(ii) Put $q_n := f'u^{-n-1}x^n$. Then $q_0 = f'u^{-1}1 = 1 = p_0$. By Lemma 9.4.1, $xa(t) = a(t)x - a'(t)$ for $a \in \mathscr{F}$.
$q_{n+1} = f'u^{-n-2}x^{n+1} = xu^{-n-1}x^n = x(f')^{-1}q_n$. Thus $q_n = p_n$ by (i).
By Lemma 9.4.1 with $a = u^{-n}$, $xu^{-n}x^{n-1} = u^{-n}x^n + nu^{-n-1}u'x^{n-1} = f'u^{-n-1}x^n$.

Structural Commentary: The recurrence determines (p_n); transfer solves it using $f = tu$.
Key Insight: The Pincherle commutator converts the shift recurrence into closed form. □

Corollary 9.4.3. *Sheffer Shift Formula*
Let (s_n) be Sheffer for (g, f), with f delta and $g \in \mathscr{F}^\times$. Write $f' = f'(t)$ and $g' = g'(t)$. Then:
(i) $\theta_{g,f} = g^{-1}\theta_f g = \left(x - \frac{g'}{g}\right)(f')^{-1}$.
(ii) $s_{n+1} = \left(x - \frac{g'}{g}\right)(f')^{-1}s_n$ for $n \geq 0$.

Proof.
(i) Since gs_n is associated with f, $\theta_{g,f} = g^{-1}\theta_f g$. By Theorem 9.4.2, $\theta_f = x(f')^{-1}$.
By Lemma 9.4.1, $g' = gx - xg$. Since f' and g commute, $g^{-1}\theta_f g = g^{-1}x(f')^{-1}g = g^{-1}xg(f')^{-1} = \left(x - \frac{g'}{g}\right)(f')^{-1}$.
(ii) By definition of the Sheffer shift, $\theta_{g,f}s_n = s_{n+1}$ for $n \geq 0$. By (i), $s_{n+1} = \theta_{g,f}s_n = \left(x - \frac{g'}{g}\right)(f')^{-1}s_n$.

Structural Commentary: Sheffer shifts are conjugated associated shifts.
Key Insight: Conjugation by g contributes the correction g'/g. □

Method 9.4.4. *Building Sheffer Sequences*
To construct the Sheffer sequence for (g, f):
(i) Verify $o(f) = 1$ and $o(g) = 0$.
(ii) If $\overline{f}$ is explicit, compute $S(y,t) := g(\overline{f}(t))^{-1}e^{y\overline{f}(t)}$, where $s_n(y) = n![t^n]S(y,t)$.
(iii) If $\overline{f}$ is unavailable, solve recursively from $f(t)s_n = ns_{n-1}$, where $\langle g(t)f(t)^k \mid s_n\rangle = n!\delta_{n,k}$.
(iv) For associated sequences, set $g = 1$ and compute p_n by Theorem 9.4.2.

Definition 9.4.5. *Stirling and Exponential Polynomials*
(i) *Stirling numbers*: $S(n,k)$ are defined by $x^n = \sum_{k=0}^{n} S(n,k)(x)_k$.
(ii) *Exponential polynomials*: define $\phi_n(x) := \sum_{k=0}^{n} S(n,k)x^k$.

(iii) *Boundary convention*: $S(n,-1)=0$ and $S(n,k)=0$ for $k>n$.

Example 9.4.6. *Lower Factorials and Stirling Numbers*
For $f(t)=e^t-1$, $f'(t)=e^t$, hence $p_{n+1}(x)=xe^{-t}p_n(x)=xp_n(x-1)$. With $p_0=1$, therefore $p_n=(x)_n$.
For $f(t)=\log(1+t)$, $\overline{f}(t)=e^t-1$, and the associated sequence is (ϕ_n).
The inverse umbral relation is $x^n=\sum_{k=0}^{n} S(n,k)(x)_k$, and $\phi_n(x)=\sum_{k=0}^{n} S(n,k)x^k$.
By the recurrence formula, $\phi_{n+1}(x)=x(1+t)\phi_n(x)=x\big(\phi_n(x)+\phi_n'(x)\big)$.
Thus $S(n+1,k)=S(n,k-1)+kS(n,k)$ by coefficient comparison.

Definition 9.4.7. *Gaussian Coefficients*
For an indeterminate q and integers $0\le k\le n$, $\binom{n}{k}_q := \prod_{j=1}^{n}(1-q^j)/\left(\prod_{j=1}^{k}(1-q^j)\prod_{j=1}^{n-k}(1-q^j)\right)$.

Remark 9.4.8. *Further Directions*
Classical umbral methods extend to many polynomial families and operations:

(i) *Families*: lower factorial, Stirling, exponential, Gould, central factorial, Abel, Mittag–Leffler, Bessel, Bell, Hermite, Bernoulli, Euler, Laguerre, Poisson–Charlier, actuarial, Meixner, Pidduck, Narumi, Boole, Peters, Mahler, and Mott polynomials.
(ii) *Operations*: connection constants, duplication formulas, Lagrange inversion, cross sequences, Steffensen sequences, operational formulas, inverse relations, recurrence solving, and binomial convolution.
(iii) *q-umbral calculus*: the deformation $\binom{n}{k}\rightsquigarrow\binom{n}{k}_q$ through the Gaussian coefficients of Definition 9.4.7.
(iv) *Logarithmic umbral calculus*: the logarithmic-type variant based on harmonic logarithms.

10 Fourier Structure

10.1 Fourier Orthogonality

Fourier structure studies trigonometric series through orthogonality, projection, kernels, and convergence, with inner-product geometry reappearing throughout.

Definition 10.1.1. *Core Fourier Objects*

(i) A *trigonometric polynomial* is a finite sum $a_0+\sum_{n=1}^{N}(a_n\cos nx+b_n\sin nx)$, equivalently $\sum_{n=-N}^{N}\alpha_n e^{inx}$.
(ii) If f is Riemann integrable on $[-\pi,\pi]$, its *Fourier coefficients* are $\widehat{f}(m):=\frac{1}{2\pi}\int_{-\pi}^{\pi}f(x)e^{-imx}\,dx$, $m\in\mathbb{Z}$, and $f(x)\sim_{\text{coef}}\sum_{m=-\infty}^{\infty}\widehat{f}(m)e^{imx}$ records coefficients, not convergence.
(iii) A sequence (ϕ_n) on $[a,b]$ is *orthonormal* if $\int_a^b\phi_n(x)\overline{\phi_m(x)}\,dx=0$ $(n\neq m)$ and $\int_a^b|\phi_n(x)|^2\,dx=1$.
Its Fourier coefficients are $c_n:=\int_a^b f(t)\overline{\phi_n(t)}\,dt$.

Key Insight: Fourier coefficients are orthonormal coordinates; convergence is a separate analytic question.

Definition 10.1.2. *Period-One Fourier Normalization*
Let $C(\mathbb{R}/\mathbb{Z};\mathbb{C})$ denote the continuous functions $f:\mathbb{R}\to\mathbb{C}$ satisfying $f(x+1)=f(x)$, $x\in\mathbb{R}$.
For $f,g\in C(\mathbb{R}/\mathbb{Z};\mathbb{C})$, set $\langle f,g\rangle_{\mathbb{T}}:=\int_0^1 f(x)\overline{g(x)}\,dx$; $\|f\|_{L^2(\mathbb{T})}:=\sqrt{\langle f,f\rangle_{\mathbb{T}}}$; and $e_n(x):=e^{2\pi inx}$ for $n\in\mathbb{Z}$.
The *period-one Fourier coefficient* is $\widehat{f}_{\mathbb{T}}(n):=\langle f,e_n\rangle_{\mathbb{T}}=\int_0^1 f(x)e^{-2\pi inx}\,dx$.
A period-one trigonometric polynomial is a finite sum $\sum_{n=-N}^{N}c_ne_n$.

Perspective 10.1.3. *Two Equivalent Fourier Clocks*
The period-one and 2π-periodic conventions differ by $t=2\pi x$; only normalizing constants change.
Key Insight: Changing Fourier clocks changes constants, not the projection geometry.

Proposition 10.1.4. *Characters Are an Orthonormal System*
For $m,n\in\mathbb{Z}$ and $N\ge 0$:

(i) $\langle e_n,e_m\rangle_{\mathbb{T}}=\delta_{n,m}$.
(ii) If $P=\sum_{k=-N}^{N}c_ke_k$, *then* $\langle P,e_n\rangle_{\mathbb{T}}=c_n$ *for* $-N\le n\le N$, *and* $\|P\|_{L^2(\mathbb{T})}^2=\sum_{k=-N}^{N}|c_k|^2$.

Proof.

(i) $\langle e_n,e_m\rangle_{\mathbb{T}}=\int_0^1 e^{2\pi i(n-m)x}\,dx$. This equals 1 if $n=m$ and $\frac{e^{2\pi i(n-m)}-1}{2\pi i(n-m)}=0$ if $n\neq m$.
(ii) By (i), $\langle P,e_n\rangle_{\mathbb{T}}=\sum_{k=-N}^{N}c_k\delta_{k,n}=c_n$, and $\|P\|_{L^2(\mathbb{T})}^2=\langle P,P\rangle_{\mathbb{T}}=\sum_{j,k=-N}^{N}c_j\overline{c_k}\delta_{j,k}=\sum_{k=-N}^{N}|c_k|^2$.

Structural Commentary: The Gram matrix of $\{e_{-N},\dots,e_N\}$ is the identity.
Key Insight: Character orthogonality kills all cross terms. □

10.2 Fourier Approximation

Perspective 10.2.1. *Fourier and Plancherel Roadmap*
Path: orthonormal characters, Fejer density, best L^2 projection, then Parseval/Plancherel.
Key Insight: Fourier theory is finite-dimensional orthogonal projection plus an approximation theorem.

Definition 10.2.2. *Periodic Convolution and Fejer Kernels*
For $f,g\in C(\mathbb{R}/\mathbb{Z};\mathbb{C})$, define their *periodic convolution* as $(f*g)(x):=\int_0^1 f(y)g(x-y)\,dy$.
For $N\ge 1$, the *Fejer kernel* is $F_N(x):=\sum_{n=-N}^{N}\left(1-\frac{|n|}{N}\right)e_n(x)=\frac{1}{N}\left|\sum_{n=0}^{N-1}e_n(x)\right|^2$.

Figure 188 schematically compares two concentration profiles with $N > M$: the larger-index kernel is narrower around 0, and the shaded window marks a central interval of width 2δ. The curves are qualitative rather than exact plots of F_M and F_N.

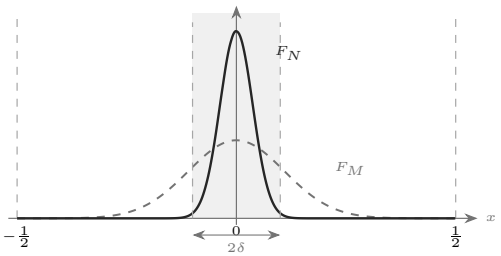

Figure 188: Qualitative concentration of period-one Fejer kernels near 0: for $N > M$, the F_N profile is narrower than F_M, and the central window has width 2δ.

Theorem 10.2.3. *Fejer Approximation on $\mathbb{R}/\mathbb{Z}$*
Let F_N be the period-one Fejer kernel, $N \geq 1$. Then:

(i) F_N is a nonnegative trigonometric polynomial and $\int_0^1 F_N(x)\,dx = 1$.
(ii) If $0 < \delta < 1/2$, then $\sup_{\delta \leq x \leq 1-\delta} F_N(x) \to 0$.
(iii) If $f \in C(\mathbb{R}/\mathbb{Z};\mathbb{C})$, then $f * F_N$ is a trigonometric polynomial for $N \geq 1$.
(iv) If $f \in C(\mathbb{R}/\mathbb{Z};\mathbb{C})$, then $f * F_N \rightrightarrows f$ on $\mathbb{R}/\mathbb{Z}$.

Proof.

(i) By definition, $F_N = \sum_{n=-N}^{N} \left(1 - \frac{|n|}{N}\right) e_n$ is trigonometric, and $F_N = \frac{1}{N}\left|\sum_{n=0}^{N-1} e_n\right|^2 \geq 0$.
Since $\int_0^1 e_n(x)\,dx = 0$ for $n \neq 0$, $\int_0^1 F_N(x)\,dx = 1$ by the e_0 coefficient.

(ii) For $x \notin \mathbb{Z}$, $F_N(x) = \frac{\sin^2(\pi N x)}{N \sin^2(\pi x)}$. If $m_\delta := \min_{\delta \leq x \leq 1-\delta} \sin^2(\pi x) > 0$, then $0 \leq F_N(x) \leq \frac{1}{N m_\delta}$ on $[\delta, 1-\delta]$.

(iii) Since $f * e_n = \widehat{f}_{\mathbb{T}}(n) e_n$ and F_N is a finite linear combination of the e_n, $f * F_N$ is a trigonometric polynomial.

(iv) Write $(f * F_N)(x) = \int_0^1 f(x-t) F_N(t)\,dt$. Let $M = \|f\|_\infty$ and $\varepsilon > 0$.
By uniform continuity, choose $0 < \delta < 1/2$ such that $|f(x-t) - f(x)| < \varepsilon$ for $x \in \mathbb{R}/\mathbb{Z}$ and $t \in [0,\delta] \cup [1-\delta, 1]$.
By (i), $F_N \geq 0$ and $\int_0^1 F_N(t)\,dt = 1$; hence $|(f * F_N)(x) - f(x)| \leq \varepsilon + 2M \sup_{\delta \leq t \leq 1-\delta} F_N(t)$.
By (ii), $\limsup_{N\to\infty} \|f * F_N - f\|_\infty \leq \varepsilon$. Since ε is arbitrary, $f * F_N \rightrightarrows f$.

Structural Commentary: Fejer kernels are positive approximate identities.
Key Insight: Normalized mass concentrating at 0 forces uniform convergence. □

Corollary 10.2.4. *Uniform Approximation by Trigonometric Polynomials*
Let $f \in C(\mathbb{R};\mathbb{C})$ be 2π-periodic. Then $\forall \varepsilon > 0$, $\exists N \geq 0$ and $c_{-N}, \ldots, c_N \in \mathbb{C}$ such that $P(x) := \sum_{n=-N}^{N} c_n e^{inx}$ satisfies $\|f - P\|_\infty < \varepsilon$.

Proof. Let $\mathbb{T} := \{z \in \mathbb{C} : |z| = 1\}$ and define $F : \mathbb{T} \to \mathbb{C}$ by $F(e^{ix}) := f(x)$.
Periodicity makes F well-defined and continuous.
The algebra $\mathcal{T} := \operatorname{span}\{z^n : n \in \mathbb{Z}\} \subset C(\mathbb{T})$ is self-adjoint, separates points, and vanishes nowhere.
By Theorem 9.2.9, choose $Q(z) = \sum_{n=-N}^{N} c_n z^n \in \mathcal{T}$ with $\|F - Q\|_{C(\mathbb{T})} < \varepsilon$.
Set $P(x) := Q(e^{ix}) = \sum_{n=-N}^{N} c_n e^{inx}$; then $\|f - P\|_\infty = \|F - Q\|_{C(\mathbb{T})} < \varepsilon$.
Structural Commentary: Trigonometric polynomials are Laurent polynomials pulled back from $\mathbb{T}$.
Key Insight: Uniform periodic approximation follows from Stone–Weierstrass on $\mathbb{T}$. □

Perspective 10.2.5. *Fourier Coefficients as Projections*
Fourier coefficients are projections onto orthonormal directions, modeled finitely by Theorems 2.1.5, 1.4.1, and 1.4.5; infinite directions make convergence separate.

Theorem 10.2.6. *Best Mean-Square Approximation by Fourier Coefficients*
Let $\langle u, v\rangle := \int_a^b u\overline{v}$ and $\|u\|_2^2 := \langle u, u\rangle$. Let (ϕ_m) be orthonormal and let f satisfy $\|f\|_2 < \infty$.
For $n \geq 1$, set $c_m := \langle f, \phi_m\rangle$, $s_n := \sum_{m=1}^{n} c_m \phi_m$, and $t_n := \sum_{m=1}^{n} \gamma_m \phi_m$. Then:

(i) $\|f - s_n\|_2 \leq \|f - t_n\|_2$, with equality iff $\gamma_m = c_m$ for $m = 1, \ldots, n$.
(ii) $\sum_{m=1}^{\infty} |c_m|^2 \leq \|f\|_2^2$, hence $c_m \to 0$.

Proof.

(i) ($\Rightarrow$) By orthonormality, $\|f - t_n\|_2^2 = \|f\|_2^2 - 2\operatorname{Re}\sum_{m=1}^{n} c_m\overline{\gamma_m} + \sum_{m=1}^{n} |\gamma_m|^2 = \|f\|_2^2 - \sum_{m=1}^{n} |c_m|^2 + \sum_{m=1}^{n} |\gamma_m - c_m|^2$. Thus $\|f - t_n\|_2^2 \geq \|f - s_n\|_2^2$; equality implies $\gamma_m = c_m$ for $1 \leq m \leq n$.

(i) ($\Leftarrow$) If $\gamma_m = c_m$ for $1 \leq m \leq n$, then $t_n = s_n$, so equality holds.

(*ii*) By the identity in (i) with $\gamma_m = c_m$, $\|f - s_n\|_2^2 = \|f\|_2^2 - \sum_{m=1}^{n} |c_m|^2 \geq 0$.

Hence $\sum_{m=1}^{n} |c_m|^2 = \|s_n\|_2^2 \leq \|f\|_2^2$ for $n \geq 1$. Letting $n \to \infty$, $\sum_{m=1}^{\infty} |c_m|^2 \leq \|f\|_2^2$.

Since $(|c_m|^2)$ is summable, $|c_m|^2 \to 0$, hence $c_m \to 0$.

Structural Commentary: Orthogonality diagonalizes the finite error.
Key Insight: Fourier coefficients are projection coordinates. □

Theorem 10.2.7. *Dirichlet Kernel and Local Fourier Convergence*
Let f be Riemann integrable and 2π-periodic, with $\widehat{f}(m) := \frac{1}{2\pi}\int_{-\pi}^{\pi} f(t)e^{-imt}\,dt$.
For $N \geq 0$, set $s_N(f;x) := \sum_{m=-N}^{N} \widehat{f}(m)e^{imx}$ and $D_N(t) := \sum_{m=-N}^{N} e^{imt}$. Then:

(i) $D_N(t) = \frac{\sin((N+\frac{1}{2})t)}{\sin(t/2)}$ *for $t \notin 2\pi\mathbb{Z}$, with $D_N(0) = 2N+1$, and $s_N(f;x) = \frac{1}{2\pi}\int_{-\pi}^{\pi} f(x-t)D_N(t)\,dt$.*
(ii) If $x \in \mathbb{R}$ and $\exists M, \delta > 0$ such that $|f(x+t) - f(x)| \leq M|t|$ for $|t| < \delta$, then $s_N(f;x) \to f(x)$.
(iii) If g is Riemann integrable and 2π-periodic and $f = g$ near x, then $s_N(f;x) - s_N(g;x) \to 0$.

Proof.

(i) For $z = e^{it} \neq 1$, $D_N(t) = z^{-N}\frac{1-z^{2N+1}}{1-z} = \frac{\sin((N+\frac{1}{2})t)}{\sin(t/2)}$, and $D_N(0) = \sum_{m=-N}^{N} 1 = 2N+1$.

After substituting $\widehat{f}(m)$ and interchanging the finite sum with the integral, $s_N(f;x) = \frac{1}{2\pi}\int_{-\pi}^{\pi} f(u)\sum_{m=-N}^{N} e^{im(x-u)}\,du = \frac{1}{2\pi}\int_{-\pi}^{\pi} f(x-t)D_N(t)\,dt$.

(ii) By (i) and $\frac{1}{2\pi}\int_{-\pi}^{\pi} D_N(t)\,dt = 1$, $s_N(f;x) - f(x) = \frac{1}{2\pi}\int_{-\pi}^{\pi}(f(x-t) - f(x))D_N(t)\,dt$.

Set $q_x(t) := \frac{f(x-t)-f(x)}{\sin(t/2)}$ for $0 < |t| \leq \pi$ and $q_x(0) := 0$. The hypothesis makes q_x bounded near 0 and Riemann integrable on $[-\pi,\pi]$. Hence $s_N(f;x) - f(x) = \frac{1}{2\pi}\int_{-\pi}^{\pi} q_x(t)\sin((N+\frac{1}{2})t)\,dt$.

Since $\sin((N+\frac{1}{2})t) = \sin Nt\cos(t/2) + \cos Nt\sin(t/2)$, both terms tend to 0 by Theorem 10.2.6 for $q_x(t)\cos(t/2)$ and $q_x(t)\sin(t/2)$.

(iii) For $h := f - g$, $h = 0$ near x, so $s_N(h;x) \to h(x) = 0$ by (ii).
By linearity, $s_N(h;x) = s_N(f;x) - s_N(g;x)$.

Structural Commentary: Dirichlet kernels express partial sums as oscillatory local averages.
Key Insight: Local regularity makes the oscillatory error vanish. □

Theorem 10.2.8. *Parseval's Theorem for Trigonometric Fourier Series*
Let f, g be Riemann integrable and 2π-periodic.
Set $\langle u, v\rangle_2 := \frac{1}{2\pi}\int_{-\pi}^{\pi} u(x)\overline{v(x)}\,dx$, $\|u\|_2^2 := \langle u, u\rangle_2$, and $s_N(f) := \sum_{|n|\leq N} \widehat{f}(n)e^{inx}$. Then:

(i) $\|f - s_N(f)\|_2 \to 0$.
(ii) $\langle f, g\rangle_2 = \sum_{n\in\mathbb{Z}} \widehat{f}(n)\overline{\widehat{g}(n)}$.
(iii) $\|f\|_2^2 = \sum_{n\in\mathbb{Z}} \left|\widehat{f}(n)\right|^2$.

Proof.

(i) Put $d_N(u) := \|u - s_N(u)\|_2$. If u is continuous, choose a trigonometric polynomial P with $\|u - P\|_2 < \varepsilon$ by Corollary 10.2.4. For $N \geq \deg P$, $d_N(u) \leq \|u - P\|_2 < \varepsilon$ by Theorem 10.2.6, so $d_N(u) \to 0$.
For Riemann integrable f, choose continuous h with $\|f - h\|_2 < \varepsilon$.
Since $\|s_N(h - f)\|_2 \leq \|h - f\|_2$, $d_N(f) \leq 2\|f - h\|_2 + d_N(h)$; hence $\limsup_{N\to\infty} d_N(f) \leq 2\varepsilon$. Let $\varepsilon \downarrow 0$.

(ii) By orthogonality, $\langle e^{inx}, g\rangle_2 = \overline{\widehat{g}(n)}$. Hence $\langle s_N(f), g\rangle_2 = \sum_{|n|\leq N} \widehat{f}(n)\langle e^{inx}, g\rangle_2 = \sum_{|n|\leq N} \widehat{f}(n)\overline{\widehat{g}(n)}$.

By (i) and Cauchy–Schwarz, $\langle s_N(f), g\rangle_2 \to \langle f, g\rangle_2$.

(iii) Set $g = f$ in (ii). Then $\widehat{g}(n) = \widehat{f}(n)$ and $\langle f, f\rangle_2 = \|f\|_2^2$, so $\|f\|_2^2 = \sum_{n\in\mathbb{Z}} \left|\widehat{f}(n)\right|^2$.

Structural Commentary: Density turns finite projection identities into L^2 identities.
Key Insight: Partial Fourier projections converge in L^2. □

Method 10.2.9. *Fourier Proof Patterns*
(i) *Characters*: use orthogonality of e_n to compute coefficients and finite-dimensional projections.
(ii) *Kernels*: rewrite partial sums or averages as convolutions with Dirichlet or Fejer kernels.
(iii) *Approximation*: use Fejer positivity or Stone–Weierstrass to approximate continuous periodic functions by trigonometric polynomials.
(iv) *L^2 control*: project onto finite orthonormal spans, then pass to limits by density.
(v) *Localization*: express the error as an oscillatory integral and use local regularity near the point.

Key Insight: Fourier theory is finite-dimensional orthogonal projection plus an approximation theorem.

10.3 Further Topics in Fourier Analysis

Example 10.3.1. *A Gaussian Fourier Integral*
Define $f(t) = \int_{-\infty}^{\infty} e^{-x^2}\cos(xt)\,dx$ and $g(t) = -\int_{-\infty}^{\infty} xe^{-x^2}\sin(xt)\,dx$.
For $R > 0$, set $f_R(t) := \int_{-R}^{R} e^{-x^2}\cos(xt)\,dx$ and $g_R(t) := -\int_{-R}^{R} xe^{-x^2}\sin(xt)\,dx$. Then $f_R' = g_R$ by Theorem 7.2.3.
The Gaussian tail bounds make $g_R \rightrightarrows g$ on every bounded t-interval and $f_R(t_0) \to f(t_0)$ at each fixed t_0, so $f' = g$ by Theorem 7.2.4.

By Theorem 2.2.3 on $[-R, R]$, $2g_R(t) + tf_R(t) = 2e^{-R^2}\sin(Rt)$. Letting $R \to \infty$, $2f'(t) + tf(t) = 0$.
By Theorem 9.1.22(iv), $f(0) = \sqrt{\pi}$. Since $\frac{d}{dt}\left(e^{t^2/4}f(t)\right) = 0$, $f(t) = \sqrt{\pi}\exp\left(-\frac{t^2}{4}\right)$.

Part XIII
Measure Foundations and Extension

1 Sigma-Algebras and Measurable Spaces

1.1 Sigma-Algebras and Measurable Structures

Measure theory first builds measurable sets, then measurable functions and integrals. Outer measure covers from outside; measurability splits test sets without losing measure.

Perspective 1.1.1. *Why Abstract Measure Comes First*
Lebesgue integration is built so that, under hypotheses such as domination, $f_n \to f$ implies $\int f_n\,d\mu \to \int f\,d\mu$. The abstract data separate into a measurable space $(X, \mathcal{M})$, a countably additive measure $\mu : \mathcal{M} \to [0, +\infty]$, and an integral defined by approximation from simple functions.
Key Insight: Countable additivity is the set-level structure behind the convergence theorems.

Definition 1.1.2. *σ-Algebras and Measurable Spaces*
Let X be a set. A family $\mathcal{M} \subseteq \mathcal{P}(X)$ is a *σ-algebra* on X if:

(i) $\emptyset, X \in \mathcal{M}$;
(ii) $E \in \mathcal{M}$ implies $X \setminus E \in \mathcal{M}$;
(iii) $E_n \in \mathcal{M}$ for $n \in \mathbb{N}$ implies $\bigcup_{n=1}^{\infty} E_n \in \mathcal{M}$.

The pair $(X, \mathcal{M})$ is a *measurable space*; the members of $\mathcal{M}$ are *measurable sets*.

Proposition 1.1.3. *Closure and Generation for σ-Algebras*
Let $\mathcal{M} \subseteq \mathcal{P}(X)$ be a σ-algebra.

(i) $(E_n)_{n\in\mathbb{N}} \subseteq \mathcal{M} \Rightarrow \bigcap_{n=1}^{\infty} E_n \in \mathcal{M}$.
(ii) If $(\mathcal{M}_\alpha)_{\alpha\in A}$ is a nonempty family of σ-algebras on X, then $\bigcap_{\alpha\in A} \mathcal{M}_\alpha$ is a σ-algebra on X.
(iii) For $\mathcal{A} \subseteq \mathcal{P}(X)$, let $\mathscr{S}_{\mathcal{A}}$ be the family of σ-algebras $\mathcal{N}$ on X with $\mathcal{A} \subseteq \mathcal{N}$. Then $\sigma(\mathcal{A}) := \bigcap_{\mathcal{N}\in\mathscr{S}_{\mathcal{A}}} \mathcal{N}$ is the smallest σ-algebra containing $\mathcal{A}$.

Proof.
(i) By Theorem 1.5.2, $\bigcap_n E_n = X \setminus \bigcup_n (X \setminus E_n) \in \mathcal{M}$ since $(X \setminus E_n)_{n\in\mathbb{N}} \subseteq \mathcal{M}$.
(ii) Set $\mathcal{N} := \bigcap_{\alpha\in A} \mathcal{M}_\alpha$. Then $\emptyset, X \in \mathcal{N}$, and $E \in \mathcal{N}$ implies $X \setminus E \in \mathcal{N}$. Likewise $(E_n) \subseteq \mathcal{N}$ implies $\bigcup_n E_n \in \mathcal{N}$.
(iii) The indexing class in the displayed definition is nonempty since $\mathcal{P}(X)$ belongs to it. By (ii), its intersection is a σ-algebra; it contains $\mathcal{A}$ and is contained in every σ-algebra containing $\mathcal{A}$.

Structural Commentary: Generation is intersection over all admissible σ-algebras.
Key Insight: Intersections preserve universal closure properties. □

Example 1.1.4. *Basic σ-Algebras*
Standard models:

(i) Extremes: $\{\emptyset, X\} \subseteq \mathcal{M} \subseteq \mathcal{P}(X)$ for every σ-algebra $\mathcal{M}$ on X.
(ii) For $E \subseteq X$, $\sigma(\{E\}) = \{\emptyset, E, X \setminus E, X\}$, with repetitions omitted.
(iii) On $\mathbb{N}$, if $O := \{2n-1 : n \in \mathbb{N}\}$, then $\sigma(\{O\}) = \{\emptyset, O, \mathbb{N} \setminus O, \mathbb{N}\}$.
(iv) If X is uncountable, $\mathcal{C}_X := \{E \subseteq X : E \text{ is countable or } X \setminus E \text{ is countable}\}$ is the countable–cocountable σ-algebra.

Key Insight: A σ-algebra records exactly which distinctions the theory is allowed to observe.

Definition 1.1.5. *Borel and Extended Borel σ-Algebras*

(i) For $n \in \mathbb{N}$, the *Borel σ-algebra* on $\mathbb{R}^n$ is $\mathcal{B}(\mathbb{R}^n) := \sigma(\{U \subseteq \mathbb{R}^n : U \text{ is open}\})$. On $\mathbb{R}$, it is also generated by open intervals, closed intervals, half-open intervals, or open half-rays $(a, +\infty)$.
(ii) The *extended Borel σ-algebra* on $\overline{\mathbb{R}}$ is $\overline{\mathcal{B}} := \{E \cup F : E \in \mathcal{B}(\mathbb{R}),\ F \subseteq \{-\infty, +\infty\}\}$.

Definition 1.1.6. *Monotone Classes*
A nonempty $\mathcal{C} \subseteq \mathcal{P}(X)$ is a *monotone class* iff $(E_n) \subseteq \mathcal{C},\ E_n \uparrow E \Rightarrow E \in \mathcal{C}$ and $(F_n) \subseteq \mathcal{C},\ F_n \downarrow F \Rightarrow F \in \mathcal{C}$.
For $\mathcal{A} \subseteq \mathcal{P}(X)$, define $\mathfrak{M}_{\mathcal{A}} := \{\mathcal{C} \subseteq \mathcal{P}(X) : \mathcal{C} \text{ is a monotone class, } \mathcal{A} \subseteq \mathcal{C}\}$; $\operatorname{mon}(\mathcal{A}) := \bigcap \mathfrak{M}_{\mathcal{A}}$.
Then $\operatorname{mon}(\mathcal{A})$ is the least monotone class containing $\mathcal{A}$, and $\operatorname{mon}(\mathcal{A}) \subseteq \sigma(\mathcal{A})$.
Key Insight: Monotone closure captures limits, not finite unions.

Definition 1.1.7. *Rings and σ-Rings of Sets*
Let $\mathcal{A} \subseteq \mathcal{P}(X)$.

(i) $\mathcal{A}$ is a *ring of sets* iff $\emptyset \in \mathcal{A}$ and $A, B \in \mathcal{A} \Rightarrow A \cup B,\ A \setminus B \in \mathcal{A}$
(ii) $\mathcal{A}$ is a *σ-ring* iff it is a ring and $(A_n) \subseteq \mathcal{A} \Rightarrow \bigcup_{n=1}^{\infty} A_n \in \mathcal{A}$

Structural Commentary: Rings support finite operations; σ-rings support countable unions.

Definition 1.1.8. *Algebras of Sets and Premeasures*
Let X be a set.

(i) An *algebra of sets* (or *field of sets*) on X is $\mathcal{A} \subseteq \mathcal{P}(X)$ such that $\emptyset, X \in \mathcal{A}$; $E \in \mathcal{A} \Rightarrow X \setminus E \in \mathcal{A}$; and $E_1, \dots, E_n \in \mathcal{A} \Rightarrow \bigcup_{j=1}^{n} E_j \in \mathcal{A}$. Equivalently, $\mathcal{A}$ is a ring of sets containing X.
(ii) A *premeasure* (or *measure on an algebra*) on $\mathcal{A}$ is $\mu : \mathcal{A} \to [0, +\infty]$ such that $\mu(\emptyset) = 0$ and, whenever $(E_n)_{n\in\mathbb{N}} \subseteq \mathcal{A}$ is pairwise disjoint with $\bigcup_{n=1}^{\infty} E_n \in \mathcal{A}$, then $\mu\left(\bigcup_{n=1}^{\infty} E_n\right) = \sum_{n=1}^{\infty} \mu(E_n)$.

Key Insight: Premeasures are countably additive where the algebra permits unions.

Theorem 1.1.9. *Monotone Class Theorem for Algebras*
Let X be a set, let $\mathcal{A} \subseteq \mathcal{P}(X)$ be an algebra, and set $\mathcal{C} := \text{mon}(\mathcal{A})$. Then $\mathcal{C} = \sigma(\mathcal{A})$.

Proof.
(i) *Setup*: Since $\sigma(\mathcal{A})$ is monotone and contains $\mathcal{A}$, $\mathcal{C} \subseteq \sigma(\mathcal{A})$ by minimality. It remains to prove that $\mathcal{C}$ is a σ-algebra.
(ii) *Complements*: Set $\mathcal{D} := \{E \in \mathcal{C} : E^c \in \mathcal{C}\}$. If $E_n \uparrow E$ in $\mathcal{D}$, then $E_n^c \downarrow E^c$; if $E_n \downarrow E$, then $E_n^c \uparrow E^c$. Thus $\mathcal{D}$ is monotone. Since $\mathcal{A} \subseteq \mathcal{D}$, $\mathcal{C} \subseteq \mathcal{D}$ by minimality, so $\mathcal{C}$ is closed under complements.
(iii) *Finite Intersections*: For $B \in \mathcal{C}$, set $\mathcal{D}_B := \{E \in \mathcal{C} : E \cap B \in \mathcal{C}\}$. This class is monotone. If $B \in \mathcal{A}$, then $\mathcal{A} \subseteq \mathcal{D}_B$ by algebra closure, hence $\mathcal{C} \subseteq \mathcal{D}_B$ by minimality. Therefore $E \cap B \in \mathcal{C}$ for $E \in \mathcal{C}$ and $B \in \mathcal{A}$. Fixing $E \in \mathcal{C}$, the preceding conclusion implies $\mathcal{A} \subseteq \mathcal{D}_E$, hence $\mathcal{C} \subseteq \mathcal{D}_E$ by minimality. Thus $\mathcal{C}$ is closed under finite intersections and under finite unions by complement closure.
(iv) *Countable Unions*: If $(E_n) \subseteq \mathcal{C}$, then $F_N := \bigcup_{n=1}^N E_n \in \mathcal{C}$ and $F_N \uparrow \bigcup_{n=1}^\infty E_n$, so $\bigcup_{n=1}^\infty E_n \in \mathcal{C}$.
(v) *Conclusion*: Hence $\mathcal{C}$ is a σ-algebra containing $\mathcal{A}$, so $\sigma(\mathcal{A}) \subseteq \mathcal{C}$.
Structural Commentary: Monotone lifting establishes Boolean closure, then countable unions.
Key Insight: Show each closure property holds on a monotone class containing $\mathcal{A}$. □

Corollary 1.1.10. *Monotone-Class Test*
Let $\mathcal{A} \subseteq \mathcal{P}(X)$ be an algebra and let $\mathcal{C} \subseteq \mathcal{P}(X)$ be a monotone class. If $\mathcal{A} \subseteq \mathcal{C}$, then $\sigma(\mathcal{A}) \subseteq \mathcal{C}$.

Proof. Since $\mathcal{A} \subseteq \mathcal{C}$ and $\mathcal{C}$ is monotone, $\text{mon}(\mathcal{A}) \subseteq \mathcal{C}$. By Theorem 1.1.9, $\text{mon}(\mathcal{A}) = \sigma(\mathcal{A})$.
Structural Commentary: Algebra checks plus monotone stability control $\sigma(\mathcal{A})$.
Key Insight: Prove on the algebra; extend by monotone closure. □

2 Measures, Charges, and Basic Examples

2.1 Measures, Charges, and Basic Constructions

Definition 2.1.1. *Set Functions and Additivity*
Let $\mathcal{A} \subseteq \mathcal{P}(X)$.
(i) A *set function* on $\mathcal{A}$ is $\phi : \mathcal{A} \to [-\infty, +\infty]$ with $\{+\infty, -\infty\} \nsubseteq \phi(\mathcal{A})$.
(ii) ϕ is *additive* iff $A \cap B = \emptyset \Rightarrow \phi(A \cup B) = \phi(A) + \phi(B)$
(iii) ϕ is *countably additive* iff $(A_n) \subseteq \mathcal{A}$ pairwise disjoint, $\bigcup_n A_n \in \mathcal{A} \Rightarrow \phi\left(\bigcup_{n=1}^\infty A_n\right) = \sum_{n=1}^\infty \phi(A_n)$.

Definition 2.1.2. *Measures on Measurable Spaces*
Let $(X, \mathcal{M})$ be a measurable space. A *measure* on $(X, \mathcal{M})$ is a map $\mu : \mathcal{M} \to [0, +\infty]$ such that:
(i) $\mu(\emptyset) = 0$;
(ii) if $(E_n) \subseteq \mathcal{M}$ is pairwise disjoint, then $\mu\left(\bigcup_{n=1}^\infty E_n\right) = \sum_{n=1}^\infty \mu(E_n)$
The triple $(X, \mathcal{M}, \mu)$ is a *measure space*.
Key Insight: Measure is countably additive size on the chosen observable sets.

Definition 2.1.3. *Finite and σ-Finite Measures*
Let $(X, \mathcal{M}, \mu)$ be a measure space.
(i) For nonnegative terms, $\sum_{n=1}^\infty a_n := \lim_{N\to\infty} \sum_{n=1}^N a_n \in [0, +\infty]$.
(ii) μ is *finite* iff $\mu(X) < +\infty$.
(iii) μ is *σ-finite* iff there exist $E_n \in \mathcal{M}$ such that $X = \bigcup_{n=1}^\infty E_n$ and $\mu(E_n) < +\infty$ for all n.
(iv) A measurable set $E \in \mathcal{M}$ has *finite measure* iff $\mu(E) < +\infty$.
(v) A measurable set $E \in \mathcal{M}$ is *σ-finite* iff $E = \bigcup_{n=1}^\infty E_n$ for some $E_n \in \mathcal{M}$ with $\mu(E_n) < +\infty$ for all n.
Key Insight: σ-finiteness replaces one finite global bound by a countable finite-measure exhaustion.

Example 2.1.4. *First Abstract Measures*
(i) The zero set function $\mu(E) = 0$ on $\mathcal{M}$ is a finite measure.
(ii) If $X \neq \emptyset$ and $\mathcal{M} = 2^X$, $\mu(\emptyset) = 0$ and $\mu(E) = +\infty$ for $E \neq \emptyset$ give a measure, neither finite nor σ-finite.
(iii) For $p \in X$, the *unit mass* $\delta_p(E) := \mathbf{1}_E(p)$ on 2^X is a finite measure.
(iv) On $2^{\mathbb{N}}$, *counting measure* is $\#(E)$ for finite E and $+\infty$ otherwise; it is σ-finite.
More generally, $(a_n) \subseteq [0, +\infty]$ gives $\mu(E) := \sum_{n\in E} a_n$, and every measure on $2^{\mathbb{N}}$ is uniquely of this form.
(v) If X is uncountable and $\mathcal{M} = 2^X$, $\mu(E) = 0$ for countable E and $\mu(E) = +\infty$ otherwise defines a measure.
(vi) If X is uncountable and $\mathcal{C}_X = \{E \subseteq X : E \text{ is countable or } X \setminus E \text{ is countable}\}$, then $\mu(E) = 0$ on countable sets and $\mu(E) = 1$ on cocountable sets defines a measure on $\mathcal{C}_X$.
(vii) On $2^{\mathbb{N}}$, $\mu(E) = 0$ for finite E and $\mu(E) = +\infty$ otherwise is not a measure, since $\mathbb{N} = \bigcup_{n=1}^\infty \{n\}$ gives $+\infty \neq 0$; the constant $+\infty$ rule fails at $\emptyset$.
(viii) Lebesgue measure on $\mathcal{B}(\mathbb{R})$ is σ-finite and gives length $b - a$ to standard intervals; Borel–Stieltjes measures come from increasing right-continuous functions.
Structural Commentary: Measures may be zero, atomic, counting-type, cardinality-based, or geometric.
Key Insight: Countable additivity turns disjoint decompositions into nonnegative series.

Proposition 2.1.5. *Elementary Measure Constructions*
Let $(X, \mathcal{M})$ be a measurable space.
(i) If μ is a measure on $\mathcal{M}$ and $A \in \mathcal{M}$, then $\mu_A(E) := \mu(A \cap E)$ defines a measure μ_A on $\mathcal{M}$.
(ii) If $\mu_1, \ldots, \mu_m$ are measures on $\mathcal{M}$ and $a_1, \ldots, a_m \geq 0$, then $\lambda := \sum_{j=1}^m a_j \mu_j$ is a measure on $\mathcal{M}$.
(iii) If $(\mu_n)_{n\geq 1}$ are measures on $\mathcal{M}$ with $\mu_n(X) = 1$, then $\lambda := \sum_{n=1}^\infty 2^{-n}\mu_n$ is a measure on $\mathcal{M}$ and $\lambda(X) = 1$.

Proof.
(i) $\mu_A(\emptyset) = 0$. If (E_k) is disjoint in $\mathcal{M}$, then $A \cap \bigsqcup_k E_k = \bigsqcup_k (A \cap E_k)$, whence $\mu_A(\bigsqcup_k E_k) = \sum_k \mu_A(E_k)$.
(ii) $\lambda(\emptyset) = 0$. For disjoint (E_k), $\lambda(\bigsqcup_k E_k) = \sum_{j=1}^m a_j \sum_k \mu_j(E_k) = \sum_k \lambda(E_k)$ by finite summation.
(iii) $\lambda(\emptyset) = 0$. For disjoint (E_k), $\lambda(\bigsqcup_k E_k) = \sum_n 2^{-n} \sum_k \mu_n(E_k) = \sum_k \lambda(E_k)$ by nonnegative reordering.
Also $\lambda(X) = \sum_n 2^{-n}\mu_n(X) = \sum_n 2^{-n} = 1$.

Structural Commentary: New measures come from restriction, superposition, and countable convex mixtures.
Key Insight: Nonnegative series make the bookkeeping order-independent. □

Proposition 2.1.6. *Basic Laws for Measures*
Let $(X, \mathcal{M}, \mu)$ be a measure space.

(i) For every $n \geq 1$, if $E_1, \dots, E_n \in \mathcal{M}$ are pairwise disjoint, then $\mu\left(\bigcup_{k=1}^{n} E_k\right) = \sum_{k=1}^{n} \mu(E_k)$.
(ii) If $A, B \in \mathcal{M}$ and $A \subseteq B$, then $\mu(A) \leq \mu(B)$.
(iii) If $A, B \in \mathcal{M}$, $A \subseteq B$, and $\mu(A) < +\infty$, then $\mu(B \setminus A) = \mu(B) - \mu(A)$. In particular, if $\mu(A) = 0$, then $\mu(B \setminus A) = \mu(B)$.
(iv) If $E \in \mathcal{M}$ and $(E_k)_{k\geq 1} \subseteq \mathcal{M}$ satisfy $E \subseteq \bigcup_{k=1}^{\infty} E_k$, then $\mu(E) \leq \sum_{k=1}^{\infty} \mu(E_k)$.

Proof.

(i) Define $G_k = E_k$ for $1 \leq k \leq n$ and $G_k = \emptyset$ for $k > n$. Then (G_k) is pairwise disjoint and $\mu\left(\bigcup_{k=1}^{n} E_k\right) = \mu\left(\bigcup_{k=1}^{\infty} G_k\right) = \sum_{k=1}^{\infty} \mu(G_k) = \sum_{k=1}^{n} \mu(E_k)$ by countable additivity.
(ii) Since $B = A \sqcup (B \setminus A)$, $\mu(B) = \mu(A) + \mu(B \setminus A)$ by (i). Hence $\mu(A) \leq \mu(B)$ since $\mu(B \setminus A) \geq 0$.
(iii) Since $B = A \sqcup (B \setminus A)$, $\mu(B) = \mu(A) + \mu(B \setminus A)$ by (i). Because $\mu(A) < +\infty$, $\mu(B \setminus A) = \mu(B) - \mu(A)$ by subtraction. If $\mu(A) = 0$, this becomes $\mu(B \setminus A) = \mu(B)$.
(iv) Set $F_1 = E \cap E_1$ and $F_k = E \cap \left(E_k \setminus \bigcup_{j=1}^{k-1} E_j\right)$ for $k \geq 2$. Then $(F_k)_{k\geq 1} \subseteq \mathcal{M}$ is pairwise disjoint, $\bigcup_{k=1}^{\infty} F_k = E$, and $F_k \subseteq E_k$ for all k. Hence $\mu(E) = \sum_{k=1}^{\infty} \mu(F_k) \leq \sum_{k=1}^{\infty} \mu(E_k)$ by countable additivity and (ii).

Structural Commentary: Finite additivity establishes order and excision; disjointization turns covers into sums.
Key Insight: Measure disjoint pieces, then compare. □

Theorem 2.1.7. *Continuity from Below*
Let $\mathcal{A}$ be a ring of subsets of X, and let ϕ be a countably additive set function on $\mathcal{A}$.
If $(A_n)_{n\geq 1} \subseteq \mathcal{A}$ and $A \in \mathcal{A}$ satisfy $A_n \subseteq A_{n+1}$ for all n and $A = \bigcup_{n=1}^{\infty} A_n$, then $\lim_{N\to\infty} \phi(A_N) = \phi(A)$.

Proof. Set $B_1 = A_1$ and $B_n = A_n \setminus A_{n-1}$ for $n \geq 2$. Since $\mathcal{A}$ is a ring, each $B_n \in \mathcal{A}$.
The sets (B_n) are pairwise disjoint, $A_N = \bigsqcup_{n=1}^{N} B_n$, and $A = \bigsqcup_{n=1}^{\infty} B_n$.
By countable additivity, applied to the finite union by appending empty sets, $\phi(A_N) = \sum_{n=1}^{N} \phi(B_n)$, while $\phi(A) = \sum_{n=1}^{\infty} \phi(B_n)$ by countable additivity. Thus $\lim_{N\to\infty} \phi(A_N) = \phi(A)$.
Structural Commentary: Increasing chains split into disjoint increments.
Key Insight: Continuity is convergence of partial sums. □

Definition 2.1.8. *Charges*
Let $(X, \mathcal{M})$ be a measurable space. A *charge* is a map $\lambda : \mathcal{M} \to \mathbb{R}$ such that:
(i) $\lambda(\emptyset) = 0$.
(ii) For every pairwise disjoint $(E_n) \subseteq \mathcal{M}$, $\sum_{n=1}^{\infty} \lambda(E_n)$ converges in $\mathbb{R}$ and $\lambda\left(\bigcup_{n=1}^{\infty} E_n\right) = \sum_{n=1}^{\infty} \lambda(E_n)$.

Key Insight: A charge is a real-valued countably additive set function.

Definition 2.1.9. *Variation Candidates of a Charge*
Let λ be a charge on $\mathcal{M}$. For $E \in \mathcal{M}$, define
(i) $\mathfrak{P}_{\mathcal{M}}(E) := \{(A_j)_{j=1}^{n} : n \in \mathbb{N},\ E = \bigsqcup_{j=1}^{n} A_j,\ A_j \in \mathcal{M}\}$, the finite measurable partitions of E;
(ii) $\pi_\lambda(E) := \sup\{\lambda(A) : A \subseteq E,\ A \in \mathcal{M}\}$, the *positive variation* candidate;
(iii) $\nu_\lambda(E) := \sup\{\sum_{j=1}^{n} |\lambda(A_j)| : (A_j)_{j=1}^{n} \in \mathfrak{P}_{\mathcal{M}}(E)\}$, the *total variation* candidate.

For $E = \emptyset$, the empty partition is allowed and contributes 0.

Proposition 2.1.10. *Charge Operations and Variation Measures*
Let $(X, \mathcal{M})$ be a measurable space, let $m \geq 1$, and let $\lambda, \lambda_1, \dots, \lambda_m$ be charges on $\mathcal{M}$.

(i) If $a_1, \dots, a_m \in \mathbb{R}$ and $\Lambda : \mathcal{M} \to \mathbb{R}$ is defined by $\Lambda(E) := \sum_{j=1}^{m} a_j \lambda_j(E)$, then Λ is a charge.
(ii) $\pi_\lambda : \mathcal{M} \to [0, +\infty]$ is a measure.
(iii) $\nu_\lambda : \mathcal{M} \to [0, +\infty]$ is a measure.

Proof.

(i) $\Lambda(\emptyset) = 0$. For $E = \bigsqcup_n E_n$, $\sum_n \Lambda(E_n)$ converges as $\sum_{j=1}^{m} a_j \sum_n \lambda_j(E_n)$; $\Lambda(E) = \sum_{j=1}^{m} a_j \sum_n \lambda_j(E_n) = \sum_n \Lambda(E_n)$.
(ii) $\pi_\lambda(\emptyset) = 0$ and $\pi_\lambda \geq 0$. Let $E = \bigsqcup_n E_n$. For measurable $A \subseteq E$, $\lambda(A) = \sum_n \lambda(A \cap E_n) \leq \sum_n \pi_\lambda(E_n)$, so $\pi_\lambda(E) \leq \sum_n \pi_\lambda(E_n)$. Put $S_N = \sum_{n=1}^{N} \pi_\lambda(E_n)$. If $S_N < +\infty$, choose measurable $A_n \subseteq E_n$ for $n \leq N$ with $\lambda(A_n) > \pi_\lambda(E_n) - \frac{\varepsilon}{N}$; then $\pi_\lambda(E) > S_N - \varepsilon$. If $S_N = +\infty$, some E_ℓ has $\pi_\lambda(E_\ell) = +\infty$, hence $\pi_\lambda(E) = +\infty$. Thus $\pi_\lambda(E) \geq S_N$ for all N, and equality follows as $N \to \infty$.
(iii) $\nu_\lambda(\emptyset) = 0$ and $\nu_\lambda \geq 0$. Let $E = \bigsqcup_n E_n$ and $v(P) = \sum_{A\in P} |\lambda(A)|$. For $P = (A_j)_{j=1}^{r} \in \mathfrak{P}_{\mathcal{M}}(E)$, $v(P) \leq \sum_{j=1}^{r} \sum_n |\lambda(A_j \cap E_n)| \leq \sum_n \nu_\lambda(E_n)$ by refinement with (E_n), so $\nu_\lambda(E) \leq \sum_n \nu_\lambda(E_n)$. Put $T_N = \sum_{n=1}^{N} \nu_\lambda(E_n)$. If $T_N < +\infty$, choose $P_n \in \mathfrak{P}_{\mathcal{M}}(E_n)$ for $n \leq N$ with $v(P_n) > \nu_\lambda(E_n) - \frac{\varepsilon}{N}$.

After adjoining the tail $\bigcup_{n>N} E_n$, $\nu_\lambda(E) > T_N - \varepsilon$. If $T_N = +\infty$, some E_ℓ has $\nu_\lambda(E_\ell) = +\infty$, and partitions of E_ℓ extend to E, so $\nu_\lambda(E) = +\infty$. Thus $\nu_\lambda(E) \geq T_N$ for all N, and equality follows as $N \to \infty$.

Structural Commentary: Suprema preserve additivity after refinement.
Key Insight: Refine first, then take suprema. □

3 Outer Measures and Caratheodory Extension

3.1 Outer Measures and Extension Theorems

Definition 3.1.1. *Abstract Outer Measure and Clean Division*
Let M be a set.

(i) An *abstract outer measure* on M is a map $\omega : 2^M \to [0, +\infty]$ such that $\omega(\emptyset) = 0$, $A \subseteq B \Rightarrow \omega(A) \leq \omega(B)$, and $\omega(\bigcup_{k=1}^{\infty} A_k) \leq \sum_{k=1}^{\infty} \omega(A_k)$ for all $A, B, A_k \subseteq M$.
(ii) For an outer measure ω, $E \subseteq M$ is *ω-measurable* iff $\omega(X) = \omega(X \cap E) + \omega(X \cap E^c)$ for every $X \subseteq M$.

Definition 3.1.2. *Outer Measure Induced by a Covering Family*
Let $\mathcal{S} \subseteq \mathcal{P}(X)$ and let $\rho : \mathcal{S} \to [0, +\infty]$.

(i) For $E \subseteq X$, $\mathcal{C}_{\mathcal{S}}(E) := \{(S_k)_{k\geq 1} \in \mathcal{S}^{\mathbb{N}} : E \subseteq \bigcup_{k=1}^{\infty} S_k\}$.
(ii) The induced map $\rho^* : \mathcal{P}(X) \to [0, +\infty]$ is defined by $\rho^*(\emptyset) = 0$ and,
for $E \neq \emptyset$, $\rho^*(E) := \inf_{(S_k) \in \mathcal{C}_{\mathcal{S}}(E)} \sum_{k=1}^{\infty} \rho(S_k)$, with $\inf \emptyset = +\infty$.

The map ρ^* is the *outer measure induced by ρ and $\mathcal{S}$*.
Key Insight: Minimize total ρ-cost over countable $\mathcal{S}$-covers.

Proposition 3.1.3. *Cover-Induced Outer Measure*
For $\mathcal{S} \subseteq \mathcal{P}(X)$ and $\rho : \mathcal{S} \to [0, +\infty]$, the cover-induced map $\rho^* : \mathcal{P}(X) \to [0, +\infty]$ is an outer measure on X.

Proof. By construction, $\rho^*(\emptyset) = 0$ and $\rho^* \geq 0$. If $A \subseteq B$, then $\mathcal{C}_{\mathcal{S}}(B) \subseteq \mathcal{C}_{\mathcal{S}}(A)$, hence $\rho^*(A) \leq \rho^*(B)$.
Let $E = \bigcup_k E_k$, $I = \{k : E_k \neq \emptyset\}$, and assume $I \neq \emptyset$ and $\sum_k \rho^*(E_k) < +\infty$.
Choose $(S_{k,j})_j \in \mathcal{C}_{\mathcal{S}}(E_k)$ for $k \in I$ with $\sum_j \rho(S_{k,j}) < \rho^*(E_k) + \varepsilon 2^{-k}$.
Since $(S_{k,j})_{k\in I, j\geq 1}$ covers E, $\rho^*(E) \leq \sum_{k\in I} \sum_j \rho(S_{k,j}) \leq \sum_k \rho^*(E_k) + \varepsilon$; let $\varepsilon \downarrow 0$. Excluded cases are immediate.

Structural Commentary: Inclusion orders covers; regrouping covers sums.
Key Insight: Covers generate subadditivity. □

Lemma 3.1.4. *Finite-Measure Test for Caratheodory Measurability*
Let $\omega : 2^M \to [0, +\infty]$ be an outer measure. Then $E \subseteq M$ is ω-measurable iff, for all $X \subseteq M$, $\omega(X) < +\infty \Longrightarrow \omega(X) \geq \omega(X \cap E) + \omega(X \cap E^c)$.

Proof.
($\Rightarrow$) If E is ω-measurable, then $\omega(X) = \omega(X \cap E) + \omega(X \cap E^c)$ $\forall X \subseteq M$, hence finite-test inequality holds.
($\Leftarrow$) For all $X \subseteq M$, $\omega(X) \leq \omega(X \cap E) + \omega(X \cap E^c)$ by $X = (X \cap E) \sqcup (X \cap E^c)$ and subadditivity. If $\omega(X) < +\infty$, the reverse inequality holds by hypothesis; if $\omega(X) = +\infty$, it is automatic in $[0, +\infty]$. Thus equality holds for every X.

Structural Commentary: To verify a clean split, only finite outer-measure test sets need real work.
Key Insight: Subadditivity supplies one inequality for free. □

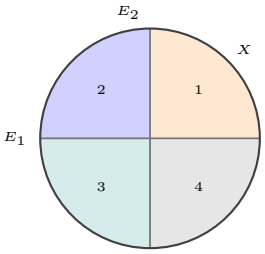

Figure 189: Two cuts split X into four regions; $E_1 \setminus E_2$ is region 2.

Figure 189 records the four intersections used when two measurable cuts are combined.

Definition 3.1.5. *Zero Sets*
For outer measure $\omega : 2^M \to [0, +\infty]$, *$\omega$-zero set* is $Z \subseteq M$ with $\omega(Z) = 0$; $\mathcal{Z}_\omega := \{Z \subseteq M : \omega(Z) = 0\}$.

Theorem 3.1.6. *Caratheodory Measurable Sets*
Let $\omega : 2^M \to [0, +\infty]$ be an outer measure.
Let $\mathcal{M}_\omega := \{E \subseteq M : \omega(X) = \omega(X \cap E) + \omega(X \cap E^c)\ \forall X \subseteq M\}$ and $\mathcal{Z}_\omega := \{Z \subseteq M : \omega(Z) = 0\}$. Then:
(i) $\mathcal{Z}_\omega \subseteq \mathcal{M}_\omega$;
(ii) $\mathcal{M}_\omega$ is a σ-algebra;
(iii) $\omega|_{\mathcal{M}_\omega}$ is countably additive;
(iv) if $E \in \mathcal{M}_\omega$ and $Z \in \mathcal{Z}_\omega$, then $E \cup Z, E \setminus Z, E \triangle Z \in \mathcal{M}_\omega$ and $\omega(E \cup Z) = \omega(E \setminus Z) = \omega(E \triangle Z) = \omega(E)$.

Proof.

(i) If $Z \in \mathcal{Z}_\omega$ and $X \subseteq M$, then $\omega(X) \le \omega(X \cap Z) + \omega(X \cap Z^c) \le 0 + \omega(X)$, so equality holds and $Z \in \mathcal{M}_\omega$.

(ii) Complements are immediate. If $E, F \in \mathcal{M}_\omega$, with $E^1 = E$, $E^0 = E^c$, $F^1 = F$, and $F^0 = F^c$, then $\omega(X) = \sum_{\epsilon,\eta\in\{0,1\}} \omega(X \cap E^\epsilon \cap F^\eta)$; hence finite Boolean combinations are measurable.
For pairwise disjoint $E_i \in \mathcal{M}_\omega$, set $E = \bigsqcup_i E_i$ and $F_N = (\bigcup_{i=1}^N E_i)^c$.
By finite splitting, $\omega(X) \ge \sum_{i=1}^N \omega(X \cap E_i) + \omega(X \cap E^c)$ for every N.
After $N \to \infty$, this is the reverse inequality to $\omega(X) \le \omega(X \cap E) + \omega(X \cap E^c) \le \sum_{i=1}^\infty \omega(X \cap E_i) + \omega(X \cap E^c)$ by subadditivity; hence equality holds.
Since $\omega(X \cap E) \le \sum_i \omega(X \cap E_i)$ and $\omega(X) \le \omega(X \cap E) + \omega(X \cap E^c)$, $E \in \mathcal{M}_\omega$.
General countable unions follow from $H_1 = E_1$ and $H_n = E_n \setminus \bigcup_{i<n} E_i$.

(iii) If $E = \bigsqcup_{i=1}^\infty E_i$ with $E_i \in \mathcal{M}_\omega$, then $\omega(E) = \sum_{i=1}^\infty \omega(E_i)$ by the equality in (ii) with $X = E$.

(iv) By (i)–(ii), $E \cup Z, E \setminus Z, E \triangle Z \in \mathcal{M}_\omega$.
Since $E \cap Z$ and $Z \setminus E$ are null, $\omega(E \setminus Z) = \omega(E \cup Z) = \omega(E \triangle Z) = \omega(E)$ by additivity.

Structural Commentary: Measurable sets preserve countable additivity.
Key Insight: Measurable cuts turn subadditivity into equality. □

Corollary 3.1.7. *Disjointization of Countable Measurable Unions*
Let $\omega : 2^M \to [0, +\infty]$ be an outer measure and let $(E_k)_{k\ge1} \subseteq \mathcal{M}_\omega$.
Set $F_1 := E_1$ and $F_k := E_k \setminus \bigcup_{i=1}^{k-1} E_i$ for $k \ge 2$.
Then (F_k) is pairwise disjoint in $\mathcal{M}_\omega$, $\bigcup_{k\ge1} F_k = \bigcup_{k\ge1} E_k$, and $\omega(\bigcup_{k\ge1} E_k) = \sum_{k\ge1} \omega(F_k)$ in $[0, +\infty]$.

Proof. Since $\mathcal{M}_\omega$ is a σ-algebra, $F_k = E_k \cap (\bigcup_{i<k} E_i)^c \in \mathcal{M}_\omega$. If $i < k$, then $F_i \cap F_k \subseteq E_i \cap (\bigcup_{j<k} E_j)^c = \emptyset$.
For $x \in \bigcup_{k\ge1} E_k$, $x \in F_{\min\{j : x\in E_j\}}$; hence $\bigcup_{k\ge1} F_k = \bigcup_{k\ge1} E_k$, and $\omega(\bigcup_{k\ge1} E_k) = \sum_{k\ge1} \omega(F_k)$ by countable additivity.
Structural Commentary: Disjointization turns unions into sums.
Key Insight: Peel off earlier pieces so a countable union becomes a disjoint sum. □

Definition 3.1.8. *Countable Cover Classes*
Let $\mathcal{S} \subseteq \mathcal{P}(X)$.

(i) *Countable-union class*: $\mathcal{S}_\sigma := \left\{ \bigcup_{n=1}^\infty S_n : (S_n)_{n\ge1} \in \mathcal{S}^{\mathbb{N}} \right\}$.

(ii) *Countable-intersection class*: $\mathcal{S}_{\sigma\delta} := \left\{ \bigcap_{n=1}^\infty A_n : (A_n)_{n\ge1} \in (\mathcal{S}_\sigma)^{\mathbb{N}} \right\}$.

Key Insight: $\mathcal{S}_\sigma$ closes under countable unions; $\mathcal{S}_{\sigma\delta}$ then closes once under countable intersections.

Proposition 3.1.9. *Finite Outer-Measure Envelope*
Let $\mathcal{S} \subseteq \mathcal{P}(X)$, let $\rho : \mathcal{S} \to [0, +\infty]$, and let ρ^* be the cover-induced map.
If $\emptyset \ne E \subseteq X$ and $\rho^*(E) < +\infty$, then there exists $A \in \mathcal{S}_{\sigma\delta}$ such that:

(i) $E \subseteq A$ and $\rho^*(A) = \rho^*(E)$.
(ii) If E and every $S \in \mathcal{S}$ are ρ^*-measurable, then A is ρ^*-measurable and $\rho^*(A \setminus E) = 0$.

Proof. $\forall n \ge 1$, choose $(S_{n,k})_{k\ge1} \in \mathcal{C}_\mathcal{S}(E)$ with $\sum_{k=1}^\infty \rho(S_{n,k}) < \rho^*(E) + \frac{1}{n}$. Set $A_n := \bigcup_{k=1}^\infty S_{n,k}$, $A := \bigcap_{n=1}^\infty A_n$.
Then $A_n \in \mathcal{S}_\sigma$, $A \in \mathcal{S}_{\sigma\delta}$, $E \subseteq A \subseteq A_n$, and $\rho^*(A_n) < \rho^*(E) + \frac{1}{n}$.

(i) By monotonicity, $\rho^*(E) \le \rho^*(A) \le \rho^*(A_n) < \rho^*(E) + \frac{1}{n}$ for all n, hence $\rho^*(A) = \rho^*(E)$.

(ii) If E and every $S \in \mathcal{S}$ are ρ^*-measurable, then the ρ^*-measurable sets form a σ-algebra, so A_n and A are ρ^*-measurable. Since $E \subseteq A$ and $\rho^*(E) < +\infty$, $\rho^*(A \setminus E) = \rho^*(A) - \rho^*(E) = 0$ by excision.

Structural Commentary: Finite cost produces a countable-intersection envelope.
Key Insight: Cover within $\frac{1}{n}$, then intersect. □

Definition 3.1.10. *Outer Measure Generated by a Premeasure*
Let $\mu : \mathcal{A} \to [0, +\infty]$ be a premeasure on an algebra $\mathcal{A} \subseteq \mathcal{P}(X)$.

(i) *Algebra covers*: For $B \subseteq X$, set $\mathcal{C}_\mathcal{A}(B) := \{(E_j)_{j\ge1} \in \mathcal{A}^{\mathbb{N}} : B \subseteq \bigcup_{j=1}^\infty E_j\}$.

(ii) *Generated outer measure*: Define $\mu^* : \mathcal{P}(X) \to [0, +\infty]$ by $\mu^*(\emptyset) = 0$ and, for $B \ne \emptyset$, $\mu^*(B) := \inf_{(E_j)\in\mathcal{C}_\mathcal{A}(B)} \sum_{j=1}^\infty \mu(E_j)$, with $\inf \emptyset = +\infty$.

Key Insight: Cover arbitrary sets by algebra sets and minimize total premeasure.

Lemma 3.1.11. *Generated Outer-Measure Properties*
Let $\mu : \mathcal{A} \to [0, +\infty]$ be a premeasure on an algebra $\mathcal{A} \subseteq \mathcal{P}(X)$.
For $B \subseteq X$, put $\mathcal{C}_\mathcal{A}(B) := \{(E_j) \in \mathcal{A}^{\mathbb{N}} : B \subseteq \bigcup_j E_j\}$.
Set $\inf \emptyset = +\infty$, $\mu^*(\emptyset) = 0$, and $\mu^*(B) := \inf_{(E_j)\in\mathcal{C}_\mathcal{A}(B)} \sum_j \mu(E_j)$ for $B \ne \emptyset$. Then:

(i) $\mu^*(\emptyset) = 0$.
(ii) If $C \subseteq D \subseteq X$, then $\mu^*(C) \le \mu^*(D)$.
(iii) If $(B_n)_{n\ge1} \subseteq \mathcal{P}(X)$, then $\mu^*(\bigcup_{n=1}^\infty B_n) \le \sum_{n=1}^\infty \mu^*(B_n)$.
(iv) If $E \in \mathcal{A}$, then $\mu^*(E) = \mu(E)$.

Proof.

(i) This is the assigned value of $\mu^*(\emptyset)$.

(ii) If $C \subseteq D$, then $\mathcal{C}_{\mathcal{A}}(D) \subseteq \mathcal{C}_{\mathcal{A}}(C)$; hence $\mu^*(C) \le \mu^*(D)$ by taking infima.

(iii) Let $B = \bigcup_n B_n$ and $I = \{n : B_n \neq \emptyset\}$. If $I = \emptyset$ or $\sum_n \mu^*(B_n) = +\infty$, the claim is immediate.

Otherwise, for $\varepsilon > 0$ choose $(E_{n,k})_{k\ge1} \in \mathcal{C}_{\mathcal{A}}(B_n)$ for $n \in I$ with $\sum_k \mu(E_{n,k}) < \mu^*(B_n) + \varepsilon 2^{-n}$.

Then $(E_{n,k})_{n\in I, k\ge1}$ covers B, so $\mu^*(B) \le \sum_{n\in I}\sum_k \mu(E_{n,k}) \le \sum_n \mu^*(B_n) + \varepsilon$; let $\varepsilon \downarrow 0$.

(iv) By the cover $E, \emptyset, \emptyset, \ldots$, $\mu^*(E) \le \mu(E)$. Conversely, for any cover $(F_n) \in \mathcal{C}_{\mathcal{A}}(E)$, set $G_n := E \cap \left(F_n \setminus \bigcup_{k<n} F_k\right)$.

Then (G_n) is disjoint in $\mathcal{A}$, $\bigcup_n G_n = E$, and $G_n \subseteq F_n$, so $\mu(E) = \sum_n \mu(G_n) \le \sum_n \mu(F_n)$.

Hence $\mu(E) \le \mu^*(E)$ by taking infima.

Structural Commentary: Cover containment and regrouping establish the outer-measure axioms.
Key Insight: Disjointize algebra covers to recover μ. □

Proposition 3.1.12. *Single-Set Envelope Comparison*
Let $\mu : \mathcal{A} \to [0,+\infty]$ be a premeasure on an algebra $\mathcal{A} \subseteq \mathcal{P}(X)$, let μ^* be the generated outer measure, and define $\mu^\sharp : \mathcal{P}(X) \to [0,+\infty]$ by $\mu^\sharp(B) := \inf\{\mu(C) : C \in \mathcal{A},\ B \subseteq C\}$ with $\inf\emptyset = +\infty$.

(i) $\mu^\sharp(E) = \mu(E)$ for every $E \in \mathcal{A}$.
(ii) $\mu^*(B) \le \mu^\sharp(B)$ for every $B \subseteq X$.

Proof.

(i) If $E \in \mathcal{A}$, then E is admissible, so $\mu^\sharp(E) \le \mu(E)$.
Conversely, $E \subseteq C \in \mathcal{A}$ implies $\mu(E) \le \mu(C)$ by monotonicity of μ, hence $\mu(E) \le \mu^\sharp(E)$.

(ii) If no $C \in \mathcal{A}$ contains B, then $\mu^\sharp(B) = +\infty$. Otherwise, $\mu^*(B) \le \mu(C)$ by the algebra cover $C, \emptyset, \emptyset, \ldots$ for each $C \in \mathcal{A}$ with $B \subseteq C$. Hence $\mu^*(B) \le \mu^\sharp(B)$ by taking infima over such C.

Structural Commentary: One algebra superset is a special countable cover.
Key Insight: The single-set envelope is larger. □

Counterexample 3.1.13. *Single-Set Envelopes Need Not Be Outer Measures*
Let X be uncountable, let $\mathcal{A}$ be the finite–cofinite algebra on X, and set $\mu(E) := 0$ for finite E, $\mu(E) := +\infty$ for cofinite E. Then μ is a premeasure, $\mu^*(B) = 0$ iff B is countable, and $\mu^\sharp(B) = 0$ iff B is finite.
For any countably infinite $S \subseteq X$, $\mu^\sharp(S) = +\infty$ while $S = \bigcup_{x\in S}\{x\}$ and $\sum_{x\in S}\mu^\sharp(\{x\}) = 0$, so $\mu^\sharp$ is not countably subadditive.
Structural Commentary: Countable covers can be strictly smaller than one-set covers.
Key Insight: Outer measure is built from countable covers precisely to recover countable subadditivity.

Theorem 3.1.14. *Generated Caratheodory Extension*
Let $\mu : \mathcal{A} \to [0,+\infty]$ be a premeasure on an algebra $\mathcal{A} \subseteq \mathcal{P}(X)$. For $B \subseteq X$, put $\mathcal{C}_{\mathcal{A}}(B) := \{(E_j) \in \mathcal{A}^{\mathbb{N}} : B \subseteq \bigcup_j E_j\}$. Define $\mu^*(\emptyset) = 0$, $\mu^*(B) := \inf_{(E_j)\in\mathcal{C}_{\mathcal{A}}(B)} \sum_j \mu(E_j)$ for $B \neq \emptyset$ with $\inf\emptyset = +\infty$, and $\mathcal{C}_\mu := \{E \subseteq X : (\forall B \subseteq X)\ \mu^*(B) = \mu^*(B\cap E) + \mu^*(B \setminus E)\}$. Then:

(i) $\mathcal{A} \subseteq \mathcal{C}_\mu$ and $\mu^*|_{\mathcal{A}} = \mu$.
(ii) $\mathcal{C}_\mu$ is a σ-algebra on X.
(iii) $\mu^*|_{\mathcal{C}_\mu}$ is a complete measure extending μ.

Proof. By Lemma 3.1.11, μ^* is an outer measure and $\mu^*|_{\mathcal{A}} = \mu$.

(i) Let $E \in \mathcal{A}$ and $B \subseteq X$. By subadditivity, $\mu^*(B) \le \mu^*(B\cap E) + \mu^*(B \setminus E)$. If $(F_n) \in \mathcal{C}_{\mathcal{A}}(B)$, then $F_n \cap E, F_n \setminus E \in \mathcal{A}$ and $\mu(F_n) = \mu(F_n\cap E) + \mu(F_n \setminus E)$, so $\mu^*(B\cap E) + \mu^*(B\setminus E) \le \sum_n \mu(F_n)$.

Infimizing over (F_n) establishes equality; hence $E \in \mathcal{C}_\mu$. Moreover, $\mu^*|_{\mathcal{A}} = \mu$ by Lemma 3.1.11.

(ii) The class $\mathcal{C}_\mu$ is exactly the μ^*-measurable class $\mathcal{M}_{\mu^*}$.
By Theorem 3.1.6(ii), $\mathcal{C}_\mu$ is a σ-algebra on X.

(iii) By Theorem 3.1.6(iii), $\mu^*|_{\mathcal{C}_\mu}$ is countably additive. If $A \subseteq Z \in \mathcal{C}_\mu$ and $\mu^*(Z) = 0$, then $\mu^*(A) = 0$ by monotonicity and $A \in \mathcal{C}_\mu$ by Theorem 3.1.6(i). Thus $\mu^*|_{\mathcal{C}_\mu}$ is complete, and it extends μ by (i).

Structural Commentary: Caratheodory equality is the additivity domain.
Key Insight: Algebra sets split every algebra cover. □

Proposition 3.1.15. *Caratheodory Splitters for Finitely Subadditive Size*
Let $\alpha : \mathcal{P}(X) \to [0,+\infty)$ satisfy $0 \le \alpha(E) \le \alpha(E\cup F) \le \alpha(E) + \alpha(F)$ for all $E, F \subseteq X$.
Set $\mathcal{S} := \{E \subseteq X : (\forall A \subseteq X)\ \alpha(A) = \alpha(A\cap E) + \alpha(A \setminus E)\}$.

(i) If $\mathcal{S} \neq \emptyset$, then $\mathcal{S}$ is an algebra on X.
(ii) If $E, F \in \mathcal{S}$ and $E \cap F = \emptyset$, then $\alpha(E\cup F) = \alpha(E) + \alpha(F)$.
(iii) The hypothesis $\mathcal{S} \neq \emptyset$ in (i) is necessary: if $\alpha \equiv 1$, then $\mathcal{S} = \emptyset$.

Proof.

(i) Choose $E_0 \in \mathcal{S}$. By splitting $\emptyset$, $\alpha(\emptyset) = 0$, hence $\emptyset, X \in \mathcal{S}$.
By complement symmetry, $E \in \mathcal{S} \Rightarrow X\setminus E \in \mathcal{S}$. For $E, F \in \mathcal{S}$ and $A \subseteq X$, put $A_{11} = A\cap E\cap F$, $A_{10} = A\cap E\setminus F$, $A_{01} = A\cap F\setminus E$, and $A_{00} = A \setminus (E\cup F)$. By successive splitting,
$\alpha(A) = \alpha(A_{11}) + \alpha(A_{10}) + \alpha(A_{01}) + \alpha(A_{00})$; $\alpha(A\setminus(E\cap F)) = \alpha(A_{10}) + \alpha(A_{01}) + \alpha(A_{00})$.
Thus $\alpha(A) = \alpha(A\cap E\cap F) + \alpha(A\setminus(E\cap F))$, so $E\cap F \in \mathcal{S}$. Finite unions follow by complements.

(ii) Since $F \subseteq X \setminus E$, $\alpha(E\cup F) = \alpha(E) + \alpha(F)$ by the splitting identity for E with $A = E\cup F$.

(iii) If $\alpha \equiv 1$ and $E \in \mathcal{S}$, then $1 = 1 + 1$ by the splitting identity with $A = \emptyset$, which is impossible.

Structural Commentary: Splitters are Boolean once one splitter exists.
Key Insight: Empty-set splitting forces $\alpha(\emptyset) = 0$. □

Theorem 3.1.16. *σ-Finite Generated Extensions Are Unique*
Let $\mu : \mathcal{A} \to [0, +\infty]$ be a premeasure on an algebra $\mathcal{A} \subseteq \mathcal{P}(X)$, let μ^* be generated by μ, and put $\mathcal{C}_\mu := \{E \subseteq X : (\forall B \subseteq X)\ \mu^*(B) = \mu^*(B \cap E) + \mu^*(B \setminus E)\}$. Assume $X = \bigcup_n F_n$; $F_n \in \mathcal{A}$, $\mu(F_n) < +\infty$ $\forall n$.

(i) $\mu^*|_{\mathcal{C}_\mu}$ is a measure on $\mathcal{C}_\mu$ and extends μ.
(ii) If ν is a measure on $\mathcal{C}_\mu$ with $\nu|_{\mathcal{A}} = \mu$, then $\nu = \mu^*|_{\mathcal{C}_\mu}$.

Proof.
(i) By Theorem 3.1.14, $\mathcal{C}_\mu$ is a σ-algebra, $\mathcal{A} \subseteq \mathcal{C}_\mu$, and $\mu^*|_{\mathcal{C}_\mu}$ is a complete measure with $(\mu^*|_{\mathcal{C}_\mu})|_{\mathcal{A}} = \mu$.
(ii) Let ν be a measure on $\mathcal{C}_\mu$ with $\nu|_{\mathcal{A}} = \mu$.
If $G \in \mathcal{C}_\mu$ and $G \subseteq \bigcup_n A_n$ with $A_n \in \mathcal{A}$, then $\nu(G) \le \sum_n \mu(A_n)$; hence $\nu(G) \le \mu^*(G)$.
If $\mu(X) < +\infty$, then $\nu(E) = \mu^*(E)$ by the bound for $G = E, X \setminus E$ and the identity $\nu(E) + \nu(X \setminus E) = \nu(X) = \mu^*(X) = \mu^*(E) + \mu^*(X \setminus E)$. In general, put $H_N := \bigcup_{j=1}^{N} F_j$. Then $H_N \in \mathcal{A}$ and $\mu(H_N) < +\infty$.
By the bound for $E \cap H_N, H_N \setminus E$ and $\nu(E \cap H_N) + \nu(H_N \setminus E) = \nu(H_N) = \mu^*(H_N) = \mu^*(E \cap H_N) + \mu^*(H_N \setminus E)$, one has $\nu(E \cap H_N) = \mu^*(E \cap H_N)$. Since $E \cap H_N \uparrow E$, $\nu(E) = \mu^*(E)$ by continuity from below.

Structural Commentary: Finite uniqueness localizes along a finite-mass exhaustion.
Key Insight: Compare on each finite piece, then pass upward. □

Corollary 3.1.17. *Uniqueness on the Generated σ-Algebra*
Let $\mu : \mathcal{A} \to [0, +\infty]$ be a premeasure on an algebra $\mathcal{A} \subseteq \mathcal{P}(X)$, and assume $X = \bigcup_n F_n$ with $F_n \in \mathcal{A}$ and $\mu(F_n) < +\infty$. If measures ν_1, ν_2 on $\sigma(\mathcal{A})$ extend μ, then $\nu_1 = \nu_2$.

Proof. Put $H_n := \bigcup_{j=1}^{n} F_j$. Then $H_n \in \mathcal{A}$, $H_n \uparrow X$, and $\nu_i(H_n) = \mu(H_n) < +\infty$.
For fixed n, $\mathcal{D}_n := \{E \in \sigma(\mathcal{A}) : \nu_1(E \cap H_n) = \nu_2(E \cap H_n)\}$ is a Dynkin class by finite mass on H_n and contains $\mathcal{A}$, since $A \cap H_n \in \mathcal{A}$.
As $\mathcal{A}$ is a π-system, $\mathcal{D}_n = \sigma(\mathcal{A})$ by the π-λ theorem.
Hence $\nu_1(E \cap H_n) = \nu_2(E \cap H_n)$ for all n; since $E \cap H_n \uparrow E$, $\nu_1(E) = \nu_2(E)$ by continuity from below.
Structural Commentary: Finite exhaustions reduce uniqueness to Dynkin closure.
Key Insight: Compare on H_n, then pass upward. □

Example 3.1.18. *Why σ-Finiteness Matters*
Let $X = \mathbb{Q} \cap (0, 1]$, and let $\mathcal{A}$ be the algebra of finite unions of sets $(a, b] \cap X$, where $0 \le a < b \le 1$ and $a, b \in \mathbb{Q}$.
(i) *Infinite algebra pieces*: Every nonempty $A \in \mathcal{A}$ is infinite.
(ii) *Generated σ-algebra*: For $r \in X$, choose $a_n \in \mathbb{Q} \cap [0, r)$ with $a_n \uparrow r$.
Then $\{r\} = \bigcap_{n=1}^{\infty} ((a_n, r] \cap X) \in \sigma(\mathcal{A})$, hence $\sigma(\mathcal{A}) = \mathcal{P}(X)$.
(iii) *Nonunique extensions*: Let μ_1 be counting measure and $\mu_2 = 2\mu_1$ on $\mathcal{P}(X)$.
Since every nonempty $A \in \mathcal{A}$ is infinite, $\mu_1|_{\mathcal{A}} = \mu_2|_{\mathcal{A}}$, but $\mu_1(\{r\}) = 1 \ne 2 = \mu_2(\{r\})$ for $r \in X$.
Thus uniqueness may fail without σ-finiteness.
Key Insight: Infinite algebra pieces cannot determine singleton scale.

3.2 Euclidean Cells and Cell Outer Measure

Definition 3.2.1. *Cells, Intervals, and Volume in $\mathbb{R}^p$*
Fix $p \ge 1$.
(i) *Cells in $\mathbb{R}$*. For $a \le b$, a cell with endpoints a, b is $I \in \{(a, b), [a, b], (a, b], [a, b)\}$.
If $a = b$, only $[a, a]$ is nonempty.
(ii) *Length*. If I is a cell with endpoints $a \le b$, then $\ell(I) := b - a$; unbounded intervals $(-\infty, a)$, $(-\infty, a]$, $[a, +\infty)$, $(a, +\infty)$, and $\mathbb{R}$ are not cells and have length $+\infty$.
(iii) *Cells in $\mathbb{R}^p$*. A cell is $I = \prod_{i=1}^{p} I_i$, each I_i a cell in $\mathbb{R}$; $\prod_i (a_i, b_i)$ is open, $\prod_i [a_i, b_i]$ is closed, $\prod_i [a_i, b_i)$ is *southwest*, $\prod_i (a_i, b_i]$ is *northeast*, and I is a *cube* iff $\ell(I_1) = \cdots = \ell(I_p)$.
(iv) *Volume*. For a cell $I = \prod_{i=1}^{p} I_i$ with endpoints $a_i \le b_i$, $\mathrm{vol}_p(I) := \prod_{i=1}^{p} \ell(I_i) = \prod_{i=1}^{p} (b_i - a_i)$.
Also $\mathrm{vol}_p(\emptyset) := 0$ and $\mathrm{vol}_p(I^\circ) = \mathrm{vol}_p(\overline{I}) = \mathrm{vol}_p(I)$.
(v) *Unbounded products*. For $I = \prod_{i=1}^{p} I_i$ with possibly unbounded intervals, $\mathrm{vol}_p(I) = 0$ if $\exists j : \ell(I_j) = 0$, $\mathrm{vol}_p(I) = +\infty$ if $\ell(I_i) > 0$ for all i and $\exists j : \ell(I_j) = +\infty$, and $\mathrm{vol}_p(I) = \prod_{i=1}^{p} \ell(I_i)$ otherwise.

Remark 3.2.2. *Cells versus Intervals*
Cells are precisely bounded intervals with finite endpoints, so every cell is an interval but not conversely.
Open cells are open in $\mathbb{R}^p$, closed cells are closed in $\mathbb{R}^p$, and nonempty half-open cells are neither.
In $\mathbb{R}$, $(-\infty, a)$ and $(b, +\infty)$ are open, $(-\infty, a]$ and $[b, +\infty)$ are closed, and $\mathbb{R} = (-\infty, +\infty)$ is clopen.
Key Insight: Topology likes open and closed endpoints; measure bookkeeping often likes half-open endpoints.

Proposition 3.2.3. *Half-Open Cell Calculus*
Fix $\sigma \in \{\text{southwest}, \text{northeast}\}$, and let $\mathcal{H}_\sigma$ be the half-open cells in $\mathbb{R}^p$ with orientation σ.

(i) Any finite Boolean combination of $H_1, \dots, H_n \in \mathcal{H}_\sigma$ is $\bigsqcup_{r=1}^{N} K_r$ with $K_r \in \mathcal{H}_\sigma$.
(ii) If $H \in \mathcal{H}_\sigma$, then $\mathbb{R}^p \setminus H = \bigsqcup_{r=1}^{\infty} K_r$ for some $K_r \in \mathcal{H}_\sigma$.
(iii) For $H \in \mathcal{H}_\sigma$ and $\delta > 0$, $H = \bigsqcup_{r=1}^{N} K_r$ for some $K_r \in \mathcal{H}_\sigma$ with $\operatorname{diam} K_r < \delta$.

Proof.
(i) For coordinate endpoints $E_j = \{c_{j,0} < \cdots < c_{j,m_j}\}$ of $H_1, \dots, H_n$, set $[a, b)_\sigma = [a, b)$ if $\sigma = \text{southwest}$ and $[a, b)_\sigma = (a, b]$ if $\sigma = \text{northeast}$, $\mathcal{P}_j = \{[c_{j,q-1}, c_{j,q})_\sigma : 1 \le q \le m_j\}$, and $\mathcal{G} = \{\prod_{j=1}^{p} P_j : P_j \in \mathcal{P}_j\}$.
Every finite Boolean combination is $\bigsqcup_{G \in \mathcal{G}'} G$, $\mathcal{G}' \subseteq \mathcal{G}$.

(ii) Write $H = \prod_{j=1}^{p} H_j$ and $D_s = (\prod_{j<s} H_j) \times (\mathbb{R} \setminus H_s) \times \mathbb{R}^{p-s}$; then $\mathbb{R}^p \setminus H = \bigsqcup_{s=1}^{p} D_s$. Decomposing each one-dimensional ray and $\mathbb{R}$ into countably many bounded σ-half-open intervals and taking products produces the required union. By Corollary 6.2.17, the product family is countable.
(iii) Choose m with $2^{-m}(\sum_{j=1}^{p} \ell(H_j)^2)^{1/2} < \delta$. After m bisections per coordinate, each subcell has diameter $< \delta$; disjointness and volume preservation follow coordinatewise.

Structural Commentary: Half-open cells behave like grid atoms: finite set operations become finite grid selection.
Key Insight: Half-open endpoints prevent overlap while still partitioning boxes cleanly. □

Definition 3.2.4. *Translation of a Set*
If $A \subseteq \mathbb{R}^p$ and $t \in \mathbb{R}^p$, the translate of A by t is $t + A := \{t + a : a \in A\}$.

Proposition 3.2.5. *Cell Volume Is Translation Invariant*
Let $I = \prod_{i=1}^{p} I_i$ be a cell in $\mathbb{R}^p$ and $t = (t_i)_{i=1}^{p} \in \mathbb{R}^p$.
Then $t + I = \prod_{i=1}^{p}(t_i + I_i)$ is a cell with the same endpoint pattern as I, and $\mathrm{vol}_p(t + I) = \mathrm{vol}_p(I)$.

Proof. Let $a_i \le b_i$ be the endpoints of I_i. Then $t_i + I_i$ has endpoints $t_i + a_i \le t_i + b_i$, unchanged endpoint inclusion, and $\ell(t_i + I_i) = (t_i + b_i) - (t_i + a_i) = \ell(I_i)$. Hence $\mathrm{vol}_p(t + I) = \prod_{i=1}^{p} \ell(t_i + I_i) = \prod_{i=1}^{p} \ell(I_i) = \mathrm{vol}_p(I)$.
Structural Commentary: Translation moves location but not side lengths.
Key Insight: Coordinate volume depends only on side lengths. □

Definition 3.2.6. *Elementary Sets and Regularity in $\mathbb{R}^p$*
(i) *Elementary sets.* $\mathcal{E} := \{\bigcup_{r=1}^{n} I_r : n \in \mathbb{N}\}$, where each $I_r \subseteq \mathbb{R}^p$ is a bounded cell.
(ii) *Elementary volume.* If $A = \bigsqcup_{r=1}^{n} I_r$ with cells I_r, set $m(A) := \sum_{r=1}^{n} \mathrm{vol}_p(I_r)$.
(iii) *Regularity.* A nonnegative additive $\mu : \mathcal{E} \to [0, +\infty]$ is regular iff $\forall A \in \mathcal{E}$, $\forall \varepsilon > 0$, $\exists F, G \in \mathcal{E}$ with $F \subseteq A \subseteq G$, F closed, G open, and $\mu(G) - \varepsilon \le \mu(A) \le \mu(F) + \varepsilon$.

$\mathcal{E}$ is a ring; every $A \in \mathcal{E}$ admits a finite disjoint cell decomposition; m is well defined, additive, and regular.

Perspective 3.2.7. *Box Volume and Linear Algebra*
For a box $B = \prod_i (a_i, b_i)$ or $\prod_i [a_i, b_i]$, $m(B) = \prod_i (b_i - a_i)$, the diagonal case of determinant volume scaling.
Measure extends this product rule beyond boxes.
Key Insight: Lebesgue measure starts from determinant-style coordinate volume.

Proposition 3.2.8. *Lattice Counts Recover Cell Volume*
Fix $p \ge 1$. For $q \ge 1$ and $A \subseteq \mathbb{R}^q$, write $N_{\mathbb{Z}}(A) := \#(A \cap \mathbb{Z}^q)$, and for $\lambda > 0$ set $D_\lambda A := \{\lambda x : x \in A\}$.
If $I = \prod_{j=1}^{p} I_j$ is a bounded cell in $\mathbb{R}^p$, then $\lim_{\lambda \to +\infty} \lambda^{-p} N_{\mathbb{Z}}(D_\lambda I) = \mathrm{vol}_p(I)$.

Proof. For a bounded interval $J \subseteq \mathbb{R}$ with length L, $\max\{0, \lambda L - 1\} \le N_{\mathbb{Z}}(D_\lambda J) \le \lambda L + 1$.
Hence $\lambda^{-1} N_{\mathbb{Z}}(D_\lambda J) \to L$ if $L > 0$, and $N_{\mathbb{Z}}(D_\lambda J) \le 1$ if $L = 0$.
Let $L_j := \ell(I_j)$. Since $D_\lambda I = \prod_j D_\lambda I_j$, $N_{\mathbb{Z}}(D_\lambda I) = \prod_j N_{\mathbb{Z}}(D_\lambda I_j)$.
If every $L_j > 0$, then $\lambda^{-p} N_{\mathbb{Z}}(D_\lambda I) = \prod_j \lambda^{-1} N_{\mathbb{Z}}(D_\lambda I_j) \to \prod_j L_j = \mathrm{vol}_p(I)$.
If some $L_j = 0$, then $N_{\mathbb{Z}}(D_\lambda I) = O(\lambda^{p-1})$, so $\lambda^{-p} N_{\mathbb{Z}}(D_\lambda I) \to 0 = \mathrm{vol}_p(I)$.
Structural Commentary: Coordinate lattice density multiplies.
Key Insight: Endpoint effects are lower order. □

Perspective 3.2.9. *Outer Measure as Overestimation*
Elementary $A = \bigsqcup_{r=1}^{n} I_r$ have $m(A) = \sum_{r=1}^{n} \mathrm{vol}_p(I_r)$.
General $E \subseteq \mathbb{R}^p$, e.g. $D = \{(x, y) \in \mathbb{R}^2 : x^2 + y^2 \le 1\}$, need not be a finite disjoint cell union.
Replace decompositions by countable cell covers $E \subseteq \bigcup_{k=1}^{\infty} I_k$ and minimize $\sum_{k=1}^{\infty} \mathrm{vol}_p(I_k)$.
Key Insight: Outer covers size every $E \subseteq \mathbb{R}^p$ before measurability.

Definition 3.2.10. *Cell-Cover Outer Measure*
For $E \subseteq \mathbb{R}^p$, let $\mathcal{C}(E)$ be the countable cell covers $(I_k)_{k \ge 1}$ with $E \subseteq \bigcup_{k=1}^{\infty} I_k$. Define $m_p^*(E) := \inf_{(I_k) \in \mathcal{C}(E)} \sum_{k=1}^{\infty} \mathrm{vol}_p(I_k)$.

Here $\mathcal{C}(E) \neq \emptyset$ since $E \subseteq \bigcup_{j=1}^{\infty} [-j, j]^p$, and the sum is a nonnegative extended-real series, hence order-independent.

Proposition 3.2.11. *Equivalent Covering Families*
Let $E \subseteq \mathbb{R}^p$, $\delta > 0$, and fix a half-open orientation σ. Let $\mathcal{C}_{\mathsf{cl}}(E), \mathcal{C}_{\mathsf{op}}(E), \mathcal{C}_\sigma(E), \mathcal{C}_\delta(E) \subseteq \mathcal{C}(E)$ denote covers by closed cells, open cells, σ-half-open cells, and cells with diameter $< \delta$, respectively.
For $\mathcal{F} \subseteq \mathcal{C}(E)$, put $\alpha(\mathcal{F}) := \inf_{(I_k) \in \mathcal{F}} \sum_k \mathrm{vol}_p(I_k)$. Then $m_p^*(E) = \alpha(\mathcal{C}_{\mathsf{cl}}(E)) = \alpha(\mathcal{C}_{\mathsf{op}}(E)) = \alpha(\mathcal{C}_\sigma(E)) = \alpha(\mathcal{C}_\delta(E))$.

Proof. Let $\mathfrak{C} := \{\mathcal{C}_{\mathsf{cl}}(E), \mathcal{C}_{\mathsf{op}}(E), \mathcal{C}_\sigma(E), \mathcal{C}_\delta(E)\}$. Since each $\mathcal{F} \in \mathfrak{C}$ satisfies $\mathcal{F} \subseteq \mathcal{C}(E)$, $\alpha(\mathcal{F}) \ge m_p^*(E)$.
Conversely, fix $(I_k) \in \mathcal{C}(E)$ and $\varepsilon > 0$. The chain $I_k \subseteq \overline{I_k} \subseteq J_k$, with J_k open and $\sum_k \mathrm{vol}_p(J_k) \le \sum_k \mathrm{vol}_p(I_k) + \varepsilon$, followed by disjoint σ-half-open decomposition and finite δ-subdivision, produces covers in every $\mathcal{F} \in \mathfrak{C}$ of total volume $\le \sum_k \mathrm{vol}_p(I_k) + \varepsilon$. Infimize over (I_k) and let $\varepsilon \downarrow 0$.
Structural Commentary: Cover normalizations preserve the infimum.
Key Insight: Change endpoints, then refine. □

Proposition 3.2.12. *Basic Properties of Cell-Cover Outer Measure*
For $E, F, E_n \subseteq \mathbb{R}^p$,
(i) Null empty set. $0 \le m_p^*(E) \le +\infty$ *and* $m_p^*(\emptyset) = 0$.
(ii) Monotonicity. $E \subseteq F \Longrightarrow m_p^*(E) \le m_p^*(F)$.
(iii) Subadditivity. $m_p^*(\bigcup_{n=1}^{\infty} E_n) \le \sum_{n=1}^{\infty} m_p^*(E_n)$.

Proof.

(i) Since all cover sums lie in $[0,+\infty]$, $0 \le m_p^*(E) \le +\infty$; moreover, $m_p^*(\emptyset) = 0$ by the cover $(\emptyset, \emptyset, \dots)$.
(ii) If $E \subseteq F$, then $\mathcal{C}(F) \subseteq \mathcal{C}(E)$, hence $\inf_{\mathcal{C}(E)} \le \inf_{\mathcal{C}(F)}$.
(iii) If some $m_p^*(E_n) = +\infty$, the claim is trivial.
Otherwise, for $\varepsilon > 0$, choose $(I_k^n)_{k\ge1} \in \mathcal{C}(E_n)$ with $\sum_k \mathrm{vol}_p(I_k^n) \le m_p^*(E_n) + \varepsilon 2^{-n}$.
Then $(I_k^n)_{(n,k)\in\mathbb{N}^2}$ countable, covers $\bigcup_n E_n$, and $m_p^*(\bigcup_n E_n) \le \sum_{n,k} \mathrm{vol}_p(I_k^n) \le \sum_n m_p^*(E_n) + \varepsilon$.
Structural Commentary: Countable subadditivity is proved by merging near-optimal covers.
Key Insight: Nonnegative double sums may be scanned in one sequence. □

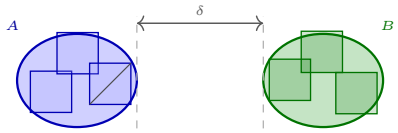

Figure 190: Positive distance separates cells with $\operatorname{diam} I_k < \delta$.

Figure 190 shows why a cell of diameter below the gap δ cannot meet both sets.

Theorem 3.2.13. *Additivity at Positive Distance*
Let $A, B \subseteq \mathbb{R}^p$ be nonempty and disjoint, and suppose $\mathrm{dist}(A,B) := \inf\{\|a-b\|_2 : a \in A,\ b \in B\} > 0$.
Then $m_p^*(A \cup B) = m_p^*(A) + m_p^*(B)$.

Proof. By Proposition 3.2.12, $m_p^*(A \cup B) \le m_p^*(A) + m_p^*(B)$. For the reverse inequality, set $\delta := \mathrm{dist}(A,B)$. If $m_p^*(A \cup B) = +\infty$, done.
Otherwise, given $\varepsilon > 0$, choose $(I_n) \in \mathcal{C}(A \cup B)$ with $\operatorname{diam} I_n < \delta$ and $\sum_n \mathrm{vol}_p(I_n) \le m_p^*(A \cup B) + \varepsilon$.
Put $N_A := \{n : I_n \cap A \ne \emptyset\}$ and $N_B := \{n : I_n \cap B \ne \emptyset\}$. Since $N_A \cap N_B = \emptyset$, $(I_n)_{n\in N_A}$ covers A, $(I_n)_{n\in N_B}$ covers B, and $m_p^*(A) + m_p^*(B) \le \sum_{n\in N_A} \mathrm{vol}_p(I_n) + \sum_{n\in N_B} \mathrm{vol}_p(I_n) \le \sum_n \mathrm{vol}_p(I_n) \le m_p^*(A \cup B) + \varepsilon$. Let $\varepsilon \downarrow 0$.
Structural Commentary: Positive separation lets a sufficiently fine cover be sorted unambiguously.
Key Insight: Countable subadditivity becomes equality when no small cell can touch both pieces. □

Theorem 3.2.14. *Outer Measure of a Cell*
If I is a cell in $\mathbb{R}^p$, then $m_p^*(I) = \mathrm{vol}_p(I)$.

Proof. By the cover $(I, \emptyset, \dots)$, $m_p^*(I) \le \mathrm{vol}_p(I)$. For the reverse inequality, the case $\mathrm{vol}_p(I) = 0$ follows by nonnegativity.
Assume $\mathrm{vol}_p(I) > 0$ and fix $\varepsilon > 0$. Choose a closed cell $J \subseteq I$ with $\mathrm{vol}_p(I) - \varepsilon < \mathrm{vol}_p(J)$, taking $J = I$ when I is closed. For any open-cell cover (G_k) of I, $J \subseteq \bigcup_{k=1}^m G_k$ for some m by compactness.
Let $\mathcal{Q}$ be the finite rectangular grid determined by the faces of $J, \overline{G_1}, \dots, \overline{G_m}$. Up to zero-volume boundary atoms, each $Q \in \mathcal{Q}$ with $Q \subseteq J$ lies in some G_k, hence $\mathrm{vol}_p(J) \le \sum_{k=1}^m \mathrm{vol}_p(G_k) \le \sum_{k=1}^\infty \mathrm{vol}_p(G_k)$.
By Proposition 3.2.11, the infimum of the open-cell cover sums is $m_p^*(I)$, so $\mathrm{vol}_p(I) - \varepsilon < \mathrm{vol}_p(J) \le m_p^*(I)$. Let $\varepsilon \downarrow 0$.
Structural Commentary: Compact inner cells reduce covers to finite grids.
Key Insight: Outer measure is calibrated so that cells keep their original volume. □

Corollary 3.2.15. *Outer Measure of Real Intervals*
Let $J \subseteq \mathbb{R}$ be a nonempty interval, and set $\ell(J) = +\infty$ when J is unbounded. Then $m_1^*(J) = \ell(J)$.

Proof. If J is bounded, then J is a one-dimensional cell, so $m_1^*(J) = \mathrm{vol}_1(J) = \ell(J)$ by Theorem 3.2.14.
If J is unbounded, then for every $N \in \mathbb{N}$ there exists a bounded interval $I_N \subseteq J$ with $\ell(I_N) = N$.
Hence $m_1^*(J) \ge m_1^*(I_N) = N$ by monotonicity and the bounded case. Thus $m_1^*(J) = +\infty = \ell(J)$.
Structural Commentary: Cells calibrate bounded intervals; monotonicity handles unbounded ones.
Key Insight: Infinite length is forced by arbitrarily long bounded subintervals. □

Theorem 3.2.16. *Translation Invariance of Outer Measure*
For $E \subseteq \mathbb{R}^p$ and $t \in \mathbb{R}^p$, $m_p^*(t+E) = m_p^*(E)$.

Proof. The map $\mathcal{C}(E) \to \mathcal{C}(t+E)$, $(I_k) \mapsto (t + I_k)$, is bijective with inverse $(J_k) \mapsto (-t + J_k)$.
By Proposition 3.2.5, $\sum_k \mathrm{vol}_p(t + I_k) = \sum_k \mathrm{vol}_p(I_k)$, so the two infima are equal.
Structural Commentary: Translate covers forward and backward.
Key Insight: Translation invariance of cell volume lifts directly to translation invariance of outer measure. □

3.3 Caratheodory Measurability and Lebesgue Measure

Definition 3.3.1. *Outer Measure and μ-Measurable Sets*
Let $\mathcal{E}$ and $\mathcal{E}_{\mathrm{op}}$ denote the elementary and open elementary subsets of $\mathbb{R}^p$, let $\mu : \mathcal{E} \to [0,\infty)$ be additive and regular, and set $A \triangle B := (A \setminus B) \cup (B \setminus A)$.

(i) For $E \subseteq \mathbb{R}^p$, $\mu^*(E) := \inf\{\sum_{n=1}^\infty \mu(A_n) : E \subseteq \bigcup_{n=1}^\infty A_n,\ A_n \in \mathcal{E}_{\mathrm{op}}\}$.
(ii) $d_\mu(A,B) := \mu^*(A \triangle B)$.
(iii) $\mathcal{M}_F(\mu)$ is the class of *finitely μ-measurable* sets: $E \in \mathcal{M}_F(\mu)$ iff $\exists (E_k)_{k\ge1} \subseteq \mathcal{E}$ with $d_\mu(E_k, E) \to 0$.
(iv) $\mathcal{M}(\mu)$ is the class of *μ-measurable* sets: $E \in \mathcal{M}(\mu)$ iff $E = \bigcup_{k=1}^\infty E_k$ for some $E_k \in \mathcal{M}_F(\mu)$.

Perspective 3.3.2. *Outer Measure as Outside Approximation*
Outer measure covers A from outside; $d_\mu(A,B) = \mu^*(A \triangle B)$ measures closeness.
Key Insight: Countable subadditivity collects near-optimal covers.

Theorem 3.3.3. *Elementary Approximation Extension*
Let $\mathcal{E}$, $\mathcal{E}_{\mathrm{op}}$, μ^*, d_μ, $\mathcal{M}_F(\mu)$, and $\mathcal{M}(\mu)$ be as in Definition 3.3.1. Then:

(i) $\mu^*(A) = \mu(A)$ for every $A \in \mathcal{E}$;

(ii) μ^* *is countably subadditive on* $2^{\mathbb{R}^p}$;
(iii) $\mathcal{M}(\mu)$ *is a* σ*-ring;*
(iv) $\mu^*|_{\mathcal{M}(\mu)}$ *is a measure.*

Proof.

(i) Let $A \in \mathcal{E}$. For $\varepsilon > 0$, choose $G \in \mathcal{E}_{\mathrm{op}}$ with $A \subseteq G$ and $\mu(G) \le \mu(A) + \varepsilon$ by regularity; then $\mu^*(A) \le \mu(A)$.
Conversely, choose closed elementary $F \subseteq A$ with $\mu(F) \ge \mu(A) - \varepsilon$ by regularity. Every open elementary cover of A covers F; some finite subfamily covers F by compactness, and its total μ-mass is at least $\mu(F)$ by additivity.
After taking infima and letting $\varepsilon \downarrow 0$, $\mu(A) \le \mu^*(A)$.

(ii) Let $E_j \subseteq \mathbb{R}^p$ for $j \ge 1$, and let $\varepsilon > 0$. For each j, choose an open elementary cover $(A_{j,n})_{n\ge1}$ of E_j with $\sum_{n=1}^{\infty} \mu(A_{j,n}) \le \mu^*(E_j) + \varepsilon 2^{-j}$. Then $(A_{j,n})_{j,n}$ covers $\bigcup_{j=1}^{\infty} E_j$, so $\mu^*(\bigcup_j E_j) \le \sum_j \mu^*(E_j) + \varepsilon$; let $\varepsilon \downarrow 0$.

(iii) If $A_k \to A$ and $B_k \to B$ in d_μ, with $A_k, B_k \in \mathcal{E}$, then $d_\mu(A_k \diamond B_k, A \diamond B) \le d_\mu(A_k, A) + d_\mu(B_k, B)$ for $\diamond \in \{\cup, \cap, \setminus\}$. Hence $\mathcal{M}_F(\mu)$ is a ring. Since difference distributes over countable unions, $\mathcal{M}(\mu)$ is a σ-ring.

(iv) If $A = \bigsqcup_{j=1}^{\infty} A_j$ with $A_j \in \mathcal{M}_F(\mu)$, then $\mu^*(A) \le \sum_j \mu^*(A_j)$ by subadditivity.
By finite additivity on $\mathcal{M}_F(\mu)$, $\mu^*(A) \ge \sum_{j=1}^{N} \mu^*(A_j)$ for every N, hence $\mu^*(A) \ge \sum_j \mu^*(A_j)$.
Disjointize countable $\mathcal{M}_F(\mu)$-decompositions.

Structural Commentary: Elementary sets are completed under the distance measured by symmetric difference.
Key Insight: Approximate by elementary sets, prove identities there, then pass through $d_\mu(A, B)$. □

Definition 3.3.4. *Extended and Lebesgue Measure*
Let μ^* be the outer measure induced by μ and let $\mathcal{M}(\mu)$ be its measurable class.

(i) The *extended measure* of μ is $\mu_{\mathrm{ext}} := \mu^*|_{\mathcal{M}(\mu)}$, usually denoted again by μ.
(ii) If $\mu = m$ is elementary volume on $\mathbb{R}^p$, then $m^*|_{\mathcal{M}(m)}$ is *Lebesgue measure* on $\mathbb{R}^p$.

By Proposition 3.2.11, the outer measure m_n^* from Definition 3.2.10 equals the infimum of total box volume over countable open-box covers.

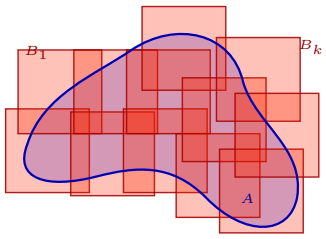

Figure 191: Cover $A \subseteq \bigcup_k B_k$ by squares; minimize $\sum_k |B_k|$.

Figure 191 depicts the open-box minimization used in the first construction step.

Method 3.3.5. *Lebesgue Measure Construction*

(i) *Cover from outside*
For $A \subseteq \mathbb{R}^n$, define $m_n^*(A) := \inf\left\{\sum_{j\in J} \mathrm{vol}_n(B_j) : (B_j)_{j\in J} \text{ covers } A,\ J \text{ at most countable}\right\}$.
This is defined for every set, but it is only countably subadditive in general.

(ii) *Keep the clean splitters*
Call A measurable when every test set $X \subseteq \mathbb{R}^n$ splits additively: $m_n^*(X) = m_n^*(X \cap A) + m_n^*(X \cap A^c)$.
These measurable sets form a σ-algebra.

(iii) *Restrict the outer measure*
Define Lebesgue measure on measurable sets by $m(A) := m_n^*(A)$.
On this restricted class, m is countably additive.

Key Insight: Outer measure sizes all sets; clean splitting restores additivity.

Definition 3.3.6. *Lebesgue* σ*-Algebra via Caratheodory*

(i) $\mathcal{L}^n := \{E \subseteq \mathbb{R}^n : E \text{ is } m_n^*\text{-measurable}\}$ is the *Lebesgue* σ*-algebra*.
(ii) $m := m_n^*|_{\mathcal{L}^n}$ is *Lebesgue measure*; for $E \in \mathcal{L}^n$, write $m(E) = m_n^*(E)$.

Proposition 3.3.7. *Outer-Null Sets Are Lebesgue Measurable*
If $Z \subseteq \mathbb{R}^n$ *and* $m_n^*(Z) = 0$*, then:*
(i) $Z \in \mathcal{L}^n$;
(ii) $m(Z) = 0$;
(iii) $\mathcal{P}(Z) \subseteq \mathcal{L}^n$ *and* $m(W) = 0$ *for every* $W \subseteq Z$.

Proof.

(i) For $A \subseteq \mathbb{R}^n$, $m_n^*(A \cap Z) = 0$ by monotonicity, so $m_n^*(A) \le m_n^*(A \cap Z) + m_n^*(A \cap Z^c) = m_n^*(A \cap Z^c) \le m_n^*(A)$; hence Z satisfies Caratheodory's criterion.

(ii) Since $Z \in \mathcal{L}^n$, $m(Z) = m_n^*(Z) = 0$.

(iii) If $W \subseteq Z$, then $m_n^*(W) \le m_n^*(Z) = 0$ by monotonicity; by (i)–(ii) applied to W, $W \in \mathcal{L}^n$ and $m(W) = 0$.

Structural Commentary: Lebesgue measure is complete because outer-null subsets split every test set trivially.
Key Insight: A zero piece cannot disturb additivity. □

Example 3.3.8. *Countable Real Sets Are Outer-Null*
Let $C \subseteq \mathbb{R}$ be finite or countable, and choose $(c_k)_{k\geq 1}$ with $C \subseteq \{c_k : k \geq 1\}$. For $\varepsilon > 0$, choose open intervals $I_k \ni c_k$ with $\ell(I_k) < \varepsilon 2^{-k}$. Then $C \subseteq \bigcup_{k\geq 1} I_k$, so $0 \leq m_1^*(C) \leq \sum_{k=1}^{\infty} \ell(I_k) < \varepsilon$. Since $\varepsilon > 0$ is arbitrary, $m_1^*(C) = 0$. By Proposition 3.3.7, $C \in \mathcal{L}^1$ and $m(C) = 0$.
Key Insight: A countable list can spend a rapidly decreasing measure budget around its points.

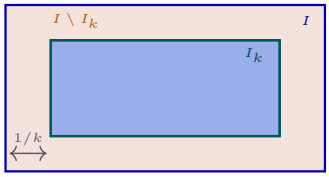

Figure 192: Inner cells I_k exhaust I; the collar $I \setminus I_k$ has vanishing volume.

Figure 192 depicts the shrinking inner cells and vanishing collar used in the positive-volume case.

Proposition 3.3.9. *Cells Are Lebesgue Measurable*
Let $I \subseteq \mathbb{R}^n$ be a coordinate cell. Then $I \in \mathcal{L}^n$ and $m(I) = \mathrm{vol}_n(I)$.

Proof. If $\mathrm{vol}_n(I) = 0$, then $m_n^*(I) = 0$ by Theorem 3.2.14, and $I \in \mathcal{L}^n$ with $m(I) = 0$ by Proposition 3.3.7.
Assume $\mathrm{vol}_n(I) > 0$. For small $r > 0$, let I_r be the inward r-shrink of I.
Then $\mathrm{dist}(I_r, \mathbb{R}^n \setminus I) > 0$ and $\eta_r := m_n^*(I \setminus I_r) \to 0$ by finite slab covers.
Fix $A \subseteq \mathbb{R}^n$ with $m_n^*(A) < +\infty$. The sets $A \cap I_r$ and $A \setminus I$ have positive distance whenever both are nonempty, so $m_n^*(A) \geq m_n^*(A \cap I_r) + m_n^*(A \setminus I)$ by Theorem 3.2.13; the empty cases are immediate.
Since $A \cap I \subseteq (A \cap I_r) \cup (I \setminus I_r)$, $m_n^*(A \cap I) \leq m_n^*(A \cap I_r) + \eta_r$; hence $m_n^*(A) \geq m_n^*(A \cap I) + m_n^*(A \setminus I) - \eta_r$.
After letting $r \downarrow 0$, the finite-measure test inequality holds, so $I \in \mathcal{L}^n$ by Lemma 3.1.4.
By Theorem 3.2.14, $m(I) = m_n^*(I) = \mathrm{vol}_n(I)$.
Structural Commentary: Cells are the bridge between coordinate volume and Lebesgue measure.
Key Insight: Shrink, split, let the collar vanish. □

3.4 Caratheodory-Hahn Extension

Definition 3.4.1. *Premeasures on Set Families*
Let $\emptyset \neq \mathcal{S} \subseteq \mathcal{P}(X)$ and $\mu : \mathcal{S} \to [0, +\infty]$.

(i) μ is *finitely additive on $\mathcal{S}$* if $\mu(\bigcup_{k=1}^{n} E_k) = \sum_{k=1}^{n} \mu(E_k)$ $\forall$ finite pairwise disjoint family $E_k \in \mathcal{S}$ with $\bigcup_{k=1}^{n} E_k \in \mathcal{S}$.

(ii) μ is *countably monotone on $\mathcal{S}$* if, for all $E, E_1, E_2, \ldots \in \mathcal{S}$ with $E \subseteq \bigcup_{k=1}^{\infty} E_k$, $\mu(E) \leq \sum_{k=1}^{\infty} \mu(E_k)$.

(iii) μ is a *premeasure on $\mathcal{S}$* if μ is finitely additive on $\mathcal{S}$, countably monotone on $\mathcal{S}$, and $\emptyset \in \mathcal{S} \Rightarrow \mu(\emptyset) = 0$.

Structural Commentary: No closure property of $\mathcal{S}$ is assumed; additivity is imposed only for finite disjoint unions which remain in $\mathcal{S}$, and countable monotonicity only for countable $\mathcal{S}$-covers of members of $\mathcal{S}$.

Proposition 3.4.2. *Necessary Conditions for Extension*
Let $\emptyset \neq \mathcal{S} \subseteq \mathcal{P}(X)$, let $\mu : \mathcal{S} \to [0, +\infty]$, let μ^* be the outer measure induced by μ, and put $\overline{\mu} := \mu^*|_{\mathcal{M}_{\mu^*}}$.
If $\mathcal{S} \subseteq \mathcal{M}_{\mu^*}$ and $\overline{\mu}(E) = \mu(E)$ for all $E \in \mathcal{S}$, then the following hold:
(i) $\emptyset \in \mathcal{S} \Rightarrow \mu(\emptyset) = 0$.
(ii) μ is finitely additive on $\mathcal{S}$.
(iii) μ is countably monotone on $\mathcal{S}$.
Hence μ is a premeasure on $\mathcal{S}$.

Proof. By the extension hypotheses, $\mu(F) = \overline{\mu}(F) = \mu^*(F)$ for every $F \in \mathcal{S}$.

(i) If $\emptyset \in \mathcal{S}$, then $\mu(\emptyset) = \overline{\mu}(\emptyset) = 0$.

(ii) Let $n \geq 1$, let $E_1, \ldots, E_n \in \mathcal{S}$ be pairwise disjoint, and assume $F := \bigcup_{k=1}^{n} E_k \in \mathcal{S}$.

Since $\overline{\mu}$ is a measure, $\mu(F) = \overline{\mu}(F) = \sum_{k=1}^{n} \overline{\mu}(E_k) = \sum_{k=1}^{n} \mu(E_k)$.

(iii) Let $E, E_1, E_2, \ldots \in \mathcal{S}$ and $E \subseteq \bigcup_{k=1}^{\infty} E_k$. By monotonicity and countable subadditivity of μ^*,

$\mu(E) = \mu^*(E) \leq \mu^*(\bigcup_{k=1}^{\infty} E_k) \leq \sum_{k=1}^{\infty} \mu^*(E_k) = \sum_{k=1}^{\infty} \mu(E_k)$.

Structural Commentary: The measure extension handles finite disjoint unions; μ^* handles countable covers.
Key Insight: Outer subadditivity supplies the inequality even when $\bigcup_k E_k \notin \mathcal{S}$. □

Definition 3.4.3. *Relative Complements and Semirings*
Let $\emptyset \neq \mathcal{S} \subseteq \mathcal{P}(X)$.

(i) $\mathcal{S}$ is *closed under relative complements* if $A, B \in \mathcal{S} \Rightarrow A \setminus B \in \mathcal{S}$.

(ii) $\mathcal{S}$ is a *semiring of sets* if, for all $A, B \in \mathcal{S}$, $A \cap B \in \mathcal{S}$ and $A \setminus B = \bigsqcup_{j=1}^{n} C_j$ for some $n \geq 0$ and $C_j \in \mathcal{S}$.

Structural Commentary: Relative-complement closure gives $\emptyset = A \setminus A \in \mathcal{S}$ and $A \cap B = A \setminus (A \setminus B) \in \mathcal{S}$.

Theorem 3.4.4. *Extension from Relative-Complement Families*
Let $\emptyset \neq \mathcal{S} \subseteq \mathcal{P}(X)$ be closed under relative complements, let $\mu : \mathcal{S} \to [0, +\infty]$ be a premeasure, and let μ^* be the outer measure induced by μ. Then:

(i) $\mu^*(E) = \mu(E)$ *for every* $E \in \mathcal{S}$.
(ii) $\mathcal{S} \subseteq \mathcal{M}_{\mu^*}$.

Proof.

(i) Fix $E \in \mathcal{S}$. The one-set cover gives $\mu^*(E) \leq \mu(E)$. If $(E_k)_{k\geq 1} \subseteq \mathcal{S}$ covers E, then countable monotonicity gives $\mu(E) \leq \sum_{k=1}^{\infty} \mu(E_k)$; taking the infimum over all such covers gives $\mu(E) \leq \mu^*(E)$.

(ii) Fix $A \in \mathcal{S}$. By Lemma 3.1.4, it suffices to prove $\mu^*(B \cap A) + \mu^*(B \setminus A) \leq \mu^*(B)$ for every $B \subseteq X$ with $\mu^*(B) < +\infty$. Let $\varepsilon > 0$ and choose an $\mathcal{S}$-cover $(E_k)_{k\geq 1}$ of B with $\sum_{k=1}^{\infty} \mu(E_k) < \mu^*(B) + \varepsilon$.

For each k, relative-complement closure gives $E_k \setminus A \in \mathcal{S}$ and $E_k \cap A = E_k \setminus (E_k \setminus A) \in \mathcal{S}$. By finite additivity, $\mu(E_k) = \mu(E_k \cap A) + \mu(E_k \setminus A)$. Since $(E_k \cap A)_{k\geq 1}$ covers $B \cap A$ and $(E_k \setminus A)_{k\geq 1}$ covers $B \setminus A$, $\mu^*(B \cap A) + \mu^*(B \setminus A) \leq \sum_{k=1}^{\infty} \mu(E_k \cap A) + \sum_{k=1}^{\infty} \mu(E_k \setminus A) = \sum_{k=1}^{\infty} \mu(E_k) < \mu^*(B) + \varepsilon$. Let $\varepsilon \downarrow 0$.

Structural Commentary: Countable monotonicity identifies μ with μ^*; finite additivity splits covers.
Key Insight: Relative complements turn one cover into inside/outside covers. □

Remark 3.4.5. *Two Roles of a Premeasure*
In Theorem 3.4.4, finite additivity is used to split each covering set across A and A^c, while countable monotonicity is used to force $\mu^*(E) = \mu(E)$ on the original family.
Key Insight: Measurability comes from finite splitting; extension equality comes from countable cover control.

Proposition 3.4.6. *Finite-Union Extension from a Semiring*
Let $\mathcal{S}$ be a semiring of subsets of X, and set $\mathcal{S}' := \{\bigsqcup_{k=1}^{n} A_k : n \geq 0,\ A_1, \ldots, A_n \in \mathcal{S}\}$. If $\mu : \mathcal{S} \to [0, +\infty]$ is a premeasure, define $\mu' : \mathcal{S}' \to [0, +\infty]$ by $\mu'(\bigsqcup_{k=1}^{n} A_k) := \sum_{k=1}^{n} \mu(A_k)$ for any disjoint representation. Then:

(i) $\mathcal{S}'$ *is closed under relative complements.*
(ii) μ' *is well-defined and extends* μ.
(iii) μ' *is a premeasure on* $\mathcal{S}'$.
(iv) μ' *is the unique premeasure on* $\mathcal{S}'$ *extending* μ.

Proof.

(i) Let $E = \bigsqcup_{i=1}^{r} A_i$ and $F = \bigsqcup_{j=1}^{s} B_j$ in $\mathcal{S}'$.
For each i, repeated semiring differences decompose $A_i \setminus F$ into finitely many disjoint $\mathcal{S}$-sets.
These decompositions, over $i = 1, \ldots, r$, form a finite disjoint $\mathcal{S}$-decomposition of $E \setminus F$, so $E \setminus F \in \mathcal{S}'$.

(ii) If $E = \bigsqcup_{i=1}^{r} A_i = \bigsqcup_{j=1}^{s} B_j$, then $A_i = \bigsqcup_{j=1}^{s} (A_i \cap B_j)$ and $B_j = \bigsqcup_{i=1}^{r} (A_i \cap B_j)$ with all intersections in $\mathcal{S}$.
Finite additivity of μ gives $\sum_{i=1}^{r} \mu(A_i) = \sum_{i=1}^{r} \sum_{j=1}^{s} \mu(A_i \cap B_j) = \sum_{j=1}^{s} \mu(B_j)$, so μ' is well-defined.
If $A \in \mathcal{S}$, the one-piece representation gives $\mu'(A) = \mu(A)$.

(iii) Since $\emptyset$ is the empty union, $\mu'(\emptyset) = 0$.
Finite additivity of μ' follows by refining finitely many disjoint $\mathcal{S}'$-sets to their disjoint $\mathcal{S}$-pieces.
For countable monotonicity, let $E = \bigsqcup_{i=1}^{r} A_i \in \mathcal{S}'$, let $F_m = \bigsqcup_{j=1}^{N_m} B_{mj} \in \mathcal{S}'$, assume $E \subseteq \bigcup_{m=1}^{\infty} F_m$.
For each i, $A_i \subseteq \bigcup_{m,j} (A_i \cap B_{mj})$ with $A_i \cap B_{mj} \in \mathcal{S}$, so $\mu(A_i) \leq \sum_{m,j} \mu(A_i \cap B_{mj})$.
Summing over i gives $\mu'(E) \leq \sum_m \sum_j \sum_i \mu(A_i \cap B_{mj})$.
For fixed m, j, repeated semiring differences decompose $B_{mj} \setminus \bigcup_i (A_i \cap B_{mj})$ into finitely many disjoint $\mathcal{S}$-sets, so finite additivity gives $\sum_i \mu(A_i \cap B_{mj}) \leq \mu(B_{mj})$. Thus $\mu'(E) \leq \sum_m \sum_j \mu(B_{mj}) = \sum_m \mu'(F_m)$.

(iv) If ν is a premeasure on $\mathcal{S}'$ extending μ, then finite additivity gives
$\nu(\bigsqcup_{k=1}^{n} A_k) = \sum_{k=1}^{n} \nu(A_k) = \sum_{k=1}^{n} \mu(A_k) = \mu'(\bigsqcup_{k=1}^{n} A_k)$ for every disjoint representation. Hence $\nu = \mu'$.

Structural Commentary: Finite disjoint unions close a semiring under relative complements.
Key Insight: All estimates reduce to intersections of semiring pieces. □

Theorem 3.4.7. *Caratheodory-Hahn Extension from a Semiring*
Let $\mathcal{S}$ be a semiring of subsets of X, let $\mu : \mathcal{S} \to [0, +\infty]$ be a premeasure, let μ^* be the outer measure induced by μ, and set $\overline{\mu} := \mu^*|_{\mathcal{M}_{\mu^*}}$. Then:

(i) $\mathcal{S} \subseteq \mathcal{M}_{\mu^*}$ *and* $\overline{\mu}(A) = \mu(A)$ *for every* $A \in \mathcal{S}$.
(ii) If $X = \bigcup_{k\geq 1} S_k$ *with* $S_k \in \mathcal{S}$ *and* $\mu(S_k) < +\infty$, *then* $\overline{\mu}$ *is* σ*-finite.*
(iii) Under the hypothesis in (ii), if ν *is a measure on* $\mathcal{M}_{\mu^*}$ *with* $\nu(A) = \mu(A)$ *for every* $A \in \mathcal{S}$, *then* $\nu = \overline{\mu}$.

Proof.

(i) Let $(\mathcal{S}', \mu')$ be the finite-union extension from Proposition 3.4.6. The $\mathcal{S}$- and $\mathcal{S}'$-cover infima coincide, so μ^* is also induced by μ'. Theorem 3.4.4 gives $\mathcal{S}' \subseteq \mathcal{M}_{\mu^*}$ and $\mu^*|_{\mathcal{S}'} = \mu'$. Since $\mu'|_{\mathcal{S}} = \mu$, the claim follows.

(ii) Assume $X = \bigcup_{k\geq 1} S_k$, $S_k \in \mathcal{S}$, $\mu(S_k) < +\infty$. By (i), each $S_k \in \mathcal{M}_{\mu^*}$, $\overline{\mu}(S_k) = \mu(S_k) < +\infty$, so $\overline{\mu}$ is σ-finite.

(iii) Assume (ii), and let ν be a measure on $\mathcal{M}_{\mu^*}$ extending μ. By finite additivity, $\nu = \overline{\mu} = \mu'$ on $\mathcal{S}'$.

Hence every $\mathcal{S}'$-cover of $E \in \mathcal{M}_{\mu^*}$ gives $\nu(E) \leq$ its μ'-mass, so $\nu(E) \leq \overline{\mu}(E)$. Put $H_n := \bigcup_{k=1}^{n} S_k \in \mathcal{S}'$.

Then $H_n \uparrow X$ and $\nu(H_n) = \overline{\mu}(H_n) = \mu'(H_n) < +\infty$.
Applying $\nu \leq \overline{\mu}$ to $E \cap H_n$ and $H_n \setminus E$ forces $\nu(E \cap H_n) = \overline{\mu}(E \cap H_n)$, because both measures split the same finite mass H_n.
Since $E \cap H_n \uparrow E$, continuity from below gives $\nu(E) = \overline{\mu}(E)$.

Structural Commentary: Pass to finite disjoint unions, then exhaust by finite-mass pieces.
Key Insight: $\mathcal{S}'$ supplies relative complements and the cover infimum for uniqueness. □

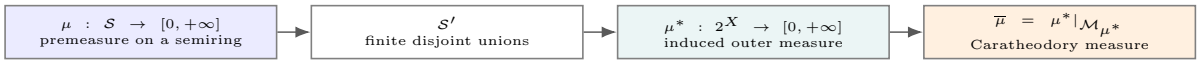

Figure 193: Caratheodory-Hahn: pass to $\mathcal{S}'$, form μ^* by cover infima, then $\overline{\mu} := \mu^*|_{\mathcal{M}_{\mu^*}}$ with $\overline{\mu}|_{\mathcal{S}} = \mu$.

Corollary 3.4.8. *Agreement on a σ-Finite Semiring*
Let $\mathcal{S}$ be a semiring of subsets of X, let $\mathcal{B} := \sigma(\mathcal{S})$, and let ν_1, ν_2 be measures on $\mathcal{B}$ with $\nu_1|_{\mathcal{S}} = \nu_2|_{\mathcal{S}}$.
If $X = \bigcup_{k\geq 1} S_k$ for some $S_k \in \mathcal{S}$ with $\nu_1(S_k) = \nu_2(S_k) < +\infty$ for all k, then $\nu_1 = \nu_2$.

Proof. Let $\mathcal{S}'$ be the finite-disjoint-union closure of $\mathcal{S}$. Finite additivity gives $\nu_1 = \nu_2$ on $\mathcal{S}'$.
Put $H_n := \bigcup_{k=1}^{n} S_k \in \mathcal{S}'$; then $H_n \uparrow X$ and $\nu_i(H_n) < +\infty$. For fixed n, $\mathcal{D}_n := \{E \in \mathcal{B} : \nu_1(E \cap H_n) = \nu_2(E \cap H_n)\}$ is a Dynkin class containing the π-system $\mathcal{S}$, since $A \cap H_n \in \mathcal{S}'$ for $A \in \mathcal{S}$. Hence $\mathcal{D}_n = \mathcal{B}$.
Thus $\nu_1(E \cap H_n) = \nu_2(E \cap H_n)$ $\forall E \in \mathcal{B}$ and $n \geq 1$; since $E \cap H_n \uparrow E$, continuity from below gives $\nu_1(E) = \nu_2(E)$.
Structural Commentary: Localize to finite-mass H_n, then apply π-λ.
Key Insight: Agreement on $\mathcal{S}$ propagates through $\mathcal{S}'$ and the exhaustion. □

Example 3.4.9. *Bounded Intervals and Rectangles Are Semirings*
Let $\mathcal{I}$ be the bounded intervals of $\mathbb{R}$, and let $\mathcal{R}_n := \{I_1 \times \cdots \times I_n : I_j \in \mathcal{I}\}$.

(i) $\mathcal{I}$ is a semiring: if $I, J \in \mathcal{I}$, then $I \cap J \in \mathcal{I}$ and $I \setminus J$ is a disjoint union of at most two members of $\mathcal{I}$.
(ii) $\mathcal{R}_n$ is a semiring in $\mathbb{R}^n$: intersections are coordinatewise products, and $R \setminus Q$ decomposes by coordinate cuts into finitely many disjoint rectangles in $\mathcal{R}_n$.

Thus length on $\mathcal{I}$ and rectangular volume on $\mathcal{R}_n$ fit the Caratheodory-Hahn extension pattern.

3.5 Metric Outer Measures and Hausdorff Measure

Metric outer measures are outer measures whose additivity recognizes positive separation. They abstract the positive-distance additivity of Euclidean cell-cover outer measure from Theorem 3.2.13.

Definition 3.5.1. *Metric/Caratheodory Outer Measure*
Let (X, d) be a metric space and let $\omega : 2^X \to [0, +\infty]$ be an outer measure.

(i) For nonempty $A, B \subseteq X$, $\operatorname{dist}(A, B) := \inf\{d(a, b) : a \in A,\ b \in B\}$.
(ii) ω is *metric outer measure* if $\operatorname{dist}(A, B) > 0 \Rightarrow \omega(A \cup B) = \omega(A) + \omega(B)$ $\forall$ nonempty $A, B \subseteq X$.

Key Insight: Positive metric separation forces outer-measure additivity.

Definition 3.5.2. *Separation by a Real-Valued Function*
Let X be a set and let $\varphi : X \to \mathbb{R}$. Sets $A, B \subseteq X$ are *φ-separated* if, for some $r < s$, one of A, B is contained in $\{\varphi \leq r\}$ and the other is contained in $\{\varphi \geq s\}$.

Proposition 3.5.3. *Separation by One Real-Valued Function*
Let X be a set, let $\omega : 2^X \to [0, +\infty]$ be an outer measure, and let $\varphi : X \to \mathbb{R}$. If $\omega(A \cup B) = \omega(A) + \omega(B)$ for every φ-separated pair $A, B \subseteq X$, then $\varphi : (X, \mathcal{M}_\omega) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))$ is measurable.

Proof. Fix $t \in \mathbb{R}$, put $E_t := \{\varphi > t\}$, and fix $A \subseteq X$ with $\omega(A) < +\infty$. Set $B := A \cap E_t$ and $C := A \setminus E_t$.
For $n \geq 1$, let $B_n := A \cap \{\varphi > t + \frac{1}{n}\}$, $B_0 := \emptyset$, and $R_n := B_n \setminus B_{n-1}$.
Same-parity strips are pairwise φ-separated, so $\sum_{n\geq 1} \omega(R_n) < +\infty$. Given $\varepsilon > 0$, choose n with $\sum_{k>n} \omega(R_k) < \varepsilon$.
Since $B \subseteq B_n \cup \bigcup_{k>n} R_k$ and B_n, C are φ-separated, $\omega(B) + \omega(C) \leq \omega(B_n \cup C) + \varepsilon \leq \omega(A) + \varepsilon$.
Let $\varepsilon \downarrow 0$, then $\omega(A) \geq \omega(A \cap E_t) + \omega(A \setminus E_t)$; Lemma 3.1.4 gives $E_t \in \mathcal{M}_\omega$ for every t, hence φ is measurable.
Structural Commentary: Measurability reduces to a finite-mass split of each level set.
Key Insight: Summable level strips leave an arbitrarily small boundary layer. □

Theorem 3.5.4. *Metric Outer Measures Measure Borel Sets*
Let (X, d) be a metric space and let $\omega : 2^X \to [0, +\infty]$ be a metric outer measure. Then:

(i) Every closed $F \subseteq X$ belongs to $\mathcal{M}_\omega$.
(ii) $\mathcal{B}(X) \subseteq \mathcal{M}_\omega$.

Proof.

(i) The case $F = \emptyset$ is immediate. For nonempty closed F, set $\varphi(x) := \operatorname{dist}(\{x\}, F)$. Proposition 5.1.22 gives φ 1-Lipschitz and $F = \varphi^{-1}(\{0\})$, so φ-separated pairs have positive distance. Metric additivity verifies Proposition 3.5.3; hence φ is $\mathcal{M}_\omega$-measurable and $F \in \mathcal{M}_\omega$.
(ii) By (i), all closed sets lie in the σ-algebra $\mathcal{M}_\omega$; since they generate $\mathcal{B}(X)$, $\mathcal{B}(X) \subseteq \mathcal{M}_\omega$.

Structural Commentary: Distance functions turn closed sets into real-valued separation tests.
Key Insight: Closed measurability plus generation gives Borel measurability. □

Definition 3.5.5. *Hausdorff Outer Measure*
Let (X,d) be a metric space, $\alpha>0$, $\varepsilon>0$.

(i) $\mathcal{H}^*_{\alpha,\varepsilon}(\emptyset):=0$; $\mathcal{H}^*_{\alpha,\varepsilon}(E):=\inf\{\sum_{k=1}^{\infty}(\operatorname{diam}A_k)^\alpha : E\subseteq\bigcup_{k=1}^{\infty}A_k,\ \emptyset\neq A_k\subseteq X,\ \operatorname{diam}A_k<\varepsilon\}$, nonempty $E\subseteq X$
(ii) If $0<\varepsilon_1<\varepsilon_2$, then $\mathcal{H}^*_{\alpha,\varepsilon_1}(E)\geq\mathcal{H}^*_{\alpha,\varepsilon_2}(E)$.
(iii) $\mathcal{H}^*_\alpha(E):=\sup_{\varepsilon>0}\mathcal{H}^*_{\alpha,\varepsilon}(E)=\lim_{\varepsilon\downarrow0}\mathcal{H}^*_{\alpha,\varepsilon}(E)$.

Key Insight: $\mathcal{H}^*_\alpha$ is the limiting cost of countable small-diameter covers.

Figure 194: $\operatorname{dist}(E,F)=\delta$ and $\operatorname{diam}A_k<\delta$: each A_k meets at most one of E,F.

Theorem 3.5.6. *Hausdorff Measure on Borel Sets*
Let (X,d) be a metric space and let $\alpha>0$. Then:
(i) $\mathcal{H}^*_\alpha:2^X\to[0,+\infty]$ is a metric outer measure.
(ii) $\mathcal{H}_\alpha:=\mathcal{H}^*_\alpha|_{\mathcal{B}(X)}$ is a measure on $\mathcal{B}(X)$, called the α-dimensional Hausdorff measure on X.

Proof.

(i) For each $\varepsilon>0$, $\mathcal{H}^*_{\alpha,\varepsilon}(\emptyset)=0$, monotonicity is immediate from admissible covers, and countable subadditivity follows by joining admissible ε-covers; hence $\mathcal{H}^*_\alpha(\bigcup_i E_i)=\sup_{\varepsilon>0}\mathcal{H}^*_{\alpha,\varepsilon}(\bigcup_i E_i)\leq\sum_i\mathcal{H}^*_\alpha(E_i)$.
Thus $\mathcal{H}^*_\alpha$ is an outer measure. If $\operatorname{dist}(E,F)=\delta>0$ and $0<\varepsilon<\delta$, every admissible ε-cover of $E\cup F$ splits into disjoint subcovers of E and F, so $\mathcal{H}^*_{\alpha,\varepsilon}(E\cup F)\geq\mathcal{H}^*_{\alpha,\varepsilon}(E)+\mathcal{H}^*_{\alpha,\varepsilon}(F)$.
Letting $\varepsilon\downarrow0$ and using subadditivity gives metric additivity.
(ii) By (i), $\mathcal{H}^*_\alpha$ is a metric outer measure; Theorem 3.5.4 gives $\mathcal{B}(X)\subseteq\mathcal{M}_{\mathcal{H}^*_\alpha}$.
Since $\mathcal{H}^*_\alpha|_{\mathcal{M}_{\mathcal{H}^*_\alpha}}$ is a measure, its restriction $\mathcal{H}^*_\alpha|_{\mathcal{B}(X)}=\mathcal{H}_\alpha$ is a measure on $\mathcal{B}(X)$.

Structural Commentary: Cover infima give the outer measure; separated cover splitting gives metric additivity.
Key Insight: Small-diameter covers cannot straddle positive gaps. □

Remark 3.5.7. *One-Dimensional Calibration*
On $\mathbb{R}$, interval covers give $\mathcal{H}^*_1((a,b])\leq b-a$, and every diameter cover of $(a,b]$ enlarges to interval covers with arbitrarily small extra total length, giving $\mathcal{H}^*_1((a,b])\geq b-a$. Hence $\mathcal{H}^*_1((a,b])=b-a$, and uniqueness of the Borel extension from half-open intervals gives $\mathcal{H}_1=m$ on $\mathcal{B}(\mathbb{R})$.

Example 3.5.8. *Finite Sets Have Zero Positive-Dimensional Hausdorff Measure*
If $E=\{x_1,\dots,x_N\}\subseteq X$ and $\alpha>0$, then $\mathcal{H}^*_\alpha(E)=0$: for every $\varepsilon>0$, the singleton cover $E\subseteq\bigcup_{j=1}^{N}\{x_j\}$ is admissible and has total α-content $\sum_{j=1}^{N}(\operatorname{diam}\{x_j\})^\alpha=0$.
Key Insight: Finite sets are covered by zero-diameter singletons.

Proposition 3.5.9. *Hausdorff Measures Decrease Through Dimension*
Let (X,d) be a metric space, let $E\subseteq X$, and let $0<\alpha<\beta$. If $\mathcal{H}^*_\alpha(E)<+\infty$, then $\mathcal{H}^*_\beta(E)=0$.

Proof. Fix $\varepsilon>0$. Choose admissible ε-cover (A_k) of E with $\sum_k(\operatorname{diam}A_k)^\alpha\leq\mathcal{H}^*_{\alpha,\varepsilon}(E)+1\leq\mathcal{H}^*_\alpha(E)+1$.
Since $\operatorname{diam}A_k<\varepsilon$, $\sum_k(\operatorname{diam}A_k)^\beta=\sum_k(\operatorname{diam}A_k)^{\beta-\alpha}(\operatorname{diam}A_k)^\alpha\leq\varepsilon^{\beta-\alpha}(\mathcal{H}^*_\alpha(E)+1)$.
Hence $\mathcal{H}^*_{\beta,\varepsilon}(E)\leq\varepsilon^{\beta-\alpha}(\mathcal{H}^*_\alpha(E)+1)$. Letting $\varepsilon\downarrow0$ gives $\mathcal{H}^*_\beta(E)=0$.
Structural Commentary: Compare one small cover at dimensions α and β.
Key Insight: The factor $\varepsilon^{\beta-\alpha}$ kills finite α-content. □

Definition 3.5.10. *Hausdorff Dimension*
For $E\subseteq X$, the *Hausdorff dimension* is $\dim_H(E):=\inf\{\beta>0:\mathcal{H}^*_\beta(E)=0\}$, with $\inf\emptyset:=+\infty$.

Remark 3.5.11. *Dimension as a Critical Exponent*
For $E\subseteq X$, set $Z_E:=\{\beta>0:\mathcal{H}^*_\beta(E)=0\}$. Proposition 3.5.9 gives $Z_E=(\dim_H(E),+\infty)$ or $[\dim_H(E),+\infty)$ inside $(0,+\infty)$, so $\dim_H(E)$ is the zero-measure threshold for the Hausdorff scale.

4 Borel, Lebesgue, and Stieltjes Measures

4.1 Borel, Lebesgue, and Stieltjes Measure Constructions

Proposition 4.1.1. *Half-Open Interval Algebra on $\mathbb{R}$*
Let $\mathcal{F}$ be the algebra of finite disjoint unions of $(a,b]$, $(-\infty,b]$, $(a,+\infty)$ $(a,b\in\mathbb{R})$, and $\mathbb{R}$. Set $\ell((a,b])=b-a$ and $\ell((-\infty,b])=\ell((a,+\infty))=\ell(\mathbb{R})=+\infty$, extending additively over disjoint unions. Then
(i) $\mathcal{F}$ is an algebra on $\mathbb{R}$ and $\sigma(\mathcal{F})=\mathcal{B}(\mathbb{R})$.
(ii) ℓ is a premeasure on $\mathcal{F}$.

Proof.

(i) Generator complements lie in $\mathcal{F}$, hence $\mathcal{F}$ is an algebra.
Since $\mathcal{F} \subseteq \mathcal{B}(\mathbb{R})$ and $(a,b) = \bigcup_{n>1/(b-a)} (a, b-1/n]$, $\sigma(\mathcal{F}) = \mathcal{B}(\mathbb{R})$.

(ii) Normal forms make ℓ well defined and finitely additive.

For countable additivity, reduce to $(a,b] = \bigsqcup_{j\geq 1} (a_j, b_j]$: finite subunions give $\sum_{j=1}^{N} (b_j - a_j) \leq b - a$.

Conversely, choose $\varepsilon_j > 0$ with $\sum_{j\geq 1} \varepsilon_j < \varepsilon$; by compactness, $\exists$ finite $K \subseteq \mathbb{N}$ s.t. $[a+\delta, b] \subseteq \bigcup_{j\in K} (a_j, b_j + \varepsilon_j)$, hence $b - a - \delta \leq \sum_{j\in K} (b_j - a_j + \varepsilon_j) \leq \sum_{j\geq 1} (b_j - a_j) + \varepsilon$.

Let $\delta, \varepsilon \downarrow 0$. Truncation handles half-lines; finite disjoint unions follow componentwise.

Structural Commentary: Lebesgue measure starts as length on a finite interval algebra, not on all subsets.
Key Insight: Compactness supplies the reverse inequality in countable additivity of interval length. □

Remark 4.1.2. *Why the Half-Open Convention Matters*
Finite unions generated by (a,b), $(-\infty,b)$, $(a,+\infty)$, and $\mathbb{R}$ still generate $\mathcal{B}(\mathbb{R})$, but are not an algebra, where $(0,1)^c = (-\infty,0] \cup [1,+\infty)$. Half-open endpoints make complements remain in the starting family.

Definition 4.1.3. *Borel–Stieltjes and Lebesgue–Stieltjes Measures*
Let $g : \mathbb{R} \to \mathbb{R}$ be increasing and right-continuous, and set $g(\pm\infty) := \lim_{x\to\pm\infty} g(x) \in \overline{\mathbb{R}}$.
Let $\mathcal{I} := \{(a,b] : a < b\} \cup \{(-\infty, b] : b \in \mathbb{R}\} \cup \{(a,+\infty) : a \in \mathbb{R}\} \cup \{\mathbb{R}\}$ and $\mathcal{F} := \operatorname{alg}(\mathcal{I})$.

(i) Define G_g on $\mathcal{I}$ by endpoint increments and set $\mu_g(\bigsqcup_{j=1}^m I_j) := \sum_{j=1}^m G_g(I_j)$ for disjoint $I_j \in \mathcal{I}$.
(ii) The unique extension of μ_g to $\mathcal{B}(\mathbb{R})$ is the *Borel–Stieltjes measure generated by g*.
(iii) The completion of this Borel measure is the *Lebesgue–Stieltjes measure generated by g*.

Theorem 4.1.4. *Borel–Stieltjes Measure Existence*
Let $g : \mathbb{R} \to \mathbb{R}$ be increasing and right-continuous, and put $g(\pm\infty) := \lim_{x\to\pm\infty} g(x) \in \overline{\mathbb{R}}$.
Set $\mathcal{I} := \{(a,b] : a < b\} \cup \{(-\infty, b] : b \in \mathbb{R}\} \cup \{(a,+\infty) : a \in \mathbb{R}\} \cup \{\mathbb{R}\}$ and $\mathcal{F} := \operatorname{alg}(\mathcal{I})$.
Define G_g on $\mathcal{I}$ by endpoint increments and set $\mu_g(\bigsqcup_{j=1}^m I_j) := \sum_{j=1}^m G_g(I_j)$ for disjoint $I_j \in \mathcal{I}$. Then:

(i) μ_g is a σ-finite premeasure on $\mathcal{F}$ and has a unique extension to $\mathcal{B}(\mathbb{R})$, again denoted μ_g.
(ii) If $g = \mathrm{id}_{\mathbb{R}}$, then μ_g is Lebesgue measure.
(iii) If g is continuous, then $\mu_g(J) = g(b) - g(a)$ for $J \in \{(a,b), [a,b), (a,b], [a,b]\}$, $a < b$.

Proof.

(i) Normal forms give well-defined finite additivity: G_g-increments telescope and $G_g \geq 0$.
If $(a,b] = \bigsqcup_{j\geq 1}(a_j, b_j]$, finite subunions give $\sum_{j=1}^N G_g((a_j,b_j]) \leq G_g((a,b])$.
Conversely, compactness gives finite K with $[a+\varepsilon, b] \subseteq \bigcup_{j\in K}(a_j, b_j+\varepsilon_j)$. Hence $g(b) - g(a+\varepsilon) \leq \sum_{j\in K}(g(b_j+\varepsilon_j) - g(a_j))$. Let $\varepsilon, \varepsilon_j \downarrow 0$, hence countable additivity on bounded generators.
Half-lines follow by truncation, finite unions componentwise, so μ_g is a premeasure. Since $\mathbb{R} = \bigcup_{n\geq 1}(-n, n]$ and $\mu_g((-n,n]) = g(n) - g(-n) < +\infty$, μ_g is σ-finite; Theorem 3.1.16 gives uniqueness.
(ii) If $g = \mathrm{id}_{\mathbb{R}}$, then $G_g((a,b]) = b - a$, so μ_g agrees with half-open length on $\mathcal{F}$.
Uniqueness identifies its Borel extension with Lebesgue measure.
(iii) If g is continuous, then $(x - 1/n, x] \downarrow \{x\}$ gives $\mu_g(\{x\}) = \lim_n (g(x) - g(x - 1/n)) = 0$.

Structural Commentary: Stieltjes measure replaces ordinary length $b - a$ by the increment $g(b) - g(a)$.
Key Insight: Right-continuity aligns the half-open interval convention with countable covers. □

Proposition 4.1.5. *Finite Borel Measures Give Stieltjes Generators*
Let ν be finite on $\mathcal{B}(\mathbb{R})$ and set $g(x) := \nu((-\infty, x])$. Then:

(i) g is increasing and right-continuous;
(ii) $g(-\infty) = 0$ and $g(+\infty) = \nu(\mathbb{R})$;
(iii) $\nu((a,b]) = g(b) - g(a)$ for $a \leq b$;
(iv) $\nu = \mu_g$ on $\mathcal{B}(\mathbb{R})$.

Proof.

(i) If $a \leq b$, then $(-\infty, a] \subseteq (-\infty, b]$, so $g(a) \leq g(b)$. If $x_n \downarrow x$, then $(-\infty, x_n] \downarrow (-\infty, x]$.
Finite continuity from above gives $g(x_n) \downarrow g(x)$.
(ii) Since $(-\infty, -n] \downarrow \emptyset$ and $(-\infty, n] \uparrow \mathbb{R}$, continuity from above/below gives $g(-\infty) = 0$ and $g(+\infty) = \nu(\mathbb{R})$.
(iii) For $a \leq b$, $(-\infty, b] = (-\infty, a] \sqcup (a, b]$, hence $\nu((a,b]) = g(b) - g(a)$.
(iv) By (ii)–(iii), ν and μ_g agree on $\mathcal{I}$, hence on $\mathcal{F}$. Theorem 4.1.4 gives $\nu = \mu_g$ on $\mathcal{B}(\mathbb{R})$.

Structural Commentary: A finite real-line measure is encoded by its cumulative mass function.
Key Insight: Right-continuity of distribution functions is continuity from above for measures. □

Example 4.1.6. *Basic Borel–Stieltjes Generators*
The following generators illustrate the interval rule in Theorem 4.1.4.

(i) If $g(x) = 2x$, then $\mu_g = 2m$ on $\mathcal{B}(\mathbb{R})$.
(ii) If $g(x) = \arctan x$, then $\mu_g((a,b]) = \arctan b - \arctan a = \int_a^b (1+x^2)^{-1}\, dx$ and $\mu_g(\mathbb{R}) = \pi$.
(iii) If $g(x) = 0$ for $x < 0$ and $g(x) = 1$ for $x \geq 0$, then $\mu_g = \delta_0$.
(iv) If $g(x) = 0$ for $x < 0$ and $g(x) = x$ for $x \geq 0$, then $\mu_g(E) = m(E \cap [0, +\infty))$ for Borel E.

Lemma 4.1.7. *Open Sets Are Countable Unions of Rational Boxes*
For every open $G \subseteq \mathbb{R}^n$, there is a countable $\Sigma \subseteq \{\prod_{i=1}^n (a_i, b_i) : a_i, b_i \in \mathbb{Q},\ a_i < b_i\}$ such that $G = \bigcup_{B\in\Sigma} B$.

Proof. Let $\mathcal{B}_{\mathbb{Q}} := \{\prod_{i=1}^{n}(a_i, b_i) : a_i, b_i \in \mathbb{Q},\ a_i < b_i\}$; then $\mathcal{B}_{\mathbb{Q}}$ is countable since $\mathbb{Q}^{2n}$ is countable.
Set $\Sigma := \{B \in \mathcal{B}_{\mathbb{Q}} : B \subseteq G\}$. The inclusion $\bigcup_{B\in\Sigma} B \subseteq G$ is immediate.
If $x \in G$, choose $r > 0$ with $B_r(x) \subseteq G$, then choose $a_i, b_i \in \mathbb{Q}$ with $x_i - r/n < a_i < x_i < b_i < x_i + r/n$.
Thus $x \in B := \prod_i (a_i, b_i) \subseteq B_r(x) \subseteq G$, so $x \in \bigcup_{B\in\Sigma} B$.
Structural Commentary: Rational boxes give a countable Euclidean base.
Key Insight: Openness supplies a ball; density of $\mathbb{Q}$ supplies rational box endpoints inside it. □

Theorem 4.1.8. *Lebesgue Measure Basic Properties*
Let $m = m_n^*|_{\mathcal{L}^n}$.

(i) $\mathcal{B}(\mathbb{R}^n) \subseteq \mathcal{L}^n$, and $\mathcal{L}^n$ is closed under $E \mapsto E^c$, countable $\cup$, and countable $\cap$.
(ii) For $E, F, E_k \in \mathcal{L}^n$, $0 \le m(E)$, $E \subseteq F \Rightarrow m(E) \le m(F)$, and $m(\bigcup_k E_k) \le \sum_k m(E_k)$.
(iii) If $(E_k) \subseteq \mathcal{L}^n$ are pairwise disjoint, then $m(\bigsqcup_k E_k) = \sum_k m(E_k)$.
(iv) $m([0,1]^n) = 1$, and $E \in \mathcal{L}^n$, $t \in \mathbb{R}^n$ imply $E + t \in \mathcal{L}^n$ and $m(E + t) = m(E)$.

Proof.

(i) By Theorem 3.1.6, $\mathcal{L}^n$ is a σ-algebra, hence closed under complements and countable unions/intersections. Open boxes are cells, hence in $\mathcal{L}^n$ by Proposition 3.3.9; by Lemma 4.1.7, each open $G = \bigcup_j B_j$ with rational open boxes B_j, so $G \in \mathcal{L}^n$. Thus $\mathcal{B}(\mathbb{R}^n) = \sigma(\mathcal{O}_{\mathbb{R}^n}) \subseteq \mathcal{L}^n$.
(ii) Since $m = m_n^*|_{\mathcal{L}^n}$, nonnegativity follows from $m_n^* \ge 0$. If $E \subseteq F$, then $m(E) \le m(F)$ by outer-measure monotonicity. Also $m(\bigcup_k E_k) = m_n^*(\bigcup_k E_k) \le \sum_k m_n^*(E_k) = \sum_k m(E_k)$ by outer-measure subadditivity.
(iii) If $(E_k) \subseteq \mathcal{L}^n$ pairwise disjoint, by Theorem 3.1.6, m countably additive on $\mathcal{L}^n$, so $m(\bigsqcup_k E_k) = \sum_k m(E_k)$.
(iv) By Theorem 3.2.14, since $[0,1]^n$ is a cell, $m([0,1]^n) = \mathrm{vol}_n([0,1]^n) = 1$.
For translation, let $A \subseteq \mathbb{R}^n$. By Theorem 3.2.16 and
$E \in \mathcal{L}^n$, $m_n^*(A) = m_n^*(A - t) = m_n^*((A - t) \cap E) + m_n^*((A - t) \cap E^c) = m_n^*(A \cap (E + t)) + m_n^*(A \cap (E + t)^c)$; hence $E + t \in \mathcal{L}^n$, and $m(E + t) = m_n^*(E + t) = m_n^*(E) = m(E)$.

Structural Commentary: The wish list is recovered only after restricting outer measure to measurable sets.
Key Insight: The box-cover construction gives size; the measurable-set condition restores additivity. □

Theorem 4.1.9. *Uniqueness from Open Cells*
Let ν be a measure on $\mathcal{L}^n$ with $\nu(I) = \mathrm{vol}_n(I)$ for every open cell $I \subseteq \mathbb{R}^n$. Then $\nu = m$ on $\mathcal{L}^n$.

Proof. Fix $N \in \mathbb{N}$, $Q_N = (-N, N)^n$. If $E \in \mathcal{L}^n$ and $E \subseteq Q_N$, then any open-cell cover $E \subseteq \bigcup_j J_j$ gives $\nu(E) \le \sum_j \nu(J_j) = \sum_j \mathrm{vol}_n(J_j)$, hence $\nu(E) \le m(E)$ by infimum.
Applying this to E and $Q_N \setminus E$, and using $\nu(Q_N) = m(Q_N) < +\infty$, yields $\nu(E) + \nu(Q_N \setminus E) = m(E) + m(Q_N \setminus E)$ with each left summand $\le$ its right counterpart; hence $\nu(E) = m(E)$.
For arbitrary $E \in \mathcal{L}^n$, set $A_1 = E \cap Q_1$, $A_N = E \cap (Q_N \setminus Q_{N-1})$ for $N > 1$.
Then $E = \bigsqcup_N A_N$, each $A_N \subseteq Q_N$, and countable additivity gives $\nu(E) = \sum_N \nu(A_N) = \sum_N m(A_N) = m(E)$.
Structural Commentary: Agreement on coordinate cells determines the whole Lebesgue measure.
Key Insight: Covers give $\nu \le m$ locally; finite complements force equality. □

Method 4.1.10. *Translation Invariance by Moving the Test Set*

(i) For $t \in \mathbb{R}^n$ and $A \subseteq \mathbb{R}^n$, translated box covers give $m_n^*(A + t) = m_n^*(A)$.
(ii) If $E \in \mathcal{L}^n$, then for all $A \subseteq \mathbb{R}^n$, $(A \cap (E + t)) - t = (A - t) \cap E$ and $(A \cap (E + t)^c) - t = (A - t) \cap E^c$.
(iii) Apply the Caratheodory split for E to $A - t$ to get $E + t \in \mathcal{L}^n$ and $m(E + t) = m(E)$.

Key Insight: Translation invariance of outer measure transports the clean-splitting identity.

Proposition 4.1.11. *First Borel Hierarchy Examples*
In $\mathbb{R}^p$:

(i) If $G = \bigcap_{n\ge1} U_n$ with U_n open or $F = \bigcup_{n\ge1} C_n$ with C_n closed, then $G, F \in \mathcal{B}(\mathbb{R}^p) \subseteq \mathcal{L}^p$.
(ii) Any set obtained from open or closed sets by countably many $\cup, \cap, ^c$ operations is Borel.
(iii) In $\mathbb{R}$, $\{0\} = \bigcap_{n\ge1} (-\frac{1}{n}, \frac{1}{n})$ is G_δ but not open.
(iv) In $\mathbb{R}$, $(0,1) = \bigcup_{n\ge2} [\frac{1}{n}, 1 - \frac{1}{n}]$ is F_σ but not closed.

Proof.

(i) Since $\mathcal{B}(\mathbb{R}^p) = \sigma(\mathcal{O}_{\mathbb{R}^p})$, it contains open sets, closed sets by complements, and countable $\cap, \cup$ by σ-algebra closure; Theorem 4.1.8 gives $\mathcal{B}(\mathbb{R}^p) \subseteq \mathcal{L}^p$.
(ii) This is Proposition 1.1.3 applied to $\mathcal{B}(\mathbb{R}^p)$.
(iii) For $x \in \mathbb{R}$, $x = 0 \iff |x| < \frac{1}{n}$ for all $n \ge 1$; the singleton $\{0\}$ is not open.
(iv) For $x \in \mathbb{R}$, $0 < x < 1 \iff \exists n \ge 2 : \frac{1}{n} \le x \le 1 - \frac{1}{n}$; the interval $(0,1)$ is not closed.

Structural Commentary: Borel sets are generated by countable topological operations.
Key Insight: Countable intersections and unions quickly leave the class of open and closed sets. □

Perspective 4.1.12. *Why Not Measure Every Subset?*
Vitali-type sets show m_1^* is not additive on $2^{\mathbb{R}}$: disjoint unions and refinements can break additivity.
Thus measure is m^* on clean splitters E: $m^*(X) = m^*(X \cap E) + m^*(X \cap E^c)$ for all X.
Key Insight: Outer measure is universal; measure lives on clean splitters.

Definition 4.1.13. *Null Sets and Real-Line Measure Zero*
Let $(X, \mathcal{A}, \mu)$ be a measure space and let $A \subseteq \mathbb{R}$.

(i) $N \subseteq X$ is *null* iff $N \in \mathcal{A}$ and $\mu(N) = 0$.
(ii) A has *measure zero* iff $\forall \varepsilon > 0$, $\exists$ open intervals (O_n) with $A \subseteq \bigcup_{n=1}^{\infty} O_n$ and $\sum_{n=1}^{\infty} |O_n| \le \varepsilon$.
(iii) If $A \subseteq [a, b]$, then A has *content zero* iff the condition in (ii) holds with finitely many intervals.

For Lebesgue measure on $\mathbb{R}$, null sets are also *zero sets*.

Proposition 4.1.14. *Basic Measure-Zero Examples on $\mathbb{R}$*

(i) Every finite $A \subseteq \mathbb{R}$ has content 0.
(ii) Every countable $A \subseteq \mathbb{R}$ has measure 0.
(iii) The Cantor set P has content 0.

Proof.

(i) For $A = \{a_1, \dots, a_N\}$ and $\varepsilon > 0$, choose open $I_j \ni a_j$ with $|I_j| < \frac{\varepsilon}{N}$; then $A \subseteq \bigcup_{j=1}^{N} I_j$ and $\sum_{j=1}^{N} |I_j| < \varepsilon$. The case $A = \emptyset$ is trivial.

(ii) For $A = \{a_j : j \in \mathbb{N}\}$ and $\varepsilon > 0$, choose open $I_j \ni a_j$ with $|I_j| < \frac{\varepsilon}{2^j}$; then $A \subseteq \bigcup_{j\geq 1} I_j$ and $\sum_{j\geq 1} |I_j| < \varepsilon$.

(iii) Given $\varepsilon > 0$, choose N with $\left(\frac{2}{3}\right)^N < \frac{\varepsilon}{2}$. If $E_N = \bigcup_{k=1}^{2^N} J_k$, $|J_k| = 3^{-N}$, choose open $I_k \supseteq J_k$ with $|I_k| < 3^{-N} + \frac{\varepsilon}{2^{N+1}}$; then $P \subseteq \bigcup_{k=1}^{2^N} I_k$ and $\sum_{k=1}^{2^N} |I_k| < \left(\frac{2}{3}\right)^N + \frac{\varepsilon}{2} < \varepsilon$.

Structural Commentary: Zero size means arbitrarily small interval covers.
Key Insight: Lists split ε by terms; Cantor stages have length $(\frac{2}{3})^N \to 0$. □

Corollary 4.1.15. *Uncountable Null Sets Exist*
There exists $P \subseteq \mathbb{R}$ such that:

(i) $|P| = 2^{\aleph_0}$;
(ii) $P \in \mathcal{L}^1$ and $m(P) = 0$.

Proof. Let $P := \{\sum_{k=1}^{\infty} \varepsilon_k 3^{-k} : \varepsilon_k \in \{0, 2\}\}$.

(i) The map $(\varepsilon_k) \mapsto \sum_k \varepsilon_k 3^{-k}$ identifies P with $\{0,2\}^{\mathbb{N}}$, so $|P| = 2^{\aleph_0}$.
(ii) At stage N, P is covered by 2^N closed intervals of length 3^{-N}, hence $m_1^*(P) \leq (2/3)^N$ for all N. Letting $N \to \infty$ gives $m_1^*(P) = 0$, so outer-null completeness gives $P \in \mathcal{L}^1$ and $m(P) = 0$.

Structural Commentary: Cantor coding separates cardinality from length.
Key Insight: Null need not mean countable. □

Corollary 4.1.16. *Real-Line Lebesgue Measure Checks*
Let m be Lebesgue measure on $\mathbb{R}$.

(i) $a < b \Rightarrow m((a,b)) = m((a,b]) = m([a,b)) = m([a,b]) = b - a$.
(ii) $A \subseteq \mathbb{R}$ countable $\Rightarrow A \in \mathcal{B}(\mathbb{R})$ and $m(A) = 0$.
(iii) $\emptyset \neq G \subseteq \mathbb{R}$ open $\Rightarrow m(G) > 0$.
(iv) $K \subseteq \mathbb{R}$ compact $\Rightarrow m(K) < +\infty$.

Proof.

(i) By cell volume, $m([a,b]) = b - a$; endpoint sets finite null; add or delete $\{a\}, \{b\}$ does not change measure.
(ii) If $A = \{a_k : k \in J\}$ with J finite or countable, then $A = \bigcup_{k\in J}\{a_k\} \in \mathcal{B}(\mathbb{R})$; $m(A) \leq \sum_{k\in J} m(\{a_k\}) = 0$.
(iii) Choose $(a,b) \subseteq G$ with $a < b$; by monotonicity and (i), $m(G) \geq m((a,b)) = b - a > 0$.
(iv) Compact K is bounded, so $K \subseteq [-R, R]$ for some $R > 0$; hence $m(K) \leq m([-R,R]) = 2R < +\infty$.

Structural Commentary: On $\mathbb{R}$, length, null endpoints, and compact boundedness give quick measure estimates.
Key Insight: Nonempty open sets contain intervals; compact sets fit inside one. □

Example 4.1.17. *A Positive-Measure Cantor-Type Set with No Interval*
Let $S_0 = [0,1]$ and, for $n \geq 1$, let R_n be the union of the middle open intervals of length 2^{-2n} removed from the 2^{n-1} components of S_{n-1}; set $S_n := S_{n-1} \setminus R_n$ and $S := \bigcap_{n=0}^{\infty} S_n$.
Then $m(R_n) = 2^{-n-1}$, $\sum_{n\geq 1} m(R_n) = 1/2$, so $S = [0,1] \setminus \bigcup_n R_n$ is compact with $m(S) = 1/2$.
Since every component of S_n has length $\leq 2^{-n}$, no interval (a,b) can lie in S; hence $\operatorname{int} S = \emptyset$.
Structural Commentary: Summable removals leave measure; repeated splitting kills interior.
Key Insight: Total removed length controls measure; repeated splitting controls interior.

5 Continuity and Regularity of Measures

5.1 Measure Continuity and Regularity

Corollary 5.1.1. *Measure Continuity*
Let μ be a measure, and let (E_k) and (F_k) be measurable sequences.

(i) If $E_k \uparrow E$, then $\mu(E_k) \uparrow \mu(E)$.
(ii) If $F_k \downarrow F$ and $\mu(F_1) < +\infty$, then $\mu(F_k) \downarrow \mu(F)$.

Proof.

(i) Set $G_1 = E_1$ and $G_k = E_k \setminus E_{k-1}$ for $k \geq 2$.
Then $E_k = \bigsqcup_{j=1}^{k} G_j$ and $E = \bigsqcup_{j\geq 1} G_j$, so $\mu(E_k) = \sum_{j=1}^{k} \mu(G_j) \uparrow \sum_{j\geq 1} \mu(G_j) = \mu(E)$.
(ii) Apply (i) to $H_k = F_1 \setminus F_k \uparrow F_1 \setminus F$. Since $\mu(F_1) < +\infty$, $\mu(F_k) = \mu(F_1) - \mu(H_k) \downarrow \mu(F_1) - \mu(F_1 \setminus F) = \mu(F)$.

Structural Commentary: Monotone set limits are disjoint series or complements of such series.
Key Insight: Downward continuity needs one finite anchor so subtraction is legal. □

Definition 5.1.2. *Limit Inferior and Superior of Sets*
For $(E_n) \subseteq \mathcal{P}(X)$, define $\limsup_n E_n := \bigcap_{m=1}^{\infty} \bigcup_{n\geq m} E_n$ and $\liminf_n E_n := \bigcup_{m=1}^{\infty} \bigcap_{n\geq m} E_n$.

(i) *Infinitely often*: $x \in \limsup_n E_n$ iff $\{n : x \in E_n\}$ is infinite;
(ii) *Eventually always*: $x \in \liminf_n E_n$ iff $\{n : x \notin E_n\}$ is finite;

(iii) *Set limit*: if $\limsup_n E_n = \liminf_n E_n$, write $\lim_n E_n$ for the common set.

Proposition 5.1.3. *Basic Laws for Set Limits*
Let $(E_n) \subseteq \mathcal{P}(X)$.

(i) $\emptyset \subseteq \liminf_n E_n \subseteq \limsup_n E_n \subseteq X$.

(ii) $E_n \uparrow E \implies \liminf_n E_n = \limsup_n E_n = E = \bigcup_n E_n$.

(iii) $E_n \downarrow E \implies \liminf_n E_n = \limsup_n E_n = E = \bigcap_n E_n$.

(iv) $(E_n) \subseteq \mathcal{M} \implies \liminf_n E_n, \limsup_n E_n \in \mathcal{M}$.

Proof.

(i) Since $\bigcap_m \bigcup_{n\geq m} E_n \subseteq \bigcup_{n\geq 1} E_n \subseteq X$ and $\bigcap_{n\geq m} E_n \subseteq \bigcup_{n\geq m} E_n$ for all m, the inclusions follow.

(ii) If $E_n \uparrow E$, then $\{n : x \in E_n\}$ is nonempty iff it is cofinite, hence $\liminf_n E_n = \limsup_n E_n = \bigcup_n E_n = E$.

(iii) If $E_n \downarrow E$, then $\{n : x \in E_n\}$ is infinite iff it is all of $\mathbb{N}$, hence $\liminf_n E_n = \limsup_n E_n = \bigcap_n E_n = E$.

(iv) If $(E_n) \subseteq \mathcal{M}$, then $\bigcup_{n\geq m} E_n$, $\bigcap_{n\geq m} E_n \in \mathcal{M}\ \forall m$; countable closure gives $\limsup_n E_n, \liminf_n E_n \in \mathcal{M}$.

Structural Commentary: Set limsup means infinitely often; set liminf means eventually always.
Key Insight: Translate the definitions into pointwise membership statements. □

Proposition 5.1.4. *Measure Bounds for Set Limits*
Let (E_n) be measurable in a measure space $(X, \mathcal{M}, \mu)$.

(i) $\mu(\liminf_n E_n) \leq \liminf_n \mu(E_n)$.

(ii) $\mu(\bigcup_{n=1}^{\infty} E_n) < +\infty \implies \limsup_n \mu(E_n) \leq \mu(\limsup_n E_n)$.

Proof.

(i) Set $A_m := \bigcap_{n\geq m} E_n$. Then $A_m \uparrow \liminf_n E_n$ and $A_m \subseteq E_n$ for all $n \geq m$, so $\mu(A_m) \leq \inf_{n\geq m} \mu(E_n)$.
By continuity from below, $\mu(\liminf_n E_n) = \lim_m \mu(A_m) \leq \sup_m \inf_{n\geq m} \mu(E_n) = \liminf_n \mu(E_n)$.

(ii) Set $B_m := \bigcup_{n\geq m} E_n$. $B_m \downarrow \limsup_n E_n$, $\mu(B_1) < +\infty$, $E_n \subseteq B_m\ \forall n \geq m$, so $\sup_{n\geq m} \mu(E_n) \leq \mu(B_m)$.
By continuity from above, $\limsup_n \mu(E_n) = \inf_m \sup_{n\geq m} \mu(E_n) \leq \lim_m \mu(B_m) = \mu(\limsup_n E_n)$.

Structural Commentary: Tail intersections increase to liminf; tail unions decrease to limsup.
Key Insight: Compare each tail envelope to the corresponding tail bounds of the measures. □

Definition 5.1.5. *Almost Everywhere*
Let $(X, \mathcal{M}, \mu)$ be a measure space, let $E \in \mathcal{M}$, and let $P(x)$ be a property on E.

(i) P holds *μ-almost everywhere on E* iff $\exists N \in \mathcal{M}$ with $N \subseteq E$, $\mu(N) = 0$, and P holds on $E \setminus N$.

(ii) For Lebesgue measure, write *almost everywhere*.

Theorem 5.1.6. *First Borel–Cantelli Lemma*
Let $(X, \mathcal{M}, \mu)$ be measure space, $(E_n) \subseteq \mathcal{M}$, set $L := \limsup_n E_n = \bigcap_{m\geq 1} \bigcup_{n\geq m} E_n$. Assume $\sum_{n=1}^{\infty} \mu(E_n) < +\infty$.

(i) $L \in \mathcal{M}$ and $\mu(L) = 0$.

(ii) μ-almost every $x \in X$ belongs to at most finitely many E_n.

Proof.

(i) Set $B_m := \bigcup_{n\geq m} E_n$. Then $B_m \downarrow L$ and $\mu(B_m) \leq \sum_{n\geq m} \mu(E_n)$.
Since $\mu(B_1) \leq \sum_{n\geq 1} \mu(E_n) < +\infty$, continuity from above gives $\mu(L) = \lim_{m\to\infty} \mu(B_m) \leq \lim_{m\to\infty} \sum_{n\geq m} \mu(E_n) = 0$.

(ii) Since $x \in L \iff \forall m\, \exists n \geq m$ with $x \in E_n$, L is the set of points lying in infinitely many E_n.
By (i), outside the null set L, membership occurs only finitely often.

Structural Commentary: Summable tails force the limsup set to have zero measure.
Key Insight: Points appearing infinitely often must lie in every tail union. □

Remark 5.1.7. *Borel Sets, Null Sets, and Regular Approximation*
Open, closed, and Borel subsets of $\mathbb{R}^p$ are measurable. Each $A \in \mathcal{M}(\mu)$ admits closed–open approximations $F \subseteq A \subseteq G$ with $\mu(G \setminus A)$ and $\mu(A \setminus F)$ arbitrarily small. In Lebesgue measure, one may take $F_\sigma \subseteq A \subseteq G_\delta$ with $\mu(G_\delta \setminus F_\sigma) = 0$. Null sets form a σ-ring, and countable subsets of $\mathbb{R}^p$ are null.
Structural Commentary: Measurable sets are Borel sets modified by null sets.
Key Insight: Regularity explains why open and closed approximations are enough for integration.

Proposition 5.1.8. *Local Measurability on Bounded Cubes*
For arbitrary $E \subseteq \mathbb{R}^p$, $E \in \mathcal{L}^p \iff E \cap [-n, n]^p \in \mathcal{L}^p$ for all $n \in \mathbb{N}$.

Proof.

($\Rightarrow$) If $E \in \mathcal{L}^p$, then $E \cap [-n, n]^p \in \mathcal{L}^p$ for all n, since $[-n, n]^p$ is Borel.

($\Leftarrow$) If $E \cap [-n, n]^p \in \mathcal{L}^p$ for all n, then $E = \bigcup_{n=1}^{\infty} (E \cap [-n, n]^p) \in \mathcal{L}^p$.

Structural Commentary: Nested Borel cubes exhaust $\mathbb{R}^p$.
Key Insight: Measurability is local along a countable exhaustion. □

Proposition 5.1.9. *Local Measurability on Unit Intervals*
Let $I_n := (n, n+1]$, $n \in \mathbb{Z}$. For $E \subseteq \mathbb{R}$, $E \in \mathcal{L}^1$ iff $E \cap I_n \in \mathcal{L}^1$ for all $n \in \mathbb{Z}$.

Proof.
($\Rightarrow$) Since $I_n \in \mathcal{B}(\mathbb{R}) \subseteq \mathcal{L}^1$, $E \in \mathcal{L}^1$ implies $E \cap I_n \in \mathcal{L}^1$ for all n.
($\Leftarrow$) If $E \cap I_n \in \mathcal{L}^1$ for all n, then $E = \bigcup_{n\in\mathbb{Z}} (E \cap I_n) \in \mathcal{L}^1$.
Structural Commentary: A countable Borel exhaustion localizes measurability.
Key Insight: Local measurable pieces patch by countable unions. □

Proposition 5.1.10. *Finite Measure Meeting Every Unit Interval*
With $I_n := (n, n+1]$, there exists $E \in \mathcal{B}(\mathbb{R})$ such that $0 < m(E \cap I_n)$ for all $n \in \mathbb{Z}$ and $m(E) < +\infty$.

Proof. Set $\varepsilon_n := 2^{-|n|-3}$ and $E := \bigcup_{n\in\mathbb{Z}} (n, n+\varepsilon_n]$. Then $(n, n+\varepsilon_n] \subseteq I_n$ are pairwise disjoint Borel intervals, so $E \in \mathcal{B}(\mathbb{R})$ and $m(E \cap I_n) = \varepsilon_n > 0$. Countable additivity gives $m(E) = \sum_{n\in\mathbb{Z}} \varepsilon_n = \frac{3}{8} < +\infty$.
Structural Commentary: Finite measure can be spread over countably many cells.
Key Insight: Positive local masses can be summable globally. □

Proposition 5.1.11. *Null Sets Form a Sigma-Ideal*
Let $(X, \mathcal{M}, \mu)$ be a measure space and $\mathcal{Z} := \{N \in \mathcal{M} : \mu(N) = 0\}$.
Then $\mathcal{Z}$ is a σ-ring, and $N \in \mathcal{Z}$, $E \in \mathcal{M}$ imply $N \cap E \in \mathcal{Z}$.

Proof. If $(N_k) \subseteq \mathcal{Z}$, then $\mu(\bigcup_k N_k) \le \sum_k \mu(N_k) = 0$, so $\bigcup_k N_k \in \mathcal{Z}$.
If $A, B \in \mathcal{Z}$, then $A \setminus B \subseteq A$, hence $A \setminus B \in \mathcal{Z}$. Finally, $N \cap E \subseteq N$ gives $N \cap E \in \mathcal{Z}$.
Structural Commentary: Null sets are stable under countable unions and measurable cuts.
Key Insight: Monotonicity makes every measurable piece of a null set null. □

Proposition 5.1.12. *Completed Sigma-Algebra*
Let $(X, \mathcal{M}, \mu)$ be measure space, $\mathcal{Z} := \{N \in \mathcal{M} : \mu(N) = 0\}$; $\overline{\mathcal{M}}_\mu := \{A \subseteq X : \exists E \in \mathcal{M},\ \exists N \in \mathcal{Z},\ A \triangle E \subseteq N\}$.
(i) $\mathcal{M} \subseteq \overline{\mathcal{M}}_\mu$, and $\overline{\mathcal{M}}_\mu$ is a σ-algebra;
(ii) $A \subseteq N \in \mathcal{Z} \Longrightarrow A \in \overline{\mathcal{M}}_\mu$;
(iii) $\overline{\mathcal{M}}_\mu = \{E \cup Z : E \in \mathcal{M},\ \exists N \in \mathcal{Z},\ Z \subseteq N\}$.

Proof.
(i) For $E \in \mathcal{M}$, $E \triangle E = \emptyset$, so $\mathcal{M} \subseteq \overline{\mathcal{M}}_\mu$. If $A \triangle E \subseteq N$, then $A^c \triangle E^c = A \triangle E \subseteq N$.
If $A_k \triangle E_k \subseteq N_k$, then $(\bigcup_k A_k) \triangle (\bigcup_k E_k) \subseteq \bigcup_k N_k \in \mathcal{Z}$. Hence $\overline{\mathcal{M}}_\mu$ is a σ-algebra.
(ii) If $A \subseteq N \in \mathcal{Z}$, then $A \triangle \emptyset \subseteq N$, so $A \in \overline{\mathcal{M}}_\mu$.
(iii) If $A \triangle E \subseteq N$, then $A = (E \setminus N) \cup (A \cap N)$, with $E \setminus N \in \mathcal{M}$ and $A \cap N \subseteq N$.
Conversely, if $A = E \cup Z$ and $Z \subseteq N \in \mathcal{Z}$, then $A \triangle E \subseteq Z \subseteq N$.
Structural Commentary: Completion adds all null modifications of measurable sets.
Key Insight: Equality modulo null sets is the membership criterion. □

Proposition 5.1.13. *Completed Measure*
Let $(X, \mathcal{M}, \mu)$ be a measure space, $\mathcal{Z} := \{N \in \mathcal{M} : \mu(N) = 0\}$,
and $\overline{\mathcal{M}}_\mu := \{A \subseteq X : \exists E \in \mathcal{M},\ \exists N \in \mathcal{Z},\ A \triangle E \subseteq N\}$. For $A \in \overline{\mathcal{M}}_\mu$, define $\overline{\mu}(A) := \mu(E)$ whenever $E \in \mathcal{M}$ and $A \triangle E \subseteq N \in \mathcal{Z}$.
Then $\overline{\mu}$ is a well-defined complete measure on $\overline{\mathcal{M}}_\mu$, and $\overline{\mu}|_{\mathcal{M}} = \mu$.

Proof. If $A \triangle E \subseteq N_1$ and $A \triangle F \subseteq N_2$, with $E, F \in \mathcal{M}$ and $N_1, N_2 \in \mathcal{Z}$, then $E \triangle F \subseteq N_1 \cup N_2$, so $\mu(E) = \mu(F)$. Hence $\overline{\mu}$ is well defined; since $E \triangle E = \emptyset$, $\overline{\mu}|_{\mathcal{M}} = \mu$.
For disjoint $(A_k) \subseteq \overline{\mathcal{M}}_\mu$, choose $E_k \in \mathcal{M}$ and $N_k \in \mathcal{Z}$ with $A_k \triangle E_k \subseteq N_k$, and set $N := \bigcup_k N_k$.
Then $E_i \cap E_j \subseteq N$ for $i \neq j$. Put $F_1 := E_1$ and $F_k := E_k \setminus \bigcup_{j<k} E_j$.
Then (F_k) disjoint, $A_k \triangle F_k \subseteq N$, $(\bigcup_k A_k) \triangle (\bigcup_k F_k) \subseteq N$, so $\overline{\mu}\left(\bigcup_k A_k\right) = \mu\left(\bigcup_k F_k\right) = \sum_k \mu(F_k) = \sum_k \overline{\mu}(A_k)$.
If $A \subseteq B \in \overline{\mathcal{M}}_\mu$ and $\overline{\mu}(B) = 0$, choose $E \in \mathcal{M}$ and $N \in \mathcal{Z}$ with $B \triangle E \subseteq N$.
Then $\mu(E) = 0$, so $A \subseteq B \subseteq E \cup N \in \mathcal{Z}$; hence $A \in \overline{\mathcal{M}}_\mu$ and $\overline{\mu}(A) = 0$.
Structural Commentary: The completed measure ignores null errors.
Key Insight: Null perturbations do not change countable additivity. □

5.2 Radon Measures on Locally Compact Spaces

Radon measure theory is where topology and measure start determining one another. The topological input is a locally compact Hausdorff space; the measure-theoretic output is a Borel measure that can be recovered from open neighborhoods, compact subsets, and compactly supported continuous test functions.

Definition 5.2.1. *Locally Compact Borel Setup*
Let $(X, \mathcal{T})$ be a topological space.
(i) X is *locally compact* if every $x \in X$ admits $U \in \mathcal{T}$ with $x \in U$ and $\overline{U}$ compact.
(ii) The *Borel σ-algebra* is $\mathcal{B}(X) := \sigma(\mathcal{T})$.
(iii) For $f : X \to \mathbb{R}$, define $\operatorname{supp} f := \overline{\{x \in X : f(x) \neq 0\}}$.
(iv) $C_c(X)$ is the subspace of $C(X, \mathbb{R})$ consisting of functions with compact support.

Proposition 5.2.2. *Compact Neighborhood Shrinking*
Let X be locally compact and Hausdorff, $K \subseteq X$ compact, and $O \subseteq X$ open with $K \subseteq O$.
Then there is an open $V \subseteq X$ such that $K \subseteq V$, $\overline{V} \subseteq O$, and $\overline{V}$ is compact.

Proof. For each $x \in K$, choose open $U_x \ni x$ with $\overline{U_x}$ compact.
Normality of the compact Hausdorff space $\overline{U_x}$ gives a relatively open $W_x \ni x$ with $\overline{W_x}^{\overline{U_x}} \subseteq O \cap U_x$.
Choose open $A_x \subseteq X$ with $W_x = A_x \cap \overline{U_x}$ and set $V_x := A_x \cap U_x$. Then $x \in V_x$ and $\overline{V_x} \subseteq \overline{W_x}^{\overline{U_x}} \subseteq O \cap U_x$.
The family $(V_x)_{x\in K}$ covers K, so $K \subseteq \bigcup_{i=1}^n V_{x_i}$ for some $x_1, \dots, x_n \in K$.
Set $V := \bigcup_{i=1}^n V_{x_i}$. Then $\overline{V} = \bigcup_{i=1}^n \overline{V_{x_i}} \subseteq O$, and $\overline{V}$ is compact as a finite union of compact sets.
Structural Commentary: Shrink each point neighborhood inside O, then take a finite union.
Key Insight: Compactness converts local shrinkings into one global compact neighborhood. □

Proposition 5.2.3. *Compactly Supported Cutoff*
Let X be locally compact and Hausdorff, $K \subseteq X$ compact, and $O \subseteq X$ open with $K \subseteq O$.
Then there is $f \in C_c(X)$ such that $0 \le f \le 1$ on X, $f|_K = 1$, and $\operatorname{supp} f \subseteq O$.

Proof. Choose open $V \subseteq X$ as in Proposition 5.2.2, so $K \subseteq V$, $\overline{V}$ is compact, and $\overline{V} \subseteq O$.
The disjoint sets K and $\overline{V} \setminus V$ are closed in the compact Hausdorff space $\overline{V}$.
By Urysohn's lemma, Theorem 6.3.20, there is $f_0 : \overline{V} \to [0,1]$ with $f_0|_K = 1$ and $f_0|_{\overline{V}\setminus V} = 0$.
Define $f : X \to [0,1]$ by $f|_{\overline{V}} = f_0$ and $f|_{X\setminus V} = 0$.
Closed-set pasting gives $f \in C_c(X)$ with $f|_K = 1$ and $\operatorname{supp} f \subseteq \overline{V} \subseteq O$.
Structural Commentary: Apply Urysohn separation on $\overline{V}$ and extend by zero.
Key Insight: The compact neighborhood forces the extension to have compact support. □

Proposition 5.2.4. *Finite Partition of Unity on a Compact Set*
Let X be locally compact and Hausdorff, $K \subseteq X$ compact, and $O_1, \dots, O_n \subseteq X$ open with $K \subseteq \bigcup_{i=1}^n O_i$.
Then there are $\varphi_1, \dots, \varphi_n \in C_c(X)$ such that $0 \le \varphi_i \le 1$, $\operatorname{supp} \varphi_i \subseteq O_i$ for every i, and $(\sum_{i=1}^n \varphi_i)|_K = 1$.

Proof. For each $x \in K$, choose $i(x)$ with $x \in O_{i(x)}$ and, by Proposition 5.2.2, an open $V_x \ni x$ with $\overline{V_x}$ compact and $\overline{V_x} \subseteq O_{i(x)}$. Choose $x_1, \dots, x_m \in K$ with $K \subseteq \bigcup_{j=1}^m V_{x_j}$, write $i_j := i(x_j)$, and set $U_i := \bigcup_{\{j : i_j = i\}} V_{x_j}$.
Then $K \subseteq \bigcup_i U_i$, each U_i is open, and $\overline{U_i}$ is compact with $\overline{U_i} \subseteq O_i$.
For $U_i \neq \emptyset$, Proposition 5.2.3 gives $f_i \in C_c(X)$ with $0 \le f_i \le 1$, $f_i|_{\overline{U_i}} = 1$, $\operatorname{supp} f_i \subseteq O_i$; set $f_i = 0$ otherwise. Applying the same proposition to $K \subseteq \bigcup_i U_i$ gives $h \in C_c(X)$ with $0 \le h \le 1$, $h|_K = 1$, and $\operatorname{supp} h \subseteq \bigcup_i U_i$.
Set $g := \sum_{i=1}^n f_i$ and $d := g + 1 - h$. Since $g \ge 1$ on $\operatorname{supp} h$ and $h = 0$ off $\operatorname{supp} h$, $d \ge 1$. Hence $\varphi_i := f_i/d$ belongs to $C_c(X)$, satisfies $0 \le \varphi_i \le 1$, and has $\operatorname{supp} \varphi_i \subseteq O_i$. On K, $h = 1$ and $g \ge 1$, so $d = g$ and $(\sum_{i=1}^n \varphi_i)|_K = 1$.
Structural Commentary: Build finitely many local cutoffs, then normalize their sum.
Key Insight: The auxiliary cutoff keeps the denominator positive where local cutoffs vanish. □

Theorem 5.2.5. *Locally Compact Separation and Cutoff Package*
Let X be Hausdorff. The following are equivalent.

(i) X is locally compact.
(ii) For every compact $K \subseteq O \in \mathcal{T}$, there is open $V \supseteq K$ with $\overline{V}$ compact and $\overline{V} \subseteq O$.
(iii) For every compact $K \subseteq O \in \mathcal{T}$, there is $f \in C_c(X)$ with $0 \le f \le 1$, $f|_K = 1$, and $f|_{X\setminus O} = 0$.

Proof.

(*i*) $\Rightarrow$ (*ii*) Proposition 5.2.2.
(*i*) $\Rightarrow$ (*iii*) Proposition 5.2.3.
(*ii*) $\Rightarrow$ (*i*) For $x \in X$, apply (ii) to $K = \{x\}$ and $O = X$; the resulting open $V \ni x$ has compact closure.
(*iii*) $\Rightarrow$ (*i*) For $x \in X$, apply (iii) to $K = \{x\}$ and $O = X$, and set $U := f^{-1}((1/2, 3/2))$.
Then $x \in U$ and $\overline{U} \subseteq f^{-1}([1/2, 3/2]) \subseteq \operatorname{supp} f$, so $\overline{U}$ is compact.

Structural Commentary: Compact cutoffs recover compact neighborhoods through level sets.
Key Insight: Compact-neighborhood shrinking and compactly supported cutoffs are equivalent local forms of local compactness. □

Method 5.2.6. *Metric Cutoff Formula*
Let X be locally compact and Hausdorff, assume that ρ induces its topology.
Let $K \subseteq O \subseteq X$ with K compact and O open, and choose open $U \subseteq X$ with $K \subseteq U$, $\overline{U}$ compact, and $\overline{U} \subseteq O$.
For every nonempty $A \subseteq X$, set $\operatorname{dist}_A(x) := \inf_{a\in A} \rho(x, a)$.

(i) *Empty Set*: If $K = \emptyset$, set $f := 0$.
(ii) *Trivial Complement*: If $K \neq \emptyset$ and $X \setminus U = \emptyset$, set $f := 1$.
(iii) *Distance Ratio*: Otherwise, set $f(x) := \dfrac{\operatorname{dist}_{X\setminus U}(x)}{\operatorname{dist}_{X\setminus U}(x) + \operatorname{dist}_K(x)}$.

In case (iii), K and $X \setminus U$ are disjoint closed sets, so the denominator is positive; continuity of distance functions gives $f \in C(X, [0,1])$.
In all cases, $f \in C_c(X)$, $f|_K = 1$, $f|_{X\setminus U} = 0$, and $\operatorname{supp} f \subseteq \overline{U} \subseteq O$.
Key Insight: Metric distances give an explicit compactly supported cutoff.

Proposition 5.2.7. *Alexandroff One-Point Compactification*
Let $(X, \mathcal{T})$ be locally compact and Hausdorff, let $\omega \notin X$, and write $\mathcal{K}(X)$ for the compact subsets of X.
Set $X^* := X \cup \{\omega\}$ and $\mathcal{T}^* := \mathcal{T} \cup \{X^* \setminus K : K \in \mathcal{K}(X)\}$. Let $\iota : X \hookrightarrow X^*$ be the inclusion.

(i) $\mathcal{T}^*$ is a topology on X^*, $(X^*, \mathcal{T}^*)$ is compact Hausdorff, and $\iota : X \to X^* \setminus \{\omega\}$ is a homeomorphism.
(ii) Every $h \in C(K, \mathbb{R})$ with $K \subseteq X$ compact has an extension $\widetilde{h} \in C(X, \mathbb{R})$ satisfying $\widetilde{h}|_K = h$.

Proof.

(i) Compact subsets of the Hausdorff space X are closed.
Thus $U \setminus C \in \mathcal{T}$ and $(X^* \setminus C) \cap (X^* \setminus D) = X^* \setminus (C \cup D)$ for $U \in \mathcal{T}$ and $C, D \in \mathcal{K}(X)$.
If $\omega \notin \bigcup_\alpha U_\alpha$, then $\bigcup_\alpha U_\alpha \in \mathcal{T}$; otherwise choose $U_{\alpha_0} = X^* \setminus C$, so $X^* \setminus \bigcup_\alpha U_\alpha$ is closed in C and hence compact. Thus $\mathcal{T}^*$ is a topology.
Any open cover contains $X^* \setminus C$ for some $C \in \mathcal{K}(X)$, and finitely many remaining members cover C; hence X^* is compact. Points of X are already separated.

For $x \in X$, choose open $V \ni x$ with $\overline{V}$ compact; then V and $X^* \setminus \overline{V}$ separate x and ω.
Finally, $\mathcal{T}^*|_X = \mathcal{T}$ since $X \setminus C \in \mathcal{T}$ for $C \in \mathcal{K}(X)$, so ι is a homeomorphism onto $X^* \setminus \{\omega\}$.

(ii) By (i), X^* is compact Hausdorff and hence normal. The compact set K is closed in X^*, and h is bounded.
Tietze extension, Theorem 6.3.22, gives $H \in C(X^*, \mathbb{R})$ with $H|_K = h$. Set $\widetilde{h} := H|_X$.

Structural Commentary: Neighborhoods of ω are complements of compact subsets of X.
Key Insight: Compactification transfers extension problems to a compact Hausdorff space. □

Definition 5.2.8. *Radon Measures and Radon Premeasures*
Let $(X, \mathcal{T})$ be a topological space, and write $\mathcal{K}(X)$ for its compact subsets.

(i) $\nu : \mathcal{B}(X) \to [0, +\infty]$ is a *Radon measure* if $\nu(K) < +\infty \ \forall K \in \mathcal{K}(X)$, $\nu(E) = \inf\{\nu(O) : E \subseteq O,\ O \in \mathcal{T}\}\ \forall E \in \mathcal{B}(X)$, and $\nu(O) = \sup\{\nu(K) : K \subseteq O,\ K \in \mathcal{K}(X)\}\ \forall O \in \mathcal{T}$.

(ii) $\mu : \mathcal{T} \to [0, +\infty]$ is a *Radon premeasure* if $\mu(U) < +\infty\ \forall U \in \mathcal{T}$ with $\overline{U} \in \mathcal{K}(X)$ and $\mu(O) = \sup\{\mu(U) : U \in \mathcal{T},\ \overline{U} \in \mathcal{K}(X),\ \overline{U} \subseteq O\}\ \forall O \in \mathcal{T}$.

Lemma 5.2.9. *Open Envelope for a Topological Premeasure*
Let $\mu : \mathcal{T} \to [0, +\infty]$ be a premeasure. For $E \subseteq X$, define $\mu^*(E) := \inf\{\sum_{j=1}^{\infty} \mu(U_j) : E \subseteq \bigcup_{j=1}^{\infty} U_j,\ U_j \in \mathcal{T}\}$.
Then $\mu^*(E) = \inf\{\mu(U) : E \subseteq U,\ U \in \mathcal{T}\}$.

Proof.

(⇒) Set $I(E) := \inf\{\mu(U) : E \subseteq U,\ U \in \mathcal{T}\}$. Every $U \in \mathcal{T}$ with $E \subseteq U$ is a one-set cover, so $\mu^*(E) \le I(E)$.

(⇐) If $(U_j)_{j \ge 1} \subseteq \mathcal{T}$ covers E, then $U := \bigcup_{j=1}^{\infty} U_j$ belongs to $\mathcal{T}$ and satisfies $\mu(U) \le \sum_{j=1}^{\infty} \mu(U_j)$.
Hence $I(E) \le \sum_{j=1}^{\infty} \mu(U_j)$; taking the infimum over covers gives $I(E) \le \mu^*(E)$.

Structural Commentary: Replace each countable cover by its union.
Key Insight: Subadditivity makes the union no more expensive than the cover. □

Lemma 5.2.10. *Open-Set Test for Caratheodory Measurability*
Let $\mu : \mathcal{T} \to [0, +\infty]$ be a premeasure, let μ^* be the outer measure induced by open covers, and let $E \subseteq X$.
Assume $\mu(O) \ge \mu^*(O \cap E) + \mu^*(O \setminus E)$ for every $O \in \mathcal{T}$ with $\mu(O) < +\infty$. Then E is μ^*-measurable.

Proof. Fix $A \subseteq X$. Outer subadditivity gives $\mu^*(A) \le \mu^*(A \cap E) + \mu^*(A \setminus E)$.
If $\mu^*(A) = +\infty$, the reverse inequality is automatic. Otherwise, for $\varepsilon > 0$, Lemma 5.2.9 gives $O \in \mathcal{T}$ with $A \subseteq O$ and $\mu(O) < \mu^*(A) + \varepsilon$, so $\mu^*(A \cap E) + \mu^*(A \setminus E) \le \mu^*(O \cap E) + \mu^*(O \setminus E) \le \mu(O) < \mu^*(A) + \varepsilon$.
Letting $\varepsilon \downarrow 0$ gives the reverse inequality, hence the Caratheodory criterion.
Structural Commentary: Approximate A by an open envelope of nearly equal outer mass.
Key Insight: Open-set splitting propagates to all sets through outer regularity. □

Proposition 5.2.11. *Open Sets from a Radon Premeasure Are Measurable*
Let X be locally compact and Hausdorff, $\mu : \mathcal{T} \to [0, +\infty]$ Radon premeasure, μ^* open-cover outer measure.

(i) $\mu^*|_{\mathcal{T}} = \mu$.
(ii) Every $V \in \mathcal{T}$ is μ^*-measurable.

Proof.

(i) The one-set cover gives $\mu^*(V) \le \mu(V)$ for $V \in \mathcal{T}$.
Every $(U_j)_{j \ge 1} \subseteq \mathcal{T}$ covering V satisfies $\mu(V) \le \mu(\bigcup_j U_j) \le \sum_j \mu(U_j)$, so $\mu(V) \le \mu^*(V)$.

(ii) Let $V, O \in \mathcal{T}$ with $\mu(O) < +\infty$.
For $\varepsilon > 0$, choose $U \in \mathcal{T}$ with $\overline{U}$ compact, $\overline{U} \subseteq O \cap V$, and $\mu(U) > \mu(O \cap V) - \varepsilon$.
Since U and $O \setminus \overline{U}$ are disjoint open subsets of O and $O \setminus V \subseteq O \setminus \overline{U}$,
$\mu(O) \ge \mu(U) + \mu(O \setminus \overline{U}) \ge \mu^*(O \cap V) - \varepsilon + \mu^*(O \setminus V)$ by (i). Let $\varepsilon \downarrow 0$ and apply Lemma 5.2.10.

Structural Commentary: Inner approximation leaves an open remainder containing $O \setminus V$.
Key Insight: Open inner regularity yields Caratheodory splitting. □

Theorem 5.2.12. *Radon Premeasure Extension*
Let X be locally compact and Hausdorff, let $\mu : \mathcal{T} \to [0, +\infty]$ be a Radon premeasure, let μ^* be its open-cover outer measure, write $\mathcal{K}(X)$ for the compact subsets of X, and set $\widehat{\mu} := \mu^*|_{\mathcal{B}(X)}$.

(i) $\widehat{\mu}|_{\mathcal{T}} = \mu$.
(ii) $\widehat{\mu}$ is a Radon measure on $\mathcal{B}(X)$.

Proof.

(i) For $O \in \mathcal{T} \subseteq \mathcal{B}(X)$, $\widehat{\mu}(O) = \mu^*(O) = \mu(O)$ by Proposition 5.2.11; hence $\widehat{\mu}|_{\mathcal{T}} = \mu$.

(ii) Let $\mathcal{C}_{\mu^*}$ be the Caratheodory σ-algebra of μ^*. Proposition 5.2.11 gives $\mathcal{T} \subseteq \mathcal{C}_{\mu^*}$, hence $\mathcal{B}(X) = \sigma(\mathcal{T}) \subseteq \mathcal{C}_{\mu^*}$.
As $\mu^*|_{\mathcal{C}_{\mu^*}}$ is measure, so is $\widehat{\mu}$. Lemma 5.2.9, (i) give $\widehat{\mu}(E) = \inf\{\widehat{\mu}(O) : E \subseteq O,\ O \in \mathcal{T}\}$ for $E \in \mathcal{B}(X)$.
For $K \in \mathcal{K}(X)$, Proposition 5.2.2 gives $K \subseteq U \in \mathcal{T}$ with $\overline{U} \in \mathcal{K}(X)$, so $\widehat{\mu}(K) \le \widehat{\mu}(U) = \mu(U) < +\infty$.
For $O \in \mathcal{T}$, inner regularity and (i) give
$\widehat{\mu}(O) = \sup\{\mu(U) : U \in \mathcal{T},\ \overline{U} \in \mathcal{K}(X),\ \overline{U} \subseteq O\} \le \sup\{\widehat{\mu}(K) : K \in \mathcal{K}(X),\ K \subseteq O\} \le \widehat{\mu}(O)$.

Structural Commentary: $\mathcal{T} \subseteq \mathcal{C}_{\mu^*}$ yields $\widehat{\mu}$ on $\mathcal{B}(X)$; $K \in \mathcal{K}(X) \Rightarrow \widehat{\mu}(K) < +\infty$.
Key Insight: Open inner regularity becomes compact inner regularity after extension. □

Theorem 5.2.13. *Radon Measures Determined by $C_c(X)$*
Let X be locally compact and Hausdorff, and let μ_1, μ_2 be Radon measures on $\mathcal{B}(X)$.
If $\int_X f \, d\mu_1 = \int_X f \, d\mu_2$ for every $f \in C_c(X)$, then $\mu_1 = \mu_2$.

Proof. Write $\mathcal{K}(X)$ for the compact subsets of X. Let $K \in \mathcal{K}(X)$ and $\varepsilon > 0$.
By outer regularity, choose $O \in \mathcal{T}$ with $K \subseteq O$ and $\mu_i(O \setminus K) < \varepsilon$ for $i = 1, 2$.
Choose $f \in C_c(X)$ with $0 \le f \le 1$, $f|_K = 1$, and $\operatorname{supp} f \subseteq O$, and set $r_i := \int_{O\setminus K} f \, d\mu_i$.
Then $0 \le r_i < \varepsilon$ and $\int_X f \, d\mu_i = \mu_i(K) + r_i$, so $|\mu_1(K) - \mu_2(K)| = |r_1 - r_2| < \varepsilon$.
Hence $\mu_1 = \mu_2$ on $\mathcal{K}(X)$, and inner then outer regularity give $\mu_1|_{\mathcal{T}} = \mu_2|_{\mathcal{T}}$ and $\mu_1 = \mu_2$ on $\mathcal{B}(X)$.
Structural Commentary: $C_c(X)$ identifies μ_1 and μ_2 on $\mathcal{K}(X)$.
Key Insight: $\mathcal{K}(X) \to \mathcal{T} \to \mathcal{B}(X)$ by Radon regularity. □

Figure 195: Riesz–Markov: local compactness supplies cutoffs; orange denotes Caratheodory extension.

Theorem 5.2.14. *Riesz–Markov Theorem on $C_c(X)$*
Let X be locally compact and Hausdorff, $I : C_c(X) \to \mathbb{R}$ linear with $I(f) \ge 0$ $\forall f \in C_c(X)$ satisfying $f \ge 0$.
Then $\exists$ a unique Radon measure $\widehat{\mu}$ on $\mathcal{B}(X)$ such that $I(f) = \int_X f \, d\widehat{\mu}$ $\forall f \in C_c(X)$.

Proof. For $O \in \mathcal{T}$, define $\mu(O) := \sup\{I(f) : f \in C_c(X),\ 0 \le f \le 1,\ \operatorname{supp} f \subseteq O\}$ and $\mu(\emptyset) := 0$.

(i) *Premeasure*: If $O \subseteq \bigcup_{j=1}^{\infty} O_j$ and f is admissible for $\mu(O)$, a finite partition $(\varphi_\ell)_{\ell=1}^m$ subordinate to a finite subcover of $\operatorname{supp} f$ gives $f = \sum_{\ell=1}^{m} f\varphi_\ell$ and $I(f) \le \sum_{\ell=1}^{m} \mu(O_{j_\ell}) \le \sum_{j=1}^{\infty} \mu(O_j)$, so μ is countably subadditive. For disjoint $O_1, O_2 \in \mathcal{T}$, countable subadditivity gives one inequality and admissible f_1, f_2 give $\mu(O_1) + \mu(O_2) \le \mu(O_1 \cup O_2)$, hence finite additivity.

(ii) *Radon Regularity*: For $a < \mu(O)$, choose admissible f with $I(f) > a$ and $U \in \mathcal{T}$ with $\operatorname{supp} f \subseteq U \subseteq \overline{U} \subseteq O$ and $\overline{U}$ compact. Then $\mu(U) > a$, proving inner regularity. If $\overline{U}$ is compact, a cutoff $g \in C_c(X)$ with $g|_{\overline{U}} = 1$ dominates every admissible f for $\mu(U)$, so $\mu(U) \le I(g) < +\infty$. Thus μ is a Radon premeasure.

(iii) *Extension*: Stages (i)–(ii) make μ a Radon premeasure on $\mathcal{T}$. Theorem 5.2.12 applies to its open-cover outer measure and yields the Radon measure $\widehat{\mu} := \mu^*|_{\mathcal{B}(X)}$ with $\widehat{\mu}|_{\mathcal{T}} = \mu$.

(iv) *Identification*: Let $0 \le f \le 1$ belong to $C_c(X)$, choose $O \in \mathcal{T}$ with $\operatorname{supp} f \subseteq O$ and $\overline{O}$ compact, and set $\psi_k := \min\{1, \max\{0, nf - (k-1)\}\}$, $O_0 := O$, $O_{n+1} := \emptyset$, $O_k := \{x \in O : f(x) > \frac{k-1}{n}\}$ for $1 \le k \le n$.

Then $f = \frac{1}{n} \sum_{k=1}^{n} \psi_k$, $\operatorname{supp} \psi_k \subseteq O_{k-1}$, and $\psi_k|_{O_{k+1}} = 1$, so $\mu(O_{k+1}) \le I(\psi_k) \le \mu(O_{k-1})$

and $\mu(O_{k+1}) \le \int_X \psi_k \, d\widehat{\mu} \le \mu(O_{k-1})$. Therefore $|I(f) - \int_X f \, d\widehat{\mu}| \le \frac{1}{n} \sum_{k=1}^{n} (\mu(O_{k-1}) - \mu(O_{k+1})) \le \frac{2\mu(O)}{n}$.

Letting $n \to \infty$, scaling, and $f = f^+ - f^-$ give $I(f) = \int_X f \, d\widehat{\mu}$ for every $f \in C_c(X)$.
Uniqueness follows from Theorem 5.2.13.

Structural Commentary: Open-set contents and compactly supported cutoffs build the Radon measure before identifying its integral.
Key Insight: Layer functions recover I from $\widehat{\mu}$. □

Theorem 5.2.15. *Lusin Approximation for Radon Measures*
Let X be locally compact Hausdorff, let μ be Radon on $\mathcal{B}(X)$, let $f : X \to \mathbb{R}$ be Borel, and set $A := \{f \ne 0\}$ with $\mu(A) < +\infty$. For every $\varepsilon > 0$, there exist $X_0 \in \mathcal{B}(X)$ and $g \in C_c(X)$ such that:
(i) $g = f$ on X_0.
(ii) $\mu(X \setminus X_0) < \varepsilon$.

Proof. Set $\delta := \varepsilon/4$. Choose $M > 0$ with $\mu(A_M) < \delta$, where $A_M := A \cap \{|f| > M\}$, and put $B := A \setminus A_M$.
For $n \ge 1$, choose finite-valued Borel $s_n : B \to [-M, M]$ with $\|s_n - f\|_{\infty, B} \le \frac{1}{n}$.
Let $s_n(B) = \{a_{n,1}, \dots, a_{n,m_n}\}$ and $E_{n,j} := s_n^{-1}(\{a_{n,j}\})$. Inner regularity gives compact $K_{n,j} \subseteq E_{n,j}$, $\mu(E_{n,j} \setminus K_{n,j}) < \frac{\delta}{2^n m_n}$. Set $F_n := \bigcup_{j=1}^{m_n} K_{n,j}$ and $F := \bigcap_{n=1}^{\infty} F_n$.

Then F is compact, $B \setminus F \subseteq \bigcup_{n\ge1} \bigcup_{j=1}^{m_n} (E_{n,j} \setminus K_{n,j})$, and $\mu(B \setminus F) \le \delta$.
For each n, $F \cap E_{n,j} = F \cap K_{n,j}$ is closed in F, so $s_n|_F \in C(F)$; since $s_n|_F \to f|_F$ uniformly, $f|_F \in C(F)$.
Choose $W \in \mathcal{T}$ with $F \subseteq W$ and $\mu(W \setminus F) < \delta$, then choose $O \in \mathcal{T}$ by Proposition 5.2.2 with $F \subseteq O \subseteq \overline{O} \subseteq W$ and $\overline{O}$ compact.
Extend $f|_F$ to $H \in C(X)$ by Proposition 5.2.7, choose $q \in C_c(X)$ with $q|_F = 1$ and $\operatorname{supp} q \subseteq O$ by Proposition 5.2.3, and set $g := qH$, $X_0 := F \cup (X \setminus (A \cup O))$. Then $g \in C_c(X)$ and $X_0 \in \mathcal{B}(X)$.

(i) On F, $g = qH = f$; on $X \setminus (A \cup O)$, $f = q = 0$.
(ii) $X \setminus X_0 \subseteq (A \setminus F) \cup (O \setminus F)$, $\mu(A \setminus F) \le \mu(A_M) + \mu(B \setminus F) < 2\delta$, $\mu(O \setminus F) \le \mu(W \setminus F) < \delta$; $\mu(X \setminus X_0) < 3\delta < \varepsilon$.

Structural Commentary: Compact core plus cutoff extension.
Key Insight: Discard a small set to make Borel data continuous. □

5.3 Invariant Measures on Compact Groups

Compact groups are the meeting point of topological symmetry and Radon measure theory. The compactness supplies fixed points in dual spaces, and Riesz–Markov converts those fixed functionals into invariant Borel measures.

Definition 5.3.1. *Compact Groups and Haar Measures*
For a group G, $A \subseteq G$, and $g \in G$, set $gA := \{ga : a \in A\}$ and $Ag := \{ag : a \in A\}$.

(i) A *topological group* is G with Hausdorff topology such that $(g, h) \mapsto gh$ and $g \mapsto g^{-1}$ are continuous.
(ii) A *compact group* is a topological group whose underlying topological space is compact.

(iii) A Borel measure μ on $\mathcal{B}(G)$ is *left-invariant* if $\mu(gA) = \mu(A)$ for all $g \in G$ and $A \in \mathcal{B}(G)$.
(iv) A Borel measure μ on $\mathcal{B}(G)$ is *right-invariant* if $\mu(Ag) = \mu(A)$ for all $g \in G$ and $A \in \mathcal{B}(G)$.
(v) A *Haar measure* on a compact group G is a left-invariant Radon probability measure on $\mathcal{B}(G)$.

Definition 5.3.2. *Regular Actions on $C(G)$*
Let G be compact, $C(G)$ be continuous maps $G \to \mathbb{R}$ with $\|f\|_\infty := \max_{x\in G} |f(x)|$. For $g, x \in G$ and $f \in C(G)$:
(i) The *left regular action* is $\pi_{\mathrm{L}} : G \to \mathcal{L}(C(G))$, $[\pi_{\mathrm{L}}(g)f](x) := f(g^{-1}x)$.
(ii) The *right regular action* is $\pi_{\mathrm{R}} : G \to \mathcal{L}(C(G))$, $[\pi_{\mathrm{R}}(g)f](x) := f(xg^{-1})$.
(iii) A *probability functional* is $\psi \in C(G)^*$ with $\psi(\mathbf{1}_G) = 1$ and $f \geq 0 \Rightarrow \psi(f) \geq 0$ for all $f \in C(G)$.

Theorem 5.3.3. *Kakutani Fixed Probability Functional*
Let G be a compact group. Then there are probability functionals $\psi_{\mathrm{L}}, \psi_{\mathrm{R}} \in C(G)^*$ such that $\psi_{\mathrm{L}}(\pi_{\mathrm{L}}(g)f) = \psi_{\mathrm{L}}(f)$ and $\psi_{\mathrm{R}}(\pi_{\mathrm{R}}(g)f) = \psi_{\mathrm{R}}(f)$ for every $g \in G$ and $f \in C(G)$.

Proof. Let $\mathcal{P}(G) := \{\psi \in C(G)^* : \psi(\mathbf{1}_G) = 1,\ \forall f \in C(G)\ (f \geq 0 \Rightarrow \psi(f) \geq 0)\}$. Then $\delta_e \in \mathcal{P}(G)$, $\mathcal{P}(G)$ is convex and weak-* closed, and $\psi \in \mathcal{P}(G) \Rightarrow \|\psi\|_{\mathrm{op}} = 1$; hence $\mathcal{P}(G)$ is weak-* compact by Banach–Alaoglu.
For $g \in G$, set $T_{\mathrm{L}}(g)\psi := \psi \circ \pi_{\mathrm{L}}(g^{-1})$ and $T_{\mathrm{R}}(g)\psi := \psi \circ \pi_{\mathrm{R}}(g)$. Since $\pi_{\mathrm{L}}, \pi_{\mathrm{R}}$ preserve $\mathbf{1}_G$ and $C(G)_+$ and are norm-continuous in g, T_{L} and T_{R} are continuous affine G-actions on $\mathcal{P}(G)$.
Kakutani gives $\psi_{\mathrm{L}}, \psi_{\mathrm{R}} \in \mathcal{P}(G)$ with $T_{\mathrm{L}}(g)\psi_{\mathrm{L}} = \psi_{\mathrm{L}}$ and $T_{\mathrm{R}}(g)\psi_{\mathrm{R}} = \psi_{\mathrm{R}}$ for all $g \in G$.
Thus $\psi_{\mathrm{L}} \circ \pi_{\mathrm{L}}(g) = \psi_{\mathrm{L}}$ and $\psi_{\mathrm{R}} \circ \pi_{\mathrm{R}}(g) = \psi_{\mathrm{R}}$ for all $g \in G$.
Structural Commentary: Compactness lives in $\mathcal{P}(G)$; invariance comes from fixed points.
Key Insight: A fixed probability functional is invariant. □

Method 5.3.4. *Fixed Functional Pattern*
For a compact group G, set $\mathcal{P}(G) := \{\psi \in C(G)^* : \psi(\mathbf{1}_G) = 1,\ \forall f \in C(G)\ (f \geq 0 \Rightarrow \psi(f) \geq 0)\}$.
(i) Show $\mathcal{P}(G) \neq \varnothing$ via $\delta_x(f) := f(x)$, $x \in G$.
(ii) Show $\mathcal{P}(G)$ is weak-* compact convex: $\psi \in \mathcal{P}(G) \Rightarrow \|\psi\|_{\mathrm{op}} = 1$, Banach–Alaoglu, and weak-* closed defining conditions.
(iii) Define $T_{\mathrm{L}}(g)\psi := \psi \circ \pi_{\mathrm{L}}(g^{-1})$ or $T_{\mathrm{R}}(g)\psi := \psi \circ \pi_{\mathrm{R}}(g)$. For $T = T_{\mathrm{L}}, T_{\mathrm{R}}$, check $T(g)\mathcal{P}(G) \subseteq \mathcal{P}(G)$ and weak-* continuity.
(iv) Apply Kakutani: find $\psi \in \mathcal{P}(G)$ with $T(g)\psi = \psi$ for all $g \in G$.
(v) Apply Riesz–Markov, $\psi(f) = \int_G f\, d\mu$, and read $T(g)\psi = \psi$ as invariance of μ.
Structural Commentary: Compact state space plus adjoint action.
Key Insight: Haar measure is an invariant state represented by Riesz–Markov.

Proposition 5.3.5. *Translated Measures and Test Functions*
Let G be a compact group, let μ be a Borel measure on $\mathcal{B}(G)$, and fix $g \in G$.
Set $L_g(x) := gx$ and $R_g(x) := xg$ for $x \in G$.
For $A \in \mathcal{B}(G)$, define $\mu_g^{\mathrm{L}}(A) := \mu(L_g(A)) = \mu(gA)$ and $\mu_g^{\mathrm{R}}(A) := \mu(R_g(A)) = \mu(Ag)$.
(i) μ_g^{L} and μ_g^{R} are Borel measures on $\mathcal{B}(G)$.
(ii) If μ is Radon, then μ_g^{L} and μ_g^{R} are Radon.
(iii) For every $f \in C(G)$, $\int_G \pi_{\mathrm{L}}(g)f\, d\mu = \int_G f\, d\mu_g^{\mathrm{L}}$ and $\int_G \pi_{\mathrm{R}}(g)f\, d\mu = \int_G f\, d\mu_g^{\mathrm{R}}$.

Proof. For every $h \in G$, the maps L_h and R_h are homeomorphisms of G.
(i) Since L_g and R_g map Borel sets bijectively onto Borel sets, μ_g^{L} and μ_g^{R} are defined on $\mathcal{B}(G)$. If $(A_n)_{n\geq 1}$ are pairwise disjoint Borel sets, then $L_g(\bigcup_n A_n) = \bigcup_n L_g(A_n)$ and $R_g(\bigcup_n A_n) = \bigcup_n R_g(A_n)$, with disjoint unions; countable additivity follows from countable additivity of μ.
(ii) Since $L_{g^{-1}}^{-1} = L_g$ and $R_{g^{-1}}^{-1} = R_g$, $\mu_g^{\mathrm{L}} = (L_{g^{-1}})_*\mu$ and $\mu_g^{\mathrm{R}} = (R_{g^{-1}})_*\mu$. If μ is Radon, pushforward by a homeomorphism preserves compact sets, open sets, and Radon regularity. Hence both translated measures are Radon.
(iii) For $f \in C(G)$, the pushforward identity gives $\int_G f\, d\mu_g^{\mathrm{L}} = \int_G f \circ L_{g^{-1}}\, d\mu = \int_G \pi_{\mathrm{L}}(g)f\, d\mu$ and $\int_G f\, d\mu_g^{\mathrm{R}} = \int_G f \circ R_{g^{-1}}\, d\mu = \int_G \pi_{\mathrm{R}}(g)f\, d\mu$.
Structural Commentary: Translated measures are inverse-translation pushforwards.
Key Insight: Measure translation is dual to test-function precomposition. □

Theorem 5.3.6. *Haar Measure on Compact Groups*
Let G be a compact group. Let $\mathcal{P}_{\mathrm{L}}(G)$ and $\mathcal{P}_{\mathrm{R}}(G)$ be the left- and right-invariant Radon probability measures on $\mathcal{B}(G)$, respectively.
(i) $\mathcal{P}_{\mathrm{L}}(G) \neq \emptyset$.
(ii) $\mathcal{P}_{\mathrm{R}}(G) \neq \emptyset$.
(iii) For every $(\lambda, \rho) \in \mathcal{P}_{\mathrm{L}}(G) \times \mathcal{P}_{\mathrm{R}}(G)$, $\lambda = \rho$.
Consequently, G admits a unique Haar measure, and this measure is right-invariant.

Proof. For a Radon probability measure σ on $\mathcal{B}(G)$, set $\Phi_\sigma(f) := \int_G f\, d\sigma$ for $f \in C(G)$.
(i) Choose ψ_{L} from Theorem 5.3.3. Riesz–Markov gives a Radon probability measure μ with $\psi_{\mathrm{L}} = \Phi_\mu$ on $C(G) = C_c(G)$. For $g \in G$, Proposition 5.3.5 gives $\Phi_{\mu_g^{\mathrm{L}}}(f) = \Phi_\mu(\pi_{\mathrm{L}}(g)f) = \Phi_\mu(f)$ for every $f \in C(G)$. Thus $\mu_g^{\mathrm{L}} = \mu$ by Theorem 5.2.13, so $\mu(gA) = \mu(A)$ for every $A \in \mathcal{B}(G)$ and $\mu \in \mathcal{P}_{\mathrm{L}}(G)$.
(ii) Choose ψ_{R} from Theorem 5.3.3. Riesz–Markov gives a Radon probability measure ν with $\psi_{\mathrm{R}} = \Phi_\nu$ on $C(G) = C_c(G)$. For $g \in G$, Proposition 5.3.5 gives $\Phi_{\nu_g^{\mathrm{R}}}(f) = \Phi_\nu(\pi_{\mathrm{R}}(g)f) = \Phi_\nu(f)$ for every $f \in C(G)$. Thus $\nu_g^{\mathrm{R}} = \nu$ by Theorem 5.2.13, so $\nu(Ag) = \nu(A)$ for every $A \in \mathcal{B}(G)$ and $\nu \in \mathcal{P}_{\mathrm{R}}(G)$.
(iii) Let $(\lambda, \rho) \in \mathcal{P}_{\mathrm{L}}(G) \times \mathcal{P}_{\mathrm{R}}(G)$, fix $f \in C(G)$, and set $h_f(x, y) := f(xy)$. Fubini applies to $h_f \in C(G \times G)$. Left-invariance gives $\int_G h_f(x, y)\, d\lambda(y) = \Phi_\lambda(f)$ for every x, and right-invariance gives $\int_G h_f(x, y)\, d\rho(x) = \Phi_\rho(f)$ for every y. Since $\lambda(G) = \rho(G) = 1$, Fubini gives $\Phi_\lambda(f) = \Phi_\rho(f)$. Hence $\lambda = \rho$ by Theorem 5.2.13.

Taking $\mu \in \mathcal{P}_{\mathrm{L}}(G)$ from (i) and $\nu \in \mathcal{P}_{\mathrm{R}}(G)$ from (ii), (iii) gives $\mu = \nu$, so μ is right-invariant. If η is Haar, then $\eta \in \mathcal{P}_{\mathrm{L}}(G)$ and (iii) gives $\eta = \nu$, so Haar measure is unique.
Structural Commentary: Fixed states give existence; Fubini gives uniqueness.
Key Insight: Invariance makes both iterated integrals constant. □

Proposition 5.3.7. *Point Masses of Haar Measure*
Let G be a compact group, and let μ be Haar measure on $\mathcal{B}(G)$.

(i) If G is finite, then every $A \subseteq G$ is Borel and $\mu(A) = \frac{|A|}{|G|}$.
(ii) If G is infinite, then $\mu(\{x\}) = 0$ for every $x \in G$.

Proof. Set $c := \mu(\{e\})$. For each $x \in G$, left-invariance gives $\mu(\{x\}) = \mu(x\{e\}) = c$.

(i) If G is finite, then G is discrete, so every $A \subseteq G$ is Borel. Since $1 = \mu(G) = \sum_{x \in G} \mu(\{x\}) = |G|\, c$, one has $c = \frac{1}{|G|}$, and finite additivity gives $\mu(A) = \sum_{a \in A} \mu(\{a\}) = \frac{|A|}{|G|}$.

(ii) If G is infinite and $c > 0$, choose $n \in \mathbb{N}$ with $n > \frac{1}{c}$ and distinct $x_1, \ldots, x_n \in G$.
Finite additivity gives $1 = \mu(G) \geq \sum_{j=1}^{n} \mu(\{x_j\}) = nc > 1$, a contradiction; hence $c = 0$.

Structural Commentary: Translation reduces point masses to one scalar.
Key Insight: Normalization fixes or kills that scalar. □

Proposition 5.3.8. *Nonempty Open Sets Have Positive Haar Measure*
Let G be a compact group, μ be Haar measure on $\mathcal{B}(G)$, $O \subseteq G$ be nonempty and open. Then $\mu(O) > 0$.

Proof. Choose $a \in O$. For each $x \in G$, $x = (xa^{-1})a \in (xa^{-1})O$, so $\{gO : g \in G\}$ is an open cover of G.
Compactness gives $g_1, \ldots, g_n \in G$ such that $G = \bigcup_{j=1}^{n} g_j O$. If $\mu(O) = 0$, then left-invariance and subadditivity give $1 = \mu(G) \leq \sum_{j=1}^{n} \mu(g_j O) = \sum_{j=1}^{n} \mu(O) = 0$, a contradiction. Hence $\mu(O) > 0$.
Structural Commentary: Compactness gives a finite translate cover.
Key Insight: Zero mass cannot cover total mass. □

6 Regular Approximation and Caratheodory Tests

6.1 Borel Approximation and Regular Measurable Sets

The Caratheodory definition is intrinsic to outer measure, but in $\mathbb{R}^p$ it has a topological shadow: measurable sets are exactly those that can be approximated by open, closed, compact, and cell-built sets up to arbitrarily small error. That bridge is also the route to the first nonmeasurable and non-Borel examples.

Lemma 6.1.1. *Outer Approximation by Open and G_δ Sets*
For $A \subseteq \mathbb{R}^p$:

(i) for every $\varepsilon > 0$, there exists open $G \subseteq \mathbb{R}^p$ with $A \subseteq G$ and $m(G) \leq m_p^*(A) + \varepsilon$;
(ii) $m_p^*(A) = \inf\{m(G) : A \subseteq G,\ G \subseteq \mathbb{R}^p \text{ open}\}$;
(iii) there exists G_δ set $H \supseteq A$ with $m(H) = m_p^*(A)$.

Proof.

(i) If $m_p^*(A) = +\infty$, take $G = \mathbb{R}^p$.
If $m_p^*(A) < +\infty$, choose an open-cell cover $A \subseteq \bigcup_k I_k$ with $\sum_k \mathrm{vol}_p(I_k) \leq m_p^*(A) + \varepsilon$, and set $G := \bigcup_k I_k$.
Then G is open, $A \subseteq G$, and $m(G) \leq \sum_k m(I_k) = \sum_k \mathrm{vol}_p(I_k) \leq m_p^*(A) + \varepsilon$.

(ii) By (i), $\inf\{m(G) : A \subseteq G,\ G \subseteq \mathbb{R}^p \text{ open}\} \leq m_p^*(A) + \varepsilon$ for all $\varepsilon > 0$; let $\varepsilon \downarrow 0$.
Conversely, $A \subseteq G$ gives $m_p^*(A) \leq m_p^*(G) = m(G)$ for open G; take the infimum over G.

(iii) If $m_p^*(A) = +\infty$, take $H = \mathbb{R}^p$.
If $m_p^*(A) < +\infty$, choose open $G_n \supseteq A$ with $m(G_n) \leq m_p^*(A) + 1/n$ and set $H := \bigcap_n G_n$.
Then H is G_δ, $A \subseteq H$, and $m_p^*(A) \leq m(H) \leq m(G_n) \leq m_p^*(A) + 1/n$ for all n, so $m(H) = m_p^*(A)$.

Structural Commentary: Outer measure can be realised by a Borel envelope from outside.
Key Insight: Infima over cell covers can be repackaged as open-set approximation. □

Corollary 6.1.2. *Null Sets Sit Inside Borel Null Sets*
Let $Z \subseteq \mathbb{R}^p$ with $m_p^*(Z) = 0$. Then there exists $B \subseteq \mathbb{R}^p$ such that:

(i) $Z \subseteq B$;
(ii) $B \in \mathcal{B}(\mathbb{R}^p)$;
(iii) $m(B) = 0$.

Proof. By Lemma 6.1.1, choose open sets $(G_n)_{n \geq 1}$ in $\mathbb{R}^p$ and set $B := \bigcap_{n=1}^{\infty} G_n$ so that $Z \subseteq B$ and $m(B) = m_p^*(Z)$.

(i) The chosen envelope satisfies $Z \subseteq B$.

(ii) Since each G_n is open, $B = \bigcap_{n=1}^{\infty} G_n \in \mathcal{B}(\mathbb{R}^p)$.

(iii) Since $m_p^*(Z) = 0$, $m(B) = m_p^*(Z) = 0$.

Structural Commentary: A null set has a G_δ null envelope.
Key Insight: Outer approximation gives a Borel null superset. □

Theorem 6.1.3. *Open and G_δ Characterizations of Measurability*
For $E \subseteq \mathbb{R}^p$, the following are equivalent:

(i) $E \in \mathcal{L}^p$;

(ii) $\forall \varepsilon > 0$, $\exists$ *open* $G \subseteq \mathbb{R}^p$ *such that* $E \subseteq G$ *and* $m_p^*(G \setminus E) < \varepsilon$;
(iii) $\exists$ G_δ *set* $H \subseteq \mathbb{R}^p$ *such that* $E \subseteq H$ *and* $m_p^*(H \setminus E) = 0$;
(iv) $\exists$ G_δ *set* $H \subseteq \mathbb{R}^p$ *and* $Z \in \mathcal{L}^p$ *such that* $Z \subseteq H$, $m(Z) = 0$, *and* $E = H \setminus Z$.

Proof.

(i) $\Rightarrow$ (ii). If $m(E) < +\infty$, choose open $G \supseteq E$ with $m(G) \leq m(E) + \varepsilon/2$.
Since $E \in \mathcal{L}^p$, $m_p^*(G \setminus E) = m(G) - m(E) < \varepsilon$. If $m(E) = +\infty$, set $E_1 := E \cap \{x : \|x\|_2 \leq 1\}$ and $E_n := E \cap \{x : n-1 < \|x\|_2 \leq n\}$ for $n \geq 2$. For each n, choose open $G_n \supseteq E_n$ with $m_p^*(G_n \setminus E_n) < \varepsilon 2^{-n}$; then $G := \bigcup_n G_n$ is open, $E \subseteq G$, and $G \setminus E \subseteq \bigcup_n (G_n \setminus E_n)$, so $m_p^*(G \setminus E) < \varepsilon$.
(ii) $\Rightarrow$ (iii). Choose open $G_n \supseteq E$ with $m_p^*(G_n \setminus E) < 1/n$, and set $H := \bigcap_n G_n$.
Then H is G_δ, $E \subseteq H$, and $H \setminus E \subseteq G_n \setminus E$ for all n; hence $m_p^*(H \setminus E) = 0$.
(iii) $\Rightarrow$ (i). Since H is G_δ, $H \in \mathcal{B}(\mathbb{R}^p) \subseteq \mathcal{L}^p$. Also $m_p^*(H \setminus E) = 0$ implies $H \setminus E \in \mathcal{L}^p$ by Proposition 3.3.7.
Thus $E = H \setminus (H \setminus E) \in \mathcal{L}^p$.
(iii) $\Leftrightarrow$ (iv). If (iii) holds, set $Z := H \setminus E$; then $Z \subseteq H$, $m(Z) = 0$, and $E = H \setminus Z$.
Conversely, if (iv) holds, then $E \subseteq H$ and $H \setminus E = Z$, so $m_p^*(H \setminus E) = 0$.

Structural Commentary: Lebesgue measurable sets are G_δ sets with null material removed.
Key Insight: Small open excess becomes a null G_δ excess after countably many approximations. □

Corollary 6.1.4. *Open Outer Regularity for Measurable Sets*
If $E \in \mathcal{L}^p$, *then*

(i) $\forall \varepsilon > 0$, $\exists$ *open* $G \supseteq E$ *such that* $m(G) \leq m(E) + \varepsilon$;
(ii) $m(E) = \inf\{m(G) : E \subseteq G,\ G \subseteq \mathbb{R}^p \text{ open}\}$.

Proof.

(i) By Theorem 6.1.3, choose open $G \supseteq E$ with $m_p^*(G \setminus E) < \varepsilon$.
If $m(E) < +\infty$, then $m(G) = m(E) + m(G \setminus E) \leq m(E) + \varepsilon$; if $m(E) = +\infty$, the inequality is trivial.
(ii) From (i), $\inf_G m(G) \leq m(E)$. Conversely, $E \subseteq G$ gives $m(E) \leq m(G)$ by monotonicity; take $\inf_G$.

Structural Commentary: Measurable sets are measured from outside by open supersets.
Key Insight: Open excess controls the outer regular infimum. □

Theorem 6.1.5. *Closed and F_σ Characterizations of Measurability*
For $E \subseteq \mathbb{R}^p$, *the following are equivalent:*

(i) $E \in \mathcal{L}^p$;
(ii) $\forall \varepsilon > 0$, $\exists$ *closed* $F \subseteq E$ *such that* $m_p^*(E \setminus F) < \varepsilon$;
(iii) $\exists$ F_σ *set* $K \subseteq E$ *such that* $m_p^*(E \setminus K) = 0$;
(iv) $\exists$ F_σ *set* $K \subseteq E$ *and* $Z \in \mathcal{L}^p$ *such that* $Z \subseteq E$, $m(Z) = 0$, *and* $E = K \cup Z$.

Proof.

(i) $\Rightarrow$ (ii). Since $E^c \in \mathcal{L}^p$, Theorem 6.1.3 gives open $G \supseteq E^c$ with $m_p^*(G \setminus E^c) < \varepsilon$. Set $F := G^c$.
Then F is closed, $F \subseteq E$, and $E \setminus F = G \setminus E^c$, so $m_p^*(E \setminus F) < \varepsilon$.
(ii) $\Rightarrow$ (iii). Choose closed $F_n \subseteq E$ with $m_p^*(E \setminus F_n) < 1/n$, and set $K := \bigcup_n F_n$.
Then K is F_σ, $K \subseteq E$, and $E \setminus K \subseteq E \setminus F_n$ for all n; hence $m_p^*(E \setminus K) = 0$.
(iii) $\Rightarrow$ (i). Since K is F_σ, $K \in \mathcal{B}(\mathbb{R}^p) \subseteq \mathcal{L}^p$. Also $m_p^*(E \setminus K) = 0$ implies $E \setminus K \in \mathcal{L}^p$ by Proposition 3.3.7.
Thus $E = K \cup (E \setminus K) \in \mathcal{L}^p$.
(iii) $\Leftrightarrow$ (iv). If (iii) holds, set $Z := E \setminus K$; then $Z \subseteq E$, $m(Z) = 0$, and $E = K \cup Z$.
Conversely, if (iv) holds, then $E \setminus K \subseteq Z$, so $m_p^*(E \setminus K) = 0$.

Structural Commentary: Inside approximation is the complement of outside approximation.
Key Insight: Measurable sets are also F_σ sets with null material added. □

Corollary 6.1.6. *Closed Inner Regularity*
If $E \in \mathcal{L}^p$, *then*

(i) $\forall \varepsilon > 0$, $\exists$ *closed* $F \subseteq E$ *such that* $m(E) \leq m(F) + \varepsilon$;
(ii) $m(E) = \sup\{m(F) : F \subseteq E,\ F \subseteq \mathbb{R}^p \text{ closed}\}$.

Proof.

(i) By Theorem 6.1.5, choose closed $F \subseteq E$ with $m_p^*(E \setminus F) < \varepsilon$.
Since $F \in \mathcal{L}^p$ and $E = F \sqcup (E \setminus F)$, $m(E) = m(F) + m(E \setminus F) \leq m(F) + \varepsilon$.
(ii) From (i), $m(E) \leq \sup_F m(F)$. Conversely, $F \subseteq E$ gives $m(F) \leq m(E)$; take $\sup_F$.

Structural Commentary: Measurable sets are measured from inside by closed subsets.
Key Insight: Small discarded measure controls the inner regular supremum. □

Corollary 6.1.7. *Lebesgue Regularity and Borel Completion on $\mathbb{R}$*
For $A \in \mathcal{L}^1$,

(i) $m(A) = \inf\{m(G) : A \subseteq G,\ G \text{ open in } \mathbb{R}\}$.
(ii) $m(A) = \sup\{m(K) : K \subseteq A,\ K \text{ compact in } \mathbb{R}\}$, *finite-measure case applied to* $A \cap (-n, n]$; $m(A) = +\infty$.
(iii) There exists $B \in \mathcal{B}(\mathbb{R})$ *with* $A \subseteq B$ *and* $m(B \setminus A) = 0$; *equivalently,* $\mathcal{L}^1$ *is the completion of* $\mathcal{B}(\mathbb{R})$.

Proof.

(i) For $\varepsilon > 0$, regular approximation gives open $G \supseteq A$ with $m(G \setminus A) < \varepsilon$, hence $m(G) \leq m(A) + \varepsilon$.
Monotonicity gives the reverse inequality.
(ii) If $m(A) < +\infty$, choose closed $F \subseteq A$ with $m(A \setminus F) < \varepsilon$. Since $F \cap [-n, n] \uparrow F$, continuity from below gives compact $K = F \cap [-n, n]$ with $m(F) - m(K) < \varepsilon$, so $m(A) - m(K) < 2\varepsilon$. If $m(A) = +\infty$, apply the finite case to $A_n = A \cap (-n, n]$ and let $n \to \infty$.

(iii) Choose open $G_k \supseteq A$ with $m(G_k \setminus A) < 1/k$, and set $B = \bigcap_k G_k$. Then $B \in \mathcal{B}(\mathbb{R})$, $A \subseteq B$, and $m(B \setminus A) = 0$. Thus every Lebesgue set is Borel plus a null subset.
Conversely, Borel sets and null subsets are Lebesgue measurable.

Structural Commentary: Lebesgue sets are Borel sets plus null-set ambiguity.
Key Insight: Open outer approximation and compact inner approximation are the usable form of regularity. □

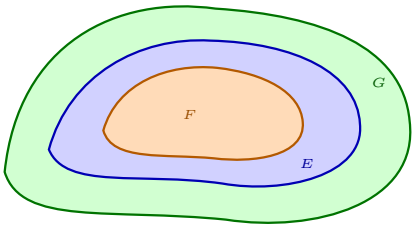

Figure 196: Regular approximation sandwiches E between F and G with small excess.

Theorem 6.1.8. *Lebesgue Measurable Non-Borel Sets Exist*
(i) There exists $E \subseteq \mathbb{R}$ such that $E \in \mathcal{L}^1$ and $E \notin \mathcal{B}(\mathbb{R})$.
(ii) $\mathcal{B}(\mathbb{R}) \subsetneq \mathcal{L}^1$.

Proof.
(i) Lemma 4.1.7 gives $|\mathcal{B}(\mathbb{R})| \leq \mathfrak{c}$. Let C be the Cantor set. Since $|C| = \mathfrak{c}$ and $m(C) = 0$, Proposition 3.3.7 gives $\mathcal{P}(C) \subseteq \mathcal{L}^1$, so $|\mathcal{L}^1| \geq 2^{\mathfrak{c}} > \mathfrak{c}$. Hence some $E \in \mathcal{L}^1$ is not Borel.
(ii) Proposition 4.1.11 gives $\mathcal{B}(\mathbb{R}) \subseteq \mathcal{L}^1$, and (i) makes the containment proper.

Structural Commentary: Countable generation is smaller than completion by null subsets.
Key Insight: Completeness creates more measurable sets than topology can generate. □

6.2 Compact and Cell Approximation

Theorem 6.2.1. *Compact Approximation at Finite Outer Measure*
Let $E \subseteq \mathbb{R}^p$ with $m_p^*(E) < +\infty$. Then $E \in \mathcal{L}^p$ iff $\forall \varepsilon > 0$, $\exists$ compact $K \subseteq E$ with $m_p^*(E \setminus K) < \varepsilon$.

Proof.
($\Rightarrow$) Since $m(E) < +\infty$, choose closed $F \subseteq E$ with $m(E \setminus F) < \frac{\varepsilon}{2}$ by Theorem 6.1.5.
Let $Q_N := [-N, N]^p$. Since $F \cap Q_N \uparrow F$, continuity from below gives N with $m(F \setminus Q_N) < \frac{\varepsilon}{2}$.
Then $K := F \cap Q_N$ is compact, $K \subseteq E$, and $m_p^*(E \setminus K) = m(E \setminus K) \leq m(E \setminus F) + m(F \setminus Q_N) < \varepsilon$.
($\Leftarrow$) Choose compact $K_n \subseteq E$ with $m_p^*(E \setminus K_n) < \frac{1}{n}$ and set $K := \bigcup_{n \geq 1} K_n$.
Then K is F_σ, hence $K \in \mathcal{L}^p$, and $E \setminus K \subseteq E \setminus K_n$ for all n, so $m_p^*(E \setminus K) = 0$.
By Proposition 3.3.7, $E \setminus K \in \mathcal{L}^p$, hence $E = K \cup (E \setminus K) \in \mathcal{L}^p$.

Structural Commentary: Finite measure permits bounded truncation before inner closure.
Key Insight: Compact approximation is closed approximation plus a finite-measure tail estimate. □

Theorem 6.2.2. *Finite Cell Approximation in Symmetric Difference*
If $E \in \mathcal{L}^p$ and $m(E) < +\infty$, then $\forall \varepsilon > 0$, $\exists U = \bigcup_{j=1}^{N} I_j$ with I_j bounded open cells and $m(E \triangle U) < \varepsilon$.

Proof. Choose compact $K \subseteq E$ with $m(E \setminus K) < \frac{\varepsilon}{2}$ by Theorem 6.2.1, and open $G \supseteq E$ with $m_p^*(G \setminus E) < \frac{\varepsilon}{2}$ by Theorem 6.1.3. For each $x \in K$, choose a bounded open cell I_x with $x \in I_x$ and $\overline{I_x} \subseteq G$. Compactness gives $I_1, \ldots, I_N$ with $K \subseteq U := \bigcup_{j=1}^{N} I_j \subseteq G$. Then $E \triangle U \subseteq (E \setminus K) \cup (G \setminus E)$, so subadditivity gives $m(E \triangle U) < \varepsilon$.
Structural Commentary: Compactness turns a countable open cover into a finite geometric approximant.
Key Insight: Approximate from outside by cells and from inside by a compact core. □

Corollary 6.2.3. *Cell Approximation Variant Choices*
Let $E \in \mathcal{L}^p$ with $m(E) < +\infty$, and let $\varepsilon > 0$. There exists $A \subseteq \mathbb{R}^p$ with $m(E \triangle A) < \varepsilon$ in each format:
(i) A is a finite union of bounded open cells;
(ii) A is a finite union of bounded closed cells;
(iii) A is a finite union of bounded half-open cells of a fixed orientation.

Proof.
(i) By Theorem 6.2.2, choose $A = \bigcup_{j=1}^{N} I_j$ with I_j bounded open cells and $m(E \triangle A) < \varepsilon$.
(ii) Choose a finite open-cell union $U = \bigcup_{j=1}^{M} J_j$ with $m(E \triangle U) < \frac{\varepsilon}{2}$. If $M = 0$, take $A = \emptyset$; otherwise choose closed cells $C_j \subseteq J_j$ with $m(J_j \setminus C_j) < \frac{\varepsilon}{2M}$ and set $A := \bigcup_{j=1}^{M} C_j$. Then $m(U \setminus A) < \frac{\varepsilon}{2}$, so $m(E \triangle A) < \varepsilon$.
(iii) Choose a finite open-cell union U with $m(E \triangle U) < \varepsilon$. Refine by the finite coordinate grid from the endpoints of the open cells, and let A be the union of the half-open grid atoms contained in U.
Then $U \triangle A$ is contained in finitely many cell faces, each outer-null, so $m(E \triangle A) < \varepsilon$.

Structural Commentary: Cell format changes only boundary-null pieces.
Key Insight: A compact core inside an open envelope permits finite cell variants. □

Corollary 6.2.4. *Real-Line Finite Open-Interval Approximation*

If $E \in \mathcal{L}^1$ and $m(E) < +\infty$, then $\forall \varepsilon > 0$, $\exists O = \bigcup_{j=1}^{N} I_j$ with I_j pairwise disjoint bounded open intervals and $m(E \setminus O) + m(O \setminus E) = m(E \triangle O) < \varepsilon$.

Proof. By Theorem 6.2.2 with $p = 1$, choose a finite union U of bounded open intervals with $m(E \triangle U) < \varepsilon$. Write $U = O = \bigcup_{j=1}^{N} I_j$ as the disjoint union of its open interval components.
Since $E \setminus O$ and $O \setminus E$ are disjoint measurable sets, additivity gives $m(E \triangle O) = m(E \setminus O) + m(O \setminus E) < \varepsilon$.
Structural Commentary: Merge finite open intervals into disjoint components.
Key Insight: A compact core makes the countable cover finite; interval merging makes it disjoint. □

6.3 Caratheodory Tests and Inner Measure

Theorem 6.3.1. *Outer Measure Additivity with One Measurable Set*
Let $E \in \mathcal{L}^p$ and $F \subseteq \mathbb{R}^p$. Then $m_p^*(E \cup F) + m_p^*(E \cap F) = m(E) + m_p^*(F)$.

Proof. Since $E \in \mathcal{L}^p$, Caratheodory splitting: $m_p^*(E \cup F) = m(E) + m_p^*(F \setminus E)$; $m_p^*(F) = m_p^*(E \cap F) + m_p^*(F \setminus E)$.
Hence $m_p^*(E \cup F) + m_p^*(E \cap F) = m(E) + m_p^*(F)$.
Structural Commentary: One measurable cut splits arbitrary sets exactly.
Key Insight: Split both $E \cup F$ and F along the same measurable cut E. □

Corollary 6.3.2. *Disjoint Additivity and Difference*
Let $E \in \mathcal{L}^p$ and $F \subseteq \mathbb{R}^p$.
(i) $E \cap F = \emptyset \implies m_p^*(E \cup F) = m(E) + m_p^*(F)$.
(ii) $E \subseteq F,\ m(E) < +\infty \implies m_p^*(F \setminus E) = m_p^*(F) - m(E)$.

Proof.
(i) By Theorem 6.3.1, $m_p^*(E \cup F) + m_p^*(E \cap F) = m(E) + m_p^*(F)$.
Since $E \cap F = \emptyset$ and $m_p^*(\emptyset) = 0$, $m_p^*(E \cup F) = m(E) + m_p^*(F)$.
(ii) Since $E \subseteq F$, Caratheodory splitting gives $m_p^*(F) = m(E) + m_p^*(F \setminus E)$; subtract $m(E) < +\infty$.
Structural Commentary: Exact splitting yields disjoint sums and finite differences.
Key Insight: Disjointness removes the overlap; containment isolates the remainder. □

Remark 6.3.3. *Excision Needs Measurability*
Let $E \subseteq \mathbb{R}^p$ with $m_p^*(E) < +\infty$. Open approximation may give, $\forall \varepsilon > 0$, an open $G \supseteq E$ with $m(G) - m_p^*(E) < \varepsilon$, but this does not imply $m_p^*(G \setminus E) < \varepsilon$. If $E \in \mathcal{L}^p$, Corollary 6.3.2 gives $m_p^*(G \setminus E) = m(G) - m(E)$.
Key Insight: Small open excess becomes small set difference only after E is a Caratheodory splitter.

Theorem 6.3.4. *Finite Outer Measure Inner Test*
If $m_p^*(E) < +\infty$, then $E \in \mathcal{L}^p \iff \exists B \in \mathcal{L}^p,\ B \subseteq E,\ m(B) = m_p^*(E)$.

Proof.
($\Rightarrow$) Set $B := E$. Then $B \in \mathcal{L}^p$, $B \subseteq E$, and $m(B) = m(E) = m_p^*(E)$.
($\Leftarrow$) Assume $B \in \mathcal{L}^p$, $B \subseteq E$, and $m(B) = m_p^*(E)$.
Since $m(B) < +\infty$, the difference formula gives $m_p^*(E \setminus B) = m_p^*(E) - m(B) = 0$.
Thus $E \setminus B \in \mathcal{L}^p$, and $E = B \cup (E \setminus B) \in \mathcal{L}^p$.
Structural Commentary: Exact inner mass leaves only a null remainder.
Key Insight: Equality of outer mass converts containment into measurability. □

Theorem 6.3.5. *Single Finite Container Test*
Let $A \in \mathcal{L}^p$, $m(A) < +\infty$, and $E \subseteq A$. Then $E \in \mathcal{L}^p \iff m(A) = m_p^*(E) + m_p^*(A \setminus E)$.

Proof.
($\Rightarrow$) Since $E \in \mathcal{L}^p$ and $E \subseteq A$,
Caratheodory splitting of A by E gives $m(A) = m(E) + m(A \setminus E) = m_p^*(E) + m_p^*(A \setminus E)$.
($\Leftarrow$) Choose G_δ set $H \supseteq A \setminus E$ with $m(H) = m_p^*(A \setminus E)$. Since $A \setminus E \subseteq A \cap H \subseteq H$, $m(A \cap H) = m_p^*(A \setminus E)$.
Set $B := A \setminus H$. $B \in \mathcal{L}^p$, $B \subseteq E$; $m(B) = m(A) - m(A \cap H) = m_p^*(E)$. By Theorem 6.3.4, $E \in \mathcal{L}^p$.
Structural Commentary: Inside a finite measurable container, Caratheodory only needs to be tested once.
Key Insight: Outer-approximate the complement; the remainder has full outer mass. □

Corollary 6.3.6. *Bounded Inner Measure Test*
For bounded cell $Q \subseteq \mathbb{R}^p$ and $E \subseteq Q$, define $m_{*,Q}(E) := m(Q) - m_p^*(Q \setminus E)$. Then $E \in \mathcal{L}^p \iff m_{*,Q}(E) = m_p^*(E)$.

Proof.
($\Rightarrow$) If $E \in \mathcal{L}^p$, then $m(Q) = m(E) + m_p^*(Q \setminus E)$, hence $m_{*,Q}(E) = m_p^*(E)$.
($\Leftarrow$) If $m_{*,Q}(E) = m_p^*(E)$, then $m(Q) = m_p^*(E) + m_p^*(Q \setminus E)$, so $E \in \mathcal{L}^p$ by the finite-container test.
Structural Commentary: Bounded inner measure tests one finite container.
Key Insight: Equality of inner and outer measure is a bounded version of Caratheodory. □

7 Vitali, Steinhaus, and Nonmeasurable Sets

7.1 Vitali, Steinhaus, and Nonmeasurability

Definition 7.1.1. *Difference Sets and Vitali Selectors*

(i) *Difference set*: for $A \subseteq \mathbb{R}^p$, $A - A := \{x - y : x, y \in A\}$; $A \subseteq B \Longrightarrow A - A \subseteq B - B$.
(ii) *Rational equivalence*: $x \sim_{\mathbb{Q}^p} y \iff x - y \in \mathbb{Q}^p$; equivalently, $[x]_{\mathbb{Q}^p} = x + \mathbb{Q}^p$.
(iii) *Vitali selector*: choose $\mathcal{V} \subseteq \mathbb{R}^p$ such that $|\mathcal{V} \cap (x + \mathbb{Q}^p)| = 1$ for every $x \in \mathbb{R}^p$.
(iv) *Rational translate*: for $q \in \mathbb{Q}^p$, $\mathcal{V}_q := q + \mathcal{V}$.

Lemma 7.1.2. *Steinhaus Lemma for Compact Sets*
If $K \subseteq \mathbb{R}^p$ is compact and $m(K) > 0$, then $\exists \delta > 0$ such that $B(0, \delta) \subseteq K - K$.

Proof. Choose open $G \supseteq K$ with $m(G) < 2m(K)$. Since K is compact and G^c is closed, set $\delta := \operatorname{dist}(K, G^c) > 0$. If $\|x\|_2 < \delta$, then $x + K \subseteq G$. If $(x + K) \cap K = \emptyset$, translation invariance and additivity give
$2m(K) = m(x + K) + m(K) = m((x + K) \cup K) \leq m(G) < 2m(K)$, a contradiction.
Hence $(x + K) \cap K \neq \emptyset$, so $x = k_1 - k_2 \in K - K$. Thus $B(0, \delta) \subseteq K - K$.
Structural Commentary: A positive compact set overlaps all sufficiently small translates of itself.
Key Insight: Disjoint small translates cannot fit inside a tight open envelope. □

Theorem 7.1.3. *Steinhaus Theorem*
If $E \in \mathcal{L}^p$ and $m(E) > 0$, then $\exists \delta > 0$ such that $B(0, \delta) \subseteq E - E$.

Proof. Set $E_n := E \cap B(0, n)$. Since $E_n \uparrow E$ and $m(E) > 0$, choose n with $0 < m(E_n) < +\infty$.
By compact inner approximation, choose compact $K \subseteq E_n$ with $m(K) > 0$.
Lemma 7.1.2 gives $\delta > 0$ with $B(0, \delta) \subseteq K - K \subseteq E - E$.
Structural Commentary: Positive measurable sets contain positive compact cores.
Key Insight: Difference-set thickness follows from compact inner regularity. □

Lemma 7.1.4. *Bounded Disjoint Translates Force Nullity*
Let $E \in \mathcal{L}^1$ and $\Lambda \subseteq \mathbb{R}$ be bounded, with E bounded and Λ countably infinite.
If $(\lambda + E)_{\lambda \in \Lambda}$ are pairwise disjoint, then $m(E) = 0$.

Proof. Since E and Λ are bounded, $U := \bigcup_{\lambda \in \Lambda} (\lambda + E)$ is bounded, so $m(U) < +\infty$.
By disjointness, countable additivity, and translation invariance, $m(U) = \sum_{\lambda \in \Lambda} m(\lambda + E) = \sum_{\lambda \in \Lambda} m(E)$.
Since Λ is countably infinite, finiteness forces $m(E) = 0$.
Structural Commentary: Infinitely many disjoint bounded translates cannot all carry positive equal mass.
Key Insight: Boundedness gives a finite container; translation invariance makes every summand the same. □

Proposition 7.1.5. *Real-Line Vitali Choice Sets*
Let $E \subseteq \mathbb{R}$ with $m_1^*(E) > 0$, and write $x \sim y$ iff $x - y \in \mathbb{Q}$.
(i) There exists bounded $E_0 \subseteq E$ with $m_1^*(E_0) > 0$.
(ii) If $C \subseteq E_0$ contains exactly one point from each $\sim$-class meeting E_0, then $C \notin \mathcal{L}^1$.
In particular, E contains a nonmeasurable subset.

Proof.
(i) Since $E = \bigcup_{n \geq 1} (E \cap [-n, n])$, countable subadditivity gives n with $E_0 := E \cap [-n, n]$ satisfying $m_1^*(E_0) > 0$.
(ii) Choose $b > 0$ with $E_0 \subseteq [-b, b]$ and set $\Lambda_0 := [-2b, 2b] \cap \mathbb{Q}$. Suppose $C \in \mathcal{L}^1$.
From $\lambda + c = \lambda' + c'$ with $\lambda, \lambda' \in \Lambda_0$ and $c, c' \in C$, we get $c - c' = \lambda' - \lambda \in \mathbb{Q}$; selector uniqueness gives $c = c'$ and $\lambda = \lambda'$. Thus $(\lambda + C)_{\lambda \in \Lambda_0}$ is pairwise disjoint, and Lemma 7.1.4 gives $m(C) = 0$.
For every $x \in E_0$, choose $c \in C$ with $x - c \in \mathbb{Q}$; since $x, c \in [-b, b]$, $x - c \in \Lambda_0$, so $E_0 \subseteq \bigcup_{\lambda \in \Lambda_0} (\lambda + C)$.
The right side is a countable union of null measurable sets, contradicting $m_1^*(E_0) > 0$.
Structural Commentary: Bounded rational shifts force the contradiction.
Key Insight: Selectors are either null under disjoint shifts or cover too much by null shifts. □

Lemma 7.1.6. *Rational Translates of a Vitali Selector Partition $\mathbb{R}^p$*
Let $(q_i)_{i \geq 1}$ enumerate $\mathbb{Q}^p$.
(i) $\mathbb{R}^p = \bigcup_{i=1}^{\infty} \mathcal{V}_{q_i}$.
(ii) Each $x \in \mathbb{R}^p$ has a unique representation $x = q_i + v$ with $i \in \mathbb{N}$ and $v \in \mathcal{V}$; hence $\mathbb{R}^p = \bigsqcup_{i=1}^{\infty} \mathcal{V}_{q_i}$.

Proof.
(i) For $x \in \mathbb{R}^p$, choose the unique $v \in \mathcal{V} \cap (x + \mathbb{Q}^p)$. Then $x - v = q_i$ for some i, so $x = q_i + v \in \mathcal{V}_{q_i}$.
(ii) If $q_i + v = q_j + w$ with $v, w \in \mathcal{V}$, then $v - w = q_j - q_i \in \mathbb{Q}^p$.
Selector uniqueness gives $v = w$, hence $q_i = q_j$ and $i = j$.
Structural Commentary: Rational translates enumerate the equivalence classes selected by $\mathcal{V}$.
Key Insight: One representative per class makes the rational translates disjoint and exhaustive. □

Theorem 7.1.7. *Vitali Selectors Are Nonmeasurable*
If $\mathcal{V} \subseteq \mathbb{R}^p$ is a Vitali selector, then $\mathcal{V} \notin \mathcal{L}^p$.

Proof. Assume $\mathcal{V} \in \mathcal{L}^p$.
(i) If $m(\mathcal{V}) > 0$, Steinhaus gives $\delta > 0$ with $B(0, \delta) \subseteq \mathcal{V} - \mathcal{V}$. Choose $0 \neq q \in \mathbb{Q}^p \cap B(0, \delta)$. Then $q = v_1 - v_2$ for some $v_1, v_2 \in \mathcal{V}$, so $v_1 \sim_{\mathbb{Q}^p} v_2$; selector uniqueness gives $v_1 = v_2$, hence $q = 0$, contradiction.

(ii) If $m(\mathcal{V}) = 0$, then each translate $\mathcal{V}_{q_i}$ is null. By Lemma 7.1.6, $\mathbb{R}^p = \bigsqcup_i \mathcal{V}_{q_i}$, so every bounded cell is contained in a countable union of null sets and has measure 0, contradicting positive cell volume.

Structural Commentary: Positive and zero measure are both impossible.
Key Insight: Steinhaus forbids positive measure; countable translated partition forbids zero measure. □

Theorem 7.1.8. *Nonmeasurable Subsets Are Everywhere*
If $E \subseteq \mathbb{R}^p$ and $m_p^*(E) > 0$, then $\exists N \subseteq E$ with $N \notin \mathcal{L}^p$.

Proof. Let (q_i) enumerate $\mathbb{Q}^p$ and set $E_i := E \cap \mathcal{V}_{q_i}$.
If $E_i \in \mathcal{L}^p$ and $m(E_i) > 0$, then $E_i - E_i$ contains a ball about 0, so $0 \neq q \in \mathbb{Q}^p \cap (E_i - E_i)$.
But $E_i \subseteq q_i + \mathcal{V}$, so $q = (q_i + v_1) - (q_i + v_2) = v_1 - v_2$ with $v_1, v_2 \in \mathcal{V}$, contradicting selector uniqueness.
Hence each measurable E_i is null. If every E_i were measurable, then $E = \bigcup_i E_i$ would satisfy $m_p^*(E) = 0$, contradiction. Thus some $E_i \subseteq E$ is nonmeasurable.
Structural Commentary: Any positive outer-measure set meets the Vitali partition in a nonmeasurable piece.
Key Insight: Vitali pieces cannot be measurable and positive. □

Corollary 7.1.9. *Nonadditive Decompositions*
(i) If $E \in \mathcal{L}^p$ and $0 < m(E) < +\infty$, then $\exists B, C \notin \mathcal{L}^p$ such that $E = B \sqcup C$ and $m(E) < m_p^*(B) + m_p^*(C)$.
(ii) If $B \notin \mathcal{L}^p$, $m_p^*(B) < +\infty$, and H is G_δ with $B \subseteq H$, $m(H) = m_p^*(B)$, then $C := H \setminus B \notin \mathcal{L}^p$ and $m(H) = m_p^*(B \cup C) < m_p^*(B) + m_p^*(C)$.

Proof.
(i) Pick $B \subseteq E$, $B \notin \mathcal{L}^p$, and put $C := E \setminus B$. Then $C \notin \mathcal{L}^p$, else $B = E \setminus C \in \mathcal{L}^p$.
Subadditivity gives $\leq$; equality would force $B \in \mathcal{L}^p$ by the finite-container test in E.
(ii) Since $H \in \mathcal{L}^p$, $C \in \mathcal{L}^p$ would give $B = H \setminus C \in \mathcal{L}^p$, contradiction. Also $m_p^*(C) > 0$, else $C \in \mathcal{L}^p$.
Thus $B \cup C = H$ and $m(H) = m_p^*(B)$ give $m_p^*(B \cup C) = m(H) < m_p^*(B) + m_p^*(C)$.

Structural Commentary: Nonmeasurability appears exactly as strict failure of additive splitting.
Key Insight: Equality in a finite measurable container is a measurability test. □

Theorem 7.1.10. *A Nonmeasurable Set with Only Null Measurable Pieces*
There exists $\mathcal{U} \subseteq \mathbb{R}^p$ such that:
(i) if $F \in \mathcal{L}^p$ and $F \subseteq \mathcal{U}$, then $m(F) = 0$;
(ii) if $F \in \mathcal{L}^p$ and $F \subseteq \mathcal{U}^c$, then $m(F) = 0$;
(iii) $\mathcal{U} \notin \mathcal{L}^p$.

Proof. Let $e := (1, \dots, 1)$, $G_0 := \mathbb{Q}^p + (2\sqrt{2})\mathbb{Z}e$, $G_1 := \sqrt{2}e + G_0$, $G := G_0 \sqcup G_1 = \mathbb{Q}^p + \sqrt{2}\mathbb{Z}e$; G_0, G_1 dense.
Let $\mathcal{E}$ select one representative from each class modulo G, and set $\mathcal{U} := G_0 + \mathcal{E}$.
Then $\mathbb{R}^p = (G_0 + \mathcal{E}) \sqcup (G_1 + \mathcal{E})$ and $\mathcal{U}^c = G_1 + \mathcal{E} = \sqrt{2}e + \mathcal{U}$.
(i) Suppose $F \in \mathcal{L}^p$, $F \subseteq \mathcal{U}$, and $m(F) > 0$. By Steinhaus, $B(0, r) \subseteq F - F$ for some $r > 0$; choose $g_1 \in G_1 \cap B(0, r)$. Since $F \subseteq G_0 + \mathcal{E}$, $g_1 = (g_0 + s_1) - (g_0' + s_2)$ for some $g_0, g_0' \in G_0$ and $s_1, s_2 \in \mathcal{E}$. Thus $s_1 - s_2 = g_1 - g_0 + g_0' \in G$, so $s_1 = s_2$ and $g_1 = g_0 - g_0' \in G_0$, contradicting $G_0 \cap G_1 = \emptyset$.
(ii) If $F \in \mathcal{L}^p$ and $F \subseteq \mathcal{U}^c = \sqrt{2}\,e + \mathcal{U}$, then $F - \sqrt{2}\,e \subseteq \mathcal{U}$ and $m(F) = m(F - \sqrt{2}\,e) = 0$ by (i).
(iii) If $\mathcal{U} \in \mathcal{L}^p$, then (i)–(ii) give $m(\mathcal{U}) = m(\mathcal{U}^c) = 0$, so $m([0,1]^p) = 0$, contradiction.

Structural Commentary: This construction partitions representatives using two dense cosets.
Key Insight: Positive measurable pieces force forbidden coset differences. □

8 Cantor–Lebesgue Singular Function

8.1 Cantor-Lebesgue Singular Function Construction

Definition 8.1.1. *Cantor–Lebesgue Singular Function*
Let P be the Cantor set. For $k \geq 1$, let $I_{k,1}, \dots, I_{k,2^k-1}$ list, left to right, the components of the stage-k removed set U_k. Set $U := \bigcup_{k \geq 1} U_k = [0,1] \setminus P$.

(i) For $x \in U$, choose $k \geq 1$ and $1 \leq j \leq 2^k - 1$ with $x \in I_{k,j}$, and set $\varphi(x) := \frac{j}{2^k}$.
(ii) This value is independent of the chosen stage: if $I_{k,j} = I_{\ell,m}$ with $\ell \geq k$, then $m = 2^{\ell-k} j$ and $\frac{m}{2^\ell} = \frac{j}{2^k}$.
(iii) On P, set $\varphi(0) := 0$ and $\varphi(x) := \sup\{\varphi(t) : t \in U \cap [0, x]\}$ for $x \in P \setminus \{0\}$.

The resulting $\varphi : [0,1] \to [0,1]$ is the *Cantor–Lebesgue singular function*.

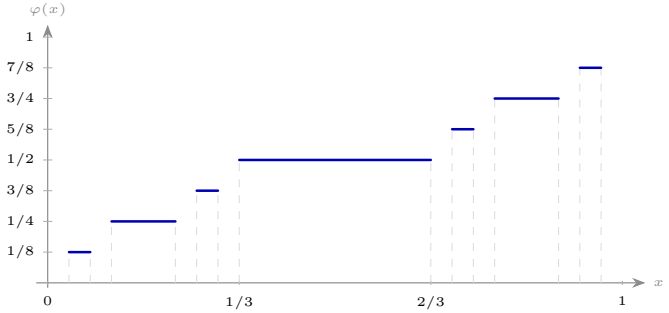

Figure 197: Horizontal segments show the Cantor–Lebesgue plateaus on the intervals removed through stage 3.

Proposition 8.1.2. *Properties of the Singular Function*
Let P be the Cantor set, $U := [0,1] \setminus P$, and $\varphi : [0,1] \to [0,1]$ the Cantor–Lebesgue singular function. Then:

(i) φ *is nondecreasing.*
(ii) φ *is continuous on* $[0,1]$.
(iii) $\varphi([0,1]) = [0,1]$.
(iv) $\varphi'(x) = 0$ *for every* $x \in U$.
(v) $m(U) = 1$.

Proof.

(i) At each stage k, the components $I_{k,1}, \dots, I_{k,2^k-1}$ occur left to right and carry heights $\frac{1}{2^k}, \dots, \frac{2^k-1}{2^k}$.
Thus the prescription on U is nondecreasing, and the supremum extension on P preserves order.
(ii) If $x_0 \in U$, then $x_0 \in J$ for some component J of U and $\varphi|_J$ is constant. If $x_0 \in P$, then for each k there are $a_k, b_k \in 2^{-k}\mathbb{Z} \cap [0,1]$ with $a_k \le \varphi(x_0) \le b_k$, $b_k - a_k \le 2^{-k}$, and $\varphi(y) \in [a_k, b_k]$ for all y near x_0.
Thus $\limsup_{y \to x_0} |\varphi(y) - \varphi(x_0)| \le 2^{-k}$ for every k, hence φ is continuous at x_0.
(iii) The definition gives $\varphi(0) = 0$. For each k, the rightmost component of U_k has height $1 - 2^{-k}$, so $\varphi(1) = 1$.
By (ii) and the intermediate value theorem, $\varphi([0,1]) = [0,1]$.
(iv) For each component J of U, $\varphi|_J$ is constant; hence $\varphi'(x) = 0$ for every $x \in U$.
(v) Proposition 4.1.14 gives $m(P) = 0$; since $[0,1] = P \sqcup U$, $m(U) = m([0,1]) - m(P) = 1$.

Structural Commentary: Plateaus on U force variation onto P.
Key Insight: At stage k, neighboring plateau heights differ by 2^{-k}. □

Theorem 8.1.3. *Lebesgue Measurable Non-Borel Sets Exist*
There exist $A \subseteq [0,1]$ and a homeomorphism $\psi : [0,1] \to [0,2]$ such that $A \in \mathcal{L}^1 \setminus \mathcal{B}(\mathbb{R})$ and $\psi(A) \notin \mathcal{L}^1$.

Proof. Let P be the Cantor set, $U := [0,1] \setminus P$, φ the Cantor–Lebesgue singular function, and $\psi := \mathrm{id}_{[0,1]} + \varphi$.
Proposition 8.1.2 gives φ continuous and nondecreasing; hence ψ is continuous and strictly increasing.
Since $\psi(0) = 0$ and $\psi(1) = 2$, $\psi : [0,1] \to [0,2]$ is a homeomorphism.
Let $(J_k)_{k \ge 1}$ be the components of U. Since $\varphi|_{J_k}$ is constant, $\psi(J_k)$ is a translate of J_k and $m(\psi(J_k)) = m(J_k)$.
Thus $m(\psi(U)) = \sum_{k \ge 1} m(\psi(J_k)) = \sum_{k \ge 1} m(J_k) = m(U) = 1$.
Since $\psi(P)$ is compact and $[0,2] = \psi(P) \sqcup \psi(U)$, $m(\psi(P)) = 1$.
Choose $W \subseteq \psi(P)$ with $W \notin \mathcal{L}^1$ by Theorem 7.1.8, and set $A := \psi^{-1}(W)$. Then $A \subseteq P$ and $m(P) = 0$, so $A \in \mathcal{L}^1$. If $A \in \mathcal{B}(\mathbb{R})$, then $W = \psi(A) \in \mathcal{B}([0,2]) \subseteq \mathcal{L}^1$, contradiction. Hence $A \in \mathcal{L}^1 \setminus \mathcal{B}(\mathbb{R})$ and $\psi(A) = W \notin \mathcal{L}^1$.
Structural Commentary: Completion by null sets creates Lebesgue sets invisible to the Borel hierarchy.
Key Insight: A null Cantor set can be homeomorphically stretched to positive measure. □

Part XIV
Measure, Integration, and Functional Analysis

1 Measurable Functions and Lebesgue Integration

1.1 Measurable Functions

Definition 1.1.1. *Borel, Lebesgue, and Function Measurability*

(i) *Borel*: $\mathcal{B}(\mathbb{R}^p) := \sigma(\mathcal{O}_{\mathbb{R}^p})$; its elements are *Borel sets*.
(ii) *Lebesgue*: $\mathcal{B}(\mathbb{R}^p) \subseteq \mathcal{L}^p$, and $\mathcal{L}^p$ is obtained by adjoining subsets of Lebesgue null sets.
(iii) *Maps*: for measurable spaces $(X,\mathcal{M})$, $(Y,\mathcal{N})$, $f : X \to Y$ is *$(\mathcal{M},\mathcal{N})$-measurable* iff $\forall E \in \mathcal{N},\ f^{-1}(E) \in \mathcal{M}$.
(iv) *Borel maps*: $f : \mathbb{R}^p \to \mathbb{R}^q$ is *Borel measurable* iff $\forall B \in \mathcal{B}(\mathbb{R}^q),\ f^{-1}(B) \in \mathcal{B}(\mathbb{R}^p)$.
(v) *Thresholds*: write $\{f \bowtie a\} := \{x \in X : f(x) \bowtie a\}$ for $\bowtie \in \{>, \geq, <, \leq\}$.
Extended-real f is *$\mathcal{M}$-measurable* iff $\forall a \in \mathbb{R},\ \{f > a\} \in \mathcal{M}$.

Structural Commentary: Borel measurability tracks topology; Lebesgue measurability adds null-set completion.
Key Insight: Measurability is inverse-image stability.

Proposition 1.1.2. *Generator Test for Measurable Maps*
Let $f : X \to Y$, $\mathcal{A} \subseteq \mathcal{P}(Y)$, and $\mathcal{N} := \sigma(\mathcal{A})$.
(i) If $\forall A \in \mathcal{A},\ f^{-1}(A) \in \mathcal{M}$, then $f : X \to (Y,\mathcal{N})$ is measurable.
(ii) For real-valued f, $\forall a \in \mathbb{R},\ \{f > a\} \in \mathcal{M} \iff \forall B \in \mathcal{B}(\mathbb{R}),\ f^{-1}(B) \in \mathcal{M}$.

Proof.
(i) Let $\mathcal{G} := \{E \subseteq Y : f^{-1}(E) \in \mathcal{M}\}$. Since $f^{-1}(E^c) = f^{-1}(E)^c$ and $f^{-1}(\bigcup_n E_n) = \bigcup_n f^{-1}(E_n)$, $\mathcal{G}$ is a σ-algebra. Thus $\mathcal{A} \subseteq \mathcal{G} \Longrightarrow \mathcal{N} = \sigma(\mathcal{A}) \subseteq \mathcal{G}$.
(ii) ($\Rightarrow$) Set $\mathcal{A} := \{(a,+\infty) : a \in \mathbb{R}\}$. Since $\forall a \in \mathbb{R},\ f^{-1}((a,+\infty)) = \{f > a\} \in \mathcal{M}$ and $\sigma(\mathcal{A}) = \mathcal{B}(\mathbb{R})$, (i) gives $\forall B \in \mathcal{B}(\mathbb{R}),\ f^{-1}(B) \in \mathcal{M}$.
(ii) ($\Leftarrow$) If $\forall B \in \mathcal{B}(\mathbb{R}),\ f^{-1}(B) \in \mathcal{M}$, then $\forall a \in \mathbb{R},\ \{f > a\} = f^{-1}((a,+\infty)) \in \mathcal{M}$.

Structural Commentary: Measurability can be checked on any generating family of target sets.
Key Insight: Pullbacks turn generated σ-algebras into generated collections of preimages. □

Proposition 1.1.3. *Open-Set Test for Euclidean Targets*
Let $\Omega \subseteq \mathbb{R}^n$ be Lebesgue measurable and let $f : \Omega \to \mathbb{R}^m$. The following tests are equivalent:
(i) $\forall V \subseteq \mathbb{R}^m$ open, $f^{-1}(V)$ is measurable;
(ii) $\forall B \subseteq \mathbb{R}^m$ open boxes, $f^{-1}(B)$ is measurable;
(iii) $\forall j \in \{1,\dots,m\}$, $f_j : \Omega \to \mathbb{R}$ is threshold-measurable.
In particular, every continuous $f : \Omega \to \mathbb{R}^m$ is measurable.

Proof.
(i) $\Rightarrow$ *(ii)*. Open boxes are open.
(ii) $\Rightarrow$ *(i)*. By Lemma 4.1.7, $V = \bigcup_k B_k$ for rational boxes B_k, hence $f^{-1}(V) = \bigcup_k f^{-1}(B_k)$ is measurable.
(ii) $\Rightarrow$ *(iii)*. By *(ii)* $\Rightarrow$ *(i)*, $\{f_j > a\} = f^{-1}(\{y : y_j > a\})$ is measurable.
(iii) $\Rightarrow$ *(ii)*. If $B = \prod_{j=1}^m (a_j, b_j)$, then $f^{-1}(B) = \bigcap_{j=1}^m \big(\{f_j > a_j\} \cap \{f_j < b_j\}\big)$,
where $\{f_j < b_j\} = \Omega \setminus \bigcap_{\ell=1}^{\infty} \{f_j > b_j - \frac{1}{\ell}\}$. Thus each factor is measurable, hence so is $f^{-1}(B)$.

If f is continuous, $f^{-1}(V)$ is open relative to Ω by Theorem 5.1.18.
By Theorem 3.2.3, $f^{-1}(V) = W \cap \Omega$ for some open $W \subseteq \mathbb{R}^n$, hence it is measurable by Theorem 4.1.8.
Structural Commentary: Euclidean-valued measurability is just countable box algebra applied to inverse images.
Key Insight: Open sets reduce to rational boxes; vector functions reduce to coordinate threshold tests. □

Example 1.1.4. *Basic Measurable Functions*
Let $(X,\mathcal{M})$ be a measurable space.
(i) Constant real-valued functions are measurable, since each strict superlevel set is either X or $\emptyset$.
(ii) For $E \subseteq X$, the indicator $\mathbf{1}_E$ is measurable iff $E \in \mathcal{M}$.
(iii) Continuous maps between Euclidean measurable subsets are measurable by Proposition 1.1.3.
(iv) Monotone functions $\mathbb{R} \to \mathbb{R}$ are Borel measurable, since their strict superlevel sets are half-lines, $\mathbb{R}$, or $\emptyset$.

Key Insight: Constants, indicators of measurable sets, continuous functions, and monotone functions form the first reusable stock of measurable functions.

Theorem 1.1.5. *Closure Properties of Measurable Functions*
Let $(X,\mathcal{M})$ be a measurable space.
(i) The four tests $\forall a \in \mathbb{R},\ \{f > a\}, \{f \geq a\}, \{f < a\}, \{f \leq a\} \in \mathcal{M}$ are equivalent.
(ii) f measurable implies $|f|$ measurable.
(iii) If f_n are measurable, then $\sup_n f_n, \inf_n f_n, \limsup_n f_n, \liminf_n f_n$ are measurable.
(iv) If f, g real-valued measurable, $F : \mathbb{R}^2 \to \mathbb{R}$ continuous, then $F(f,g)$ measurable; so are $f+g$ and fg.

Proof.
(i) Use $\{f \geq a\} = \bigcap_{m \geq 1} \{f > a - \frac{1}{m}\}$; $\{f < a\} = X \setminus \{f \geq a\}$; $\{f \leq a\} = \bigcap_{m \geq 1} \{f < a + \frac{1}{m}\}$.
(ii) For $a > 0$, $\{|f| < a\} = \{f < a\} \cap \{f > -a\}$; for $a \leq 0$ the set is empty.

(iii) $\{\sup_n f_n > a\} = \bigcup_n \{f_n > a\}$. Also $\limsup_n f_n = \inf_m \sup_{n\geq m} f_n$; $\liminf_n f_n = \sup_m \inf_{n\geq m} f_n$; inf follow from (i).

(iv) For $G_a = \{(u,v) : F(u,v) > a\}$, write $G_a = \bigcup_k (\alpha_k, \beta_k) \times (\gamma_k, \delta_k)$.

Then $\{F(f,g) > a\} = \bigcup_k \big(\{\alpha_k < f < \beta_k\} \cap \{\gamma_k < g < \delta_k\}\big) \in \mathcal{M}$.

Structural Commentary: Measurability is countable set algebra applied to level sets.
Key Insight: Once threshold sets are measurable, ordinary limiting and algebraic operations stay measurable. □

Corollary 1.1.6. *Continuous Composition and Finite Lattice Operations*
Let $(X, \mathcal{M})$ be a measurable space and let $n \in \mathbb{N}_{\geq 1}$.
For $f_1, \dots, f_n : X \to \mathbb{R}$, set $\bigvee_{k=1}^n f_k := \max\{f_1, \dots, f_n\}$ and $\bigwedge_{k=1}^n f_k := \min\{f_1, \dots, f_n\}$.
(i) If $g : X \to \mathbb{R}$ is measurable and $\varphi : \mathbb{R} \to \mathbb{R}$ is continuous, then $\varphi \circ g$ is measurable.
(ii) If $f_1, \dots, f_n : X \to \mathbb{R}$ are measurable, then $\bigvee_{k=1}^n f_k$ and $\bigwedge_{k=1}^n f_k$ are measurable.

Proof.

(i) For $a \in \mathbb{R}$, $\{\varphi \circ g > a\} = g^{-1}(\varphi^{-1}((a, +\infty))) \in \mathcal{M}$, since $\varphi^{-1}((a, +\infty)) \in \mathcal{B}(\mathbb{R})$ and g is measurable.

(ii) Set $h_k = f_k$ for $1 \leq k \leq n$ and $h_k = f_n$ for $k > n$. Then (h_k) is measurable, $\bigvee_{k=1}^n f_k = \sup_{k\geq 1} h_k$, and $\bigwedge_{k=1}^n f_k = \inf_{k\geq 1} h_k$, hence both are measurable by Theorem 1.1.5(iii).

Structural Commentary: Pullbacks preserve Borel thresholds; finite lattices are finite suprema and infima.
Key Insight: Continuity and finite lattice operations preserve measurable threshold structure. □

Example 1.1.7. *Measurable Composition Can Fail*
Choose $A \in \mathcal{L}^1$ with $A \subseteq [0,1]$ and an increasing homeomorphism $\psi : [0,1] \to [0,2]$ such that $\psi(A) \notin \mathcal{L}^1$. Define

$$\widetilde{\psi}(x) := \begin{cases} x, & x \leq 0, \\ \psi(x), & 0 \leq x \leq 1, \\ x+1, & x \geq 1. \end{cases}$$

Then $\widetilde{\psi} : \mathbb{R} \to \mathbb{R}$ is a homeomorphism. Put $h := \mathbf{1}_A \circ \widetilde{\psi}^{-1}$.
The maps $\mathbf{1}_A$ and $\widetilde{\psi}^{-1}$ are measurable, but $h^{-1}((\frac{1}{2}, \frac{3}{2})) = \widetilde{\psi}(A) = \psi(A) \notin \mathcal{L}^1$.
Hence h is not Lebesgue measurable, so Lebesgue measurable functions are not composition-closed.

Definition 1.1.8. *Positive and Negative Parts*
For an extended-real-valued function f, define $f^+(x) := \sup\{f(x), 0\}$; $f^-(x) := \sup\{-f(x), 0\}$.
When f is finite-valued, $f = f^+ - f^-$ and $|f| = f^+ + f^-$; equivalently $f^+ = \frac{|f|+f}{2}$; $f^- = \frac{|f|-f}{2}$.

Corollary 1.1.9. *Measurability of Positive and Negative Parts*
If $f : X \to [-\infty, +\infty]$ is measurable, then $f^+, f^-, |f|$ are measurable.
If $f : X \to \mathbb{R}$, then f measurable $\iff$ f^+, f^- measurable.

Proof.

($\Rightarrow$) Since $\{-f > a\} = \{f < -a\}$, $-f$ is measurable.
Thus $f^+ = f \vee 0$, $f^- = (-f) \vee 0$, and $|f| = f \vee (-f)$ are measurable by finite sup-closure.

($\Leftarrow$) If $f : X \to \mathbb{R}$ and f^+, f^- are measurable, then $f = f^+ - f^-$ is measurable.

Structural Commentary: Sign decomposition is compatible with threshold-set measurability.
Key Insight: Reduce signs to suprema and finite algebra. □

Lemma 1.1.10. *Extended-Valued Measurability via the Finite Part*
Let $f : X \to \overline{\mathbb{R}}$ and set $A := f^{-1}(\{+\infty\})$, and $B := f^{-1}(\{-\infty\})$. Define $f_0(x) := \begin{cases} f(x), & x \notin A \cup B, \\ 0, & x \in A \cup B. \end{cases}$
Then f is measurable iff $A, B \in \mathcal{M}$ and $f_0 : X \to \mathbb{R}$ is measurable.

Proof.

($\Rightarrow$) If f is measurable, then $A = \bigcap_{n=1}^{\infty} \{f > n\}$; and $B = X \setminus \bigcup_{n=1}^{\infty} \{f > -n\}$, so $A, B \in \mathcal{M}$.

Also, $\{f_0 > \alpha\} = \begin{cases} \{f > \alpha\} \setminus A, & \alpha \geq 0, \\ \{f > \alpha\} \cup B, & \alpha < 0, \end{cases}$ so f_0 is measurable.

($\Leftarrow$) If $A, B \in \mathcal{M}$, f_0 is measurable, then $\{f > \alpha\} = \begin{cases} \{f_0 > \alpha\} \cup A, & \alpha \geq 0, \\ \{f_0 > \alpha\} \setminus B, & \alpha < 0, \end{cases}$ so $\{f > \alpha\} \in \mathcal{M}\ \forall \alpha \in \mathbb{R}$.

Structural Commentary: The infinite-level sets are measurable exactly when the finite core is measurable.
Key Insight: Assign harmless finite values at $\pm\infty$, then put the infinite fibers back by set algebra. □

Corollary 1.1.11. *Extended-Valued Algebra Conventions*
Let $f, g : X \to \overline{\mathbb{R}}$ be measurable.
(i) For $c \in \mathbb{R}$, cf, $|f|$, f^+, and f^- are measurable, with $0(\pm\infty) = 0$.
(ii) Let $E_1 := \{f = -\infty,\ g = +\infty\}$, $E_2 := \{f = +\infty,\ g = -\infty\}$, and $F := E_1 \cup E_2$.
If $h = f + g$ on $X \setminus F$ and $h = 0$ on F, then h is measurable.
(iii) With $0(\pm\infty) = 0$, fg is measurable.

Proof.

(i) By Lemma 1.1.10, $A_\pm(f) := \{f = \pm\infty\} \in \mathcal{M}$ and f_0 is measurable.
For $c \in \mathbb{R}$, the infinite fibers of cf are among $A_\pm(f)$ and $(cf)_0 = cf_0$, so cf is measurable.
The functions $|f|, f^+, f^-$ are measurable by Corollary 1.1.9.

(ii) $E_1, E_2 \in \mathcal{M}$. Set $f_n := \max\{-n, \min(f, n)\}$ and $g_n := \max\{-n, \min(g, n)\}$.
Then f_n, g_n are real-valued measurable and $(f_n + g_n)\mathbf{1}_{X\setminus F} \to h$ pointwise; hence h is measurable.
(iii) With f_n, g_n as in (ii), $f_n g_n$ measurable, $f_n g_n \to fg$ pointwise under $0(\pm\infty) = 0$; hence fg measurable.

Structural Commentary: Extended algebra is finite algebra plus measurable exceptional fibers.
Key Insight: Truncate first, use real-valued closure, then pass to pointwise limits. □

Definition 1.1.12. *Simple Functions*
Let $(X, \mathcal{M})$ be a measurable space.

(i) *Indicator*: for $E \subseteq X$, $\mathbf{1}_E(x) := 1$ on E and $\mathbf{1}_E(x) := 0$ on $X \setminus E$.
(ii) *Simple*: a real-valued s is simple iff $s(X)$ is finite.
(iii) *Standard representation*: if $s(X) = \{c_1, \dots, c_n\}$ and $E_i := \{s = c_i\} \neq \emptyset$, then $X = \bigsqcup_{i=1}^{n} E_i$; $s = \sum_{i=1}^{n} c_i \mathbf{1}_{E_i}$.
The pairs (c_i, E_i) are unique up to reordering.
(iv) *Measurability*: s measurable iff $E_i \in \mathcal{M}$ $\forall i$; step functions are special case $X \subseteq \mathbb{R}$ with interval level sets.

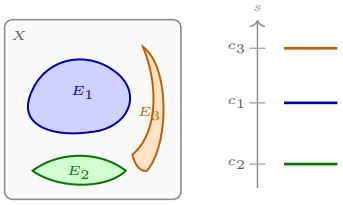

Figure 198: A simple function takes value c_i on each measurable piece E_i.

Proposition 1.1.13. *Simple Functions Form a Lattice Algebra*
Let $s, t : X \to \mathbb{R}$ be simple and $a \in \mathbb{R}$. Then as, $s + t$, st, $s \vee t$, and $s \wedge t$ are simple.
If s, t are measurable, so are these five functions.

Proof. Let $s(X) = \{c_i\}_{i=1}^m$ and $t(X) = \{d_j\}_{j=1}^n$. Each displayed range is contained in the corresponding finite set $\{ac_i\}$, $\{c_i + d_j\}$, $\{c_i d_j\}$, $\{c_i \vee d_j\}$, or $\{c_i \wedge d_j\}$, hence is finite.
If s, t are measurable, the atoms $P_{ij} := \{s = c_i\} \cap \{t = d_j\}$ are measurable and form a finite partition of X. Each displayed function is constant on every P_{ij}, so its level sets are finite unions of P_{ij}.
Structural Commentary: Algebra and lattice operations reduce to finite tables.
Key Insight: Refine two simple functions by the common partition of their level sets. □

Lemma 1.1.14. *Bounded Simple Approximation Brackets*
Let $(X, \mathcal{M})$ be a measurable space and let $f : X \to \mathbb{R}$ be bounded and $\mathcal{M}$-measurable. Then $\forall \varepsilon > 0$ $\exists$ simple $\mathcal{M}$-measurable functions $\varphi_\varepsilon, \psi_\varepsilon : X \to \mathbb{R}$ with $\varphi_\varepsilon \le f \le \psi_\varepsilon$ and $0 \le \psi_\varepsilon - \varphi_\varepsilon < \varepsilon$ on X.

Proof. Choose $c = y_0 < \cdots < y_N = d$ with $f(X) \subseteq (c, d)$ and $\max_k (y_k - y_{k-1}) < \varepsilon$.
Set $E_k := \{y_{k-1} \le f < y_k\} = \{f \ge y_{k-1}\} \cap \{f < y_k\} \in \mathcal{M}$; then $(E_k)_{k=1}^N$ partitions X.
Define $\varphi_\varepsilon := \sum_{k=1}^{N} y_{k-1} \mathbf{1}_{E_k}$ and $\psi_\varepsilon := \sum_{k=1}^{N} y_k \mathbf{1}_{E_k}$; these are $\mathcal{M}$-measurable simple functions.
For $x \in E_k$, $\varphi_\varepsilon(x) = y_{k-1} \le f(x) < y_k = \psi_\varepsilon(x)$ and $\psi_\varepsilon(x) - \varphi_\varepsilon(x) = y_k - y_{k-1} < \varepsilon$.
Structural Commentary: Pull back a finite range partition.
Key Insight: Mesh size controls the bracket gap. □

Theorem 1.1.15. *Approximation by Simple Functions*
Let $(X, \mathcal{M})$ be a measurable space.

(i) $\forall f : X \to \mathbb{R}$ $\exists$ simple functions (s_n) with $s_n \to f$ pointwise.
(ii) For $f : X \to \overline{\mathbb{R}}$, f is $\mathcal{M}$-measurable iff f is the pointwise limit of $\mathcal{M}$-measurable simple functions.
(iii) If $f : X \to \overline{\mathbb{R}}$ is $\mathcal{M}$-measurable, the approximants in (ii) may be chosen with $|s_n| \le |f|$.
If $f \ge 0$, they may be chosen with $0 \le s_n \uparrow f$.

Proof. For $u : X \to [0, +\infty]$, set $Q_n u := 2^{-n} \lfloor 2^n (u \wedge n) \rfloor$.
Then $Q_n u(X) \subseteq 2^{-n}\{0, \dots, n2^n\}$, so $Q_n u$ is simple, and binary truncation gives $0 \le Q_n u \uparrow u$.
If u is measurable, the level sets of $Q_n u$ are threshold sets of $u \wedge n$, hence $Q_n u$ is measurable.

(i) For $f : X \to \mathbb{R}$, write $f = f^+ - f^-$ and set $s_n := Q_n f^+ - Q_n f^-$. Then s_n is simple and $s_n \to f$ pointwise.
(*ii*) ($\Rightarrow$) If $f : X \to \overline{\mathbb{R}}$ is measurable, then f^+, f^- are measurable and $s_n := Q_n f^+ - Q_n f^-$ is measurable simple. Since at each x at most one of $f^+(x), f^-(x)$ is infinite, $s_n(x) \to f(x)$ in $\overline{\mathbb{R}}$.
(*ii*) ($\Leftarrow$) If measurable simple $s_n \to f$ pointwise, then $f = \liminf_n s_n$ is measurable.
(*iii*) In (*ii*) $\Rightarrow$, $|s_n| \le Q_n f^+ + Q_n f^- \le |f|$. If $f \ge 0$, take $s_n := Q_n f$.

Structural Commentary: Simple functions quantize the range of f.
Key Insight: Dyadic range partitions give pointwise approximation while preserving measurability. □

Definition 1.1.16. *Complex-Valued Measurable Functions*
A map $f : X \to \mathbb{C}$ is *measurable* iff $\operatorname{Re} f, \operatorname{Im} f : X \to \mathbb{R}$ are measurable.
Equivalently, $f = \operatorname{Re} f + i \operatorname{Im} f$ with measurable real components.

Proposition 1.1.17. *Complex Measurable Closure*
If $f, g : X \to \mathbb{C}$ are measurable, $a \in \mathbb{C}$, and $h_n : X \to \mathbb{C}$ are measurable with $h_n \to h$ pointwise, then $f + g$, fg, af, and h are measurable.

Proof. Write $f = u + iv$, $g = r + is$, and $a = \alpha + i\beta$. Then $f + g = (u + r) + i(v + s)$, $af = (\alpha u - \beta v) + i(\alpha v + \beta u)$, and $fg = (ur - vs) + i(us + vr)$, so real closure gives measurability.
If $h_n \to h$, then $\operatorname{Re} h_n \to \operatorname{Re} h$ and $\operatorname{Im} h_n \to \operatorname{Im} h$, so pointwise-limit closure gives measurability.
Structural Commentary: Complex measurability is two real measurability statements.
Key Insight: Split into real and imaginary parts. □

Definition 1.1.18. *Almost Everywhere and In Measure*
Let E be measurable.

(i) *A.E. equality*: $f \sim_{\text{a.e.}} g$ on E iff $\mu(\{x \in E : f(x) \neq g(x)\}) = 0$.
(ii) *A.E. property*: a property holds a.e. on E iff its failure set in E is null.
(iii) *Null invariance*: $\sim_{\text{a.e.}}$ is an equivalence relation.
(iv) *A.E. convergence*: $f_n \to f$ a.e. on E iff $\exists N \subseteq E$ null such that $\forall x \in E \setminus N,\ f_n(x) \to f(x)$.
(v) *In measure*: $f_n \to f$ in measure on E iff $\forall \varepsilon > 0$, $\mu(\{x \in E : |f_n(x) - f(x)| > \varepsilon\}) \to 0$.

Remark 1.1.19. *Completion and Almost-Everywhere Limits*
If $E \subseteq N \in \mathcal{M}$, $\mu(N) = 0$, and $E \notin \mathcal{M}$, then $f_n \equiv 0$ is measurable and $f_n \to \mathbf{1}_E$ a.e.,
since $\{x : f_n(x) \not\to \mathbf{1}_E(x)\} \subseteq N$. Yet $\mathbf{1}_E$ is not $\mathcal{M}$-measurable.
In the completion, every $E \subseteq N$ is measurable, so null modifications preserve measurability.
Key Insight: Almost-everywhere statements are most stable on complete measure spaces.

Corollary 1.1.20. *Pointwise and Almost-Everywhere Limits*
Let (f_n) be $\overline{\mathbb{R}}$-valued measurable functions on $(X, \mathcal{M})$, and let $f : X \to \overline{\mathbb{R}}$.

(i) If $f_n \to f$ pointwise on X, then f is measurable.
(ii) If $(X, \mathcal{M}, \mu)$ is complete and $f_n \to f$ a.e. on X, then f is measurable.

Proof.

(i) Pointwise, $f = \liminf_n f_n = \limsup_n f_n$; closure under lim inf and lim sup gives measurability.

(ii) Choose $N \in \mathcal{M}$ with $\mu(N) = 0$ and $f_n \to f$ on $X \setminus N$.
Define $g = f$ and $g_n = f_n$ on $X \setminus N$, and $g = g_n = 0$ on N.
Then each g_n is measurable and $g_n \to g$ pointwise, so g is measurable by (i).
Since $\forall a \in \mathbb{R},\ \{f > a\} \triangle \{g > a\} \subseteq N$, completeness gives $\{f > a\} \in \mathcal{M}$; hence f is measurable.

Structural Commentary: Limits reduce to upper and lower limits; a.e. limits require completion.
Key Insight: Completion is exactly what lets null modifications preserve measurability. □

Proposition 1.1.21. *Completed Measurable Functions Have Original Representatives*
Let $(X, \mathcal{M}, \mu)$ be a measure space with completion $(X, \overline{\mathcal{M}}_\mu, \overline{\mu})$.
If $f : X \to \mathbb{R}$ is $\overline{\mathcal{M}}_\mu$-measurable, then $\exists g : X \to \mathbb{R}$ that is $\mathcal{M}$-measurable and satisfies $f = g$ μ-a.e.

Proof. For $q \in \mathbb{Q}$, let $A_q := \{f > q\} \in \overline{\mathcal{M}}_\mu$, let $A_q = E_q \cup Z_q$, with $E_q \in \mathcal{M}$ and $Z_q \subseteq N_q \in \mathcal{M}$, $\mu(N_q) = 0$.
Put $N := \bigcup_{q \in \mathbb{Q}} N_q$, so $N \in \mathcal{M}$ and $\mu(N) = 0$, and define $g(x) := \begin{cases} f(x), & x \notin N, \\ 0, & x \in N. \end{cases}$.
For $q \in \mathbb{Q}$, $\{g > q\} = (E_q \setminus N) \cup \begin{cases} N, & q < 0, \\ \emptyset, & q \geq 0, \end{cases}$ belongs to $\mathcal{M}$. Hence, for $a \in \mathbb{R}$, $\{g > a\} = \bigcup_{\substack{q \in \mathbb{Q} \\ q > a}} \{g > q\} \in \mathcal{M}$.
Thus g is $\mathcal{M}$-measurable and $f = g$ on $X \setminus N$.
Structural Commentary: Completion only changes measurable functions on null sets.
Key Insight: Replace completed rational levels off one null set. □

Method 1.1.22. *Measure Proof Patterns*

(i) *Disjointize*. If $A_n \uparrow$, set $B_1 := A_1$, $B_n := A_n \setminus A_{n-1}$; then $A_n = \bigsqcup_{k \leq n} B_k$ and $\bigcup_n A_n = \bigsqcup_n B_n$.
(ii) *Approximate*. Prove on $\mathcal{E}$; use $d_\mu(C, D) := \mu^*(C \triangle D)$ and $\triangle$ estimates to pass limits through $\cup, \cap, \setminus$.
(iii) *Threshold*. For real f, show $\forall a \in \mathbb{R},\ \{f > a\} \in \mathcal{M}$; for $f : X \to \mathbb{R}^m$, use coordinate and open-set tests.
(iv) *Generators*. For $f : X \to (Y, \sigma(\mathcal{A}))$, check $\forall A \in \mathcal{A},\ f^{-1}(A) \in \mathcal{M}$.
(v) *Truncate*. For $f : X \to \overline{\mathbb{R}}$, prove results for $f_n := (-n) \vee (f \wedge n)$, then let $n \to \infty$.
(vi) *Topological bridge*. Use continuous open preimages.
Reduce Borel tests to countable interval or rectangle preimages.

Key Insight: Measure theory alternates between countable set algebra and approximation by elementary sets.

1.2 Lebesgue Integration

Lebesgue integration is calibrated on indicators, extended linearly to nonnegative simple functions, then extended by monotone approximation and positive–negative decomposition.

Perspective 1.2.1. *Simple Minorants Are the Right Primitive*
For Lebesgue measure on $\mathbb{R}$, bounded measurable functions supported on finite-measure sets form a useful intermediate class; arbitrary measure spaces need not admit that reduction.
Let $X \neq \emptyset$, $\mathcal{M} = \{\emptyset, X\}$, and $\mu(X) = +\infty$. If g is measurable and vanishes outside some $F \in \mathcal{M}$ with $\mu(F) < +\infty$, then $F = \emptyset$ and $g = 0$; hence finite-measure-support minorants of $\mathbf{1}_X$ have supremal integral 0, while the required normalization is $\int_X \mathbf{1}_X \, d\mu = \mu(X) = +\infty$.
Thus the defining minorants must include $\mathbf{1}_A$ $\forall A \in \mathcal{M}$, and more generally all nonnegative simple $s \leq f$.
Key Insight: The primitive calibration is $\int_X \mathbf{1}_A \, d\mu = \mu(A)$, with $\mu(A) = +\infty$ allowed.

Definition 1.2.2. *Lebesgue Integral*
Let $(X, \mathcal{M}, \mu)$ be a measure space and $E \in \mathcal{M}$; let $\mathcal{S}^+$ be nonnegative measurable simple functions on X.
Write $s \in \mathcal{S}^+$ as $s = \sum_{i=1}^{n} c_i \mathbf{1}_{A_i}$ with $c_i \geq 0$ and pairwise disjoint $A_i \in \mathcal{M}$.
For measurable $f \geq 0$, put $\mathcal{S}^+(f) := \{s \in \mathcal{S}^+ : s \leq f\}$; for measurable $f : X \to \overline{\mathbb{R}}$, put $f^{\pm} := (\pm f) \vee 0$.

(i) *Simple*: $\mathcal{I}_E(s) := \sum_{i=1}^{n} c_i \mu(E \cap A_i)$, with $0 \cdot (+\infty) := 0$.
(ii) *Nonnegative*: $\int_E f \, d\mu := \sup_{s \in \mathcal{S}^+(f)} \mathcal{I}_E(s)$; f integrable on $E \iff \int_E f \, d\mu < +\infty$.
(iii) *Signed*: if $\min\{\int_E f^+ \, d\mu, \int_E f^- \, d\mu\} < +\infty$, set $\int_E f \, d\mu := \int_E f^+ \, d\mu - \int_E f^- \, d\mu$.
(iv) *L^1*: $f \in \mathscr{L}^1(\mu)$ on E iff f is measurable and $\int_E |f| \, d\mu < +\infty$.
When $E = X$, write $\int f \, d\mu := \int_X f \, d\mu$ and drop "on E".

Simple functions are finite linear combinations of indicators of measurable sets: coefficients carry size, while the level sets carry measurability.

Lemma 1.2.3. *Refining a Simple Integral*
Let $s \geq 0$ be simple measurable and suppose $s = \sum_{k=1}^{m} b_k \mathbf{1}_{F_k}$ with $b_k \geq 0$ and $F_k \in \mathcal{M}$.
Then $\forall E \in \mathcal{M}$, $\mathcal{I}_E(s) = \sum_{k=1}^{m} b_k \mu(E \cap F_k)$.

Proof. For $\eta \in \{0,1\}^m$, set $F_k^1 := F_k$, $F_k^0 := F_k^c$, discard empty atoms $G_\eta := \bigcap_{k=1}^{m} F_k^{\eta_k}$. On G_η, $s = c_\eta := \sum_{\eta_k = 1} b_k$.
Group equal c_η values to recover the standard representation; finite additivity gives
$\mathcal{I}_E(s) = \sum_{\eta} c_\eta \mu(E \cap G_\eta) = \sum_{k=1}^{m} b_k \sum_{\eta : \eta_k = 1} \mu(E \cap G_\eta) = \sum_{k=1}^{m} b_k \mu(E \cap F_k)$.
Structural Commentary: Refine nonstandard sums to one finite partition.
Key Insight: Refine first, then regroup by equal function values. □

Proposition 1.2.4. *Simple Integral Algebra*
Let $(X, \mathcal{M}, \mu)$ be a measure space, let $E \in \mathcal{M}$, let $c \geq 0$, and let $s, t \in \mathcal{S}^+$. For fixed $s \in \mathcal{S}^+$, define $\nu_s : \mathcal{M} \to [0, +\infty]$ by $\nu_s(A) := \mathcal{I}_A(s)$. Then:
(i) $\mathcal{I}_E(cs) = c\mathcal{I}_E(s)$.
(ii) $\mathcal{I}_E(s + t) = \mathcal{I}_E(s) + \mathcal{I}_E(t)$.
(iii) ν_s is a measure on $\mathcal{M}$.

Proof. Write $s = \sum_i a_i \mathbf{1}_{A_i}$ and $t = \sum_j b_j \mathbf{1}_{B_j}$ on finite measurable partitions of X, with $a_i, b_j \geq 0$.

(i) $\mathcal{I}_E(cs) = \sum_i (ca_i)\mu(E \cap A_i) = c \sum_i a_i \mu(E \cap A_i) = c\mathcal{I}_E(s)$, with $0 \cdot (+\infty) = 0$.

(ii) On the common refinement $A_i \cap B_j$, $s + t = \sum_{i,j} (a_i + b_j) \mathbf{1}_{A_i \cap B_j}$.
$\mathcal{I}_E(s + t) = \sum_{i,j} (a_i + b_j) \mu(E \cap A_i \cap B_j) = \sum_i a_i \mu(E \cap A_i) + \sum_j b_j \mu(E \cap B_j)$ by Lemma 1.2.3.

(iii) For $A \in \mathcal{M}$, $\nu_s(A) = \sum_i a_i \mu(A \cap A_i)$.
Each $A \mapsto \mu(A \cap A_i)$ is a measure, and finite nonnegative sums of measures are measures.

Structural Commentary: Simple integration is weighted measure summation on finite partitions.
Key Insight: Refine to common atoms, then use finite additivity. □

Proposition 1.2.5. *Monotonicity for Nonnegative Integrals*
Let $f, g \geq 0$ be measurable and let $E, F \in \mathcal{M}$.
(i) If $f \leq g$ on E, then $\int_E f \, d\mu \leq \int_E g \, d\mu$.
(ii) If $E \subseteq F$, then $\int_E f \, d\mu \leq \int_F f \, d\mu$.

Proof.
(i) If $s \in \mathcal{S}^+(f)$, then $s\mathbf{1}_E \in \mathcal{S}^+(g)$, $\mathcal{I}_E(s) = \mathcal{I}_E(s\mathbf{1}_E) \leq \int_E g \, d\mu$. Taking $\sup_{s \in \mathcal{S}^+(f)}$ gives $\int_E f \, d\mu \leq \int_E g \, d\mu$.
(ii) If $E \subseteq F$ and $s \in \mathcal{S}^+(f)$, then $\mathcal{I}_E(s) \leq \mathcal{I}_F(s)$. Taking $\sup_{s \in \mathcal{S}^+(f)}$ gives $\int_E f \, d\mu \leq \int_F f \, d\mu$.

Structural Commentary: The nonnegative integral is a supremum over simple functions below the integrand.
Key Insight: More room below the integrand, or over a larger set, can only increase the supremum. □

Proposition 1.2.6. *Chebyshev Inequality for Nonnegative Integrals*
Let $(X, \mathcal{M}, \mu)$ be a measure space, let $E \in \mathcal{M}$, and let $f : X \to [0, +\infty]$ be measurable.
For $\lambda > 0$, set $E_\lambda := E \cap \{f \geq \lambda\}$. Then $E_\lambda \in \mathcal{M}$ and $\mu(E_\lambda) \leq \lambda^{-1} \int_E f \, d\mu$.

Proof. Measurability gives $E_\lambda \in \mathcal{M}$.
Since $\lambda \mathbf{1}_{E_\lambda} \leq f$ on E, monotonicity gives $\lambda \mu(E_\lambda) = \int_E \lambda \mathbf{1}_{E_\lambda} \, d\mu \leq \int_E f \, d\mu$; divide by $\lambda > 0$.
Structural Commentary: Level-set minorants convert mass to measure.
Key Insight: Use $\lambda \mathbf{1}_{E_\lambda} \leq f$ on E. □

Method 1.2.7. *Splitting a Simple Minorant Under a Sum*
Let $E \in \mathcal{M}$, $f, g \geq 0$ measurable, and $\omega \in \mathcal{S}^+(f + g)$ simple.
(i) *Grid*: for $n \geq 1$, use $D_n := \{0, \frac{1}{n}, \ldots, 1\}$.

(ii) *Split*: define $\varphi_n(x) := \max\{\theta\omega(x) : \theta \in D_n,\ \theta\omega(x) \le f(x)\}$; $\psi_n(x) := \big((1-\frac{1}{n})\,\omega(x) - \varphi_n(x)\big)^+$.
(iii) *Bounds*: φ_n, ψ_n are simple, $\varphi_n \le f$, $\psi_n \le g$, and $(1-\frac{1}{n})\omega \le \varphi_n + \psi_n$.
(iv) *Use*: simple additivity gives $(1-\frac{1}{n})\mathcal{I}_E(\omega) \le \int_E f\,d\mu + \int_E g\,d\mu$; then let $n \to \infty$ and take $\sup_{\omega \in \mathcal{S}^+(f+g)}$.

Key Insight: Grid-split ω between f and g, losing only $\frac{1}{n}$.

Proposition 1.2.8. *Homogeneity and Additivity for Nonnegative Integrals*
Let $f, g \ge 0$ be measurable, let $c \ge 0$, and let $E \in \mathcal{M}$. All identities are in $[0, +\infty]$, with $0 \cdot (+\infty) = 0$.
(i) Homogeneity: $\int_E cf\,d\mu = c\int_E f\,d\mu$.
(ii) Additivity: $\int_E (f+g)\,d\mu = \int_E f\,d\mu + \int_E g\,d\mu$.

Proof.
(i) If $c = 0$, both sides are 0; if $c > 0$, $s \mapsto cs$ bijects $\mathcal{S}^+(f)$ with $\mathcal{S}^+(cf)$ and satisfies $\mathcal{I}_E(cs) = c\mathcal{I}_E(s)$. Hence taking suprema gives the claim.
(ii) If $s \in \mathcal{S}^+(f)$ and $t \in \mathcal{S}^+(g)$, then $s + t \in \mathcal{S}^+(f+g)$ and $\mathcal{I}_E(s) + \mathcal{I}_E(t) = \mathcal{I}_E(s+t) \le \int_E (f+g)\,d\mu$, so taking $\sup_{s,t}$ gives $\int_E f\,d\mu + \int_E g\,d\mu \le \int_E (f+g)\,d\mu$.
Conversely, for $\omega \in \mathcal{S}^+(f+g)$, choose simple $\varphi_n \le f$ and $\psi_n \le g$ with $(1-\frac{1}{n})\omega \le \varphi_n + \psi_n$.
Then $\big(1-\frac{1}{n}\big)\,\mathcal{I}_E(\omega) \le \mathcal{I}_E(\varphi_n) + \mathcal{I}_E(\psi_n) \le \int_E f\,d\mu + \int_E g\,d\mu$. Let $n \to \infty$, then take $\sup_{\omega \in \mathcal{S}^+(f+g)}$.

Structural Commentary: The nonnegative integral is linear before signed integrability is introduced.
Key Insight: Scale minorants; split sum-minorants on a finite grid. □

Proposition 1.2.9. *Signed Decompositions Give the Same Integral*
Let $(X, \mathcal{M}, \mu)$ be a measure space, let $E \in \mathcal{M}$, and let $f, f_1, f_2 : X \to \overline{\mathbb{R}}$ be measurable. Assume $f_i \ge 0$, $\int_E f_i\,d\mu < +\infty$ for $i = 1, 2$, and $f = f_1 - f_2$ on E. Then:
(i) $f \in \mathscr{L}^1(\mu)$ on E.
(ii) $\int_E f\,d\mu = \int_E f_1\,d\mu - \int_E f_2\,d\mu$.

Proof.
(i) Since $-f_2 \le f \le f_1$ on E, $f^+ \le f_1$ and $f^- \le f_2$ on E; monotonicity gives $\int_E f^\pm\,d\mu < +\infty$.
(ii) Since $f^+ - f^- = f_1 - f_2$ on E, $f^+ + f_2 = f_1 + f^-$ on E.
Nonnegative additivity gives $\int_E f^+\,d\mu + \int_E f_2\,d\mu = \int_E f_1\,d\mu + \int_E f^-\,d\mu$; subtract the finite terms.

Structural Commentary: Finite positive decompositions determine one signed integral.
Key Insight: Move all nonnegative terms to one equality, integrate, then cancel finite terms. □

Perspective 1.2.10. *Step Functions versus Simple Functions*
Riemann: $\sup \sum_i m_i \ell(I_i)$ over interval partitions. Lebesgue: $\sup\{\mathcal{I}(s) : 0 \le s \le f,\ s = \sum_i c_i \mathbf{1}_{E_i},\ E_i \in \mathcal{M}\}$.

Structural Commentary: Riemann partitions intervals; Lebesgue partitions level sets.
Key Insight: Same finite constants, measurable pieces.

Perspective 1.2.11. *Undergraph Picture for Nonnegative Functions*
For measurable $f : \mathbb{R} \to [0, +\infty]$, set $\mathcal{U}_f := \{(x, y) \in \mathbb{R} \times [0, +\infty) : 0 \le y < f(x)\}$.
Geometrically, $\int f\,dm = m_2(\mathcal{U}_f)$; analytically, the integral is built as $\sup \mathcal{I}(s)$ over simple $0 \le s \le f$.

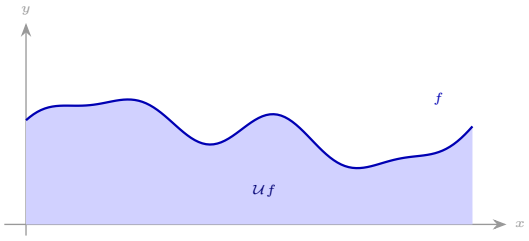

Figure 199: The integral of $f \ge 0$ is modeled by the measure of its undergraph.

Proposition 1.2.12. *Basic Integral Properties*
Let $E \in \mathcal{M}$.
(i) If f is measurable and bounded on E, and $\mu(E) < +\infty$, then $f \in \mathscr{L}^1(\mu)$ on E.
(ii) If $a \le f(x) \le b$ on E and $\mu(E) < +\infty$, then $a\mu(E) \le \int_E f\,d\mu \le b\mu(E)$.
(iii) If $f, g \in \mathscr{L}^1(\mu)$ on E and $f \le g$ on E, then $\int_E f\,d\mu \le \int_E g\,d\mu$.
(iv) If $f \in \mathscr{L}^1(\mu)$ on E, then $cf \in \mathscr{L}^1(\mu)$ on E for finite c, and $\int_E cf\,d\mu = c\int_E f\,d\mu$.
(v) If $\mu(E) = 0$ and f is measurable, then $\int_E f\,d\mu = 0$.
(vi) If $f \in \mathscr{L}^1(\mu)$ on E, $A \in \mathcal{M}$, and $A \subseteq E$, then $f \in \mathscr{L}^1(\mu)$ on A.

Proof.
(i) If $|f| \le M$ on E, then $0 \le f^\pm \le M\mathbf{1}_E$ on E, so $\int_E f^\pm\,d\mu \le M\mu(E) < +\infty$.
(ii) Since $a\mathbf{1}_E \le f \le b\mathbf{1}_E$ on E, order for the positive integral gives $a\mu(E) \le \int_E f\,d\mu \le b\mu(E)$.
(iii) Since $g - f \ge 0$ on E, $\int_E (g-f)\,d\mu \ge 0$, hence $\int_E f\,d\mu \le \int_E g\,d\mu$.
(iv) For $c \ge 0$, scale the simple approximants. For $c < 0$, use $(cf)^+ = (-c)f^-$ and $(cf)^- = (-c)f^+$.
(v) If $\mu(E) = 0$, then $\forall s \ge 0$ simple, $\mathcal{I}_E(s) = 0$, so $\int_E f^\pm\,d\mu = 0$.

(vi) Since $A \subseteq E$, $\mathcal{I}_A(s) \le \mathcal{I}_E(s)$ for $s \ge 0$ simple; hence $\int_A f^{\pm}\,d\mu \le \int_E f^{\pm}\,d\mu < +\infty$.

Structural Commentary: Estimate $f^{\pm}$ by simpler functions.
Key Insight: Monotonicity makes bounds, null sets, and restrictions immediate. □

Theorem 1.2.13. *The Integral as a Measure or Charge*
For $A \in \mathcal{M}$, define $\phi_f(A) := \int_A f\,d\mu$ when $f \ge 0$ is measurable, and define $\lambda_f(A) := \int_A f\,d\mu$ when $f \in \mathscr{L}^1(\mu)$.
(i) If $f \ge 0$ is measurable, then $\phi_f : \mathcal{M} \to [0,+\infty]$ is a measure.
(ii) If $f \in \mathscr{L}^1(\mu)$, then $\lambda_f : \mathcal{M} \to \mathbb{R}$ is finite-valued and countably additive.

Proof.
(i) For simple $s \ge 0$, $A \mapsto \mathcal{I}_A(s)$ is a measure, so $\phi_f(\emptyset) = 0$.
If $A = \bigsqcup_n A_n$, $s \in \mathcal{S}^+(f)$, then $\mathcal{I}_A(s) = \sum_n \mathcal{I}_{A_n}(s) \le \sum_n \phi_f(A_n)$; taking $\sup_s$ gives $\phi_f(A) \le \sum_n \phi_f(A_n)$. Conversely, $\forall N$, finite additivity gives $\sum_{n=1}^{N} \phi_f(A_n) = \phi_f(\bigcup_{n=1}^{N} A_n) \le \phi_f(A)$.
Let $N \to \infty$. Hence $\phi_f(A) = \sum_n \phi_f(A_n)$.
(ii) Since $f \in \mathscr{L}^1(\mu)$, $\phi_{f^+}(X), \phi_{f^-}(X) < +\infty$ and $\lambda_f = \phi_{f^+} - \phi_{f^-}$ is finite-valued.
If $A = \bigsqcup_n A_n$, then item (i) gives $\lambda_f(A) = \sum_n \phi_{f^+}(A_n) - \sum_n \phi_{f^-}(A_n) = \sum_n \lambda_f(A_n)$.

Structural Commentary: Setwise integration turns densities into measures.
Key Insight: Sup simple measures; subtract finite signs. □

Corollary 1.2.14. *Domain Additivity and Continuity for Integrable Functions*
Let $(X,\mathcal{M},\mu)$ be a measure space, let $E \in \mathcal{M}$, let $f \in \mathscr{L}^1(\mu)$ on E, and set $\mathcal{M}_E := \{A \in \mathcal{M} : A \subseteq E\}$.
(i) If $(A_n) \subseteq \mathcal{M}_E$ are pairwise disjoint, then $\int_{\bigsqcup_n A_n} f\,d\mu = \sum_n \int_{A_n} f\,d\mu$ and $\sum_n \left|\int_{A_n} f\,d\mu\right| < +\infty$.
(ii) If $A_n, A \in \mathcal{M}_E$ and $A_n \uparrow A$, then $\int_A f\,d\mu = \lim_{n\to\infty} \int_{A_n} f\,d\mu$.
(iii) If $A_n, A \in \mathcal{M}_E$ and $A_n \downarrow A$, then $\int_A f\,d\mu = \lim_{n\to\infty} \int_{A_n} f\,d\mu$.

Proof. Let $\mu_E := \mu|_{\mathcal{M}_E}$ and define $\lambda(A) := \int_A f\,d\mu$, $\nu(A) := \int_A |f|\,d\mu$ on $\mathcal{M}_E$.
By Theorem 1.2.13, λ is a finite signed measure, $\nu(E) < +\infty$, and $|\lambda(A)| \le \nu(A)$.
(i) Additivity gives $\lambda(\bigsqcup_n A_n) = \sum_n \lambda(A_n)$, and $\sum_n |\lambda(A_n)| \le \sum_n \nu(A_n) = \nu(\bigsqcup_n A_n) \le \nu(E) < +\infty$.
(ii) Set $B_1 = A_1$ and $B_n = A_n \setminus A_{n-1}$ for $n \ge 2$.
Since $A = \bigsqcup_n B_n$ and $A_N = \bigsqcup_{n\le N} B_n$, (i) gives $\lambda(A_N) = \sum_{n\le N} \lambda(B_n) \to \sum_n \lambda(B_n) = \lambda(A)$.
(iii) Set $C_n := A_1 \setminus A_n$ and $C := A_1 \setminus A$. Then $C_n \uparrow C$, so (ii) gives $\lambda(C_n) \to \lambda(C)$.
Hence $\lambda(A_n) = \lambda(A_1) - \lambda(C_n) \to \lambda(A_1) - \lambda(C) = \lambda(A)$.

Structural Commentary: Domain integrals form a finite signed measure.
Key Insight: Monotone domain limits are signed-measure continuity. □

Proposition 1.2.15. *Finite-Measure Support*
Let $(X,\mathcal{M},\mu)$ be a measure space, let $E \in \mathcal{M}$, and let $h : E \to \mathbb{R}$ be bounded and measurable.
Suppose $h = 0$ on $E \setminus E_0$ for some $E_0 \in \mathcal{M}$ with $E_0 \subseteq E$ and $\mu(E_0) < +\infty$. Then:
(i) $h \in \mathscr{L}^1(\mu)$ on E.
(ii) $\int_E h\,d\mu = \int_{E_0} h\,d\mu$.
(iii) If $E_1 \in \mathcal{M}$, $E_1 \subseteq E$, $\mu(E_1) < +\infty$, and $h = 0$ on $E \setminus E_1$, then $\int_{E_0} h\,d\mu = \int_{E_1} h\,d\mu$.

Proof.
(i) Choose $M < +\infty$ with $|h| \le M$ on E.
Since $h = 0$ on $E \setminus E_0$, $0 \le h^{\pm} \le M\mathbf{1}_{E_0}$ on E, so $\int_E h^{\pm}\,d\mu \le M\mu(E_0) < +\infty$.
(ii) Since $\int_{E\setminus E_0} h\,d\mu = 0$, $\int_E h\,d\mu = \int_{E_0} h\,d\mu$ by Corollary 1.2.14.
(iii) Apply item (ii) with E_0 and with E_1: $\int_{E_0} h\,d\mu = \int_E h\,d\mu = \int_{E_1} h\,d\mu$.

Structural Commentary: Finite support turns boundedness into integrability.
Key Insight: The integral only sees where h can be nonzero. □

Corollary 1.2.16. *Compact Continuous Functions on Finite Measure Spaces*
Let X be a compact topological space, let $\mathcal{M}$ be a σ-algebra containing the topology of X, and let $\mu(X) < +\infty$.
If $f : X \to \mathbb{R}$ is continuous, then:
(i) f is measurable.
(ii) $f \in \mathscr{L}^1(\mu)$.

Proof.
(i) $\forall O \subseteq \mathbb{R}$ open, $f^{-1}(O)$ is open in X by continuity, hence $f^{-1}(O) \in \mathcal{M}$.
(ii) The continuous image $f(X)$ is compact in $\mathbb{R}$, hence bounded.
Since $\mu(X) < +\infty$, $f \in \mathscr{L}^1(\mu)$ by Proposition 1.2.12(i).

Structural Commentary: Compactness supplies boundedness, while the measure hypothesis supplies finite mass.
Key Insight: Continuous on compact plus finite measure implies bounded measurable, hence integrable. □

Corollary 1.2.17. *Null and Finiteness Consequences for $f \ge 0$*
Let $f : X \to [0,+\infty]$ be measurable and $\phi_f(A) := \int_A f\,d\mu$.
(i) $\mu(A) = 0 \Longrightarrow \phi_f(A) = 0$ for $A \in \mathcal{M}$.
(ii) $\int_X f\,d\mu = 0 \Longleftrightarrow f = 0$ a.e.

(iii) $\int_X f\,d\mu < +\infty \Longrightarrow \mu\{f = +\infty\} = 0$ *and* $\{f > 0\}$ *is* σ*-finite.*

Proof.

(i) If $\mu(A) = 0$ and $0 \le s \le f$ is simple, then $\mathcal{I}_A(s) = 0$; hence $\phi_f(A) = \sup_s \mathcal{I}_A(s) = 0$.

(ii) ($\Rightarrow$) Set $E_n := \{f > \frac{1}{n}\}$. By Proposition 1.2.6, $\mu(E_n) \le n \int_X f\,d\mu = 0$.
Thus $\forall n,\ \mu(E_n) = 0$, and $\{f > 0\} = \bigcup_n E_n$ is null.

(ii) ($\Leftarrow$) If $N := \{f > 0\}$ null, every simple $0 \le s \le f$ vanishes on $X \setminus N$, so $\mathcal{I}_X(s) = \mathcal{I}_N(s) = 0$; take $\sup_s$.

(iii) Let $F_n := \{f \ge n\}$. By Proposition 1.2.6, $\mu(F_n) \le n^{-1} \int_X f\,d\mu$, so $\mu\{f = +\infty\} \le \mu(F_n) \to 0$.
Also $\{f > 0\} = \bigcup_n \{f > \frac{1}{n}\}$ and $\mu\{f > \frac{1}{n}\} \le n \int_X f\,d\mu < +\infty$.

Structural Commentary: Finite nonnegative integrals control threshold sets.
Key Insight: Threshold sets convert integral bounds into measure bounds. □

Theorem 1.2.18. *Absolute Integrability and Domination*
Let $(X, \mathcal{M}, \mu)$ *be a measure space and let* $E \in \mathcal{M}$. *Then:*

(i) If $f \in \mathscr{L}^1(\mu)$ *on* E, *then* $|f| \in \mathscr{L}^1(\mu)$ *on* E *and* $\left|\int_E f\,d\mu\right| \le \int_E |f|\,d\mu$.

(ii) If $f : X \to \overline{\mathbb{R}}$ *is measurable,* $g \in \mathscr{L}^1(\mu)$ *on* E, *and* $|f| \le g$ *on* E, *then* $f \in \mathscr{L}^1(\mu)$ *on* E.

Proof.

(i) Set $a := \int_E f^+\,d\mu$ and $b := \int_E f^-\,d\mu$. Since $f \in \mathscr{L}^1(\mu)$ on E, $a, b < +\infty$.
Hence $\int_E |f|\,d\mu = \int_E (f^+ + f^-)\,d\mu = a + b < +\infty$, and $\left|\int_E f\,d\mu\right| = |a - b| \le a + b = \int_E |f|\,d\mu$.

(ii) Since $|f| \le g$ on E, $g \ge 0$ on E and $\int_E g\,d\mu < +\infty$.
Also $0 \le f^\pm \le |f| \le g$ on E, so monotonicity gives $\int_E f^\pm\,d\mu < +\infty$.

Structural Commentary: Both claims reduce to finite positive and negative parts.
Key Insight: Use $|f| = f^+ + f^-$ and $0 \le f^\pm \le g$. □

Proposition 1.2.19. *Linearity of the Lebesgue Integral*
Let $(X, \mathcal{M}, \mu)$ *be a measure space, let* $E \in \mathcal{M}$, *let* $f, g \in \mathscr{L}^1(\mu)$ *on* E, *and let* $a, b \in \mathbb{R}$.
Then:

(i) For $c \in \mathbb{R}$ *and* $u \in \mathscr{L}^1(\mu)$ *on* E, $cu \in \mathscr{L}^1(\mu)$ *on* E *and* $\int_E cu\,d\mu = c\int_E u\,d\mu$.

(ii) $f + g \in \mathscr{L}^1(\mu)$ *on* E *and* $\int_E (f+g)\,d\mu = \int_E f\,d\mu + \int_E g\,d\mu$.

(iii) $af + bg \in \mathscr{L}^1(\mu)$ *on* E *and* $\int_E (af+bg)\,d\mu = a\int_E f\,d\mu + b\int_E g\,d\mu$.

Proof.

(i) Since $(cu)^\pm = c^+u^\pm + c^-u^\mp$, both $(cu)^+$ and $(cu)^-$ have finite integral. Nonnegative linearity gives $\int_E cu\,d\mu = (c^+a_u + c^-b_u) - (c^+b_u + c^-a_u) = c(a_u - b_u)$, where $a_u := \int_E u^+\,d\mu$ and $b_u := \int_E u^-\,d\mu$.

(ii) Since $|f+g| \le |f| + |g|$ and $|f| + |g| \in \mathscr{L}^1(\mu)$ on E, $f + g \in \mathscr{L}^1(\mu)$ on E by Theorem 1.2.18(ii).
Integrate $(f+g)^+ + f^- + g^- = (f+g)^- + f^+ + g^+$ over E and cancel finite terms.

(iii) By (i), $af, bg \in \mathscr{L}^1(\mu)$ on E, $\int_E af\,d\mu = a\int_E f\,d\mu$, and $\int_E bg\,d\mu = b\int_E g\,d\mu$.
Applying (ii) to af, bg gives $af + bg \in \mathscr{L}^1(\mu)$ on E and $\int_E (af+bg)\,d\mu = a\int_E f\,d\mu + b\int_E g\,d\mu$.

Structural Commentary: Signed linearity follows from finite sign pieces.
Key Insight: Integrate one nonnegative equality, then cancel finite terms. □

Proposition 1.2.20. *L^1 Level Sets, Null Changes, and Indefinite Integrals*
Let $f, g \in \mathscr{L}^1(\mu)$ *on* X, *and write* $\lambda_u(A) := \int_A u\,d\mu$.

(i) For $a > 0$, $\mu\{|f| \ge a\} \le a^{-1}\int_X |f|\,d\mu < +\infty$; *hence* $\{f \ne 0\}$ *is* σ*-finite.*

(ii) If measurable $h = 0$ *a.e., then* $h \in \mathscr{L}^1(\mu)$ *and* $\lambda_h \equiv 0$.

(iii) $\lambda_f \ge 0$ *on* $\mathcal{M} \Longrightarrow f \ge 0$ *a.e.;* $\lambda_f \equiv 0 \Longrightarrow f = 0$ *a.e.*

(iv) $\lambda_f = \lambda_g$ *on* $\mathcal{M} \Longleftrightarrow f = g$ *a.e.*

Proof.

(i) Since $a\mathbf{1}_{\{|f| \ge a\}} \le |f|$, integration gives $a\mu\{|f| \ge a\} \le \int_X |f|\,d\mu$. Also $\{f \ne 0\} = \bigcup_{k \ge 1} \{|f| \ge \frac{1}{k}\}$.

(ii) Let $N := \{h \ne 0\}$. For $A \in \mathcal{M}$, $h^\pm \mathbf{1}_A$ vanish off $A \cap N$, a null set.
Hence $\int_A h^+\,d\mu = \int_A h^-\,d\mu = 0$, so $\lambda_h(A) = 0$.

(iii) For $k \ge 1$, set $N_k := \{f \le -\frac{1}{k}\}$. By (i), $\mu(N_k) < +\infty$, and $\lambda_f(N_k) \le -k^{-1}\mu(N_k)$.
If $\lambda_f \ge 0$, then $\mu(N_k) = 0$, so $\{f < 0\} = \bigcup_k N_k$ is null. If $\lambda_f \equiv 0$, apply this to f and $-f$.

(iv) If $\lambda_f = \lambda_g$, then $\lambda_{f-g} \equiv 0$, so $f - g = 0$ a.e. by (iii). Conversely, if $f = g$ a.e., apply (ii) to $h = f - g$.

Structural Commentary: An L^1 function is detected by its integrals over all measurable sets, up to null sets.
Key Insight: Test sign on the level sets where the function is bounded away from 0. □

Proposition 1.2.21. *Finite-Measure Indicators by Intervals and Continuous Functions*
Let $A \subseteq \mathbb{R}$ *be Lebesgue measurable with* $m(A) < +\infty$. *Then* $\forall \varepsilon > 0$*:*

(i) $\exists G = \bigcup_{j=1}^{N} I_j$, I_j *open intervals, such that* $m(A \triangle G) < \varepsilon$.

(ii) $\exists f \in C(\mathbb{R})$ *such that* $0 \le f \le 1$ *and* $\int_{\mathbb{R}} |\mathbf{1}_A - f|\,dm < \varepsilon$.

Proof.

(i) Choose open $O \supseteq A$ with $m(O \setminus A) < \frac{\varepsilon}{2}$ and $m(O) < +\infty$.
Write $O = \bigsqcup_{j \geq 1} I_j$ with open intervals I_j, choose N with $m(O \setminus G) < \frac{\varepsilon}{2}$ for $G := \bigcup_{j=1}^{N} I_j$.
Then $A \setminus G \subseteq O \setminus G$ and $G \setminus A \subseteq O \setminus A$, so $m(A \triangle G) < \varepsilon$.

(ii) Apply (i) with $\frac{\varepsilon}{2}$ to get finite open G. Choose compact $K \subseteq G$ with $m(G \setminus K) < \frac{\varepsilon}{2}$, and choose piecewise-linear f with $0 \leq f \leq 1$, $f = 1$ on K, $f = 0$ on $\mathbb{R} \setminus G$.
Then $\int_{\mathbb{R}} |\mathbf{1}_G - f| \, dm \leq m(G \setminus K) < \frac{\varepsilon}{2}$, hence $\int_{\mathbb{R}} |\mathbf{1}_A - f| \, dm \leq m(A \triangle G) + \int_{\mathbb{R}} |\mathbf{1}_G - f| \, dm < \varepsilon$.

Structural Commentary: Finite-measure sets can be made geometrically simple up to small L^1 error.
Key Insight: Approximate by intervals, then smooth the indicator. □

Example 1.2.22. *Counting and Unit-Mass Integrals*

(i) *Counting*: for counting measure $\#$ on $(\mathbb{N}, 2^{\mathbb{N}})$ and $f : \mathbb{N} \to \mathbb{R}$,
$f \in \mathscr{L}^1(\#) \iff \sum_{n=1}^{\infty} |f(n)| < +\infty$, and then $\int_{\mathbb{N}} f \, d\# = \sum_{n=1}^{\infty} f(n)$.

(ii) *Unit mass*: for $(X, \mathcal{M})$, $p \in X$, and $\delta_p(E) := \mathbf{1}_E(p)$, $\int_X f \, d\delta_p = f(p)$ for measurable $f : X \to [0, +\infty]$.
If $f : X \to \mathbb{R}$ is measurable, then $f \in \mathscr{L}^1(\delta_p)$ and the same formula holds.

For δ_p, verify first on indicators, then extend to simple functions by finite linearity, to nonnegative functions by monotone simple approximation, and to real-valued functions by positive–negative splitting.

Example 1.2.23. *L^1 Is Not Closed Under Squaring*
On $X = \mathbb{N}$ with $\mathcal{M} = 2^{\mathbb{N}}$, define $\mu(E) := \sum_{n \in E} 4^{-n}$ and $f(n) := \frac{2^n}{\sqrt{n}}$.

Then $\int_X |f| \, d\mu = \sum_{n=1}^{\infty} \frac{1}{2^n \sqrt{n}} < +\infty$; $\int_X f^2 \, d\mu = \sum_{n=1}^{\infty} \frac{1}{n} = +\infty$.
The first series is dominated by the geometric series $\sum 2^{-n}$, while the second diverges by Corollary 6.1.14.
Thus $f \in \mathscr{L}^1(\mu)$ need not imply $f^2 \in \mathscr{L}^1(\mu)$.

1.3 Convergence Theorems

This subsection collects the main limit-interchange tools: monotone convergence, Fatou, and dominated convergence.

Theorem 1.3.1. *Monotone Convergence*
Let $E \in \mathcal{M}$, let f_n, f be measurable on E, and assume $0 \leq f_n \uparrow f$. Then $\int_E f_n \, d\mu \uparrow \int_E f \, d\mu$.

Proof. By monotonicity, $\int_E f_n \, d\mu \uparrow L \leq \int_E f \, d\mu$.
For $s \in \mathcal{S}^+(f)$ and $0 < c < 1$, set $E_n := \{x \in E : f_n(x) \geq c s(x)\}$.
Since $f_n \uparrow f$ and $s \leq f$, $E_n \uparrow E$, and $\int_E f_n \, d\mu \geq \int_{E_n} f_n \, d\mu \geq c \int_{E_n} s \, d\mu$.
Continuity from below for $\phi_s(A) := \int_A s \, d\mu$ gives $L \geq c \int_E s \, d\mu$. Let $c \uparrow 1$, then take $\sup_{s \in \mathcal{S}^+(f)}$.

Structural Commentary: Nonnegative integration commutes with monotone limits.
Key Insight: Simple minorants of the limit are eventually captured below the sequence. □

Theorem 1.3.2. *Series Form of Monotone Convergence*
Let $E \in \mathcal{M}$, let $f_n \geq 0$ be measurable, and set $f := \sum_{n=1}^{\infty} f_n$ on E. Then $\int_E f \, d\mu = \sum_{n=1}^{\infty} \int_E f_n \, d\mu$.

Proof. Set $S_N := \sum_{n=1}^{N} f_n$. Then $0 \leq S_N \uparrow f$.

By Theorem 1.3.1, $\int_E f \, d\mu = \lim_{N \to \infty} \int_E S_N \, d\mu = \lim_{N \to \infty} \sum_{n=1}^{N} \int_E f_n \, d\mu = \sum_{n=1}^{\infty} \int_E f_n \, d\mu$.

Structural Commentary: Nonnegative series are monotone partial sums.
Key Insight: Integrate partial sums, then pass upward. □

Corollary 1.3.3. *Beppo Levi Bounded-Integral Criterion*
Let $E \in \mathcal{M}$, let (f_n) be measurable on E, and assume $0 \leq f_n \uparrow f$ with $\sup_n \int_E f_n \, d\mu < +\infty$.
Then $f < +\infty$ a.e. on E and $\int_E f \, d\mu = \lim_n \int_E f_n \, d\mu < +\infty$.

Proof. The monotone limit f is measurable, and $\int_E f \, d\mu = \lim_n \int_E f_n \, d\mu \leq \sup_n \int_E f_n \, d\mu < +\infty$ by Theorem 1.3.1. Thus $f < +\infty$ a.e. on E by Corollary 1.2.17.
Structural Commentary: Bounded mass survives monotone limits.
Key Insight: Finite nonnegative integral forces a.e. finiteness. □

Proposition 1.3.4. *L^1 Approximation and Bounded Multipliers*
Let $f \in \mathscr{L}^1(\mu)$ on X.
(i) $\forall \varepsilon > 0$ $\exists$ a measurable simple function φ with $\int_X |f - \varphi| \, d\mu < \varepsilon$.
(ii) If g is bounded measurable, then $fg \in \mathscr{L}^1(\mu)$.

Proof.

(i) Choose simple $0 \leq s_n \uparrow f^+$ and $0 \leq t_n \uparrow f^-$. Then $\int_X (f^+ - s_n) \, d\mu \to 0$ and $\int_X (f^- - t_n) \, d\mu \to 0$.
For large n, $\varphi := s_n - t_n$ satisfies $\int_X |f - \varphi| \, d\mu \leq \int_X (f^+ - s_n) \, d\mu + \int_X (f^- - t_n) \, d\mu < \varepsilon$.

(ii) If $|g| \leq M$, then fg is measurable and $\int_X |fg| \, d\mu \leq M \int_X |f| \, d\mu < +\infty$.

Structural Commentary: L^1 is simple-closed and bounded-multiplier stable.
Key Insight: Approximate signs separately; dominate products by $M|f|$. □

Theorem 1.3.5. *Fatou's Lemma*
Let $E \in \mathcal{M}$ and let $f_n : E \to [0, +\infty]$ be measurable. Then $\int_E \liminf_n f_n \, d\mu \le \liminf_n \int_E f_n \, d\mu$.

Proof. Set $g_n := \inf_{i \ge n} f_i$. Then $0 \le g_n \uparrow \liminf_i f_i$ and $\forall i \ge n$, $g_n \le f_i$, so $\int_E g_n \, d\mu \le \inf_{i \ge n} \int_E f_i \, d\mu$.
By Theorem 1.3.1, $\int_E \liminf_i f_i \, d\mu = \lim_n \int_E g_n \, d\mu \le \lim_n \inf_{i \ge n} \int_E f_i \, d\mu = \liminf_n \int_E f_n \, d\mu$.
Structural Commentary: Replace lim inf by increasing tail infima.
Key Insight: Tail infima are monotone minorants. □

Example 1.3.6. *Strictness in Fatou's Lemma*
Fatou's inequality can be strict by concentration or escape of mass.

(i) *Concentration*: On $E = (0, 1)$ with Lebesgue measure m, set $f_n := n\mathbf{1}_{(0, \frac{1}{n})}$.
Then $f_n \to 0$ pointwise and $\forall n$, $\int_E f_n \, dm = 1$.
(ii) *Escape*: On $E = \mathbb{R}$ with Lebesgue measure m, set $g_n := \mathbf{1}_{(n, n+1)}$.
Then $g_n \to 0$ pointwise and $\forall n$, $\int_E g_n \, dm = 1$.

In either case, with $h_n = f_n$ or $h_n = g_n$, $\int_E \liminf_n h_n \, dm = 0 < 1 = \liminf_n \int_E h_n \, dm$.

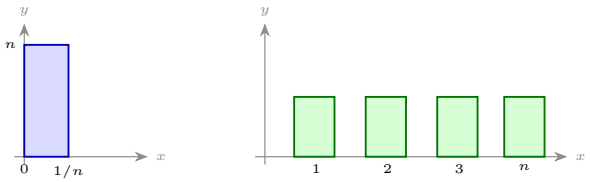

Figure 200: Strict Fatou behavior: $f_n = n\mathbf{1}_{(0, \frac{1}{n})}$ and $g_n = \mathbf{1}_{(n, n+1)}$ have integral 1 but vanish pointwise.

Theorem 1.3.7. *Dominated Convergence*
Let $E \in \mathcal{M}$, let f_n, f be measurable on E, and let $g \in \mathscr{L}^1(\mu)$ on E.
Suppose $f_n \to f$ a.e. on E and $\forall n$, $|f_n| \le g$ on E. Then:
(i) $f \in \mathscr{L}^1(\mu)$ on E.
(ii) $\lim_{n \to \infty} \int_E f_n \, d\mu = \int_E f \, d\mu$.

Proof. Choose null $N \subseteq E$ such that $f_n \to f$ on $E \setminus N$.
Changing values on N does not change integrals, so assume $f_n \to f$ everywhere on E.

(i) The pointwise limit f is measurable on E, and $|f| \le g$ on E; hence $f \in \mathscr{L}^1(\mu)$ on E by Theorem 1.2.18(ii).
(ii) Put $a_n := \int_E f_n \, d\mu$. Fatou applied to $g + f_n \ge 0$ gives $\int_E (g + f) \, d\mu \le \int_E g \, d\mu + \liminf_n a_n$.
Fatou applied to $g - f_n \ge 0$ gives $\int_E (g - f) \, d\mu \le \int_E g \, d\mu - \limsup_n a_n$.
Subtracting $\int_E g \, d\mu < +\infty$ gives $\int_E f \, d\mu \le \liminf_n a_n \le \limsup_n a_n \le \int_E f \, d\mu$.

Structural Commentary: Domination reduces signed convergence to two Fatou bounds.
Key Insight: Apply Fatou to $g + f_n$ and $g - f_n$. □

Theorem 1.3.8. *General Dominated Convergence*
Let $E \in \mathcal{M}$, let f_n, f, g be measurable on E, and let $g_n \ge 0$ be integrable on E.
Suppose $f_n \to f$ and $g_n \to g$ a.e. on E, with $\forall n$, $|f_n| \le g_n$ a.e. on E.
Assume $\lim_n \int_E g_n \, d\mu = \int_E g \, d\mu < +\infty$. Then:
(i) $\forall n$, $f_n \in \mathscr{L}^1(\mu)$ on E, and $f \in \mathscr{L}^1(\mu)$ on E.
(ii) $\lim_{n \to \infty} \int_E f_n \, d\mu = \int_E f \, d\mu$.

Proof. Choose null $N \subseteq E$ so that $f_n \to f$, $g_n \to g$, and $\forall n$, $|f_n| \le g_n$ on $E \setminus N$.
Changing values on N does not change integrals, so assume these relations hold on E.

(i) Since $|f_n| \le g_n \in \mathscr{L}^1(\mu)$, $f_n \in \mathscr{L}^1(\mu)$ on E by Theorem 1.2.18(ii).
Passing to the limit gives $|f| \le g$, and $\int_E g \, d\mu < +\infty$, hence $f \in \mathscr{L}^1(\mu)$ on E.
(ii) Put $a_n := \int_E f_n \, d\mu$, $b_n := \int_E g_n \, d\mu$, and $b := \int_E g \, d\mu$; then $b_n \to b$.
Fatou applied to $g_n + f_n \ge 0$ gives $b + \int_E f \, d\mu \le \liminf_n (b_n + a_n) = b + \liminf_n a_n$.
Fatou applied to $g_n - f_n \ge 0$ gives $b - \int_E f \, d\mu \le \liminf_n (b_n - a_n) = b - \limsup_n a_n$.
Subtracting $b < +\infty$ gives $\limsup_n a_n \le \int_E f \, d\mu \le \liminf_n a_n$, hence $a_n \to \int_E f \, d\mu$.

Structural Commentary: Varying domination works when masses converge.
Key Insight: Fatou on $g_n \pm f_n$ traps the limit. □

Corollary 1.3.9. *Monotone Convergence Almost Everywhere*
Let $E \in \mathcal{M}$ and $0 \le f_n \uparrow f$ a.e. on E. Then $\int_E f_n \, d\mu \uparrow \int_E f \, d\mu$.

Proof. Choose $N \subseteq E$ with $\mu(N) = 0$ and $f_n \uparrow f$ on $E \setminus N$. Set $g_n := f_n \mathbf{1}_{E \setminus N}$ and $g := f\mathbf{1}_{E \setminus N}$.
Then $0 \le g_n \uparrow g$, so $\int_E g_n \, d\mu \uparrow \int_E g \, d\mu$. Since $f_n = g_n$ and $f = g$ off N, the integrals over N vanish.
Structural Commentary: Monotone convergence ignores null exceptional sets.
Key Insight: Remove the exceptional set, prove the theorem there, then add back zero. □

Example 1.3.10. *Counting Measure Integrals Are Series*

Let μ be counting measure on $(\mathbb{N}, 2^{\mathbb{N}})$. For $f : \mathbb{N} \to [0, +\infty]$, set $s_N := \sum_{n=1}^{N} f(n)\mathbf{1}_{\{n\}}$; then $0 \le s_N \uparrow f$, with the case $f(k) = +\infty$ giving both sides $+\infty$. Hence $\int_{\mathbb{N}} f\, d\mu = \lim_N \int_{\mathbb{N}} s_N\, d\mu = \lim_N \sum_{n=1}^{N} f(n) = \sum_{n=1}^{\infty} f(n)$.

Structural Commentary: Counting measure turns integration into summation.
Key Insight: Finite-support truncations are the simple-function partial sums.

Example 1.3.11. *Boundary Tests for Monotone Convergence and Fatou*

On $([0, +\infty), \mathcal{B}, m)$:

(i) $f_n := \mathbf{1}_{[0,n]} \uparrow \mathbf{1}_{[0,+\infty)}$ and $\int f_n\, dm = n \uparrow +\infty$; monotone convergence allows $+\infty$.
(ii) $g_n := n^{-1}\mathbf{1}_{[n,+\infty)} \downarrow 0$ uniformly, but $\int g_n\, dm = +\infty\ \forall n$; decreasing convergence needs finite mass.
(iii) $w_n := -n^{-1}\mathbf{1}_{[0,n]} \rightrightarrows 0$, but $\int w_n\, dm = -1$; Fatou can fail without $f_n \ge 0$ or $f_n \ge -h \in L^1$.

Theorem 1.3.12. *Fatou with an Integrable Lower Bound*

Let $h \ge 0$, $h \in \mathscr{L}^1(\mu)$, and let f_n be measurable with $f_n \ge -h$.
Then, whenever the signed integrals are defined in $\overline{\mathbb{R}}$, $\int \liminf_{n\to\infty} f_n\, d\mu \le \liminf_{n\to\infty} \int f_n\, d\mu$.

Proof. Set $F_n := f_n + h \ge 0$. Fatou gives $\int \liminf_n F_n\, d\mu \le \liminf_n \int F_n\, d\mu$.
Since $\liminf_n F_n = h + \liminf_n f_n$ and $\int F_n\, d\mu = \int f_n\, d\mu + \int h\, d\mu$, subtract the finite term $\int h\, d\mu$.
Structural Commentary: Fatou survives controlled negative parts.
Key Insight: Add an integrable floor to make the sequence nonnegative. □

Remark 1.3.13. *Why the Negative Example Has No Floor*

For $w_n := -n^{-1}\mathbf{1}_{[0,n]}$, any $h \in L^1$ with $-h \le w_n\ \forall n$ must satisfy $h \ge n^{-1}$ on $[0, n]$.
Thus $h \ge k^{-1}$ on $[k-1, k]$, and $\int_0^N h\, dm \ge H_N := \sum_{k=1}^{N} \frac{1}{k} \to +\infty$, contradicting $h \in L^1$.

Perspective 1.3.14. *Domination Is the Safeguard*

$f_n \to f$ a.e. need not imply $\int f_n \to \int f$; domination $|f_n| \le g \in L^1$ restores the limit interchange.

Example 1.3.15. *A Nonuniform Limit with Vanishing Integrals*

For $x > 0$, set $f_n(x) := e^{-nx}x^{-\frac{1}{2}}$. Then $f_n \to 0$ pointwise, but $\forall \delta > 0$, $\sup_{0<x<\delta} f_n(x) = +\infty$.
For $n \ge 1$, $0 \le f_n \le g := e^{-x}x^{-\frac{1}{2}}$; $g \le x^{-\frac{1}{2}}\mathbf{1}_{(0,1]} + e^{-x}\mathbf{1}_{[1,\infty)} \in \mathscr{L}^1(0, \infty)$.
Thus dominated convergence gives $I_n := \int_0^\infty e^{-nx}x^{-\frac{1}{2}}\, dx \to 0$.
Structural Commentary: Uniform convergence is unnecessary once one integrable envelope controls the sequence.
Key Insight: Domination handles the singular behavior at 0 and the tail at infinity simultaneously.

Proposition 1.3.16. *Uniform Convergence on Finite Measure Spaces*

Assume $\mu(X) < +\infty$.

(i) If $0 \le f_n$ are measurable and $f_n \rightrightarrows f$, then $f \ge 0$ is measurable and $\int_X f\, d\mu = \lim_n \int_X f_n\, d\mu$ in $[0, +\infty]$.
(ii) If $f_n \in \mathscr{L}^1(\mu)$ and $f_n \rightrightarrows f$, then $f \in \mathscr{L}^1(\mu)$ and $\int_X f_n\, d\mu \to \int_X f\, d\mu$ in $\mathbb{R}$.

Proof.

(i) Measurability and $f \ge 0$ pass to pointwise limits. For $\varepsilon > 0$ and $n \gg 1$, $f \le f_n + \varepsilon\mathbf{1}_X$ and $f_n \le f + \varepsilon\mathbf{1}_X$.
Thus $\int_X f\, d\mu \le \int_X f_n\, d\mu + \varepsilon\mu(X)$ and $\int_X f_n\, d\mu \le \int_X f\, d\mu + \varepsilon\mu(X)$. Let $\varepsilon \downarrow 0$.
(ii) Choose N with $|f - f_N| \le 1$. Then $f = f_N + (f - f_N) \in \mathscr{L}^1(\mu)$, and
$\left|\int_X f_n\, d\mu - \int_X f\, d\mu\right| \le \int_X |f_n - f|\, d\mu \le \mu(X) \sup_X |f_n - f| \to 0$.

Structural Commentary: On finite measure spaces, uniform error controls integral error.
Key Insight: Finiteness of $\mu(X)$ turns a supremum bound into an integral bound. □

Theorem 1.3.17. *Bounded Convergence on Finite Measure Spaces*

Let $\mu(X) < +\infty$, and let $f_n, f : X \to \mathbb{R}$ be measurable.
Suppose $f_n \to f$ a.e. and $\exists M < +\infty$ such that $\forall n$, $|f_n| \le M$ a.e. Then:

(i) $f \in \mathscr{L}^1(\mu)$.
(ii) $\lim_{n\to\infty} \int_X f_n\, d\mu = \int_X f\, d\mu$.

Proof. Since $|f_n| \le M$ a.e. and $f_n \to f$ a.e., $|f| \le M$ a.e.
Set $G := M\mathbf{1}_X$. Then $G \in \mathscr{L}^1(\mu)$, since $\int_X G\, d\mu = M\mu(X) < +\infty$.

(i) Since $|f| \le G$ a.e., $f \in \mathscr{L}^1(\mu)$ by Theorem 1.2.18(ii).
(ii) Since $\forall n$, $|f_n| \le G$ a.e., $\int_X f_n\, d\mu \to \int_X f\, d\mu$ by Theorem 1.3.7(ii).

Structural Commentary: On a finite-measure space, a uniform pointwise bound is an integrable dominator.
Key Insight: Bounded convergence is the finite-measure special case of dominated convergence. □

Example 1.3.18. *Why the Finite-Measure Hypothesis Matters*

On $(\mathbb{R}, m)$, let $f_n := n^{-1}\mathbf{1}_{[0,n]}$. Then $\|f_n\|_\infty = \frac{1}{n} \to 0$, but $\int_{\mathbb{R}} f_n\, dm = 1\ \forall n$.
Thus uniform convergence need not commute with integrals when $m(\mathbb{R}) = +\infty$; Fatou only yields $0 \le 1$.

Example 1.3.19. *Why Domination Cannot Be Dropped*

On $(\mathbb{R}, m)$, let $f_n := n\mathbf{1}_{[\frac{1}{n}, \frac{2}{n}]}$. Then $f_n \to 0$ pointwise, but $\int_{\mathbb{R}} f_n\, dm = 1\ \forall n$.
Thus pointwise convergence without domination need not commute with integrals; Fatou only yields $0 \le 1$.

Theorem 1.3.20. *Absolutely Summable L^1 Series*
Let $f_n \in \mathscr{L}^1(\mu)$ and $\sum_{n\geq 1} \|f_n\|_1 < +\infty$.
Set $S_N := \sum_{n=1}^{N} f_n$. Then $\exists f : X \to \mathbb{R}$ measurable such that:
(i) $S_N \to f$ absolutely a.e.
(ii) $f \in \mathscr{L}^1(\mu)$.
(iii) $\int_X f\,d\mu = \sum_{n\geq 1} \int_X f_n\,d\mu$.

Proof. Set $G := \sum_{n\geq 1} |f_n|$. By monotone convergence, $\int_X G\,d\mu = \sum_{n\geq 1} \|f_n\|_1 < +\infty$, so $G < +\infty$ a.e. and $G \in \mathscr{L}^1(\mu)$. Define $f := \lim_N S_N$ on $\{G < +\infty\}$ and $f := 0$ elsewhere.

(i) Since $G < +\infty$ a.e., $\sum_{n\geq 1} |f_n| < +\infty$ a.e.; hence $S_N \to f$ absolutely a.e.

(ii) Since $|f| \leq G$ a.e. and $G \in \mathscr{L}^1(\mu)$, $f \in \mathscr{L}^1(\mu)$ by Theorem 1.2.18(ii).

(iii) Since $|S_N| \leq G$ and $S_N \to f$ a.e., dominated convergence gives

$$\int_X f\,d\mu = \lim_N \int_X S_N\,d\mu = \lim_N \sum_{n=1}^{N} \int_X f_n\,d\mu = \sum_{n\geq 1} \int_X f_n\,d\mu.$$

Structural Commentary: Absolute summability in L^1 gives a.e. absolute convergence and termwise integration.
Key Insight: First integrate the nonnegative majorant $\sum |f_n|$. □

Proposition 1.3.21. *L^1 Convergence Controls Absolute Integrals*
If $f_n, f \in \mathscr{L}^1(\mu)$ and $\|f_n - f\|_1 \to 0$, then:
(i) $\|f_n\|_1 \to \|f\|_1$.
(ii) $\int_X |f|\,d\mu = \lim_n \int_X |f_n|\,d\mu$.

Proof.

(i) The reverse triangle inequality gives $||f_n| - |f|| \leq |f_n - f|$; hence $\big|\|f_n\|_1 - \|f\|_1\big| \leq \|f_n - f\|_1 \to 0$.

(ii) Since $\|h\|_1 = \int_X |h|\,d\mu$, item (i) gives $\int_X |f_n|\,d\mu \to \int_X |f|\,d\mu$.

Structural Commentary: L^1 convergence is strong enough to converge the L^1 sizes.
Key Insight: The reverse triangle inequality converts function convergence into norm convergence. □

Proposition 1.3.22. *Finite Integral Localizes to Finite Measure*
Let $f : X \to [0, +\infty]$ be measurable and $\int_X f\,d\mu < +\infty$. For $n \geq 1$, set $E_n := \{\frac{1}{n} < f \leq n\}$. Then:
(i) $\forall n,\ \mu(E_n) < +\infty$.
(ii) $\int_{X\setminus E_n} f\,d\mu \downarrow 0$.
Consequently, $\forall \varepsilon > 0\ \exists E \in \mathcal{M}$ with $\mu(E) < +\infty$ and $\int_{X\setminus E} f\,d\mu < \varepsilon$.

Proof.

(i) Since $f > \frac{1}{n}$ on E_n, $\mu(E_n) \leq n \int_{E_n} f\,d\mu \leq n \int_X f\,d\mu < +\infty$.

(ii) Since $f\mathbf{1}_{E_n} \uparrow f$ a.e., monotone convergence gives $\int_{E_n} f\,d\mu \uparrow \int_X f\,d\mu$.
Thus $\int_{X\setminus E_n} f\,d\mu = \int_X f\,d\mu - \int_{E_n} f\,d\mu \downarrow 0$.

Given $\varepsilon > 0$, choose n with $\int_{X\setminus E_n} f\,d\mu < \varepsilon$ and set $E = E_n$.
Structural Commentary: Finite integral mass can be captured on a finite-measure part of the space.
Key Insight: Keep the levels where f is bounded above and away from zero. □

Proposition 1.3.23. *Setwise Convergence from Total Mass Convergence*
Let $f_n, f : X \to [0, +\infty]$ be measurable, $f_n \to f$ pointwise, and $\int_X f\,d\mu = \lim_{n\to\infty} \int_X f_n\,d\mu < +\infty$.
Then $\forall E \in \mathcal{M}$, $\int_E f\,d\mu = \lim_{n\to\infty} \int_E f_n\,d\mu$.

Proof. Fix $E \in \mathcal{M}$ and set $E^c := X \setminus E$. By Fatou, $\int_E f\,d\mu \leq \liminf_n \int_E f_n\,d\mu$ and $\int_{E^c} f\,d\mu \leq \liminf_n \int_{E^c} f_n\,d\mu$.
Since $\int_X f_n\,d\mu = \int_E f_n\,d\mu + \int_{E^c} f_n\,d\mu \to \int_X f\,d\mu < +\infty$, $\limsup_n \int_E f_n\,d\mu \leq \int_X f\,d\mu - \int_{E^c} f\,d\mu = \int_E f\,d\mu$.
Thus $\liminf_n \int_E f_n\,d\mu = \limsup_n \int_E f_n\,d\mu = \int_E f\,d\mu$.
Structural Commentary: Total mass plus Fatou on complements fixes each part.
Key Insight: A lower bound on the complement is an upper bound on the chosen set. □

Example 1.3.24. *Why the Finite Total Mass Assumption Matters*
Let $X = \mathbb{N} \times \{0, 1\}$ with counting measure, set $E := \mathbb{N} \times \{1\}$.
Define $f := \mathbf{1}_{\mathbb{N}\times\{0\}}$; $f_n := \mathbf{1}_{\{1,\dots,n\}\times\{0\}} + n\mathbf{1}_{\{n\}\times\{1\}}$.
Then $f_n \to f$ pointwise and $\int_X f\,d\mu = \lim_n \int_X f_n\,d\mu = +\infty$; $\int_E f\,d\mu = 0$, $\int_E f_n\,d\mu = n$.
Thus Proposition 1.3.23 can fail when the common total mass is infinite.

Definition 1.3.25. *Function Truncates*
For $f : X \to \mathbb{R}$ and $n \in \mathbb{N}$, define the *nth truncate*

$$T_n f(x) := (-n) \vee (f(x) \wedge n) = \begin{cases} -n, & f(x) < -n, \\ f(x), & -n \leq f(x) \leq n, \\ n, & f(x) > n. \end{cases}$$

Proposition 1.3.26. *Truncates Characterize Integrability*
Let $f : X \to \mathbb{R}$ be measurable and set $f_n := T_n f$ for $n \in \mathbb{N}$.
(i) $f \in \mathscr{L}^1(\mu) \iff \sup_n \|f_n\|_1 < +\infty$.
(ii) If $f \in \mathscr{L}^1(\mu)$, then $\int_X f_n \, d\mu \to \int_X f \, d\mu$.

Proof. $\forall n$, $T_n : \mathbb{R} \to [-n, n]$ is continuous, so f_n is measurable; moreover $f_n \to f$, $|f_n| \le |f|$, and $|f_n| \uparrow |f|$.
(i) ($\Rightarrow$) If $f \in \mathscr{L}^1(\mu)$, then $\|f_n\|_1 \le \|f\|_1$ for all n, so $\sup_n \|f_n\|_1 < +\infty$.
(i) ($\Leftarrow$) If $\sup_n \|f_n\|_1 < +\infty$, then MCT gives $\|f\|_1 = \lim_{n\to\infty} \|f_n\|_1 = \sup_n \|f_n\|_1 < +\infty$, so $f \in \mathscr{L}^1(\mu)$.
(ii) If $f \in \mathscr{L}^1(\mu)$, then DCT applied to $f_n \to f$ with $|f_n| \le |f|$ gives $\int_X f_n \, d\mu \to \int_X f \, d\mu$.
Structural Commentary: Truncation reduces L^1 questions to bounded approximants.
Key Insight: MCT reads $\|f\|_1$ from $|f_n| \uparrow |f|$; DCT passes signed integrals. □

1.4 Parameter Integrals and Differentiation

Corollary 1.4.1. *Continuity Under a Lebesgue Integral*
Let $f_t(x) := f(x,t)$ be measurable $\forall t \in [a,b]$, and suppose $\forall t \in [a,b]$, $|f_t| \le g \in \mathscr{L}^1(\mu)$. Then:
(i) If $t_0 \in [a,b]$ and $f_t \to f_{t_0}$ a.e. as $t \to t_0$, then $\lim_{t\to t_0} \int_X f_t \, d\mu = \int_X f_{t_0} \, d\mu$.
(ii) If $t \mapsto f(x,t)$ is continuous on $[a,b]$ for a.e. x, then $F(t) := \int_X f_t \, d\mu$ is continuous on $[a,b]$.

Proof.
(i) For any $t_n \to t_0$, set $u_n := f_{t_n}$. Then $u_n \to f_{t_0}$ a.e. and $|u_n| \le g$, so dominated convergence gives $\int_X u_n \, d\mu \to \int_X f_{t_0} \, d\mu$. The sequential criterion gives the claim.
(ii) If $t \mapsto f(x,t)$ is continuous a.e., then $\forall t_0 \in [a,b]$, $f_t \to f_{t_0}$ a.e. as $t \to t_0$.
By item (i), $\forall t_0 \in [a,b]$, $F(t) \to F(t_0)$, so F is continuous on $[a,b]$.
Structural Commentary: Parameter continuity reduces to dominated convergence along sequences.
Key Insight: The parameter disappears once t_n is frozen into a sequence of functions. □

Theorem 1.4.2. *Differentiation Under a Lebesgue Integral*
Let $f_t(x) := f(x,t)$ be measurable $\forall t \in [a,b]$, and suppose $f_{t_0} \in \mathscr{L}^1(\mu)$ for some $t_0 \in [a,b]$.
Assume $t \mapsto f(x,t)$ is continuous on $[a,b]$ and differentiable on (a,b) $\forall x \in X$, and $\exists g \in \mathscr{L}^1(\mu)$ such that $\forall (x,t) \in X \times (a,b)$, $|\partial_t f(x,t)| \le g(x)$. For $t \in (a,b)$, set $D_t(x) := \partial_t f(x,t)$; set $F(t) := \int_X f_t \, d\mu$. Then:
(i) $\forall t \in (a,b)$, D_t is measurable.
(ii) $\forall t \in [a,b]$, $f_t \in \mathscr{L}^1(\mu)$.
(iii) F is differentiable on (a,b), and $\forall t \in (a,b)$, $F'(t) = \int_X D_t \, d\mu$.

Proof.
(i) Fix $t \in (a,b)$ and choose $h_k \to 0$ with $t + h_k \in [a,b]$, $h_k \neq 0$.
The quotients $\frac{f_{t+h_k} - f_t}{h_k}$ are measurable and converge pointwise to D_t, so D_t is measurable.
(ii) By the mean value theorem, $|f_t - f_{t_0}| \le |t - t_0| \, g$, so $|f_t| \le |f_{t_0}| + |t - t_0| \, g \in \mathscr{L}^1(\mu)$.
(iii) If $t_n \to t \in (a,b)$ and $t_n \neq t$, then $\frac{F(t_n) - F(t)}{t_n - t} = \int_X \frac{f_{t_n} - f_t}{t_n - t} \, d\mu$. The integrand converges pointwise to D_t and has modulus at most g, so dominated convergence gives $\frac{F(t_n) - F(t)}{t_n - t} \to \int_X D_t \, d\mu$.
Structural Commentary: Bounded parameter derivatives dominate the difference quotients.
Key Insight: Differentiating the integral is just applying dominated convergence to secant slopes. □

Corollary 1.4.3. *A Pointwise Difference-Quotient Test*
Let $f_t(x) := f(x,t)$ be measurable $\forall t \in [a,b]$, let $f_{t_0} \in \mathscr{L}^1(\mu)$ for some $t_0 \in [a,b]$, and fix $t_1 \in [a,b]$.
Assume $\partial_t f(x,t_1)$ exists $\forall x$. For $t \neq t_1$, set $Q_t(x) := \frac{f_t(x) - f_{t_1}(x)}{t - t_1}$, $|Q_t| \le g$ for some $g \in \mathscr{L}^1(\mu)$.
Set $F(t) := \int_X f_t \, d\mu$. Then:
(i) $\forall t \in [a,b]$, $f_t \in \mathscr{L}^1(\mu)$.
(ii) F is differentiable at t_1, and $F'(t_1) = \int_X \partial_t f(x,t_1) \, d\mu$.

Proof.
(i) If $t_0 \neq t_1$, then $|f_{t_1}| \le |f_{t_0}| + |t_0 - t_1| \, g$; if $t_0 = t_1$, this is given.
Hence $f_{t_1} \in \mathscr{L}^1(\mu)$. For $t \neq t_1$, $|f_t| \le |f_{t_1}| + |t - t_1| \, g$, so $f_t \in \mathscr{L}^1(\mu)$.
(ii) For any $t_n \to t_1$ with $t_n \neq t_1$, $Q_{t_n} \to \partial_t f(\cdot, t_1)$ pointwise and $|Q_{t_n}| \le g$.
Dominated convergence gives $\frac{F(t_n) - F(t_1)}{t_n - t_1} \to \int_X \partial_t f(x,t_1) \, d\mu$.
Structural Commentary: One parameter point needs only domination of the secants into that point.
Key Insight: A global derivative bound is sufficient, but not necessary, for a one-point formula. □

Example 1.4.4. *Differentiating Under the Integral Sign*
For $t > 0$, set $F(t) := \int_0^\infty x^2 e^{-tx} \, dx$. For $t_0 > 0$ and $0 < |h| < \frac{t_0}{2}$, put $Q_h(x) := \frac{x^2 e^{-(t_0+h)x} - x^2 e^{-t_0 x}}{h}$.
Then $Q_h \to -x^3 e^{-t_0 x}$ pointwise and $|Q_h| \le x^3 e^{-\frac{t_0 x}{2}} \in \mathscr{L}^1(0,\infty)$. Hence $F'(t_0) = -\int_0^\infty x^3 e^{-t_0 x} \, dx$.
Structural Commentary: Parameter differentiation is a limit-interchange problem.
Key Insight: Prove a local-in-parameter integrable majorant for the difference quotients.

Example 1.4.5. *Laplace Transform Powers and Factorials*
For $t > 0$, set $I(t) := \int_0^\infty e^{-tx}\,dx$. Then $I(t) = \lim_{b\to+\infty} \frac{1-e^{-tb}}{t} = t^{-1}$.

For $[a,b] \subset (0,+\infty)$ and $k \geq 0$, $0 \leq x^k e^{-tx} \leq x^k e^{-ax} \in \mathscr{L}^1(0,\infty)$, so repeated differentiation under the integral gives $I^{(n)}(t) = (-1)^n \int_0^\infty x^n e^{-tx}\,dx$. Since $I^{(n)}(t) = (-1)^n n! t^{-n-1}$, $\forall n \in \mathbb{N}\cup\{0\}$, $\int_0^\infty x^n e^{-x}\,dx = n!$.
Structural Commentary: A parameter integral turns powers of x into derivatives in t.
Key Insight: The exponential envelope e^{-ax} controls all nearby parameter values $t \geq a$.

Corollary 1.4.6. *One Lebesgue and One Riemann Integral*
Let $f_t(x) := f(x,t)$, $t \in [a,b]$, with f_t measurable, $t \mapsto f(x,t)$ continuous a.e., and $\forall t \in [a,b]$, $|f_t| \leq g \in \mathscr{L}^1(\mu)$. Then, with Riemann integrals in t, $\int_a^b \left[\int_X f_t\,d\mu\right] dt = \int_X \left[\int_a^b f(x,t)\,dt\right] d\mu(x)$.

Proof. Set $h_t(x) := \int_a^t f(x,s)\,ds$. Then h_t is measurable, $|h_t| \leq (b-a)g$, and $\partial_t h_t = f_t$.
By differentiation under the integral, $H(t) := \int_X h_t\,d\mu$ satisfies $H'(t) = \int_X f_t\,d\mu$.
Hence $\int_a^b \left[\int_X f_t\,d\mu\right] dt = H(b) - H(a) = \int_X \left[\int_a^b f(x,t)\,dt\right] d\mu(x)$.
Structural Commentary: Finite parameter integrals move through by differentiating primitives.
Key Insight: Integrate first in the parameter up to t, then differentiate the resulting Lebesgue integral. □

Corollary 1.4.7. *Improper Parameter Interchange*
Let $f_t(x) := f(x,t)$ be measurable $\forall t \in \mathbb{R}$, and let $t \mapsto f(x,t)$ be continuous for a.e. x. Suppose $\exists g, h \in \mathscr{L}^1(\mu)$ such that $|f_t| \leq g$ $\forall t$ and $\int_{\mathbb{R}} |f(x,t)|\,dt \leq h(x)$ for a.e. x. Put $G(t) := \int_X f_t\,d\mu$, $H(x) := \int_{\mathbb{R}} f(x,t)\,dt$, and $H_R(x) := \int_{-R}^R f(x,t)\,dt$. Then:

(i) $H \in \mathscr{L}^1(\mu)$.
(ii) $\lim_{R\to+\infty} \int_{-R}^R G(t)\,dt = \int_X H\,d\mu$.

Thus $\int_{\mathbb{R}} G := \lim_{R\to+\infty} \int_{-R}^R G(t)\,dt$ exists and equals $\int_X H\,d\mu$.

Proof.
(i) Since $|H| \leq \int_{\mathbb{R}} |f(x,t)|\,dt \leq h$ a.e. and $h \in \mathscr{L}^1(\mu)$, $H \in \mathscr{L}^1(\mu)$ by Theorem 1.2.18(ii).
(ii) For $R > 0$, finite-interval interchange gives $\int_{-R}^R G(t)\,dt = \int_X H_R\,d\mu$.
Since $H_R \to H$ a.e. and $|H_R| \leq h$, dominated convergence gives $\int_X H_R\,d\mu \to \int_X H\,d\mu$.
Structural Commentary: Finite interchanges pass to improper limits under an L^1 bound.
Key Insight: Truncate in t, interchange on finite intervals, then pass $R \to +\infty$ by domination in x. □

1.5 Riemann-Lebesgue Comparison

Lemma 1.5.1. *Monotone Integral Squeeze*
Let $E \in \mathcal{M}$, $(\varphi_n), (\psi_n) \subseteq \mathscr{L}^1(\mu)$ on E, and $f : E \to \mathbb{R}$. Assume $\varphi_n \uparrow$, $\psi_n \downarrow$, $\varphi_n \leq f \leq \psi_n$ on E, and $\int_E (\psi_n - \varphi_n)\,d\mu \to 0$. Put $\varphi := \lim_n \varphi_n$ and $\psi := \lim_n \psi_n$. Then:

(i) $\varphi = \psi$ *a.e. on* E.
(ii) For $h := \varphi$, $f = h$ a.e., $h \in \mathscr{L}^1(\mu)$ on E, and $\int_E \varphi_n\,d\mu, \int_E \psi_n\,d\mu \to \int_E h\,d\mu$.

Proof.
(i) The limits φ, ψ are measurable and $\varphi \leq f \leq \psi$.
Since $0 \leq \psi - \varphi \leq \psi_n - \varphi_n$, $0 \leq \int_E (\psi - \varphi)\,d\mu \leq \int_E (\psi_n - \varphi_n)\,d\mu \to 0$; hence $\psi = \varphi$ a.e.
(ii) Let h be the common a.e. value from (i). Then $f = h$ a.e. and $|h| \leq |\varphi_1| + |\psi_1|$ a.e., so $h \in \mathscr{L}^1(\mu)$ on E.
Monotone convergence applied to $\varphi_n - \varphi_1 \uparrow h - \varphi_1$ and $\psi_1 - \psi_n \uparrow \psi_1 - h$ gives $\int_E \varphi_n\,d\mu, \int_E \psi_n\,d\mu \to \int_E h\,d\mu$.
Structural Commentary: Vanishing gaps collapse monotone envelopes.
Key Insight: Integral gaps force the two monotone limits to coincide a.e. □

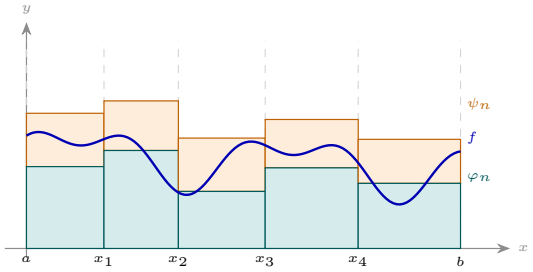

Figure 201: Step envelopes squeeze f to a common a.e. limit.

Theorem 1.5.2. *Comparison with the Riemann Integral*
Let m be Lebesgue measure on $[a,b]$ and let $f \in \mathcal{R}[a,b]$.

(i) $f \in \mathscr{L}^1(m)$.
(ii) $\int_{[a,b]} f\,dm = \int_a^b f(x)\,dx$.

Proof. Choose nested partitions P_n with $U(P_n,f) - L(P_n,f) \to 0$. Let φ_n, ψ_n be lower and upper step envelopes.
(i) Lemma 1.5.1 gives $f \in \mathscr{L}^1(m)$.

(ii) Since $\int \varphi_n\,dm = L(P_n,f)$ and $\int \psi_n\,dm = U(P_n,f)$, Lemma 1.5.1 gives $\int_{[a,b]} f\,dm = \lim_n L(P_n,f) = \lim_n U(P_n,f) = \int_a^b f(x)\,dx$.

Structural Commentary: Darboux envelopes squeeze the Lebesgue integral.
Key Insight: Vanishing Darboux gap identifies the two integral notions. □

Corollary 1.5.3. *Riemann Integrable Functions as Monotone Step Limits*
Let $f:[a,b]\to\mathbb{R}$ be Riemann integrable. Then $\exists(\varphi_n),(\psi_n)$ step-function sequences such that

(i) $\varphi_n\uparrow$, $\psi_n\downarrow$, and $\varphi_n\le f\le\psi_n$ on $[a,b]$;
(ii) $\lim_n \int_a^b \varphi_n\,dx = \lim_n \int_a^b \psi_n\,dx = \int_a^b f\,dx$;
(iii) $\varphi_n,\psi_n\to f$ a.e.; hence f is Lebesgue measurable and $\int_{[a,b]} f\,dm = \int_a^b f\,dx$.

Proof.

(i) Choose nested partitions P_n with $\max_{I\in P_n}\ell(I)\to 0$ and $U(P_n,f)-L(P_n,f)\to 0$.
Let φ_n,ψ_n be the lower and upper step envelopes on P_n; refinement gives $\varphi_n\uparrow$, $\psi_n\downarrow$, and $\varphi_n\le f\le\psi_n$.
(ii) Since $\int_a^b \varphi_n\,dx = L(P_n,f)$ and $\int_a^b \psi_n\,dx = U(P_n,f)$, by Darboux gap condition, both limits equal $\int_a^b f\,dx$.
(iii) By Lemma 1.5.1, $\exists h\in\mathscr{L}^1(m)$ with $h=f$ a.e., $\varphi_n,\psi_n\to h$ a.e., and $\int_{[a,b]} h\,dm = \lim_n \int_a^b \varphi_n\,dx = \int_a^b f\,dx$.

Structural Commentary: Riemann integrability is monotone step squeezing.
Key Insight: Refining partitions make Darboux sums into pointwise a.e. step approximations. □

Corollary 1.5.4. *Nonnegative Continuous Functions and Riemann Integrals*

(i) If $f\ge 0$ is continuous on $[a,b]$, then $\int_{[a,b]} f\,dm = \int_a^b f(x)\,dx$.
(ii) If $f\ge 0$ is continuous on $[0,+\infty)$, then $\int_{[0,+\infty)} f\,dm = \lim_{b\to+\infty}\int_0^b f(x)\,dx$ in $[0,+\infty]$.

Proof.

(i) Continuous f on $[a,b]$ is Riemann integrable; by Riemann–Lebesgue comparison, $\int_{[a,b]} f\,dm = \int_a^b f(x)\,dx$.
(ii) Put $f_b := f\mathbf{1}_{[0,b]}$. By (i), $\int_{[0,b]} f\,dm = \int_0^b f(x)\,dx$. As $b\uparrow+\infty$, $f_b\uparrow f$; monotone convergence gives the left limit, and the right limit is the nonnegative improper Riemann integral.

Structural Commentary: Compact comparison plus monotone truncation.
Key Insight: Truncate to compact intervals and pass upward. □

Theorem 1.5.5. *Lebesgue's Criterion for Riemann Integrability*
Let $f:[a,b]\to\mathbb{R}$ be bounded with discontinuity set D_f. Then $f\in\mathcal{R}[a,b]\iff m(D_f)=0$.

Proof. Set $\omega_f(x) := \lim_{r\downarrow 0}\operatorname{diam} f([a,b]\cap(x-r,x+r))$ and $D_k := \{x:\omega_f(x)\ge\frac{1}{k}\}$; then $D_f = \bigcup_{k\ge1} D_k$.

($\Rightarrow$) Fix k and $\varepsilon>0$. Choose P with $U(P,f)-L(P,f)<\frac{\varepsilon}{k}$. Set $\mathcal{B} := \{I\in P:\operatorname{int} I\cap D_k\neq\emptyset\}$.
Then $\frac{1}{k}\sum_{I\in\mathcal{B}}\ell(I)\le U(P,f)-L(P,f)$, so $\sum_{I\in\mathcal{B}}\ell(I)<\varepsilon$.
These intervals plus the partition points cover D_k; hence $m(D_k)=0$ and $m(D_f)=0$.
($\Leftarrow$) Suppose $m(D_f)=0$ and $|f|\le B$. If $B=0$, $f\in\mathcal{R}[a,b]$. For $B>0$ and $\varepsilon>0$, choose k with $\frac{b-a}{k}<\frac{\varepsilon}{2}$ and cover the compact null set D_k by finitely many intervals of total length $<\frac{\varepsilon}{4B}$.
Refining by this cover gives $U(P,f)-L(P,f)<\frac{b-a}{k}+\frac{\varepsilon}{2}<\varepsilon$, hence $f\in\mathcal{R}[a,b]$.

Structural Commentary: Darboux gaps measure oscillation.
Key Insight: Riemann failure is positive-measure discontinuity. □

Remark 1.5.6. *Small Discontinuity Sets*
The same idea underlies Theorem 1.5.5: discontinuity sets of measure zero, in the sense of Definition 4.1.13, do not obstruct Riemann integrability. Dirichlet's function fails because every point is discontinuous.

Example 1.5.7. *Dirichlet Function: Lebesgue but Not Riemann*
Let $D := \mathbf{1}_{\mathbb{Q}\cap[0,1]}$. Since $\mathbb{Q}\cap[0,1]$ is countable, $D=0$ a.e. on $[0,1]$, so $\int_{[0,1]} D\,dm = 0$.
Every nondegenerate subinterval $I\subseteq[0,1]$ meets both $\mathbb{Q}$ and $\mathbb{R}\setminus\mathbb{Q}$, hence $\inf_I D = 0$ and $\sup_I D = 1$.
Thus all lower Darboux sums are 0, all upper Darboux sums are 1, and D is not Riemann integrable.
Structural Commentary: Null support, dense oscillation.
Key Insight: A dense null set can be harmless for Lebesgue integration and fatal for Riemann integration.

Perspective 1.5.8. *Lebesgue's Criterion as a Roadmap*
For bounded $f:[a,b]\to\mathbb{R}$ with discontinuity set D_f, $f\in\mathcal{R}[a,b]\iff m(D_f)=0$.
Thus finite, countable, and null Cantor-type D_f are allowed, while $D_f=[a,b]$ is not.

1.6 Littlewood and Lusin Approximation

The measurable world is often controlled by ordinary topological objects after discarding a small exceptional set. In the real-line finite-measure setting, this principle has three recurring forms: measurable sets are nearly elementary, measurable functions are nearly continuous, and a.e. convergence is nearly uniform.

Principle 1.6.1. *Littlewood's Three Principles, Finite-Measure Form*
For subsets of the real line with finite measure:

(i) measurable sets are nearly finite unions of intervals; see Corollary 6.2.4;
(ii) measurable functions are nearly continuous; this is Lusin's theorem below;
(iii) a.e. pointwise convergence is nearly uniform; see Egoroff's theorem, Theorem 1.6.3.

Key Insight: The word "nearly" means after changing or discarding a set of arbitrarily small measure.

Definition 1.6.2. *Almost Uniform Convergence*
Let (f_n) be measurable functions on X.

(i) $f_n \to f$ *almost uniformly* if $\forall \delta > 0\ \exists E_\delta \in \mathcal{M}$ with $\mu(E_\delta) < \delta$ and $f_n \rightrightarrows f$ on $X \setminus E_\delta$.
(ii) (f_n) is *almost uniformly Cauchy* if $\forall \delta > 0\ \exists E_\delta \in \mathcal{M}$ with $\mu(E_\delta) < \delta$ s.t. (f_n) uniformly Cauchy on $X \setminus E_\delta$.

Theorem 1.6.3. *Egoroff's Theorem*
If $\mu(X) < +\infty$, $f_n \to f$ a.e., with all functions finite-valued off null set, then $f_n \to f$ almost uniformly.

Proof. Absorb the null exceptional set into every later E_δ, and assume $\forall x \in X,\ f_n(x) \to f(x)$.
For $m, n \in \mathbb{N}$, set $E_n(m) := \bigcup_{k=n}^{\infty} \{|f_k - f| \geq \frac{1}{m}\}$. Then $E_n(m) \downarrow \emptyset$, so $\mu(E_n(m)) \to 0$ by Corollary 5.1.1.
Given $\delta > 0$, choose k_m with $\mu(E_{k_m}(m)) < \delta 2^{-m}$ and set $E_\delta := \bigcup_{m \geq 1} E_{k_m}(m)$.
Then $\mu(E_\delta) < \delta$, and $x \notin E_\delta$, $k \geq k_m$ imply $|f_k(x) - f(x)| < \frac{1}{m}$; hence $f_n \rightrightarrows f$ on $X \setminus E_\delta$.
Structural Commentary: Finite measure turns decreasing bad sets with empty intersection into small bad sets.
Key Insight: A.e. convergence is almost uniform on finite measure spaces. □

Example 1.6.4. *Egoroff Needs a Finite-Valued Limit*
On $([0,1], \lambda)$, set $f_n := n\mathbf{1}_{[0,1]}$. Then $\forall x,\ f_n(x) \to +\infty$, so the pointwise limit is not finite-valued. If $f_n \to f$ almost uniformly for finite-valued measurable f, then for some E with $\lambda(E) < \frac{1}{2}$, $f_n \rightrightarrows f$ on $[0,1] \setminus E$; this nonempty set has $f_n(x) = n \to +\infty$, contradicting finite-valued pointwise convergence.

Lemma 1.6.5. *Continuous Extension from a Closed Subset of $\mathbb{R}$*
Let $F \subseteq \mathbb{R}$ be closed and let $h : F \to \mathbb{R}$ be continuous. Then $\exists g \in C(\mathbb{R})$ such that $g|_F = h$.

Proof. Cases $F = \emptyset$ and $F = \mathbb{R}$ are immediate. Otherwise $\mathbb{R} \setminus F = \bigsqcup_\alpha I_\alpha$, set $g = h$ on F; on each component:

(i) If $I_\alpha = (a, b)$, set $g(x) := \frac{b-x}{b-a}h(a) + \frac{x-a}{b-a}h(b)$.
(ii) If $I_\alpha = (-\infty, b)$, set $g(x) := h(b)$.
(iii) If $I_\alpha = (a, +\infty)$, set $g(x) := h(a)$.

The formulas give continuity off F; at $x \in F$, adjacent finite endpoints converge to x.
Hence continuity of h gives $g(y) \to h(x)$ as $y \to x$. Thus $g \in C(\mathbb{R})$ and $g|_F = h$.
Structural Commentary: Fill complementary intervals.
Key Insight: Interpolate between boundary values. □

Proposition 1.6.6. *Simple Functions Are Nearly Continuous*
Let $E \in \mathcal{L}^1$ with $m(E) < +\infty$, and $s : E \to \mathbb{R}$ measurable simple. $\forall \varepsilon > 0$, $\exists F \subseteq E$ and $g : \mathbb{R} \to \mathbb{R}$ such that:

(i) F is closed.
(ii) $g \in C(\mathbb{R})$ and $g = s$ on F.
(iii) $m(E \setminus F) < \varepsilon$.

Proof. If $E = \emptyset$, take $F = \emptyset$ and $g = 0$. Otherwise $s = \sum_{i=1}^{N} a_i \mathbf{1}_{E_i}$ with disjoint measurable E_i and $E = \bigsqcup_i E_i$. Choose closed $F_i \subseteq E_i$ with $m(E_i \setminus F_i) < \frac{\varepsilon}{N}$, set $F := \bigcup_i F_i$, and define $h : F \to \mathbb{R}$ by $h|_{F_i} := a_i$.

(i) Each F_i is closed and $N < +\infty$, so F is closed; also $F \subseteq E$.
(ii) For $x \in F_i$, the closed set $\bigcup_{j \neq i} F_j$ misses x, so h is locally constant at x in F; hence $h \in C(F)$.
$\exists g \in C(\mathbb{R})$ with $g|_F = h = s|_F$ by Lemma 1.6.5.
(iii) $m(E \setminus F) \leq \sum_i m(E_i \setminus F_i) < \varepsilon$.

Structural Commentary: Closed cores isolate simple levels.
Key Insight: Approximate each level set from inside, then extend. □

Theorem 1.6.7. *Lusin's Theorem*
Let $E \in \mathcal{L}^1$ with $m(E) < +\infty$, $f : E \to \mathbb{R}$ measurable. $\forall \varepsilon > 0$, $\exists F \subseteq E$ and $g : \mathbb{R} \to \mathbb{R}$ such that:

(i) F is closed.
(ii) $g \in C(\mathbb{R})$ and $g = f$ on F.
(iii) $m(E \setminus F) < \varepsilon$.

Proof. Take simple $s_n : E \to \mathbb{R}$ with $s_n \to f$ pointwise.
Pick $A \subseteq E$ with $s_n \to f$ uniformly on A and $m(E \setminus A) < \frac{\varepsilon}{4}$, and closed $F_0 \subseteq A$ with $m(A \setminus F_0) < \frac{\varepsilon}{4}$.
For $n \geq 1$, choose closed $F_n \subseteq E$ with $s_n|_{F_n} \in C(F_n)$ and $m(E \setminus F_n) < \varepsilon 2^{-(n+1)}$. Set $F := \bigcap_{n \geq 0} F_n$.

(i) F is an intersection of closed sets and $F \subseteq E$.
(ii) Since $F \subseteq F_0 \subseteq A$, the continuous functions $s_n|_F$ converge uniformly to $f|_F$, so $f|_F \in C(F)$.
Since F is closed and $f|_F \in C(F)$, Lemma 1.6.5 gives $\exists g \in C(\mathbb{R})$ with $g|_F = f|_F$.
(iii) $m(E \setminus F) \leq m(E \setminus F_0) + \sum_{n \geq 1} m(E \setminus F_n) < \varepsilon$.

Structural Commentary: Discard a small set to gain continuity.
Key Insight: Simple cores plus Egoroff give uniform continuous limits. □

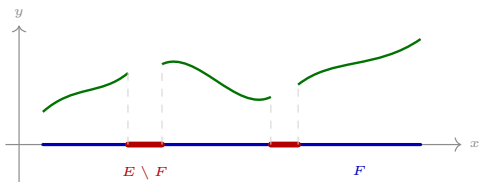

Figure 202: Lusin's theorem: keep F, discard $E \setminus F$, and extend with $g = f$ on F.

1.7 Convex Functions and Jensen's Inequality

Convexity is the geometric condition behind Jensen's inequality: averages move inside the argument, while supporting lines convert the nonlinear statement into a linear integral estimate.

Definition 1.7.1. *Convex Function on an Interval*
Let $I \subseteq \mathbb{R}$ be an interval and let $\varphi : I \to \mathbb{R}$.

(i) φ is *convex* iff $\forall x_1, x_2 \in I\ \forall \lambda \in [0,1]$, $\varphi(\lambda x_1 + (1-\lambda)x_2) \le \lambda\varphi(x_1) + (1-\lambda)\varphi(x_2)$.
(ii) Equivalently, $\forall x_1 < x < x_2$ in I, $\varphi(x) \le \frac{x_2 - x}{x_2 - x_1}\varphi(x_1) + \frac{x - x_1}{x_2 - x_1}\varphi(x_2)$.

Key Insight: Graphs lie below enclosing chords.

Lemma 1.7.2. *Chordal Slope Lemma*
Let $I \subseteq \mathbb{R}$ be an interval, let $\varphi : I \to \mathbb{R}$ be convex, and let $x_1, x, x_2 \in I$ satisfy $x_1 < x < x_2$.
Then $\frac{\varphi(x) - \varphi(x_1)}{x - x_1} \le \frac{\varphi(x_2) - \varphi(x_1)}{x_2 - x_1} \le \frac{\varphi(x_2) - \varphi(x)}{x_2 - x}$.

Proof. Since $x = \frac{x_2 - x}{x_2 - x_1}x_1 + \frac{x - x_1}{x_2 - x_1}x_2$, convexity gives $(x_2 - x_1)\varphi(x) \le (x_2 - x)\varphi(x_1) + (x - x_1)\varphi(x_2)$.
Rearrange, $(x_2 - x_1)(\varphi(x) - \varphi(x_1)) \le (x - x_1)(\varphi(x_2) - \varphi(x_1))$; $(x_2 - x)(\varphi(x_2) - \varphi(x_1)) \le (x_2 - x_1)(\varphi(x_2) - \varphi(x))$.
Divide by $(x - x_1)(x_2 - x_1) > 0$ and $(x_2 - x)(x_2 - x_1) > 0$, respectively.
Structural Commentary: One chord inequality, two rearrangements.
Key Insight: Convex secant slopes are nondecreasing. □

Proposition 1.7.3. *Increasing Derivative Gives Convexity*
Let $I \subseteq \mathbb{R}$ be open and let $\varphi : I \to \mathbb{R}$ be differentiable. If φ' is increasing on I, then φ is convex on I.
In particular, this holds if φ is twice differentiable and $\varphi'' \ge 0$ on I.

Proof. For $a < b$ in I, set $S(a,b) := \frac{\varphi(b) - \varphi(a)}{b - a}$. Let $u < v$ and $0 < \lambda < 1$, and put $x = \lambda u + (1-\lambda)v$.
By MVT, $S(u,x) = \varphi'(c_1)$, $S(x,v) = \varphi'(c_2)$ for some $c_1 \in (u,x)$, $c_2 \in (x,v)$. As $c_1 < c_2$, $S(u,x) \le S(x,v)$.
Clearing denominators, $\varphi(x) \le \frac{v - x}{v - u}\varphi(u) + \frac{x - u}{v - u}\varphi(v) = \lambda\varphi(u) + (1-\lambda)\varphi(v)$; the cases $\lambda = 0, 1$ are equality.
If $\varphi'' \ge 0$, for $a < b$, MVT gives $\varphi'(b) - \varphi'(a) = \varphi''(d)(b - a) \ge 0$ for some $d \in (a,b)$, so φ' is increasing.
Structural Commentary: MVT orders secant slopes.
Key Insight: Monotone slopes give convexity. □

Example 1.7.4. *Basic Convex Functions*
By Proposition 1.7.3, $x \mapsto x^p$ for $p \ge 1$, $x \mapsto e^{ax}$, and $x \mapsto \log(\frac{1}{x})$ are convex on $(0, +\infty)$, $\mathbb{R}$, and $(0, +\infty)$.

Proposition 1.7.5. *Finite Jensen Inequality*
Let $I \subseteq \mathbb{R}$ be an interval, $\varphi : I \to \mathbb{R}$ be convex, $x_1, \dots, x_n \in I$, $\lambda_1, \dots, \lambda_n \ge 0$ with $n \in \mathbb{N}$, $\sum_{k=1}^{n} \lambda_k = 1$.
Set $\bar{x} := \sum_{k=1}^{n} \lambda_k x_k$. Then $\bar{x} \in I$ and $\varphi(\bar{x}) \le \sum_{k=1}^{n} \lambda_k \varphi(x_k)$.

Proof. Induct on $m = \#\{k : \lambda_k > 0\}$. If $m = 1$, equality holds.
For $m \ge 2$, relabel so $\lambda_1, \dots, \lambda_m > 0$ and $\lambda_k = 0$ for $k > m$. Let $\Lambda = 1 - \lambda_m$ and $y = \Lambda^{-1} \sum_{k=1}^{m-1} \lambda_k x_k$.
By induction, $y \in I$ and $\varphi(y) \le \Lambda^{-1} \sum_{k=1}^{m-1} \lambda_k \varphi(x_k)$.
Since $\bar{x} = \Lambda y + \lambda_m x_m$, convexity gives $\bar{x} \in I$ and $\varphi(\bar{x}) \le \Lambda\varphi(y) + \lambda_m\varphi(x_m) \le \sum_{k=1}^{n} \lambda_k \varphi(x_k)$.
Structural Commentary: Induct by peeling off one weight.
Key Insight: Jensen iterates convexity. □

Lemma 1.7.6. *One-Sided Slopes and Supporting Lines*
Let $I \subseteq \mathbb{R}$ be open and let $\varphi : I \to \mathbb{R}$ be convex.

(i) $\forall x \in I$, $\varphi'(x-)$ and $\varphi'(x+)$ exist and are finite.
(ii) If $u < v$ in I, then $\varphi'(u-) \le \varphi'(u+) \le \frac{\varphi(v) - \varphi(u)}{v - u} \le \varphi'(v-) \le \varphi'(v+)$.
(iii) If $\alpha \in I$ and $\varphi'(\alpha-) \le m_0 \le \varphi'(\alpha+)$, then $\forall t \in I$, $\varphi(t) \ge \varphi(\alpha) + m_0(t - \alpha)$.

Proof. For $a < b$ in I, write $S(a,b) := \frac{\varphi(b) - \varphi(a)}{b - a}$.

(i) Fix $x \in I$ and choose $a < x < b$ in I.
If $a < r < s < x$, then $S(a,x) \le S(r,x) \le S(s,x) \le S(x,b)$ by Lemma 1.7.2, so $\lim_{r \uparrow x} S(r,x)$ exists in $\mathbb{R}$.
If $x < r < s < b$, the same lemma gives $S(a,x) \le S(x,r) \le S(x,s) \le S(x,b)$, so $\lim_{r \downarrow x} S(x,r)$ exists in $\mathbb{R}$.

(ii) Let $u < v$ in I. For $r < u < s < v$ and $u < q < v < t$, the chordal slope inequalities give
$S(r,u) \le S(u,s) \le S(u,v) \le S(q,v) \le S(v,t)$. Letting $r \uparrow u$, $s \downarrow u$, $q \uparrow v$, and $t \downarrow v$ gives asserted chain.

(iii) If $t = \alpha$, equality holds. If $t > \alpha$, then (ii) gives $m_0 \le \varphi'(\alpha+) \le S(\alpha, t)$, hence $\varphi(t) \ge \varphi(\alpha) + m_0(t-\alpha)$.
If $t < \alpha$, then (ii) gives $S(t, \alpha) \le \varphi'(\alpha-) \le m_0$, which rearranges to the same estimate.

Structural Commentary: Monotone secant slopes have finite one-sided limits.
Key Insight: One-sided slope bounds produce supporting lines. □

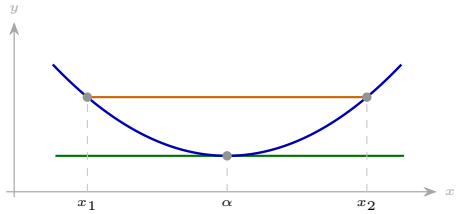

Figure 203: Color code: $y = \varphi(x)$ lies below the chord through x_1, x_2 and above the supporting line at α.

Theorem 1.7.7. *Jensen's Inequality on $[0,1]$*
Let m be Lebesgue measure on $[0,1]$, let $\varphi : \mathbb{R} \to \mathbb{R}$ be convex, and let $f, \varphi \circ f \in L^1(m)$.
Then $\varphi\left(\int f\, dm\right) \le \int \varphi(f)\, dm$.

Proof. Set $\alpha := \int f\, dm$. By Lemma 1.7.6, choose $m_0 \in [\varphi'(\alpha-), \varphi'(\alpha+)]$; $\varphi(t) \ge \varphi(\alpha) + m_0(t-\alpha)\ \forall t \in \mathbb{R}$.
Substituting $t = f$ and integrating gives $\int \varphi(f)\, dm \ge \varphi(\alpha) + m_0\left(\int f\, dm - \alpha\right) = \varphi(\alpha)$.
Structural Commentary: Support at the mean.
Key Insight: The linear term vanishes. □

Remark 1.7.8. *Integrability in Jensen*
Linear growth, $|\varphi(t)| \le c_1 + c_2\,|t|$, makes $\varphi \circ f \in L^1([0,1])$ by Proposition 4.3.4.
If $\varphi \circ f \ge 0$, Jensen's right side may be extended-valued.

2 Product Measures and Fubini Theory

2.1 Product Measures

Product measure builds measurable rectangles and reads higher-dimensional integrals through slices. The abstract construction comes first; the Euclidean statements below are its geometric specialization.

Definition 2.1.1. *Product Measurable Spaces and Sections*
Let $(X, \mathcal{M})$, $(Y, \mathcal{N})$ be measurable spaces and $Z := X \times Y$.

(i) A *measurable rectangle* is $A \times B$ with $A \in \mathcal{M}$ and $B \in \mathcal{N}$.
Set $\mathcal{Z}_0 := \{ \bigcup_{j=1}^{n} (A_j \times B_j) : A_j \in \mathcal{M},\ B_j \in \mathcal{N} \}$ and $\mathcal{M} \otimes \mathcal{N} := \sigma\{A \times B : A \in \mathcal{M},\ B \in \mathcal{N}\}$.

(ii) For $E \subseteq Z$, the *sections* are $E_x := \{y \in Y : (x,y) \in E\}$ and $E^y := \{x \in X : (x,y) \in E\}$.

(iii) For $F : Z \to \overline{\mathbb{R}}$, the *function sections* are $F_x(y) := F(x,y)$ and $F^y(x) := F(x,y)$, where defined.

Lemma 2.1.2. *Finite Rectangle Algebra*
(i) If $R_j = A_j \times B_j$, then $R_1 \cap R_2 = (A_1 \cap A_2) \times (B_1 \cap B_2)$ and $R_1 \setminus R_2 = \left[(A_1 \cap A_2) \times (B_1 \setminus B_2)\right] \sqcup \left[(A_1 \setminus A_2) \times B_1\right]$.
(ii) $\mathcal{Z}_0$ is an algebra on Z.
(iii) $\forall E \in \mathcal{Z}_0\ \exists n \ge 1$, $A_j \in \mathcal{M}$, and $B_j \in \mathcal{N}$ such that $E = \bigsqcup_{j=1}^{n} (A_j \times B_j)$.

Proof.

(i) For $(x,y) \in Z$, $(x,y) \in R_1 \cap R_2 \iff x \in A_1 \cap A_2$ and $y \in B_1 \cap B_2$.
Also, $(x,y) \in R_1 \setminus R_2$ iff $x \in A_1$, $y \in B_1$, and either $x \notin A_2$ or $y \notin B_2$.
Splitting by $x \in A_2$ gives the disjoint union in (i).

(ii) If $E = \bigcup_j R_j$ and $F = \bigcup_k S_k$, then $E \cap F = \bigcup_{j,k} (R_j \cap S_k) \in \mathcal{Z}_0$ by (i).
Repeatedly applying (i) gives $R_j \setminus F \in \mathcal{Z}_0$, hence $E \setminus F = \bigcup_j (R_j \setminus F) \in \mathcal{Z}_0$.
Since $Z = X \times Y \in \mathcal{Z}_0$, complements are differences from Z.

(iii) If $E = \bigcup_{j=1}^{n} R_j$, set $S_j := R_j \setminus \bigcup_{i<j} R_i$. Then $S_j \in \mathcal{Z}_0$ by (ii), the S_j are disjoint, and $E = \bigsqcup_j S_j$.
Writing each S_j as a finite union of rectangles and relabeling gives required finite disjoint representation.

Structural Commentary: Product rectangles behave like elementary sets for the product space.
Key Insight: Before extending to a σ-algebra, make all finite overlaps into disjoint rectangle pieces. □

Theorem 2.1.3. *Product Measure Theorem*
For measure spaces $(X, \mathcal{M}, \mu)$ and $(Y, \mathcal{N}, \nu)$, $\exists \pi : \mathcal{M} \otimes \mathcal{N} \to [0, +\infty]$ a measure such that $\forall (A,B) \in \mathcal{M} \times \mathcal{N}$, $\pi(A \times B) = \mu(A)\nu(B)$, where $0 \cdot (+\infty) = 0$. If μ, ν are σ-finite, π is unique; write $\pi = \mu \otimes \nu$.

Proof. For $E = \bigsqcup_{j=1}^{n} (A_j \times B_j) \in \mathcal{Z}_0$, set $\pi_0(E) := \sum_{j=1}^{n} \mu(A_j)\nu(B_j)$.
If $A \times B = \bigsqcup_{j \ge 1} (A_j \times B_j)$, then $\mathbf{1}_{A \times B} = \sum_{j \ge 1} \mathbf{1}_{A_j \times B_j}$, so monotone convergence in y, then x,
gives $\mu(A)\nu(B) = \sum_{j \ge 1} \mu(A_j)\nu(B_j)$. Refining two finite disjoint rectangle decompositions by intersections gives equal π_0-values; hence

π_0 is well defined. If $E = \bigsqcup_k E_k \in \mathcal{Z}_0$ with $E_k \in \mathcal{Z}_0$, write $E = \bigsqcup_i R_i$ and $E_k = \bigsqcup_\ell R_{k\ell}$.
Since $R_i = \bigsqcup_{k,\ell}(R_i \cap R_{k\ell})$, the rectangle comparison yields $\pi_0(E) = \sum_k \pi_0(E_k)$; hence π_0 is a premeasure.
Extend π_0 to $\sigma(\mathcal{Z}_0) = \mathcal{M} \otimes \mathcal{N}$. If μ, ν are σ-finite, then $\mathcal{Z}_0$ is π_0-σ-finite, so the extension is unique.
Structural Commentary: Rectangles fix the product measure.
Key Insight: Monotone convergence makes rectangle mass respect countable disjoint refinements. □

Lemma 2.1.4. *Measurable Sections*
(i) $E \in \mathcal{M} \otimes \mathcal{N}$ implies $\forall x \in X,\ E_x \in \mathcal{N}$ and $\forall y \in Y,\ E^y \in \mathcal{M}$.
(ii) If $F : Z \to \overline{\mathbb{R}}$ is $\mathcal{M} \otimes \mathcal{N}$-measurable, then F_x is $\mathcal{N}$-measurable $\forall x \in X$ and F^y is $\mathcal{M}$-measurable $\forall y \in Y$.

Proof.
(i) Fix $x \in X$ and set $\mathcal{C}_x := \{E \subseteq Z : E_x \in \mathcal{N}\}$. Since $(E^c)_x = (E_x)^c$ and $(\bigcup_n E_n)_x = \bigcup_n (E_n)_x$, $\mathcal{C}_x$ is a σ-algebra. Also $(A \times B)_x = B$ if $x \in A$ and $\emptyset$ otherwise; hence $\mathcal{M} \otimes \mathcal{N} \subseteq \mathcal{C}_x$. The E^y proof is identical.
(ii) For $a \in \mathbb{R}$, set $H_a := \{(u, v) \in Z : F(u, v) > a\} \in \mathcal{M} \otimes \mathcal{N}$. By (i), $(H_a)_x \in \mathcal{N}$ and $(H_a)^y \in \mathcal{M}$.
Since $(H_a)_x = \{y : F_x(y) > a\}$ and $(H_a)^y = \{x : F^y(x) > a\}$, all threshold sets are measurable.
Structural Commentary: Product measurability is stable under freezing one coordinate.
Key Insight: Section operations preserve the set algebra used to generate the product σ-algebra. □

Proposition 2.1.5. *Section Measures Integrate to Product Measure*
Let $(X, \mathcal{M}, \mu)$ and $(Y, \mathcal{N}, \nu)$ be σ-finite, $\pi := \mu \otimes \nu$, and $E \in \mathcal{M} \otimes \mathcal{N}$. Set $f_E(x) := \nu(E_x)$ and $g_E(y) := \mu(E^y)$.
Then f_E, g_E are measurable and $\int_X f_E \, d\mu = \pi(E) = \int_Y g_E \, d\nu$.

Proof. Assume $\mu(X), \nu(Y) < +\infty$ and let $\mathcal{C}$ be the class of E satisfying the claim.
For $E = A \times B$, $f_E = \nu(B)\mathbf{1}_A$ and $g_E = \mu(A)\mathbf{1}_B$, so $A \times B \in \mathcal{C}$; finite additivity gives $\mathcal{Z}_0 \subseteq \mathcal{C}$.
If $E_n \uparrow E$ in $\mathcal{C}$, then $(E_n)_x \uparrow E_x$ and $(E_n)^y \uparrow E^y$; MCT gives $E \in \mathcal{C}$.
If $E_n \downarrow E$, finite total mass gives downward continuity and DCT, hence $E \in \mathcal{C}$.
Thus $\mathcal{C}$ is a monotone class containing $\mathcal{Z}_0$, so $\mathcal{C} = \mathcal{M} \otimes \mathcal{N}$. For σ-finite μ, ν, choose $X_n \uparrow X$, $Y_n \uparrow Y$ with $\mu(X_n), \nu(Y_n) < +\infty$, apply the finite case to $E_n := E \cap (X_n \times Y_n)$, then let $n \to \infty$ by MCT.
Structural Commentary: Cavalieri's principle is already true for abstract σ-finite products.
Key Insight: Prove rectangles, close under monotone limits, then exhaust by finite-measure rectangles. □

Perspective 2.1.6. *Rectangle Premeasure and the Completed Product*
Let $\mathcal{R} := \{A \times B : A \in \mathcal{M},\ B \in \mathcal{N}\}$ and define $\lambda(A \times B) := \mu(A)\nu(B)$ on $\mathcal{R}$.
(i) Lemma 2.1.2 and Theorem 2.1.3 imply that λ is a semiring premeasure.
(ii) Theorem 3.4.7 extends λ to a complete measure $\overline{\lambda}$ on the Caratheodory σ-algebra $\mathcal{C}_\lambda$.
(iii) The restriction $\overline{\lambda}|_{\mathcal{M}\otimes\mathcal{N}}$ is $\mu \otimes \nu$; the full space $(X \times Y, \mathcal{C}_\lambda, \overline{\lambda})$ is the completed product.
Thus $\mathcal{C}_\lambda$ may contain $N' \subseteq N$ with $N \in \mathcal{M} \otimes \mathcal{N}$, $(\mu \otimes \nu)(N) = 0$, and $N' \notin \mathcal{M} \otimes \mathcal{N}$.
This is why some section-measurability forms of Fubini require completeness.
Key Insight: Rectangles set mass; completion adds null subsets.

2.2 Fubini and Tonelli Theorems

Theorem 2.2.1. *Tonelli's Theorem for σ-Finite Products*
Let $(X, \mathcal{M}, \mu)$, $(Y, \mathcal{N}, \nu)$ be σ-finite, Let $Z := X \times Y$, $\pi := \mu \otimes \nu$.
Let $F : Z \to [0, +\infty]$ be $\mathcal{M} \otimes \mathcal{N}$-measurable. Put $I_F(x) := \int_Y F_x \, d\nu$ and $J_F(y) := \int_X F^y \, d\mu$.
(i) I_F is $\mathcal{M}$-measurable.
(ii) J_F is $\mathcal{N}$-measurable.
(iii) $\int_X I_F \, d\mu = \int_Z F \, d\pi = \int_Y J_F \, d\nu$.

Proof. For $F = \mathbf{1}_E$, the claims follow from Proposition 2.1.5.
Finite linearity gives them for nonnegative simple $\Phi = \sum_{j=1}^n a_j \mathbf{1}_{E_j}$. Choose simple $0 \le \Phi_n \uparrow F$.
(i) Since I_{Φ_n} is $\mathcal{M}$-measurable and $I_{\Phi_n}(x) = \int_Y (\Phi_n)_x \, d\nu \uparrow \int_Y F_x \, d\nu = I_F(x)$, I_F is $\mathcal{M}$-measurable.
(ii) Since J_{Φ_n} is $\mathcal{N}$-measurable and $J_{\Phi_n}(y) = \int_X (\Phi_n)^y \, d\mu \uparrow \int_X F^y \, d\mu = J_F(y)$, J_F is $\mathcal{N}$-measurable.
(iii) From $\int_X I_{\Phi_n} \, d\mu = \int_Z \Phi_n \, d\pi = \int_Y J_{\Phi_n} \, d\nu$, MCT in X, Z, and Y gives $\int_X I_F \, d\mu = \int_Z F \, d\pi = \int_Y J_F \, d\nu$.
Structural Commentary: Approximate by nonnegative simple functions.
Key Insight: MCT passes sections and integrals together. □

Theorem 2.2.2. *Fubini's Theorem for σ-Finite Products*
Let $(X, \mathcal{M}, \mu)$ and $(Y, \mathcal{N}, \nu)$ be σ-finite, $\pi := \mu \otimes \nu$, and $F \in \mathscr{L}^1(\pi)$.
(i) $F_x \in \mathscr{L}^1(\nu)$ for μ-a.e. x and $F^y \in \mathscr{L}^1(\mu)$ for ν-a.e. y.
(ii) With $f(x) := \int_Y F_x \, d\nu$ and $g(y) := \int_X F^y \, d\mu$ on those full-measure sets, and 0 elsewhere, $f \in \mathscr{L}^1(\mu)$, $g \in \mathscr{L}^1(\nu)$, and $\int_X f \, d\mu = \int_Z F \, d\pi = \int_Y g \, d\nu$.

Proof.
(i) Tonelli on $|F|$ gives $\int_X (\int_Y |F_x| \, d\nu) d\mu = \int_Z |F| \, d\pi = \int_Y (\int_X |F^y| \, d\mu) d\nu < +\infty$, hence finite a.e.
(ii) Tonelli on F^+ and F^- gives finite identities; subtract them to obtain $\int_X f \, d\mu = \int_Z F \, d\pi = \int_Y g \, d\nu$.
Moreover $|f| \le \int_Y |F_x| \, d\nu$ and $|g| \le \int_X |F^y| \, d\mu$, so (i) gives $f, g \in \mathscr{L}^1$.
Structural Commentary: Fubini is Tonelli plus subtraction.
Key Insight: $\int |F| < +\infty$ makes the two nonnegative Tonelli identities finite enough to subtract. □

Proposition 2.2.3. *Product Borel and Measurable Building Blocks*
The following hold.

(i) $\mathcal{B}(\mathbb{R}) \otimes \mathcal{B}(\mathbb{R}) = \mathcal{B}(\mathbb{R}^2)$.
(ii) *If* $f : X \to \mathbb{R}$ *is* $\mathcal{M}$*-measurable and* $g : Y \to \mathbb{R}$ *is* $\mathcal{N}$*-measurable, then* $(x, y) \mapsto f(x)g(y)$ *is* $\mathcal{M} \otimes \mathcal{N}$*-measurable.*
(iii) *If* $u : \mathbb{R} \to \mathbb{R}$ *is Borel measurable, then* $(x, y) \mapsto u(x - y)$ *is* $\mathcal{B}(\mathbb{R}) \otimes \mathcal{B}(\mathbb{R})$*-measurable.*

Proof.

(i) Open rectangles give $\mathcal{B}(\mathbb{R}) \otimes \mathcal{B}(\mathbb{R}) \subseteq \mathcal{B}(\mathbb{R}^2)$.
Conversely, every open $O \subseteq \mathbb{R}^2$ is a countable union of rational rectangles, each in $\mathcal{B}(\mathbb{R}) \otimes \mathcal{B}(\mathbb{R})$.
(ii) For $\tilde{f}(x, y) := f(x)$ and $\tilde{g}(x, y) := g(y)$, $\{\tilde{f} > a\} = f^{-1}((a, +\infty)) \times Y$ and $\{\tilde{g} > a\} = X \times g^{-1}((a, +\infty))$.
Thus $\tilde{f}, \tilde{g}$ are measurable, so $\tilde{f}\tilde{g}$ is measurable.
(iii) The map $s(x, y) := x - y$ is continuous on $\mathbb{R}^2$, hence measurable by (i); therefore $u \circ s$ is measurable.

Structural Commentary: Product measurability supports two-variable formulas.
Key Insight: Check coordinate pullbacks on rectangles, then use ordinary measurable-function closure. □

Proposition 2.2.4. *Counting Factor Products*
Let $X = \mathbb{N}$, $\mathcal{M} = 2^{\mathbb{N}}$, μ *be counting measure, and* $(Y, \mathcal{N}, \nu)$ *be a measure space.*

(i) *For* $E \subseteq \mathbb{N} \times Y$, $E \in 2^{\mathbb{N}} \otimes \mathcal{N} \iff \forall n,\ E_n \in \mathcal{N}$, *and then* $E = \bigsqcup_{n \geq 1} (\{n\} \times E_n)$.
(ii) *The unique product measure is* $\pi = \mu \otimes \nu$ *with* $\pi(E) = \sum_{n \geq 1} \nu(E_n)$ *for* $E \in 2^{\mathbb{N}} \otimes \mathcal{N}$.
(iii) *For* $F : \mathbb{N} \times Y \to \mathbb{R}$, F *is product-measurable* $\iff \forall n,\ F_n$ *is* $\mathcal{N}$*-measurable.*
(iv) *For product-measurable* F, $F \in \mathscr{L}^1(\pi) \iff \sum_{n \geq 1} \int_Y |F_n|\, d\nu < +\infty$;
then $\int_{\mathbb{N} \times Y} F\, d\pi = \sum_{n \geq 1} \int_Y F_n\, d\nu = \int_Y \sum_{n \geq 1} F_n\, d\nu$, *with* $\sum_n F_n$ *absolutely convergent* ν*-a.e.*

Proof.

(i) ($\Rightarrow$) If $E \in 2^{\mathbb{N}} \otimes \mathcal{N}$, then $\forall n,\ E_n \in \mathcal{N}$ by Lemma 2.1.4.
(i) ($\Leftarrow$) If $\forall n,\ E_n \in \mathcal{N}$, then each $\{n\} \times E_n \in 2^{\mathbb{N}} \otimes \mathcal{N}$ and $E = \bigsqcup_{n \geq 1} (\{n\} \times E_n)$, hence $E \in 2^{\mathbb{N}} \otimes \mathcal{N}$.
(ii) Define $\pi(E) := \sum_{n \geq 1} \nu(E_n)$.
If $(E^k)_k$ are disjoint, then $(\bigsqcup_k E^k)_n = \bigsqcup_k E^k_n$, so $\pi(\bigsqcup_k E^k) = \sum_n \sum_k \nu(E^k_n) = \sum_k \pi(E^k)$.
Also $\pi(\{n\} \times A) = \nu(A)$, and (i) forces uniqueness.
(iii) ($\Rightarrow$) If F is product-measurable, then $\forall n$, F_n is measurable by Lemma 2.1.4.
(iii) ($\Leftarrow$) If $\forall n$, F_n is measurable, then $\forall a \in \mathbb{R}$, $H_a := \{F > a\}$ satisfies $(H_a)_n = \{F_n > a\} \in \mathcal{N}$,
By (i), $H_a \in 2^{\mathbb{N}} \otimes \mathcal{N}$, so F is product-measurable.
(iv) For $G \geq 0$, (ii) gives the identity for $G = \mathbf{1}_E$; linearity and MCT give $\int_{\mathbb{N} \times Y} G\, d\pi = \sum_{n \geq 1} \int_Y G_n\, d\nu$.
(iv) Apply the preceding identity to $G = |F|$: $F \in \mathscr{L}^1(\pi) \iff \sum_{n \geq 1} \int_Y |F_n|\, d\nu < +\infty$.
If finite, then $\int_Y \sum_n |F_n|\, d\nu < +\infty$, so $\sum_n F_n$ converges absolutely a.e..
Applying the nonnegative identity to F^+ and F^- and subtracting gives the integral formulas.

Structural Commentary: A product with counting measure is a measurable sequence of fibers.
Key Insight: Counting atoms turn products into sums. □

Example 2.2.5. *A Diagonal Failure Without* σ*-Finiteness*
Let $X = Y = [0, 1]$, $\mathcal{M} = \mathcal{N} = \mathcal{B}([0, 1])$, $\mu = m$, $\nu = \#$, and $D := \{(x, y) \in [0, 1]^2 : x = y\}$.
Then $D \in \mathcal{M} \otimes \mathcal{N}$, $D_x = \{x\}$, and $D^y = \{y\}$, so $\nu(D_x) = 1$ and $\mu(D^y) = 0$.
Hence $\int_X \nu(D_x)\, d\mu = 1$ but $\int_Y \mu(D^y)\, d\nu = 0$, so Tonelli–Fubini can fail without σ-finite factors.

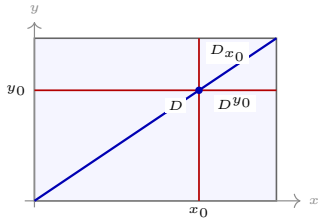

Figure 204: Diagonal sections: $\nu(D_x) = 1$ but $\mu(D^y) = 0$.

Example 2.2.6. *Nonunique Products Without* σ*-Finiteness*
Let $X = \mathbb{R}$, $\mathcal{M} = 2^{\mathbb{R}}$, and $\mu(A) = 0$ if A is countable, $\mu(A) = +\infty$ otherwise.
Define $\lambda_i : \mathcal{M} \otimes \mathcal{M} \to \{0, +\infty\}$ by $\lambda_i(E) = 0$ exactly on the following null ideals:
$\mathcal{I}_1 = \{E : E = G \cup H,\ \mathrm{pr}_x\, G$ countable, $\mathrm{pr}_y\, H$ countable$\}$
and $\mathcal{I}_2 = \{E : E = G \cup H \cup K,\ \mathrm{pr}_x\, G$ countable, $\mathrm{pr}_y\, H$ countable, $\mathrm{pr}_{y=x}\, K$ countable$\}$.
Both ideals are closed under countable unions, hence λ_i are measures.
For a rectangle $A \times B$, both measures equal $\mu(A)\mu(B)$: countable sides are null, and uncountable-by-uncountable rectangles are not in either ideal.
For $E = \{(x, y) : x + y = 0\}$, $\mathrm{pr}_{y=x}\, E$ is a point, so $\lambda_2(E) = 0$ but $\lambda_1(E) = +\infty$.

Structural Commentary: Without σ-finiteness, rectangle values need not determine a product measure.
Key Insight: Extra null lines preserve rectangles but change non-rectangles.

Example 2.2.7. *Double Series as Product Integrals*
With counting measure on $\mathbb{N}^2$, Tonelli gives, for $a_{mn} \geq 0$,
$\sum_m \sum_n a_{mn} = \sum_{(m,n)\in\mathbb{N}^2} a_{mn} = \sum_n \sum_m a_{mn} \in [0, +\infty]$.
Fubini needs integrability: set $a_{nn} = 1$, $a_{n,n+1} = -1$, and $a_{mn} = 0$ otherwise.
Then $\sum_m \sum_n a_{mn} = 0$, while $\sum_n \sum_m a_{mn} = 1$, and $\sum_{m,n} |a_{mn}| = +\infty$.

Proposition 2.2.8. *Separated Products*
Let $(X, \mathcal{M}, \mu)$ and $(Y, \mathcal{N}, \nu)$ be σ-finite. Let $f \in \mathscr{L}^1(\mu)$, $g \in \mathscr{L}^1(\nu)$, and $H(x,y) := f(x)g(y)$.
(i) $H \in \mathscr{L}^1(\mu \otimes \nu)$.
(ii) $\int_{X\times Y} H\, d(\mu\otimes\nu) = (\int_X f\, d\mu)(\int_Y g\, d\nu)$.

Proof.
(i) Proposition 2.2.3 gives measurability. Tonelli gives $\int_{X\times Y} |H|\, d(\mu\otimes\nu) = (\int_X |f|\, d\mu)(\int_Y |g|\, d\nu) < +\infty$.
(ii) Since $H \in \mathscr{L}^1(\mu\otimes\nu)$, Fubini gives $\int_{X\times Y} H\, d(\mu\otimes\nu) = (\int_X f\, d\mu)(\int_Y g\, d\nu)$.
Structural Commentary: Tonelli handles size; Fubini handles sign.
Key Insight: Separated products integrate as products of integrals. □

Corollary 2.2.9. *Equal Section Measures*
Let $(X, \mathcal{M}, \mu)$ and $(Y, \mathcal{N}, \nu)$ be σ-finite.
If $E, F \in \mathcal{M}\otimes\mathcal{N}$ and $\forall x \in X$, $\nu(E_x) = \nu(F_x)$, then $(\mu\otimes\nu)(E) = (\mu\otimes\nu)(F)$.

Proof. Set $f_E(x) := \nu(E_x)$ and $f_F(x) := \nu(F_x)$.
Since $f_E = f_F$, $(\mu\otimes\nu)(E) = \int_X f_E\, d\mu = \int_X f_F\, d\mu = (\mu\otimes\nu)(F)$ by Proposition 2.1.5.
Structural Commentary: Product mass is recovered from vertical section masses.
Key Insight: Equal fibers give equal product mass. □

Definition 2.2.10. *Convolution*
For Borel $f, g : \mathbb{R} \to \mathbb{R}$, if $y \mapsto f(x-y)g(y)$ is integrable for a.e. x,
define the *convolution* $(f * g)(x) := \int_{\mathbb{R}} f(x-y)g(y)\, dm(y)$ on that full-measure set and 0 elsewhere.

Proposition 2.2.11. *Convolution of L^1 Functions*
Let $f, g \in \mathscr{L}^1(m)$ be Borel.
(i) $f * g$ is defined for a.e. $x \in \mathbb{R}$.
(ii) $f * g \in \mathscr{L}^1(m)$.
(iii) $\int_{\mathbb{R}} |f * g|\, dm \leq (\int_{\mathbb{R}} |f|\, dm)(\int_{\mathbb{R}} |g|\, dm)$.

Proof. Set $\Phi(x,y) := f(x-y)g(y)$. By Proposition 2.2.3, Φ is product-measurable.
For fixed y, translation invariance gives $\int_{\mathbb{R}} |f(x-y)|\, dm(x) = \int_{\mathbb{R}} |f|\, dm$.
Hence Tonelli yields $\int_{\mathbb{R}^2} |\Phi|\, d(m\otimes m) = (\int_{\mathbb{R}} |f|\, dm)(\int_{\mathbb{R}} |g|\, dm) < +\infty$.
(i) Fubini gives $y \mapsto \Phi(x,y) \in \mathscr{L}^1(m)$ for a.e. x, so $f * g$ is a.e. defined.
(ii) Since $|f * g(x)| \leq \int_{\mathbb{R}} |\Phi(x,y)|\, dm(y)$ a.e., Fubini gives $\int_{\mathbb{R}} |f * g|\, dm < +\infty$.
(iii) The same estimate gives $\int_{\mathbb{R}} |f * g|\, dm \leq \int_{\mathbb{R}^2} |\Phi|\, d(m\otimes m) = (\int_{\mathbb{R}} |f|\, dm)(\int_{\mathbb{R}} |g|\, dm)$.
Structural Commentary: Apply Fubini to $\Phi(x,y) = f(x-y)g(y)$.
Key Insight: Translation invariance fixes the x-slice norm. □

Definition 2.2.12. *Products and Slices*
For $A \subseteq \mathbb{R}^n$, $B \subseteq \mathbb{R}^k$, set $A \times B \subseteq \mathbb{R}^{n+k}$.
For $E \subseteq \mathbb{R}^n \times \mathbb{R}^k$ define $E_x := \{y \in \mathbb{R}^k : (x,y) \in E\}$ as *x-slice*, and $E^y := \{x \in \mathbb{R}^n : (x,y) \in E\}$ as *y-slice*.
For $f : E \to \mathbb{R}$, write $f_x(y) = f^y(x) := f(x,y)$ where defined.

Theorem 2.2.13. *Measurable Products*
Let $A \in \mathcal{L}^n$ and $B \in \mathcal{L}^k$.
(i) $A \times B \in \mathcal{L}^{n+k}$.
(ii) $m_{n+k}(A\times B) = m_n(A)m_k(B)$, with $0 \cdot \infty = \infty \cdot 0 = 0$.

Proof. Boxes satisfy $m_{n+k}(I\times J) = m_n(I)m_k(J)$, hence so do open sets by disjoint box decompositions.
For bounded finite-measure A, B, choose $F_A \subseteq A \subseteq G_A$, $F_B \subseteq B \subseteq G_B$ with F_A, F_B closed, G_A, G_B bounded open, and $m_n(G_A \setminus F_A), m_k(G_B \setminus F_B) < \varepsilon$.
Then $F_A \times F_B \subseteq A\times B \subseteq G_A \times G_B$ and $m_n(G_A)m_k(G_B) - m_n(F_A)m_k(F_B) \to 0$.
(i) The squeeze proves $A\times B \in \mathcal{L}^{n+k}$ in the bounded finite-measure case.
For general A, B, with $A_N := A \cap [-N,N]^n$ and $B_N := B \cap [-N,N]^k$, $A\times B = \bigcup_N (A_N \times B_N) \in \mathcal{L}^{n+k}$.
(ii) The squeeze also gives $m_{n+k}(A\times B) = m_n(A)m_k(B)$ in the bounded finite-measure case.
Since $A_N \times B_N \uparrow A \times B$, $m_{n+k}(A\times B) = \lim_N m_n(A_N)m_k(B_N) = m_n(A)m_k(B)$, with $0\cdot\infty = \infty\cdot 0 = 0$.
Structural Commentary: Product measure comes from boxes and regularity.
Key Insight: Regularity turns rough measurable products into box products plus zero-set errors. □

Theorem 2.2.14. *Zero Slices*
If $E \subseteq \mathbb{R}^n \times \mathbb{R}^k$ is Lebesgue measurable, then E is null iff E_x is null for a.e. x.

Proof.
(⇒) If $m(E) = 0$, cover E by an open W with small measure.
For $X_\alpha(W) = \{x : m(W_x) > \alpha\}$, $m(W) \geq \alpha m(X_\alpha(W))$; letting $m(W) \to 0$ gives $m(E_x) = 0$ for a.e. x.

($\Leftarrow$) Remove the exceptional null base so every slice is null. For compact $K \subseteq E$, cover each K_x by a small-measure slice neighborhood; compactness gives finitely many product neighborhoods covering K, whose total measure is arbitrarily small by Theorem 2.2.13. Thus $m(K) = 0$, hence $m(E) = 0$ by regularity.

Structural Commentary: Nullity can be checked fiberwise after removing an exceptional base set.
Key Insight: Product measure turns small slice covers into small total measure. □

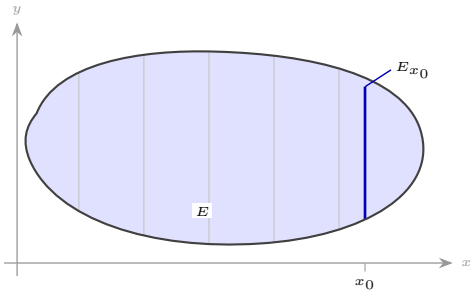

Figure 205: A planar set can be read by vertical slices; Fubini integrates the slice data over the base variable.

Theorem 2.2.15. *Cavalieri's Principle for Lebesgue Measure*
Let $n, k \in \mathbb{N}$ and $E \in \mathcal{L}^{n+k}$. For $x \in \mathbb{R}^n$ and $y \in \mathbb{R}^k$, set $E_x := \{y : (x, y) \in E\}$ and $E^y := \{x : (x, y) \in E\}$.

(i) $E_x \in \mathcal{L}^k$ for a.e. x, and $f_E(x) := m_k(E_x)$ has a measurable representative with $m_{n+k}(E) = \int_{\mathbb{R}^n} f_E \, dm_n$.
(ii) $E^y \in \mathcal{L}^n$ for a.e. y, and $g_E(y) := m_n(E^y)$ has a measurable representative with $m_{n+k}(E) = \int_{\mathbb{R}^k} g_E \, dm_k$.

Proof. Let $\mathsf{C}_x(E)$ denote: $E_x \in \mathcal{L}^k$ for a.e. x, f_E has a measurable representative, and $m_{n+k}(E) = \int_{\mathbb{R}^n} f_E \, dm_n$.

(i) Rectangles satisfy $\mathsf{C}_x(A \times B)$ since $f_{A\times B} = m_k(B)\mathbf{1}_A$; finite additivity gives finite unions.
For bounded $Q = I \times J$, $\mathcal{C}_Q := \{E \subseteq Q : \mathsf{C}_x(E)\}$ is monotone:
$E_j \uparrow E$ gives $f_{E_j} \uparrow f_E$ and MCT, while $E_j \downarrow E$ gives $f_{E_j} \downarrow f_E \le m_k(J)\mathbf{1}_I$ and DCT.
Thus $\mathcal{C}_Q$ contains all Borel $E \subseteq Q$, and exhaustion by $Q_N = [-N, N]^{n+k}$ gives all Borel E.
For $E \in \mathcal{L}^{n+k}$, choose Borel B with $m_{n+k}(E \triangle B) = 0$; then $m_k((E \triangle B)_x) = 0$ a.e. by Theorem 2.2.14.
Hence $E_x \in \mathcal{L}^k$ a.e., $f_E = f_B$ a.e., and $m_{n+k}(E) = \int_{\mathbb{R}^n} f_E \, dm_n$.

(ii) Let $\tau : \mathbb{R}^k \times \mathbb{R}^n \to \mathbb{R}^n \times \mathbb{R}^k$ be $\tau(y, x) = (x, y)$ and put $\widetilde{E} := \tau^{-1}(E)$.
Apply (i) to $\widetilde{E} \subseteq \mathbb{R}^k \times \mathbb{R}^n$ gives $\widetilde{E}_y = E^y$ a.e., $g_E(y) = m_n(\widetilde{E}_y)$, $m_{n+k}(E) = m_{n+k}(\widetilde{E}) = \int_{\mathbb{R}^k} g_E \, dm_k$.

Structural Commentary: Slices reduce product measure to base integrals.
Key Insight: Extend from rectangles, then pass null differences. □

Perspective 2.2.16. *Fubini Proof Ladder*
Fubini ladder: $\mathbf{1}_E \to$ simple $\Phi \ge 0 \to f \ge 0$ by MCT, then $f = f^+ - f^-$ when $\int |f| < +\infty$.
Theorems 2.2.1 and 2.2.2 are the abstract form.
Key Insight: Fubini is a slice theorem, proof runs through indicators, simple functions, monotone convergence.

Proposition 2.2.17. *Undergraphs and Level-Set Measurability*
Let $f : \mathbb{R}^n \to [0, \infty]$, set $F_a := \{x : f(x) > a\}$, and let $\mathcal{U}f := \{(x, t) \in \mathbb{R}^n \times [0, \infty) : 0 < t < f(x)\}$.

(i) f is Lebesgue measurable iff $\forall q \in \mathbb{Q}_{>0}$, $F_q \in \mathcal{L}^n$.
(ii) If f is Lebesgue measurable, then $\mathcal{U}f \in \mathcal{L}^{n+1}$ and $\forall t > 0$, $(\mathcal{U}f)^t = F_t$.

Proof.

(i) ($\Rightarrow$) If f is measurable, each $F_q = f^{-1}((q, +\infty])$ is in $\mathcal{L}^n$.

(i) ($\Leftarrow$) If $\forall q \in \mathbb{Q}_{>0}$, $F_q \in \mathcal{L}^n$, then for $a \ge 0$, $F_a = \bigcup_{q\in\mathbb{Q},\ q>a} F_q \in \mathcal{L}^n$, while for $a < 0$, $F_a = \mathbb{R}^n$.
Thus all strict superlevel sets are measurable, so f is measurable.

(ii) By (i), every F_r with $r \in \mathbb{Q}_{>0}$ is measurable. Since $\mathcal{U}f = \bigcup_{q,r\in\mathbb{Q},\ 0<q<r} F_r \times (q, r)$, $\mathcal{U}f \in \mathcal{L}^{n+1}$.
For $t > 0$, $(\mathcal{U}f)^t = \{x : 0 < t < f(x)\} = F_t$.

Structural Commentary: Measurability is encoded by rational superlevels.
Key Insight: Undergraph slices are superlevel sets. □

Theorem 2.2.18. *Fubini–Tonelli for Nonnegative Functions*
Let $f : \mathbb{R}^n \times \mathbb{R}^k \to [0, \infty]$ be Lebesgue measurable.
Define $F(x) := \int_{\mathbb{R}^k} f_x \, dm_k$, f_x is measurable and arbitrarily elsewhere; define $G(y) := \int_{\mathbb{R}^n} f^y \, dm_n$ analogously.

(i) f_x is measurable for a.e. x, F is measurable, and $\int_{\mathbb{R}^{n+k}} f \, dm_{n+k} = \int_{\mathbb{R}^n} F \, dm_n$.
(ii) f^y is measurable for a.e. y, G is measurable, and $\int_{\mathbb{R}^{n+k}} f \, dm_{n+k} = \int_{\mathbb{R}^k} G \, dm_k$.

Proof. Set $U := \mathcal{U}f \subseteq \mathbb{R}^{n+k} \times [0, \infty)$. Then $U \in \mathcal{L}^{n+k+1}$ by Proposition 2.2.17.

(i) By Cavalieri, U_x is measurable for a.e. x, $H(x) := m_{k+1}(U_x)$ is measurable, and $m_{n+k+1}(U) = \int_{\mathbb{R}^n} H \, dm_n$.
For such x, $U_x = \mathcal{U}(f_x)$, so f_x is measurable and $H(x) = \int_{\mathbb{R}^k} f_x \, dm_k = F(x)$.
Since $m_{n+k+1}(U) = \int_{\mathbb{R}^{n+k}} f \, dm_{n+k}$, (i) follows.

(ii) Let $\tau(y, x) = (x, y)$ and $\tilde{f} := f \circ \tau$.
Applying (i) to $\tilde{f}$ gives $\tilde{f}_y = f^y$ a.e., $\tilde{F} = G$, and $\int_{\mathbb{R}^k} G \, dm_k = \int_{\mathbb{R}^{k+n}} \tilde{f} \, dm_{k+n} = \int_{\mathbb{R}^{n+k}} f \, dm_{n+k}$.

Structural Commentary: Cavalieri applied to the undergraph.
Key Insight: $(\mathcal{U}f)_x = \mathcal{U}(f_x)$. □

Theorem 2.2.19. *Fubini for L^1 Functions*
Let $f \in L^1(\mathbb{R}^2)$.

(i) $f(x,\cdot) \in L^1(\mathbb{R})$ for a.e. x; defining $F(x) := \int_{\mathbb{R}} f(x,y)\,dy$ there and $F = 0$ elsewhere gives $F \in L^1(\mathbb{R})$.
(ii) $f(\cdot,y) \in L^1(\mathbb{R})$ for a.e. y; defining $G(y) := \int_{\mathbb{R}} f(x,y)\,dx$ there and $G = 0$ elsewhere gives $G \in L^1(\mathbb{R})$.
(iii) $\int_{\mathbb{R}} F\,dx = \int_{\mathbb{R}^2} f = \int_{\mathbb{R}} G\,dy$.

Proof. From Theorems 2.2.13–2.2.14, the identity holds for indicators.
By linearity and MCT, every measurable $h \geq 0$ satisfies $(*)$ $\int_{\mathbb{R}}(\int_{\mathbb{R}} h(x,y)\,dy)dx = \int_{\mathbb{R}^2} h = \int_{\mathbb{R}}(\int_{\mathbb{R}} h(x,y)\,dx)dy$.

(i) Applying $(*)$ to $|f|$ gives $\int_{\mathbb{R}}\int_{\mathbb{R}} |f(x,y)|\,dy\,dx = \int_{\mathbb{R}^2} |f| < +\infty$, so $f(x,\cdot) \in L^1(\mathbb{R})$ a.e.
Let $F^{\pm}(x) := \int_{\mathbb{R}} f^{\pm}(x,y)\,dy$; then $F = F^+ - F^-$ a.e. and $\int_{\mathbb{R}} |F|\,dx \leq \int_{\mathbb{R}}(F^+ + F^-)\,dx = \int_{\mathbb{R}^2} |f| < +\infty$.
(ii) Let $\tau(y,x) = (x,y)$ and $\tilde{f} := f \circ \tau$. Since τ preserves m_2, $\tilde{f} \in L^1(\mathbb{R}^2)$.
Applying (i) to $\tilde{f}$ gives $\tilde{f}(y,\cdot) = f(\cdot,y) \in L^1(\mathbb{R})$ a.e. and $\tilde{F} = G \in L^1(\mathbb{R})$.
(iii) Let $G^{\pm}(y) := \int_{\mathbb{R}} f^{\pm}(x,y)\,dx$. By $(*)$, $\int_{\mathbb{R}} F^{\pm}\,dx = \int_{\mathbb{R}^2} f^{\pm} = \int_{\mathbb{R}} G^{\pm}\,dy$. Since these quantities are finite and $F = F^+ - F^-$, $G = G^+ - G^-$ a.e., subtraction gives $\int_{\mathbb{R}} F\,dx = \int_{\mathbb{R}^2} f = \int_{\mathbb{R}} G\,dy$.

Structural Commentary: Indicators, simple functions, MCT, then $f^{\pm}$.
Key Insight: Absolute integrability permits subtraction. □

2.3 Linear Changes of Variables and Euclidean Invariance

Perspective 2.3.1. *Coordinate Splitting as a Product Identification*
For $n = m + k$, let $\Phi : \mathbb{R}^n \to \mathbb{R}^m \times \mathbb{R}^k$ be $\Phi(x_1,\ldots,x_n) = ((x_1,\ldots,x_m),(x_{m+1},\ldots,x_n))$. Then Φ sends rectangles to product rectangles and preserves rectangular volume, so m_n is the completion of $\Phi_{\#}^{-1}(m_m \otimes m_k)$. Equivalently, integration over $\mathbb{R}^{m+k}$ matches iterated integration over $\mathbb{R}^m \times \mathbb{R}^k$ whenever Fubini applies.
Key Insight: Coordinate splitting preserves Lebesgue mass.

Proposition 2.3.2. *Lipschitz Images of Lebesgue Sets*
Let $\Psi : \mathbb{R}^n \to \mathbb{R}^n$ be Lipschitz and let $E \in \mathcal{L}^n$. Then $\Psi(E) \in \mathcal{L}^n$.
Hence every linear map $\mathbb{R}^n \to \mathbb{R}^n$ preserves Lebesgue measurability.

Proof. Let L be a Lipschitz constant.

(i) $\forall I \subseteq \mathbb{R}^n$ bounded cells, $m_n^*(\Psi(I)) \leq C_{n,L}\,\mathrm{vol}_n(I)$. Indeed, partition I into grid cells of side at most δ.
Each image has diameter at most $L\sqrt{n}\,\delta$, hence lies in a cube of volume at most $C_{n,L}\delta^n$. Summing and letting $\delta \downarrow 0$ gives the estimate.
(ii) If $m_n^*(N) = 0$ and $\varepsilon > 0$, cover N by cells (I_k) with $\sum_k \mathrm{vol}_n(I_k) < \varepsilon$.
Then $\Psi(N) \subseteq \bigcup_k \Psi(I_k)$, so (i) gives $m_n^*(\Psi(N)) \leq C_{n,L}\varepsilon$; hence $m_n^*(\Psi(N)) = 0$.
(iii) If E is bounded, choose F_σ set $F \subseteq E$ with $m_n^*(E \setminus F) = 0$. Write $F = \bigcup_j F_j$ with each F_j compact.
Then $\Psi(F) = \bigcup_j \Psi(F_j)$ is Borel, $\Psi(E \setminus F)$ is null by (ii), and $\Psi(E) = \Psi(F) \cup \Psi(E \setminus F) \in \mathcal{L}^n$.
(iv) For general E, use $E = \bigcup_{r \geq 1} (E \cap [-r,r]^n)$ and apply (iii) to each bounded term.

Structural Commentary: Reduce to compact pieces plus null error.
Key Insight: Lipschitz maps preserve null sets. □

Theorem 2.3.3. *Linear Change of Variables for Nonnegative Functions*
Let $T \in \mathcal{L}(\mathbb{R}^n)$ be invertible and let $f : \mathbb{R}^n \to [0,+\infty]$ be Lebesgue measurable.

(i) $f \circ T$ is Lebesgue measurable.
(ii) $\int f \circ T\,dm_n = |\det T|^{-1} \int f\,dm_n$.

Proof.

(i) Since $(f \circ T)^{-1}((a,+\infty]) = T^{-1}(f^{-1}((a,+\infty]))$ and T^{-1} is Lipschitz, Proposition 2.3.2 gives measurability.
(ii) The $n = 1$ identity follows from $m_1(\alpha E + \beta) = |\alpha|\,m_1(E)$.
Let $\mathcal{M}_+$ denote the measurable maps $\mathbb{R}^n \to [0,+\infty]$, set $J_S(h) := \int h(Sx)\,dm_n(x)$.
Set $\mathcal{A}_n := \{S \in GL(n) : J_S(h) = |\det S|^{-1} \int h\,dm_n\ \forall h \in \mathcal{M}_+\}$.
If $S_1, S_2 \in \mathcal{A}_n$, then $J_{S_1S_2}(h) = |\det S_2|^{-1} J_{S_1}(h) = |\det(S_1S_2)|^{-1} \int h\,dm_n$, so $S_1S_2 \in \mathcal{A}_n$.
The generators $D_j(c) : x_j \mapsto cx_j$, $P_{j,j+1} : x_j \leftrightarrow x_{j+1}$, and $H_{jk}(c) : x_j \mapsto x_j + cx_k$ lie in $\mathcal{A}_n$ for $c \neq 0$ by the $n = 1$ identity, Fubini, and slice translation invariance, with determinant factors $|c|$, 1, and 1.
Row reduction gives $T \in \mathcal{A}_n$; hence $J_T(f) = |\det T|^{-1} \int f\,dm_n$.

Structural Commentary: Verify elementary row operations, then compose.
Key Insight: Only scalings change mass. □

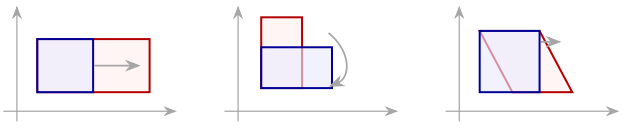

Figure 206: Original and image cells under scale, swap, and shear; Fubini checks each coordinatewise.

Corollary 2.3.4. *Invertible Linear Images of Lebesgue Sets*
Let $T \in \mathcal{L}(\mathbb{R}^n)$ be invertible and let $E \subseteq \mathbb{R}^n$.
(i) $E \in \mathcal{L}^n \iff T(E) \in \mathcal{L}^n$.
(ii) If $E \in \mathcal{L}^n$, then $m_n(T(E)) = |\det T|\, m_n(E)$.

Proof.
(i) Since T and T^{-1} are Lipschitz, Proposition 2.3.2 gives $E \in \mathcal{L}^n \iff T(E) \in \mathcal{L}^n$.
(ii) For $E \in \mathcal{L}^n$, Theorem 2.3.3 applied to $\mathbf{1}_{T(E)}$ gives $m_n(E) = \int \mathbf{1}_{T(E)}(Tx)\, dm_n(x) = |\det T|^{-1}\, m_n(T(E))$.
Structural Commentary: Measurability is Lipschitz; mass follows from indicators.
Key Insight: Indicators turn integral change into set change. □

Corollary 2.3.5. *Linear Change of Variables for L^1 Functions*
Let $T \in \mathcal{L}(\mathbb{R}^n)$ be invertible, let $f \in \mathscr{L}^1(m_n)$, and set $c_T := |\det T|^{-1}$.
(i) $f \circ T \in \mathscr{L}^1(m_n)$.
(ii) $\int f \circ T\, dm_n = c_T \int f\, dm_n$.

Proof.
(i) Apply Theorem 2.3.3 to $|f|$: $\int |f \circ T|\, dm_n = c_T \int |f|\, dm_n < +\infty$, hence $f \circ T \in \mathscr{L}^1(m_n)$.
(ii) Apply Theorem 2.3.3 to $f^{\pm}$: $\int f^{\pm} \circ T\, dm_n = c_T \int f^{\pm}\, dm_n < +\infty$.
Hence $\int f \circ T\, dm_n = \int f^+ \circ T\, dm_n - \int f^- \circ T\, dm_n = c_T \int f\, dm_n$.
Structural Commentary: Reduce signed integrals to finite positive parts.
Key Insight: Absolute integrability permits subtraction. □

Corollary 2.3.6. *Linear Images and Rigid Motions*
Let $E \in \mathcal{L}^n$.
(i) If $T \in \mathcal{L}(\mathbb{R}^n)$ is singular, then $T(E)$ is Lebesgue measurable and $m_n(T(E)) = 0$.
(ii) If $\Psi(x) = Ux + x_0$, where U is a linear isometry, then $\Psi(E) \in \mathcal{L}^n$ and $m_n(\Psi(E)) = m_n(E)$.

Proof.
(i) $T(E) \in \mathcal{L}^n$ by Proposition 2.3.2. Set $W := \operatorname{range} T$, $H := \mathbb{R}^{n-1} \times \{0\}$; choose invertible S with $S(W) \subseteq H$.
Since $H = \bigcup_N (H \cap [-N, N]^n)$ is null, $m_n(W) = 0$ by Corollary 2.3.4; hence $m_n(T(E)) = 0$.
(ii) Since U is an isometry, $|\det U| = 1$ by Proposition 1.1.19.
Thus $U(E) \in \mathcal{L}^n$ and $m_n(U(E)) = m_n(E)$ by Corollary 2.3.4.
By translation invariance, $\Psi(E) = U(E) + x_0 \in \mathcal{L}^n$ and $m_n(\Psi(E)) = m_n(U(E)) = m_n(E)$.
Structural Commentary: Singular maps land in null subspaces; rigid motions preserve determinant mass.
Key Insight: Lebesgue measure records determinant size, not the coordinate description of the set. □

3 Radon-Nikodym and Differentiation

3.1 Signed and Absolutely Continuous Measures

This subsection first decomposes finite signed set functions into measures, then compares measures by absolute continuity and singularity. Later subsections develop the local Euclidean counterpart of the Radon–Nikodym viewpoint.

Definition 3.1.1. *Positive, Negative, and Null Sets for a Charge*
Let λ be a charge on $(X, \mathcal{M})$.
(i) $\mathcal{P}_\lambda := \{P \in \mathcal{M} : \forall E \in \mathcal{M}, \lambda(E \cap P) \geq 0\}$, the *positive* sets.
(ii) $\mathcal{N}_\lambda := \{N \in \mathcal{M} : \forall E \in \mathcal{M}, \lambda(E \cap N) \leq 0\}$, the *negative* sets.
(iii) $\mathcal{Z}_\lambda := \{M \in \mathcal{M} : \forall E \in \mathcal{M}, \lambda(E \cap M) = 0\}$, the *null* sets.

Proposition 3.1.2. *Positive and Negative Set Closure*
For a charge λ:
(i) $A \in \mathcal{M}$ and $A \subseteq P \in \mathcal{P}_\lambda$ imply $A \in \mathcal{P}_\lambda$.
(ii) $A \in \mathcal{M}$ and $A \subseteq N \in \mathcal{N}_\lambda$ imply $A \in \mathcal{N}_\lambda$.
(iii) $\mathcal{P}_\lambda$ is closed under countable unions.
(iv) $\mathcal{N}_\lambda$ is closed under countable unions.

Proof.
(i) If $A \subseteq P \in \mathcal{P}_\lambda$, then $\lambda(E \cap A) = \lambda((E \cap A) \cap P) \geq 0\ \forall E \in \mathcal{M}$.
(ii) If $A \subseteq N \in \mathcal{N}_\lambda$, then $\lambda(E \cap A) = \lambda((E \cap A) \cap N) \leq 0\ \forall E \in \mathcal{M}$.
(iii) Let $(P_k) \subseteq \mathcal{P}_\lambda$ and set $P := \bigcup_{k \geq 1} P_k$. For $E \in \mathcal{M}$, set $F_1 := E \cap P_1$ and $F_k = E \cap P_k \setminus \bigcup_{j=1}^{k-1} P_j$ for $k \geq 2$.
Then (F_k) is pairwise disjoint, $\bigcup_k F_k = E \cap P$, and $F_k \subseteq P_k$, so $\lambda(F_k) \geq 0$.
Countable additivity gives $\lambda(E \cap P) = \sum_k \lambda(F_k) \geq 0$.
(iv) Apply the disjointization in (iii) to $(N_k) \subseteq \mathcal{N}_\lambda$; every disjoint piece has nonpositive charge, so $\bigcup_k N_k \in \mathcal{N}_\lambda$.
Structural Commentary: Sign sets are hereditary and countable-union stable.
Key Insight: Test sets can always be disjointized against a countable sign cover. □

Theorem 3.1.3. *Hahn Decomposition Theorem*
Let λ be a charge on $(X, \mathcal{M})$. Then $\exists P, N \in \mathcal{M}$ such that
(i) $P \cap N = \emptyset$ and $X = P \sqcup N$.

(ii) $P \in \mathcal{P}_\lambda$.
(iii) $N \in \mathcal{N}_\lambda$.
Such a pair (P, N) *is a Hahn decomposition of* X *for* λ.

Proof.

(i) Put $\alpha = \sup\{\lambda(A) : A \in \mathcal{P}_\lambda\}$. If $\alpha = +\infty$, choose $B_m \in \mathcal{P}_\lambda$, $\lambda(B_m) > m$, and set $C_m = \bigcup_{j=1}^{m} B_j$; then $C_m \in \mathcal{P}_\lambda$, $C_m \uparrow C$, and $\lambda(C_m) \geq \lambda(B_m) > m$, contradicting continuity from below and $\lambda(C) \in \mathbb{R}$.
Choose $A_n \in \mathcal{P}_\lambda$, $\lambda(A_n) \to \alpha$, replace A_n by $\bigcup_{j=1}^{n} A_j$, and set $P = \bigcup_{n\geq 1} A_n$, $N = X \setminus P$.
Hence $P, N \in \mathcal{M}$, $P \cap N = \emptyset$, and $X = P \sqcup N$.
(ii) For $E \in \mathcal{M}$, $E \cap A_n \uparrow E \cap P$ and $\lambda(E \cap A_n) \geq 0$, so continuity from below gives $\lambda(E \cap P) \geq 0$.
Thus $P \in \mathcal{P}_\lambda$, and $\lambda(P) = \alpha$.
(iii) Suppose $E \in \mathcal{M}$, $E \subseteq N$, and $\lambda(E) > 0$. Then $E \notin \mathcal{P}_\lambda$, otherwise $P \cup E \in \mathcal{P}_\lambda$ and $\lambda(P \cup E) > \alpha$.
Set $R_0 := E$. Inductively, if $R_{k-1} \notin \mathcal{P}_\lambda$, let $n_k := \min\{n \geq 1 : \exists H \in \mathcal{M},\ H \subseteq R_{k-1},\ \lambda(H) \leq -\frac{1}{n}\}$.
Choose such E_k, and set $R_k := R_{k-1} \setminus E_k$. If some $R_m \in \mathcal{P}_\lambda$, then $\lambda(R_m) = \lambda(E) - \sum_{k\leq m} \lambda(E_k) > 0$, so $P \cup R_m \in \mathcal{P}_\lambda$ and $\lambda(P \cup R_m) > \alpha$, impossible. Hence all $R_k \notin \mathcal{P}_\lambda$. Put $F_m := \bigcup_{k\leq m} E_k$ and $F := \bigcup_{k\geq 1} E_k$.
Since $\lambda(F_m) = \sum_{k\leq m} \lambda(E_k) \leq -\sum_{k\leq m} \frac{1}{n_k}$ and $F_m \uparrow F$, by finiteness of $\lambda(F)$, $\sum_k \frac{1}{n_k} < +\infty$, hence $n_k \to +\infty$.
If $G \in \mathcal{M}$ and $G \subseteq E \setminus F$, then $G \subseteq R_{k-1}$ $\forall k$, by minimality $\lambda(G) > -\frac{1}{n_k - 1}$ $\forall k \gg 1$; hence $\lambda(G) \geq 0$ and $E \setminus F \in \mathcal{P}_\lambda$. Since $\lambda(E \setminus F) = \lambda(E) - \lambda(F) > 0$, $P \cup (E \setminus F) \in \mathcal{P}_\lambda$ and $\lambda(P \cup (E \setminus F)) > \alpha$, contradiction.

Structural Commentary: A charge splits X into nonnegative-piece and nonpositive-piece regions.
Key Insight: Maximize positive mass; purify any leftover positive piece. □

Lemma 3.1.4. *Hahn Parts Are Unique up to Null Sets*
Let (P_i, N_i), $i = 1, 2$, *be Hahn decompositions for a charge* λ. $\forall E \in \mathcal{M}$*:*
(i) $\lambda(E \cap P_1) = \lambda(E \cap P_2)$.
(ii) $\lambda(E \cap N_1) = \lambda(E \cap N_2)$.

Proof. Fix $E \in \mathcal{M}$. For $\{i, j\} = \{1, 2\}$,
(i) $E \cap (P_i \setminus P_j) \subseteq P_i \cap N_j$, so $\lambda(E \cap (P_i \setminus P_j)) = 0$. Hence $\lambda(E \cap P_i) = \lambda(E \cap P_1 \cap P_2)$ for $i = 1, 2$.
(ii) $E \cap (N_i \setminus N_j) \subseteq N_i \cap P_j$, so $\lambda(E \cap (N_i \setminus N_j)) = 0$. Hence $\lambda(E \cap N_i) = \lambda(E \cap N_1 \cap N_2)$ for $i = 1, 2$.

Structural Commentary: Hahn decompositions are not unique as sets, but the measures they define are unique.
Key Insight: Positive-and-negative overlap is necessarily null. □

Definition 3.1.5. *Jordan Variations of a Charge*
Let λ be a charge, (P, N) a Hahn decomposition, and $E \in \mathcal{M}$.
(i) $\lambda^+(E) := \lambda(E \cap P)$, the *positive variation*.
(ii) $\lambda^-(E) := -\lambda(E \cap N)$, the *negative variation*.
(iii) $|\lambda|(E) := \lambda^+(E) + \lambda^-(E)$, the *total variation*.
These are independent of (P, N) by Lemma 3.1.4.

Theorem 3.1.6. *Jordan Decomposition Theorem*
Let λ *be a charge.*
(i) $\lambda = \lambda^+ - \lambda^-$.
(ii) If $\lambda = \mu - \nu$ *for finite measures* μ, ν*, then* $\lambda^+ \leq \mu$.
(iii) Under the same hypothesis, $\lambda^- \leq \nu$.

Proof. Let (P, N) be a Hahn decomposition and fix $E \in \mathcal{M}$.
(i) $\lambda(E) = \lambda(E \cap P) + \lambda(E \cap N) = \lambda^+(E) - \lambda^-(E)$.
(ii) $\lambda^+(E) = \mu(E \cap P) - \nu(E \cap P) \leq \mu(E)$.
(iii) $\lambda^-(E) = \nu(E \cap N) - \mu(E \cap N) \leq \nu(E)$.

Structural Commentary: Jordan decomposition is the minimal finite-measure difference.
Key Insight: Positive and negative Hahn pieces isolate the irreducible positive masses. □

Corollary 3.1.7. *Variation by Subsets and Null Sets*
For a charge λ *and* $E, M \in \mathcal{M}$*:*
(i) $\lambda^+(E) = \sup\{\lambda(F) : F \in \mathcal{M}, F \subseteq E\}$.
(ii) $\lambda^-(E) = -\inf\{\lambda(F) : F \in \mathcal{M}, F \subseteq E\}$.
(iii) $M \in \mathcal{Z}_\lambda \Leftrightarrow |\lambda|(M) = 0$.
(iv) $\pi_\lambda = \lambda^+$.
(v) $\nu_\lambda = |\lambda|$.

Proof.

(i) Let (P, N) be Hahn. If $F \in \mathcal{M}$ and $F \subseteq E$, then $\lambda(F) = \lambda^+(F) - \lambda^-(F) \leq \lambda^+(E)$, with equality at $F = E \cap P$.
(ii) Under the same hypotheses, $\lambda(F) \geq -\lambda^-(E)$, with equality at $F = E \cap N$.
(iii) ($\Rightarrow$) If $M \in \mathcal{Z}_\lambda$, then $\lambda^+(M) = \lambda^-(M) = 0$, so $|\lambda|(M) = 0$.

(iii) ($\Leftarrow$) If $|\lambda|(M) = 0$, then $\lambda^\pm(G \cap M) = 0$ $\forall G \in \mathcal{M}$, hence $M \in \mathcal{Z}_\lambda$.
(iv) This is (i) and the definition of π_λ.
(v) $\sum_j |\lambda(A_j)| \leq |\lambda|(E)$ $\forall$ finite measurable partitions (A_j) of E; the Hahn partition attains equality.

Structural Commentary: Variation is intrinsic to λ.
Key Insight: The positive part is the largest charge obtainable inside a set. □

Theorem 3.1.8. *Charges Form a Banach Space*
Let $\mathrm{ca}(X,\mathcal{M}) := \{\lambda : \mathcal{M} \to \mathbb{R} : \lambda \text{ is a charge}\}$ *and* $\|\lambda\|_{\mathrm{var}} := |\lambda|(X)$.
With pointwise operations, $(\mathrm{ca}(X,\mathcal{M}), \|\cdot\|_{\mathrm{var}})$ *is Banach.*

Proof.

(i) Charge linearity gives closure under pointwise operations. The variation axioms follow from $|\lambda|(X) = 0 \Rightarrow |\lambda|(E) = 0\ \forall E$, $|a\lambda| = |a|\,|\lambda|$, and $\sum_j |(\lambda+\eta)(A_j)| \le \sum_j |\lambda(A_j)| + \sum_j |\eta(A_j)|$ over finite measurable partitions (A_j).

(ii) Let (λ_n) be variation-Cauchy.
Since $|\lambda_n(E) - \lambda_m(E)| \le \|\lambda_n - \lambda_m\|_{\mathrm{var}}$, set $\lambda(E) := \lim_n \lambda_n(E)$; then λ is finitely additive.
For fixed n and finite disjoint (A_j), $\sum_j |(\lambda - \lambda_n)(A_j)| \le \limsup_m \|\lambda_m - \lambda_n\|_{\mathrm{var}}$.

(iii) For disjoint (E_k), set $E := \bigcup_k E_k$, $R_K := \bigcup_{k>K} E_k$, and choose n with $\limsup_m \|\lambda_m - \lambda_n\|_{\mathrm{var}} < \varepsilon$.
Since $\lambda_n(R_K) \to 0$, for large K, $|\lambda(R_K)| \le |\lambda_n(R_K)| + |(\lambda - \lambda_n)(R_K)| < 2\varepsilon$.
Hence $\lambda(R_K) \to 0$, so λ is countably additive.

(iv) Taking suprema in (ii) over finite partitions gives $\|\lambda - \lambda_n\|_{\mathrm{var}} \le \limsup_m \|\lambda_m - \lambda_n\|_{\mathrm{var}} \to 0$.
Hence every variation-Cauchy sequence converges in variation to a charge.

Structural Commentary: Total variation is the signed-measure analogue of an L^1 norm.
Key Insight: Variation-Cauchy controls every finite partition. □

Theorem 3.1.9. *Variations of Integral Charges*
Let $f \in \mathscr{L}^1(\mu)$ *and* $\lambda(E) := \int_E f\,d\mu$. *For* $E \in \mathcal{M}$:
(i) $\lambda^+(E) = \int_E f^+\,d\mu$.
(ii) $\lambda^-(E) = \int_E f^-\,d\mu$.
(iii) $|\lambda|(E) = \int_E |f|\,d\mu$.

Proof. Set $P := \{f \ge 0\}$ and $N := \{f < 0\}$.
For $A \in \mathcal{M}$, $\lambda(A \cap P) = \int_{A\cap P} f\,d\mu \ge 0$ and $\lambda(A \cap N) = \int_{A\cap N} f\,d\mu \le 0$, so (P,N) is Hahn. Fix $E \in \mathcal{M}$.

(i) $\lambda^+(E) = \lambda(E \cap P) = \int_E f^+\,d\mu$.
(ii) $\lambda^-(E) = -\lambda(E \cap N) = \int_E f^-\,d\mu$.
(iii) $|\lambda|(E) = \lambda^+(E) + \lambda^-(E) = \int_E |f|\,d\mu$.

Structural Commentary: Measure variations match function parts.
Key Insight: Sign sets of the density are Hahn sets. □

Definition 3.1.10. *Absolute Continuity and Singularity*
Let λ, μ be measures and let η be a charge on $(X,\mathcal{M})$.

(i) *Absolute continuity for measures*: $\lambda \ll \mu \Leftrightarrow \forall E \in \mathcal{M}, \mu(E) = 0 \Rightarrow \lambda(E) = 0$.
(ii) *Absolute continuity for charges*: $\eta \ll \mu \Leftrightarrow |\eta| \ll \mu$.
(iii) *Mutual singularity*: $\lambda \perp \mu \Leftrightarrow \exists A, B \in \mathcal{M}$ with $A \cap B = \emptyset$, $X = A \cup B$, $\lambda(A) = 0$, and $\mu(B) = 0$.

Proposition 3.1.11. *Absolute Continuity Calculus*
Let λ, μ, ν *be measures and* η *a charge.*
(i) $\lambda \ll \lambda$.
(ii) $\lambda \ll \mu \ll \nu \Rightarrow \lambda \ll \nu$.
(iii) $\ll$ *is not symmetric.*
(iv) $(\forall E \in \mathcal{M}, \mu(E) = 0 \Rightarrow \eta(E) = 0) \Rightarrow \eta^+, \eta^-, |\eta| \ll \mu$.

Proof.

(i) Reflexivity follows directly from the null-set definition.
(ii) If $\lambda \ll \mu \ll \nu$ and $\nu(E) = 0$, then $\mu(E) = 0$, hence $\lambda(E) = 0$.
(iii) On $X = \{0,1\}$, $\mathcal{M} = 2^X$, $\delta_0 \ll \#$, but $\# \not\ll \delta_0$ since $\delta_0(\{1\}) = 0$ and $\#\{1\} = 1$.
(iv) If $\mu(E) = 0$ and $F \in \mathcal{M}$ satisfies $F \subseteq E$, then $\mu(F) = 0$ and $\eta(F) = 0$.
Hence $E \in \mathcal{Z}_\eta$ and $|\eta|(E) = 0$ by Corollary 3.1.7; therefore $\eta^\pm(E) \le |\eta|(E) = 0$.

Structural Commentary: Absolute continuity is null-set order; charges reduce to variation.
Key Insight: Null sets pass to measurable subsets, so all signed pieces vanish there. □

Corollary 3.1.12. *Absolutely Continuous and Singular Forces Zero*
Let λ, μ *be measures and let* η *be a charge.*
(i) $\lambda \ll \mu$ *and* $\lambda \perp \mu$ *imply* $\lambda = 0$.
(ii) $|\eta| \perp \mu$ *implies* $\eta^+ \perp \mu$.
(iii) $|\eta| \perp \mu$ *implies* $\eta^- \perp \mu$.

Proof.

(i) Choose $X = A \cup B$ with $\lambda(A) = 0$ and $\mu(B) = 0$. Since $\lambda \ll \mu$, $\lambda(B) = 0$, hence $\lambda(X) = 0$.
(ii) Choose $X = A \cup B$ with $|\eta|(A) = 0$ and $\mu(B) = 0$. Since $\eta^+ \le |\eta|$, $\eta^+(A) = 0$.
(iii) With the same $X = A \cup B$, $\eta^-(A) \le |\eta|(A) = 0$ and $\mu(B) = 0$; hence $\eta^- \perp \mu$.

Structural Commentary: Absolute continuity and singular support are incompatible except at zero.
Key Insight: A measure supported on a null set must vanish when it also respects that null ideal. □

Example 3.1.13. *Dominating a Countable Family of Measures*
Let (μ_n) be measures with $\mu_n(X) \le 1$, and set $\lambda(E) := \sum_{n\ge 1} 2^{-n}\mu_n(E)$.

Then λ is finite, since $\lambda(X) \le 1$, and countably additive by Tonelli for nonnegative series.
The bound $2^{-n}\mu_n(E) \le \lambda(E)$ implies $\lambda(E) = 0 \Rightarrow \mu_n(E) = 0$ and $\mu_n \ll \lambda\ \forall n$.
Key Insight: A summable positive mixture packages countably many null-set tests into one reference measure.

Lemma 3.1.14. *Epsilon–Delta Form of Absolute Continuity*
Let λ be finite and μ a measure on $(X, \mathcal{M})$. Then $\lambda \ll \mu \Leftrightarrow \forall \varepsilon > 0, \exists \delta > 0, \forall E \in \mathcal{M}, \mu(E) < \delta \Rightarrow \lambda(E) < \varepsilon$.

Proof.
($\Rightarrow$) Suppose the ε-δ condition fails. Then $\exists \varepsilon > 0$ and $E_n \in \mathcal{M}$ with $\mu(E_n) < 2^{-n}$ and $\lambda(E_n) \ge \varepsilon$.
Let $F_n = \bigcup_{k\ge n} E_k$ and $F = \bigcap_n F_n$. Then $\mu(F_n) \le 2^{-n+1}$, so $\mu(F) = 0$.
Since $F_n \downarrow F$, $\lambda(F_n) \ge \varepsilon$, and λ is finite, continuity from above gives $\lambda(F) \ge \varepsilon$, contradicting $\lambda \ll \mu$.
($\Leftarrow$) If $\mu(E) = 0$, then $\forall \delta > 0,\ \mu(E) < \delta$; hence $\forall \varepsilon > 0,\ \lambda(E) < \varepsilon$, so $\lambda(E) = 0$.

Structural Commentary: For finite target measure, absolute continuity is uniform smallness on small μ-sets.
Key Insight: A failing sequence is converted into a decreasing null tail with positive λ-mass. □

Example 3.1.15. *Finite Target Is Needed*
On $(\mathbb{N}, 2^{\mathbb{N}})$, let $\lambda = \#$ and $\mu(E) := \sum_{n\in E} 2^{-n}$. Since $\mu(E) = 0 \Leftrightarrow E = \emptyset$, $\lambda \ll \mu$.

But for $E_n = \{n\}$, $\mu(E_n) = 2^{-n} \to 0$ while $\lambda(E_n) = 1$, so the ε-δ condition fails for $\varepsilon = 1$.

Example 3.1.16. *Mutual Absolute Continuity Need Not Preserve Finiteness*
On $(\mathbb{N}, 2^{\mathbb{N}})$, set $\mu(E) := \sum_{n\in E} 2^{-n}$ and $\lambda(\emptyset) = 0$, $\lambda(E) = +\infty$ for $E \ne \emptyset$.

Then $\mu(\mathbb{N}) = 1$, while λ is not σ-finite. Since both measures have null ideal $\{\emptyset\}$, $\lambda \ll \mu$ and $\mu \ll \lambda$.
Key Insight: Absolute continuity compares null sets; it does not compare finiteness, σ-finiteness, or size.

3.2 Radon-Nikodym Theorem

Theorem 3.2.1. *Radon–Nikodym Theorem*
Let λ, μ be σ-finite measures on $(X, \mathcal{M})$ with $\lambda \ll \mu$.

(i) Representation: $\exists$ measurable $f : X \to [0, +\infty)$ such that $\lambda(E) = \int_E f\, d\mu$ for $E \in \mathcal{M}$.
(ii) Uniqueness: Any two representing densities agree μ-a.e.

The μ-a.e. class of f is denoted by $\frac{d\lambda}{d\mu}$.

Proof.
(i) Assume first $\lambda(X), \mu(X) < +\infty$. For $c > 0$, let (P_k, N_k) be Hahn for $\lambda - kc\mu$, set $A_k := N_k \setminus \bigcup_{j<k} A_j$, and set $B := X \setminus \bigcup_{k\ge 1} A_k$.
If $k \ge 2$, then $A_k \subseteq N_k \cap P_{k-1}$.
Hence $E \subseteq A_k$ implies $(k-1)c\mu(E) \le \lambda(E) \le kc\mu(E)$, with the lower bound $0 \le \lambda(E)$ when $k = 1$.
Since $B \subseteq P_k$ for $k \ge 1$, $\lambda(B) \ge kc\mu(B)\ \forall k \ge 1$; finiteness and $\lambda \ll \mu$ give $\mu(B) = \lambda(B) = 0$. Set $f_c := \sum_{k\ge 1} (k-1)c\, \mathbf{1}_{A_k}$.
Countable additivity over (A_k) gives $0 \le \lambda(E) - \int_E f_c\, d\mu \le c\mu(E)$ for $E \in \mathcal{M}$.
Let $c_n := 2^{-n}$ and $f_n := f_{c_n}$. For $E \in \mathcal{M}$, $\left|\int_E (f_n - f_m)\, d\mu\right| \le (c_n + c_m)\mu(E)$; by Proposition 1.2.20, $|f_n - f_m| \le c_n + c_m$ μ-a.e. Thus $\sum_n \|f_{n+1} - f_n\|_1 < +\infty$. By Tonelli, f_n converges μ-a.e. and in $L^1(\mu)$ to a measurable $f \ge 0$. Letting $n \to \infty$ in the approximation inequality gives $\lambda(E) = \int_E f\, d\mu$.
For the σ-finite case, choose a measurable partition $X = \bigsqcup_r Y_r$ with $\lambda(Y_r), \mu(Y_r) < +\infty$. Apply the finite case on each Y_r, obtaining f_r, and set $f := \sum_r f_r \mathbf{1}_{Y_r}$.
Then $\lambda(E) = \sum_r \lambda(E \cap Y_r) = \int_E f\, d\mu$; also $f < +\infty$ μ-a.e. because $\int_{Y_r} f\, d\mu = \lambda(Y_r) < +\infty\ \forall r$.

(ii) If f, g represent λ, then $f, g \in L^1(\mu|_{Y_r})$ and $f = g$ μ-a.e. on Y_r by Proposition 1.2.20.
Taking the countable union of the exceptional sets gives $f = g$ μ-a.e. on X.

Structural Commentary: Hahn decompositions of $\lambda - c\mu$ locate density bands.
Key Insight: Summably refined band approximations converge without invoking later L^1 completeness. □

Example 3.2.2. *A Non-σ-Finite Failure*
Let $X = [0, 1]$, $\mathcal{M} = \mathcal{B}([0, 1])$, $\mu = \#$, and $\lambda = m$. Since $\mu(E) = 0 \Leftrightarrow E = \emptyset$, $\lambda \ll \mu$.
If $\lambda(E) = \int_E f\, d\mu$ for some $f \ge 0$, then $\forall x$, $0 = \lambda(\{x\}) = \int_{\{x\}} f\, d\mu = f(x)$, so $\lambda([0, 1]) = 0$, contradiction.
Thus RN can fail when μ is not σ-finite.

Example 3.2.3. *Another Non-σ-Finite Failure*
Let X be uncountable, $\mathcal{M} := \{E \subseteq X : E \text{ or } X \setminus E \text{ countable}\}$, $\mu(E) := \#E$ if E is finite and $+\infty$ otherwise, and $\lambda(E) := 0$ if E is countable and $+\infty$ otherwise. Then $\mu(E) = 0 \Leftrightarrow E = \emptyset$, so $\lambda \ll \mu$.
If $\lambda(E) = \int_E f\, d\mu$ with $f \ge 0$, then $\forall x$, $0 = \lambda(\{x\}) = \int_{\{x\}} f\, d\mu = f(x)$, forcing $\lambda(X) = 0$, contradiction.
Structural Commentary: Singleton tests determine f, but not $\lambda(X)$ without σ-finiteness.
Key Insight: Non-σ-finite domination can lose global mass.

Remark 3.2.4. *When the Radon–Nikodym Derivative Is Integrable*
In Theorem 3.2.1, $\frac{d\lambda}{d\mu} \in L^1(\mu) \Leftrightarrow \lambda(X) < +\infty$, since $\int_X \frac{d\lambda}{d\mu}\, d\mu = \lambda(X)$.

Theorem 3.2.5. *Extended-Valued Radon–Nikodym Theorem*
Let μ be σ-finite, let λ be a measure on $(X, \mathcal{M})$, and assume $\lambda \ll \mu$.

(i) Representation: $\exists f : X \to [0, +\infty]$ measurable such that $\lambda(E) = \int_E f\, d\mu$ for $E \in \mathcal{M}$.
(ii) Uniqueness: Any two representing densities agree μ-a.e.

Proof.

(i) Assume first $\mu(X) < +\infty$ and set $\alpha := \sup\{\mu(A) : A \in \mathcal{M}, \lambda(A) < +\infty\}$. Choose $(A_n) \subseteq \mathcal{M}$ with $\lambda(A_n) < +\infty$ and $\mu(A_n) \to \alpha$, and set $C_n := \bigcup_{j \le n} A_j$, $N := \bigcup_n C_n$, and $P := X \setminus N$. Then $\lambda|_N$ is σ-finite.

For $E \subseteq P$, $\lambda(E) < +\infty \Rightarrow \mu(E) = 0$, since $\mu(E) > 0$ would give $\mu(C_n \cup E) = \mu(C_n) + \mu(E) > \alpha$ eventually. Hence $\mu(E) > 0 \Rightarrow \lambda(E) = +\infty$, while $\mu(E) = 0 \Rightarrow \lambda(E) = 0$ by $\lambda \ll \mu$.

By Theorem 3.2.1, $\exists g : N \to [0, +\infty)$ measurable such that $\lambda(E \cap N) = \int_{E \cap N} g \, d\mu$. Define $f = g$ on N and $f = +\infty$ on P; preceding dichotomy gives $\lambda(E) = \int_E f \, d\mu$. For σ-finite μ, $X = \bigsqcup_r Y_r$, $\mu(Y_r) < +\infty$.

Let f_r be the finite-μ density on Y_r and set $f := \sum_r f_r \mathbf{1}_{Y_r}$. Then $\lambda(E) = \sum_r \lambda(E \cap Y_r) = \int_E f \, d\mu$.

(ii) If f, h represent λ, fix $r, m, n \in \mathbb{N}$ and set $A^r_{m,n} := Y_r \cap \{f \le m\} \cap \{h \ge f + \frac{1}{n}\}$.
Since $\int_A f \, d\mu = \int_A h \, d\mu$ for measurable $A \subseteq Y_r$ and $\int_{A^r_{m,n}} f \, d\mu < +\infty$, $\mu(A^r_{m,n}) = 0$.

Taking the union over r, m, n gives $\mu\{f < h\} = 0$; symmetry gives $\mu\{h < f\} = 0$.

Structural Commentary: Maximal finite-λ regions separate ordinary density from infinite density.
Key Insight: Outside the maximal σ-finite part, every positive-μ set has infinite λ-mass. □

Theorem 3.2.6. *Lebesgue Decomposition Theorem*
Let λ, μ be σ-finite measures on $(X, \mathcal{M})$.

(i) $\exists$ measures λ_s, λ_a with $\lambda = \lambda_s + \lambda_a$, $\lambda_s \perp \mu$, and $\lambda_a \ll \mu$.
(ii) If $(\tilde\lambda_s, \tilde\lambda_a)$ is another such pair, then $\tilde\lambda_s = \lambda_s$ and $\tilde\lambda_a = \lambda_a$.

Proof.

(i) Put $\rho := \lambda + \mu$ and choose $f = \frac{d\lambda}{d\rho}$, $g = \frac{d\mu}{d\rho}$. With $A := \{g = 0\}$ and $B := \{g > 0\}$, set $\lambda_s(E) := \lambda(E \cap A)$ and $\lambda_a(E) := \lambda(E \cap B)$.
Then $\lambda = \lambda_s + \lambda_a$. Since $\mu(A) = \int_A g \, d\rho = 0$, $\lambda_s \perp \mu$.
If $\mu(E) = 0$, then $g = 0$ ρ-a.e. on E, so $\rho(E \cap B) = 0$ and $\lambda_a(E) = 0$; hence $\lambda_a \ll \mu$.

(ii) Let $(\tilde\lambda_s, \tilde\lambda_a)$ be another such pair. Since $\lambda_s \perp \mu$ and $\tilde\lambda_a \ll \mu$, $\lambda_s \perp \tilde\lambda_a$; choose $X = C \cup D$ with $\lambda_s(C) = 0$ and $\tilde\lambda_a(D) = 0$. Then $\lambda_s(E) = \lambda_s(E \cap D) \le \lambda(E \cap D) = \tilde\lambda_s(E \cap D) \le \tilde\lambda_s(E)$.
By symmetry, $\lambda_s = \tilde\lambda_s$, hence $\lambda_a = \tilde\lambda_a$.

Structural Commentary: Split λ into μ-visible and μ-singular parts.
Key Insight: Use $\rho = \lambda + \mu$ and split where $\frac{d\mu}{d\rho} = 0$. □

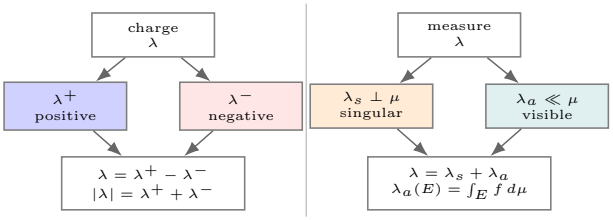

Figure 207: Charges split by sign; measures split into $\lambda_s \perp \mu$ and $\lambda_a \ll \mu$ parts.

Proposition 3.2.7. *Radon–Nikodym Calculus*
Let all measures below be σ-finite.

(i) $\lambda \ll \mu$, $g \ge 0$ measurable $\Rightarrow \int_X g \, d\lambda = \int_X g \frac{d\lambda}{d\mu} \, d\mu$.
(ii) $\nu \ll \lambda \ll \mu \Rightarrow \frac{d\nu}{d\mu} = \frac{d\nu}{d\lambda}\frac{d\lambda}{d\mu}$ μ-a.e.
(iii) $\lambda_1, \lambda_2 \ll \mu \Rightarrow \frac{d(\lambda_1+\lambda_2)}{d\mu} = \frac{d\lambda_1}{d\mu} + \frac{d\lambda_2}{d\mu}$ μ-a.e.
(iv) $\lambda \ll \mu \ll \lambda \Rightarrow \frac{d\lambda}{d\mu} = \left(\frac{d\mu}{d\lambda}\right)^{-1}$ μ-a.e.

Proof.

(i) For $g = \mathbf{1}_E$, $\int_X g \, d\lambda = \lambda(E) = \int_E \frac{d\lambda}{d\mu} \, d\mu = \int_X g \frac{d\lambda}{d\mu} \, d\mu$.
By linearity, identity holds for nonnegative simple g.
For measurable $g \ge 0$, take simple $g_n \uparrow g$ and apply monotone convergence to both sides.

(ii) Let $h := \frac{d\nu}{d\lambda}\frac{d\lambda}{d\mu}$. $\forall E \in \mathcal{M}$, (i) with $g = \mathbf{1}_E \frac{d\nu}{d\lambda}$ gives $\nu(E) = \int_E \frac{d\nu}{d\lambda} \, d\lambda = \int_E h \, d\mu$.
Hence h represents ν relative to μ, so $h = \frac{d\nu}{d\mu}$ μ-a.e.

(iii) Let $h := \frac{d\lambda_1}{d\mu} + \frac{d\lambda_2}{d\mu}$. $\forall E \in \mathcal{M}$, $\int_E h \, d\mu = \lambda_1(E) + \lambda_2(E) = (\lambda_1 + \lambda_2)(E)$.
Hence h represents $\lambda_1 + \lambda_2$ relative to μ, so uniqueness gives the identity.

(iv) Apply (ii) to $\mu \ll \lambda \ll \mu$. Since $\frac{d\mu}{d\mu} = 1$, $1 = \frac{d\mu}{d\lambda}\frac{d\lambda}{d\mu}$ μ-a.e.
Since $\mu \ll \lambda$, $\frac{d\mu}{d\lambda} > 0$ μ-a.e.; divide to obtain $\frac{d\lambda}{d\mu} = \left(\frac{d\mu}{d\lambda}\right)^{-1}$ μ-a.e.

Structural Commentary: Radon–Nikodym derivatives obey chain and linearity rules.
Key Insight: Prove identities by integrating over arbitrary measurable sets, then invoke uniqueness. □

Corollary 3.2.8. *Radon–Nikodym for Charges*
Let μ be σ-finite and let λ be a charge with $\lambda \ll \mu$. Then $\exists f \in \mathscr{L}^1(\mu)$ such that $\forall E \in \mathcal{M}$:

(i) $\lambda(E) = \int_E f \, d\mu$.
(ii) $\lambda^+(E) = \int_E f^+ \, d\mu$.
(iii) $\lambda^-(E) = \int_E f^- \, d\mu$.
(iv) $|\lambda|(E) = \int_E |f| \, d\mu$.

Proof. Since $|\lambda| \ll \mu$, $\lambda^{\pm} \ll \mu$. By Theorem 3.2.1, choose $f_{\pm} \geq 0$ with $\lambda^{\pm}(E) = \int_E f_{\pm}\, d\mu$.
Mutual singularity of λ^+ and λ^- gives $f_+ f_- = 0$ μ-a.e. Set $f := f_+ - f_-$.
Then $f^+ = f_+$ and $f^- = f_-$ μ-a.e., while $\int_X |f|\, d\mu = |\lambda|(X) < +\infty$.

(i) $\lambda(E) = \lambda^+(E) - \lambda^-(E) = \int_E f\, d\mu$.
(ii) $\lambda^+(E) = \int_E f_+\, d\mu = \int_E f^+\, d\mu$.
(iii) $\lambda^-(E) = \int_E f_-\, d\mu = \int_E f^-\, d\mu$.
(iv) $|\lambda|(E) = \lambda^+(E) + \lambda^-(E) = \int_E |f|\, d\mu$.

Structural Commentary: Signed absolute continuity is reduced to the two positive Jordan pieces.
Key Insight: Differentiate λ^+ and λ^- separately, then subtract. □

Example 3.2.9. *Radon–Nikodym Classification of Basic Stieltjes Generators*
Let m be Lebesgue measure on $\mathcal{B}(\mathbb{R})$, and let λ_i be the Borel–Stieltjes measure generated by g_i.

(i) $g_1(x) = 2x$: $\lambda_1 = 2m$, so $\lambda_1 \ll m$, $\frac{d\lambda_1}{dm} = 2$, $m \ll \lambda_1$, $\frac{dm}{d\lambda_1} = \frac{1}{2}$, and $\lambda_1(\mathbb{R}) = +\infty$.
(ii) $g_2(x) = \arctan x$: $\lambda_2(E) = \int_E (1+x^2)^{-1}\, dm$, so $\frac{d\lambda_2}{dm} = (1+x^2)^{-1}$, $\lambda_2(\mathbb{R}) = \pi$, $m \ll \lambda_2$, and $\frac{dm}{d\lambda_2} = 1 + x^2$.
(iii) $g_3 = \mathbf{1}_{[0,+\infty)}$: $\lambda_3 = \delta_0$, so $\lambda_3 \perp m$, $\lambda_3(\mathbb{R}) = 1$, $\lambda_3 \not\ll m$, and $m \not\ll \lambda_3$.
(iv) $g_4(x) = x\mathbf{1}_{[0,+\infty)}(x)$: $\lambda_4(E) = m(E \cap [0,+\infty))$, so $\lambda_4 \ll m$, $\frac{d\lambda_4}{dm} = \mathbf{1}_{[0,+\infty)}$, $m \not\ll \lambda_4$, and $\lambda_4(\mathbb{R}) = +\infty$.

Thus $\lambda_1, \lambda_2, \lambda_4 \ll m$, $\lambda_3 \perp m$, only λ_2, λ_3 are finite, and $m \ll \lambda_i$ exactly for $i = 1, 2$.
Structural Commentary: Stieltjes generators split naturally into density, atom, and restriction examples.
Key Insight: A positive density makes null sets equivalent; an atom lives on a Lebesgue-null set.

3.3 Differentiation of Measures

Definition 3.3.1. *Averages and Absolute Continuity*

(i) *Average*: for $f \in \mathscr{L}^1(E)$ and measurable $A \subseteq E$ with $m(A) > 0$, set $[f : A] := m(A)^{-1} \int_A f\, dm$.
(ii) *Density ratio*: for measurable B and cube or ball Q, $m(Q) > 0$, set $[B : Q] := \frac{m(B \cap Q)}{m(Q)}$.
(iii) *Indefinite integral*: for $f \in \mathscr{L}^1([a,b])$, $F(x) = F(a) + \int_a^x f(t)\, dt$.
(iv) *Absolute continuity*: $F : [a,b] \to \mathbb{R}$ is absolutely continuous iff $\forall \varepsilon > 0\ \exists \delta > 0$: if $(a_j, b_j)_{j=1}^N \subseteq [a,b]$ is a finite pairwise disjoint family, then $\sum_j (b_j - a_j) < \delta \Rightarrow \sum_j |F(b_j) - F(a_j)| < \varepsilon$.

Perspective 3.2.2. *Absolute Continuity as Interval Bookkeeping*
If $F(x) = \int_a^x f(t)\, dt$, absolute continuity controls total F-variation on disjoint intervals of small total length.

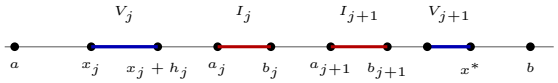

Figure 208: Interval bookkeeping for absolute continuity.

Perspective 3.3.3. *Vitali Covering Control*
Select balls disjointly by decreasing radius.
If B is rejected, then $B \cap B_j \neq \emptyset$ for some earlier B_j with $r(B) \leq r(B_j)$, hence $B \subseteq 5B_j$.
Key Insight: Disjoint balls add; fixed dilations cover misses.

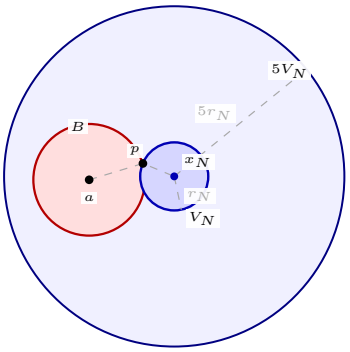

Figure 209: A comparable missed ball lies inside the fivefold dilation of the selected ball.

Definition 3.3.4. *Vitali Coverings and Density Points*
Let (M, d) be a metric space and let $A \subseteq M$.

(i) $\mathcal{V}$ is a *Vitali covering* of A iff $\forall p \in A\ \forall r > 0\ \exists V \in \mathcal{V}$ such that $p \in V$ and $\operatorname{diam}(V) < r$.
(ii) For measurable $E \subseteq \mathbb{R}^n$, its *density-point set* is $\operatorname{dp}(E) := \{p \in \mathbb{R}^n : \lim_{Q \downarrow p} [E : Q] = 1\}$, with Q cubes, equivalently balls, shrinking to p.

Theorem 3.3.5. *Vitali Covering Lemma for Balls and Cubes*
Let $E \subseteq \mathbb{R}^n$, $m^*(E) < +\infty$, and let $\mathcal{V}$ be a Vitali cover of E by closed balls or axis-parallel cubes.
Then $\exists (V_j)_{j \geq 1} \subseteq \mathcal{V}$ pairwise disjoint with $m^*(E \setminus \bigcup_{j \geq 1} V_j) = 0$.

Proof. Fix open $O \supseteq E$ with $m(O) < m^*(E) + \varepsilon$, and replace $\mathcal{V}$ by $\{V \in \mathcal{V} : V \subseteq O\}$.
Greedily choose a maximal disjoint (V_j) by dyadic diameter scales.
For a fixed dilation $V \mapsto V^*$, if $W \cap V \neq \emptyset$ and $\operatorname{diam} W \leq 2 \operatorname{diam} V$, then $W \subseteq V^*$ and $m(V^*) \leq C_n m(V)$.
Let $R = E \setminus \bigcup_j V_j$. Fix N and $p \in R$.
Since $V_1, \ldots, V_N$ are closed, choose $W \in \mathcal{V}$ with $p \in W$ and $W \cap \bigcup_{j \leq N} V_j = \emptyset$. Maximality gives some $j > N$ with $W \cap V_j \neq \emptyset$ and comparable diameter, hence $p \in W \subseteq V_j^*$. Thus $R \subseteq \bigcup_{j>N} V_j^*$.
Therefore $m^*(R) \leq C_n \sum_{j>N} m(V_j) \to 0$, because $\sum_j m(V_j) = m(\bigsqcup_j V_j) \leq m(O) < +\infty$. Hence $m^*(R) = 0$.
Structural Commentary: Vitali selection gives a disjoint cover modulo null sets.
Key Insight: $R \subseteq \bigcup_{j>N} V_j^*$ and disjoint tails vanish. □

Theorem 3.3.6. *Lebesgue Density Theorem*
For measurable $E \subseteq \mathbb{R}^n$, $\lim_{Q \downarrow p} [E : Q] = \mathbf{1}_E(p)$ for a.e. p, with $Q \downarrow p$ through cubes or balls.

Proof. Assume $m(E) < +\infty$. For $a \in (0,1)$ set $E_a := \{p \in E : \liminf_{Q \downarrow p} [E : Q] < a\}$.
Cubes $Q \ni p$ with $[E : Q] < a$ form a Vitali cover of E_a. For open $O \supseteq E_a$ with $m(O) < m(E_a) + \varepsilon$, choose disjoint $(Q_j) \subseteq O$ covering E_a modulo null sets by Theorem 3.3.5.
Hence $m(E_a) \leq \sum_j m(E_a \cap Q_j) \leq \sum_j m(E \cap Q_j) < a \sum_j m(Q_j) \leq a\, m(O) < a(m(E_a) + \varepsilon)$.
Let $\varepsilon \downarrow 0$; since $a < 1$, $m(E_a) = 0$. Thus $p \in E \setminus \bigcup_{a \in \mathbb{Q} \cap (0,1)} E_a$ has density 1. Apply same argument to bounded pieces of E^c to get density 0 a.e. on E^c; then exhaust arbitrary E by bounded pieces.
Structural Commentary: Measurable sets are locally 0 or 1 a.e.
Key Insight: Vitali turns bad density into $m(E_a) \leq a\, m(E_a)$. □

Corollary 3.3.7. *Density Points Represent a Measurable Set*
For measurable $E \subseteq \mathbb{R}^n$, $m(E \triangle \operatorname{dp}(E)) = 0$.

Proof. By Theorem 3.3.6, $[E : Q] \to 1$ at a.e. point of E, $[E : Q] \to 0$ at a.e. point of E^c; hence $E \triangle \operatorname{dp}(E)$ null.
Structural Commentary: The pointwise density dichotomy is converted into equality modulo null sets.
Key Insight: Density-one membership recovers the measurable set almost everywhere. □

Corollary 3.3.8. *Density Points Commute with Slicing Almost Everywhere*
Let $E \subseteq \mathbb{R}^n \times \mathbb{R}^k$ be measurable. For a.e. $x \in \mathbb{R}^n$, $\operatorname{dp}(E_x) = \{y : (x,y) \in \operatorname{dp}(E)\}$ up to a null subset of $\mathbb{R}^k$.

Proof. Set $D = \operatorname{dp}(E)$ and $N = E \triangle D$.
By Corollary 3.3.7, $m_{n+k}(N) = 0$; hence $m_k(N_x) = 0$ for a.e. x by Theorem 2.2.14.
Intersecting with the Fubini good set, E_x, D_x are measurable and $m_k(E_x \triangle D_x) = m_k((E \triangle D)_x) = 0$.
$m_k(E_x \triangle \operatorname{dp}(E_x)) = 0$ by Corollary 3.3.7 in $\mathbb{R}^k$. Therefore $m_k(\operatorname{dp}(E_x) \triangle D_x) = 0$.
Structural Commentary: Almost-everywhere local fullness is compatible with almost-everywhere slicing.
Key Insight: Null ambient errors have null slices for almost every base point. □

Lemma 3.3.9. *Large Averages Have Small Outer Measure*
Let $Q_0 \subseteq \mathbb{R}^n$ be a cube, let $0 \leq g \in \mathscr{L}^1(Q_0)$, and let $\lambda > 0$.
Set $A_\lambda := \{p \in Q_0 : \forall r > 0\ \exists$ a cube $Q \subseteq Q_0,\ p \in Q,\ \operatorname{diam} Q < r,\ [g : Q] > \lambda\}$. Then $m^*(A_\lambda) \leq \frac{1}{\lambda} \int_{Q_0} g\, dm$.

Proof. Let $\mathcal{V}_\lambda := \{Q \subseteq Q_0 : Q \text{ is a cube and } [g : Q] > \lambda\}$. This is a Vitali cover of A_λ; choose disjoint $(Q_j) \subseteq \mathcal{V}_\lambda$ covering A_λ modulo a null set. Then $\lambda m^*(A_\lambda) \leq \lambda \sum_j m(Q_j) < \sum_j \int_{Q_j} g\, dm \leq \int_{Q_0} g\, dm$.
Structural Commentary: Weak type for local averages.
Key Insight: Disjoint Vitali cubes turn pointwise large averages into one integral bound. □

Theorem 3.3.10. *Lebesgue Average Value Theorem*
For $f \in \mathscr{L}^1_{\mathrm{loc}}(\mathbb{R}^n)$, $\lim_{Q \downarrow p} [f : Q] = f(p)$ for a.e. $p \in \mathbb{R}^n$ with Q cubes, equivalently balls, shrinking to p.

Proof. Fix cube Q_0; to prove claim for a.e. $p \in Q_0^\circ$. For $\alpha > 0$, let $B_\alpha = \left\{ p \in Q_0^\circ : \limsup_{Q \downarrow p} |[f : Q] - f(p)| > \alpha \right\}$.
Choose $h \in C(Q_0)$ with $\|f - h\|_{L^1(Q_0)} < \eta$, and set $g = |f - h|$. Since $[h : Q] \to h(p)$, $B_\alpha \subseteq \{g > \frac{\alpha}{3}\} \cup A_{\frac{\alpha}{3}}(g)$.
By Markov and Lemma 3.3.9, $m^*(B_\alpha) \leq \frac{3}{\alpha} \int_{Q_0} g + \frac{3}{\alpha} \int_{Q_0} g < \frac{6\eta}{\alpha}$. Let $\eta \downarrow 0$; then $m(B_\alpha) = 0$.
Hence $B(Q_0) := \{p \in Q_0^\circ : \limsup_{Q \downarrow p} |[f : Q] - f(p)| > 0\} = \bigcup_{\alpha \in \mathbb{Q}_{>0}} B_\alpha$ is null.
With $Q_N := [-N, N]^n$, $\mathbb{R}^n = \bigcup_N Q_N^\circ$, so $\bigcup_N B(Q_N)$ is null.
Structural Commentary: Local averages recover the original integrable function almost everywhere.
Key Insight: Continuous approximation handles the good part; Vitali's estimate makes the bad part small. □

Theorem 3.3.11. *Lebesgue's Antiderivative Theorem*
For $f \in \mathscr{L}^1([a,b])$, define $F(x) := c + \int_a^x f(t)\, dt$.
(i) $F \in AC([a,b])$.
(ii) $F' = f$ a.e. on $[a,b]$.

Proof.

(i) Given $\varepsilon > 0$, choose $\delta > 0$ such that $m(A) < \delta$ implies $\int_A |f|\, dm < \varepsilon$.
If (α_j, β_j) are disjoint and $\sum_j (\beta_j - \alpha_j) < \delta$, then $\sum_j |F(\beta_j) - F(\alpha_j)| \le \int_{\bigcup_j (\alpha_j,\beta_j)} |f|\, dm < \varepsilon$.

(ii) For $x, x+h \in [a,b]$, let $I_h(x) := (\min\{x, x+h\}, \max\{x, x+h\})$. Then $\frac{F(x+h)-F(x)}{h} = [f : I_h(x)]$.
Extend f by 0 outside $[a,b]$; by Theorem 3.3.10 in one dimension, $[f : I_h(x)] \to f(x)$ for a.e. x.

Structural Commentary: The indefinite Lebesgue integral is the correct antiderivative for integrable functions.
Key Insight: Differentiating the integral is the same as shrinking the averaging interval. □

3.4 Monotone and Bounded-Variation Differentiation

Monotone functions are the one-dimensional model case for differentiation almost everywhere. Bounded-variation functions enter by Jordan decomposition: finite oscillation is exactly enough to write a function as the difference of two monotone functions.

Definition 3.4.1. *Bounded Variation*
Let $F : [a,b] \to \mathbb{R}$. For $a \le u < v \le b$, let $\mathcal{P}[u,v] := \{P = (x_0, \dots, x_N) : N \in \mathbb{N},\ u = x_0 < \cdots < x_N = v\}$.

(i) For $P = (x_0, \dots, x_N) \in \mathcal{P}[u,v]$, define $V(F,P) := \sum_{j=1}^{N} |F(x_j) - F(x_{j-1})|$.

(ii) Define $V_u^v(F) := \sup_{P \in \mathcal{P}[u,v]} V(F,P)$ for $u < v$, and $V_u^u(F) := 0$.

(iii) F has *bounded variation* on $[a,b]$ iff $F \in BV([a,b]) := \{G : [a,b] \to \mathbb{R} : V_a^b(G) < +\infty\}$.

Theorem 3.4.2. *Variation Function and Jordan Decomposition*
Let $F : [a,b] \to \mathbb{R}$. For $F \in BV([a,b])$, set $T_F : [a,b] \to \mathbb{R}$ by $T_F(a) := 0$ and $T_F(x) := V_a^x(F)$ for $a < x \le b$.

(i) Variation additivity: If $F \in BV([a,b])$, then $T_F(v) - T_F(u) = V_u^v(F)$ for $a \le u \le v \le b$.
(ii) Variation monotonicity: If $F \in BV([a,b])$, then T_F is nondecreasing.
(iii) Compensated monotonicity: If $F \in BV([a,b])$, then $F + T_F$ is nondecreasing.
(iv) Decomposition: If $F \in BV([a,b])$, then $F = (F + T_F) - T_F$ is a difference of nondecreasing functions.
(v) Converse: If $F = G - H$ for nondecreasing $G, H : [a,b] \to \mathbb{R}$,
then $F \in BV([a,b])$ and $V_a^b(F) \le G(b) - G(a) + H(b) - H(a)$.

Proof.

(i) Assume $F \in BV([a,b])$ and fix $a \le u \le v \le b$. The cases $u = a$ and $u = v$ are immediate; for $a < u < v$, concatenation gives $V_a^v(F) \ge V_a^u(F) + V_u^v(F)$, while inserting u into $P \in \mathcal{P}[a,v]$ and using the triangle inequality gives $V(F,P) \le V_a^u(F) + V_u^v(F)$. Taking suprema yields $V_a^v(F) = V_a^u(F) + V_u^v(F)$, QED.

(ii) By (i), $T_F(v) - T_F(u) = V_u^v(F) \ge 0$.

(iii) Since $|F(v) - F(u)| \le T_F(v) - T_F(u)$, $(F + T_F)(v) - (F + T_F)(u) \ge 0$.

(iv) The identity $F = (F + T_F) - T_F$ and (ii)–(iii) give the required monotone difference.

(v) Assume $F = G - H$ for nondecreasing $G, H : [a,b] \to \mathbb{R}$.
For $P = (x_0, \dots, x_N) \in \mathcal{P}[a,b]$, by monotonicity and triangle inequality,

$$V(F,P) \le \sum_{j=1}^{N} (G(x_j) - G(x_{j-1})) + \sum_{j=1}^{N} (H(x_j) - H(x_{j-1})) = G(b) - G(a) + H(b) - H(a).$$

Taking the supremum over P gives $V_a^b(F) \le G(b) - G(a) + H(b) - H(a) < +\infty$.

Structural Commentary: Bounded variation is exactly controlled monotone difference.
Key Insight: The variation function supplies the missing monotone part. □

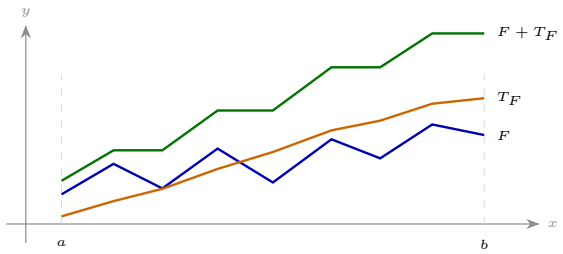

Figure 210: Variation T_F turns F into the increasing function $F + T_F$.

Example 3.4.3. *Basic Bounded-Variation Tests*

(i) If $F : [a,b] \to \mathbb{R}$ is nondecreasing, then $F \in BV([a,b])$ and $V_a^b(F) = F(b) - F(a)$.

(ii) If $F : [a,b] \to \mathbb{R}$ is L-Lipschitz, then $F \in BV([a,b])$ and $V_a^b(F) \le L(b-a)$.

(iii) Let $F : [0,1] \to \mathbb{R}$ satisfy $F(0) = 0$ and $F(x) = x\cos(\frac{\pi}{2x})$ for $0 < x \le 1$. Then F is continuous and $F \notin BV([0,1])$: for $P_n = (0, \frac{1}{2n}, \frac{1}{2n-1}, \dots, \frac{1}{2}, 1) \in \mathcal{P}[0,1]$, $V(F,P_n) = \sum_{k=1}^{n} \frac{1}{k} \to +\infty$.

Definition 3.4.4. *Upper and Lower Derivatives*
Let $I \subseteq \mathbb{R}$ be an interval, $F : I \to \mathbb{R}$, and $x \in I^\circ$.
For $h > 0$, set $Q_h(x) := \{t \in \mathbb{R} : 0 < |t| \le h,\ x + t \in I\}$ and $\Delta_t F(x) := \frac{F(x+t)-F(x)}{t}$.

(i) The *upper derivative* at x is $\overline{D}F(x) := \lim_{h \downarrow 0} \sup_{t \in Q_h(x)} \Delta_t F(x)$.

(ii) The *lower derivative* at x is $\underline{D}F(x) := \lim_{h \downarrow 0} \inf_{t \in Q_h(x)} \Delta_t F(x)$.

They exist in $\overline{\mathbb{R}}$, satisfy $\underline{D}F(x) \le \overline{D}F(x)$, and $F'(x)$ exists iff $\underline{D}F(x) = \overline{D}F(x) \in \mathbb{R}$.

Lemma 3.4.5. *Weak Bound for Upper Derivatives*
Let $F : [a,b] \to \mathbb{R}$ be nondecreasing. For $\alpha > 0$, set $E_\alpha := \{x \in (a,b) : \overline{D}F(x) \ge \alpha\}$.
Then:

(i) $m^*(E_\alpha) \le \frac{F(b)-F(a)}{\alpha}$ for every $\alpha > 0$.
(ii) $m^*\{x \in (a,b) : \overline{D}F(x) = +\infty\} = 0$.

Proof.

(i) Fix $\alpha > 0$ and $0 < \alpha' < \alpha$. For $x \in E_\alpha$ and $\delta > 0$, choose $[c,d] \subset (a,b)$ with $x \in [c,d]$, $d - c < \delta$, and $F(d) - F(c) > \alpha'(d-c)$. These intervals form a Vitali cover of E_α.
By Theorem 3.3.5, choose pairwise disjoint $I_k = [c_k, d_k]$ covering E_α modulo a null set.
Then $\alpha' m^*(E_\alpha) \le \alpha' \sum_k (d_k - c_k) < \sum_k (F(d_k) - F(c_k)) \le F(b) - F(a)$. Let $\alpha' \uparrow \alpha$.

(ii) Set $E_\infty := \{x \in (a,b) : \overline{D}F(x) = +\infty\}$. Since $E_\infty \subseteq E_n$ $\forall n \in \mathbb{N}$, (i) gives $m^*(E_\infty) \le \frac{F(b)-F(a)}{n} \to 0$.

Structural Commentary: Vitali selection converts local slope lower bounds into total rise.
Key Insight: Large local slopes are paid for by total monotone rise. □

Lemma 3.4.6. *Dini Gap Sets Are Null*
Let $F : [a,b] \to \mathbb{R}$ be nondecreasing and let $\alpha < \beta$.
Set $E_{\alpha,\beta} := \{x \in (a,b) : \underline{D}F(x) < \alpha < \beta < \overline{D}F(x)\}$. Then $m^*(E_{\alpha,\beta}) = 0$.

Proof. If $\alpha \le 0$, then $E_{\alpha,\beta} = \emptyset$ because every secant quotient of nondecreasing F is nonnegative.
Assume $0 < \alpha < \beta$, set $E = E_{\alpha,\beta}$, and fix $\varepsilon > 0$. Choose open O with $E \subseteq O \subseteq (a,b)$ and $m(O) < m^*(E) + \varepsilon$.
Since $\underline{D}F(x) < \alpha$ on E, intervals $[c,d] \subset O$ with $x \in [c,d]$, $F(d) - F(c) < \alpha(d-c)$ form Vitali cover of E.
Select pairwise disjoint $I_k = [c_k, d_k]$ covering E modulo a null set.
$\forall k$, modulo endpoints, $E \cap I_k \subseteq \{x \in (c_k, d_k) : \overline{D}(F|_{I_k})(x) \ge \beta\}$, so $m^*(E \cap I_k) \le \frac{F(d_k)-F(c_k)}{\beta}$ by Lemma 3.4.5.
Hence $m^*(E) \le \sum_k m^*(E \cap I_k) \le \frac{1}{\beta} \sum_k (F(d_k) - F(c_k)) < \frac{\alpha}{\beta} \sum_k (d_k - c_k) \le \frac{\alpha}{\beta} m(O)$.
Let $\varepsilon \downarrow 0$; then $m^*(E) \le \frac{\alpha}{\beta} m^*(E)$, and since $m^*(E) < +\infty$ and $\frac{\alpha}{\beta} < 1$, $m^*(E) = 0$.
Structural Commentary: Vitali intervals turn a slope gap into a contraction estimate.
Key Insight: Dini gaps force excess rise. □

Perspective 3.4.7. *Right Secants and Differentiation*
Right quotients $g_n(x) = n\big(F(x + \frac{1}{n}) - F(x)\big)$ encode local slope data.
Key Insight: Secants turn differentiation into slope estimates.

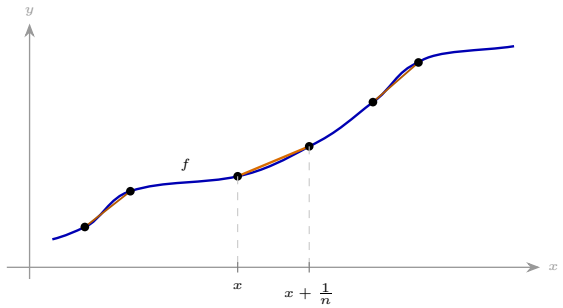

Figure 211: $g_n(x)$ is the slope of the short right secant from x to $x + \frac{1}{n}$.

Proposition 3.4.8. *Divided Differences and Moving Averages*
Let $f \in \mathscr{L}^1([a,b])$, extend f to $[a, b+1]$ by $f(x) = f(b)$ for $b < x \le b+1$, and fix $0 < h \le 1$.
For $x \in [a,b]$, set $\mathrm{Diff}_h f(x) := \frac{f(x+h)-f(x)}{h}$ and $\mathrm{Av}_h f(x) := h^{-1} \int_x^{x+h} f\, dm$.
Then $\forall a \le u < v \le b$, $\int_u^v \mathrm{Diff}_h f\, dm = \mathrm{Av}_h f(v) - \mathrm{Av}_h f(u)$.

Proof. For $a \le u < v \le b$, translation invariance gives $\int_u^v f(\cdot + h)\, dm = \int_{u+h}^{v+h} f\, dm$.
Hence $\int_u^v \mathrm{Diff}_h f\, dm = h^{-1}(\int_{u+h}^{v+h} f\, dm - \int_u^v f\, dm) = h^{-1}(\int_v^{v+h} f\, dm - \int_u^{u+h} f\, dm) = \mathrm{Av}_h f(v) - \mathrm{Av}_h f(u)$.
Structural Commentary: Difference quotients integrate to endpoint moving averages.
Key Insight: The interior contributions cancel after translation. □

Theorem 3.4.9. *Lebesgue Differentiability Theorem for Monotone Functions*
If $F : [a,b] \to \mathbb{R}$ is monotone, then F' exists a.e. on $[a,b]$.

Proof. Assume F is nondecreasing. Set $G_{\alpha,\beta} := \{\underline{D}F < \alpha < \beta < \overline{D}F\}$ for $\alpha, \beta \in \mathbb{Q}$, $\alpha < \beta$, and $E_\infty := \{\overline{D}F = +\infty\}$. Lemma 3.4.6 gives $m(G_{\alpha,\beta}) = 0$, and Lemma 3.4.5 gives $m(E_\infty) = 0$.
Outside $E_\infty \cup \bigcup_{\alpha<\beta} G_{\alpha,\beta}$, $\underline{D}F = \overline{D}F \in \mathbb{R}$, so F' exists. If F is nonincreasing, apply the result to $-F$.
Structural Commentary: Null Dini gaps plus finite upper derivative give differentiability.
Key Insight: Monotone rise controls exceptional slopes. □

Corollary 3.4.10. *Lipschitz and BV Differentiability*
Let $F : [a,b] \to \mathbb{R}$.

(i) If F is Lipschitz, then F' exists a.e. on $[a,b]$.

(ii) If $F \in BV([a,b])$, then F' exists a.e. on $[a,b]$.

Proof.

(i) If F is L-Lipschitz, then $G_+(x) := F(x) + Lx$ and $G_-(x) := Lx - F(x)$ are nondecreasing.
Their derivatives exist a.e. by Theorem 3.4.9, so $F' = \frac{G'_+ - G'_-}{2}$ a.e.

(ii) By Theorem 3.4.2, $F = G - H$ for nondecreasing G, H.
Their derivatives exist a.e. by Theorem 3.4.9, so $F' = G' - H'$ a.e.

Structural Commentary: Lipschitz and BV functions are reduced to finite combinations of monotone functions.
Key Insight: Almost-everywhere differentiability is stable under finite linear combinations. □

Corollary 3.4.11. *Absolute Continuity Implies BV Differentiability*
If $F \in AC([a,b])$, then:

(i) $F \in BV([a,b])$.
(ii) F' exists a.e. on $[a,b]$.

Proof.

(i) Choose $\delta > 0$ from absolute continuity with $\varepsilon = 1$, and choose $a = x_0 < \cdots < x_N = b$ with $x_j - x_{j-1} < \delta$. After inserting the x_j into a partition P, the increments within each $[x_{j-1}, x_j]$ have total length below δ and total F-variation below 1. Thus $V(F,P) \le N$ and $F \in BV([a,b])$.

(ii) By (i), $F \in BV([a,b])$; by Corollary 3.4.10 $\exists G \subseteq [a,b]$, $m([a,b] \setminus G) = 0$ and $F'(x) \in \mathbb{R}$ $\forall x \in G$.

Structural Commentary: Absolute continuity bounds variation; BV decomposition then gives differentiability.
Key Insight: One absolute-continuity scale controls every partition after a finite interval decomposition. □

Corollary 3.4.12. *Derivative Bounds for Monotone and BV Functions*
Let $F : [a,b] \to \mathbb{R}$.

(i) If F is nondecreasing, then $F' \ge 0$ a.e.
(ii) If F is nondecreasing, then $F' \in \mathscr{L}^1([a,b])$ and $\int_a^b F'\,dm \le F(b) - F(a)$.
(iii) If $F \in BV([a,b])$, then F' exists a.e.
(iv) If $F \in BV([a,b])$, then $F' \in \mathscr{L}^1([a,b])$.

Proof.

(i) Every secant quotient of a nondecreasing function is nonnegative; hence $F' \ge 0$ a.e. by Theorem 3.4.9.

(ii) Extend F by $F(b)$ on $(b, b+1]$, set $g_n(x) := n(F(x + \frac{1}{n}) - F(x))$. Then $g_n \ge 0$, $g_n \to F'$ a.e. on (a,b).
By Proposition 3.4.8, $\int_a^b g_n\,dm = F(b) - n\int_a^{a+\frac{1}{n}} F\,dm \le F(b) - F(a)$.
Fatou's lemma gives $\int_a^b F'\,dm \le F(b) - F(a) < +\infty$.

(iii) Corollary 3.4.10(ii) gives $\exists E \subseteq [a,b]$ with $m([a,b] \setminus E) = 0$ and $F'(x) \in \mathbb{R}$ $\forall x \in E$.

(iv) Write $F = G - H$ with G, H nondecreasing by Theorem 3.4.2. By (ii), $G', H' \in \mathscr{L}^1([a,b])$; on the full-measure set where G', H' exist, $F' = G' - H'$, so $F' \in \mathscr{L}^1([a,b])$.

Structural Commentary: BV inherits finite derivative mass from monotone parts.
Key Insight: Fatou turns right-secant bounds into an integral bound for the derivative. □

3.5 Absolute Continuity and BV Decomposition

Absolute continuity is the part of bounded variation detected by integration. The remaining bounded-variation behavior is singular: it may be monotone and continuous, but its derivative vanishes almost everywhere.

Proposition 3.5.1. *Absolutely Continuous Variation Function*
Let $F \in AC([a,b])$ and let $T_F(x) := V_a^x(F)$ be its total variation function.

(i) $T_F \in AC([a,b])$.
(ii) $F = (F + T_F) - T_F$ is a difference of two nondecreasing absolutely continuous functions.

Proof.

(i) Let $\varepsilon > 0$ and choose $\delta > 0$ from absolute continuity of F for the challenge $\frac{\varepsilon}{2}$.
Suppose $(c_k, d_k)_{k=1}^n$ are disjoint subintervals of (a,b) with $\sum_k (d_k - c_k) < \delta$.
Choose partitions P_k of $[c_k, d_k]$ such that $V_{c_k}^{d_k}(F) \le V(F, P_k) + \frac{\varepsilon}{2n}$.
Let $\mathcal{I}$ be all subintervals of all P_k; then $\mathcal{I}$ is disjoint up to endpoints and $\sum_{I \in \mathcal{I}} |I| = \sum_k (d_k - c_k)$.
Hence absolute continuity of F gives $\sum_k V(F, P_k) < \frac{\varepsilon}{2}$, thus $\sum_{k=1}^n |T_F(d_k) - T_F(c_k)| = \sum_{k=1}^n V_{c_k}^{d_k}(F) < \varepsilon$.

(ii) By (i), $T_F \in AC([a,b])$, hence $F + T_F \in AC([a,b])$.
For $x < y$, $T_F(y) - T_F(x) = V_x^y(F) \ge 0$ and $(F + T_F)(y) - (F + T_F)(x) = F(y) - F(x) + V_x^y(F) \ge 0$.
Thus T_F and $F + T_F$ are nondecreasing, and $F = (F + T_F) - T_F$.

Structural Commentary: Absolute continuity controls local variation, not just endpoint displacement.
Key Insight: Partition each local variation, then apply one absolute-continuity test to all pieces. □

Theorem 3.5.2. *Absolute Continuity via Divided Differences*
Let $F \in C([a,b])$, extend F constantly by $F(b)$ on $(b, b+1]$. Let $\operatorname{Diff}_h F(x) := \frac{F(x+h) - F(x)}{h}$, $0 < h \le 1$, $x \in [a,b]$.
Then $F \in AC([a,b])$ iff $\{\operatorname{Diff}_h F : 0 < h \le 1\}$ is uniformly integrable:
$\forall \varepsilon > 0\ \exists \delta > 0\ \forall E \in \mathcal{L}^1,\ E \subseteq [a,b]$ *and* $m(E) < \delta$ *imply* $\sup_{0<h\le 1} \int_E |\operatorname{Diff}_h F|\,dm < \varepsilon$.

Proof.

($\Leftarrow$) Assume the divided differences are uniformly integrable. Given $\varepsilon > 0$, choose $\delta > 0$ for $\frac{\varepsilon}{2}$.
For disjoint (c_k, d_k) with total length below δ, set $E := \bigcup_k (c_k, d_k)$.

By Proposition 3.4.8, $\sum_k |\mathrm{Av}_h F(d_k) - \mathrm{Av}_h F(c_k)| \le \int_E |\mathrm{Diff}_h F|\, dm < \frac{\varepsilon}{2}$.

Letting $h \downarrow 0$ gives $\sum_k |F(d_k) - F(c_k)| \le \frac{\varepsilon}{2} < \varepsilon$.

($\Rightarrow$) Suppose $F \in AC([a,b])$. By Proposition 3.5.1, write $F = U - V$ with U, V nondecreasing and absolutely continuous; since $|\mathrm{Diff}_h F| \le \mathrm{Diff}_h U + \mathrm{Diff}_h V$, assume F nondecreasing.
Let $\widetilde{F}$ be the constant extension to $[a, b+1]$.
Choose $\eta > 0$ for $\frac{\varepsilon}{2}$ in the absolute continuity of $\widetilde{F}$ and set $\delta := \frac{\eta}{2}$. If $m(E) < \delta$, take open $O \supseteq E \cap (a,b)$ with $O \cap (a,b) = \bigsqcup_j (\alpha_j, \beta_j)$ and $m(O \cap (a,b)) < \eta$; set $O_N := \bigcup_{j \le N} (\alpha_j, \beta_j)$.

For $0 < t \le h$, $\sum_{j \le N} ((\beta_j + t) - (\alpha_j + t)) < \eta$, so $\sum_{j \le N} (\widetilde{F}(\beta_j + t) - \widetilde{F}(\alpha_j + t)) < \frac{\varepsilon}{2}$.

Hence $\int_{O_N} \mathrm{Diff}_h F\, dm = \frac{1}{h} \int_0^h \sum_{j \le N} (\widetilde{F}(\beta_j + t) - \widetilde{F}(\alpha_j + t))\, dt < \frac{\varepsilon}{2}$.

Let $N \to \infty$ and use $E \subseteq O$ to get $\sup_{0<h\le 1} \int_E \mathrm{Diff}_h F\, dm < \varepsilon$.

Structural Commentary: Absolute continuity is uniform small-set control for translated secants.
Key Insight: Moving averages turn endpoint increments into integrals of divided differences. □

Theorem 3.5.3. *Fundamental Theorem for Absolutely Continuous Functions*
Let $F \in AC([a,b])$.

(i) F' exists a.e. on $[a,b]$.
(ii) $F' \in \mathscr{L}^1([a,b])$.
(iii) $F(y) - F(x) = \int_x^y F'\, dm$ for $a \le x \le y \le b$.

Proof.

(i) Corollary 3.4.11(ii) gives $\exists E \subseteq [a,b]$ with $m([a,b] \setminus E) = 0$ and $F'(x) \in \mathbb{R}$ $\forall x \in E$.
(ii) Corollary 3.4.11(i) gives $F \in BV([a,b])$, so Corollary 3.4.12(iv) gives $F' \in \mathscr{L}^1([a,b])$.
(iii) Set $f_n := \mathrm{Diff}_{\frac{1}{n}} F$. By Theorem 3.5.2, (f_n) is uniformly integrable; by (i), $f_n \to F'$ a.e.

Fix $a \le x < y \le b$ and $\varepsilon > 0$. Choose $M > 0$ with $\int_{\{|F'|>M\}} |F'|\, dm < \frac{\varepsilon}{6}$ and then $\delta > 0$ such that $M\delta < \frac{\varepsilon}{6}$ and $m(A) < \delta$ implies $\sup_n \int_A |f_n|\, dm < \frac{\varepsilon}{3}$. By Egorov's theorem, $f_n \to F'$ uniformly on $[x,y] \setminus A$ for some measurable A with $m(A) < \delta$. For large n, $\int_x^y |f_n - F'|\, dm < \varepsilon$.
Thus $\int_x^y f_n\, dm \to \int_x^y F'\, dm$. By Proposition 3.4.8, $\int_x^y f_n\, dm = \mathrm{Av}_{\frac{1}{n}} F(y) - \mathrm{Av}_{\frac{1}{n}} F(x) \to F(y) - F(x)$.

Structural Commentary: Uniform integrability is the condition that permits the discrete secant formula to pass to the derivative under the integral sign.
Key Insight: Uniform small-set control upgrades a.e. secant convergence to convergence of interval integrals. □

Corollary 3.5.4. *Indefinite Integral Characterization of Absolute Continuity*
A function $F : [a,b] \to \mathbb{R}$ satisfies:

(i) $F \in AC([a,b])$ iff $\exists g \in \mathscr{L}^1([a,b])$ such that $F(x) = F(a) + \int_a^x g\, dm$ for $x \in [a,b]$.
(ii) Any such g satisfies $g = F'$ a.e.

Proof.

(i) ($\Rightarrow$) If $F \in AC([a,b])$, Theorem 3.5.3 gives $F' \in \mathscr{L}^1([a,b])$ and $F(x) = F(a) + \int_a^x F'\, dm$; take $g = F'$.
(i) ($\Leftarrow$) If $F(x) = F(a) + \int_a^x g\, dm$ with $g \in \mathscr{L}^1([a,b])$, Theorem 3.3.11 gives $F \in AC([a,b])$.
(ii) If $F(x) = F(a) + \int_a^x g\, dm$, then Theorem 3.3.11 gives $F' = g$ a.e.

Structural Commentary: The two directions are the fundamental theorem and the antiderivative theorem.
Key Insight: Absolute continuity is exactly representability by an L^1 density. □

Proposition 3.5.5. *Radon–Nikodym on an Interval Recovers Absolute Continuity*
Let λ be a finite measure on $\mathcal{B}([a,b])$ with $\lambda \ll m$, let $f := \frac{d\lambda}{dm}$, and set $F(x) := \lambda([a,x])$.

(i) $F(y) - F(x) = \int_x^y f\, dm$ for $a \le x \le y \le b$.
(ii) $F \in AC([a,b])$.
(iii) $F' = f$ a.e. on $[a,b]$.

Proof. By Theorem 3.2.1, $f \in L^1(m)$, $\lambda(E) = \int_E f\, dm$ for $E \in \mathcal{B}([a,b])$. Since $\lambda \ll m$, $\lambda(\{x\}) = 0$ for $x \in [a,b]$.

(i) For $a \le x \le y \le b$, $\lambda(\{x\}) = 0$ gives $F(y) - F(x) = \lambda((x,y]) = \int_{(x,y]} f\, dm = \int_x^y f\, dm$.
(ii) Taking $x = a$ in (i), $F(y) = F(a) + \int_a^y f\, dm$ for $y \in [a,b]$; Corollary 3.5.4(i) gives $F \in AC([a,b])$.
(iii) Since $F = F(a) + \int_a^{(\cdot)} f\, dm$, Corollary 3.5.4(ii) gives $F' = f$ a.e. on $[a,b]$.

Structural Commentary: Interval RN representation differentiates cumulative mass.
Key Insight: No atoms, so interval increments equal density integrals. □

Remark 3.5.6. *Lebesgue–Stieltjes Integrals*
Let $g : \mathbb{R} \to \mathbb{R}$ be increasing and right-continuous, and let μ_g be its Borel–Stieltjes measure.
For $E \in \mathcal{B}(\mathbb{R})$ and bounded Borel $f : E \to \mathbb{R}$, define $\int_E f\, dg := \int_E f\, d\mu_g$.
If $J \subseteq \mathbb{R}$ is an interval, $\mu_g|_J \ll m|_J$, and $h := \frac{d\mu_g}{dm}$ on J, then $\int_E f\, dg = \int_E fh\, dm$ for every Borel $E \subseteq J$.
For $a < b$ with $[a,b] \subseteq J$, $F_a : [a,b] \to \mathbb{R}$, $F_a(x) := \mu_g([a,x])$, is absolutely continuous and satisfies $F_a' = h$ a.e. by Proposition 3.5.5. If $g|_J$ is absolutely continuous, then $h = g'$ a.e. on J.

Example 3.5.7. *Cantor–Lebesgue Function Is Not Absolutely Continuous*
Let $\varphi : [0,1] \to [0,1]$ be the Cantor–Lebesgue function: φ is continuous, nondecreasing, $\varphi(0) = 0$, $\varphi(1) = 1$, and constant on every complementary interval of the Cantor set.
At stage n, write the remaining intervals as $I_{n,k} = [c_{n,k}, d_{n,k}]$, $1 \le k \le 2^n$, so $\sum_k |I_{n,k}| = (\frac{2}{3})^n$.

Since φ is constant on the deleted gaps, $\sum_{k=1}^{2^n} (\varphi(d_{n,k}) - \varphi(c_{n,k})) = 1$.

By continuity, choose $c_{n,k} < \alpha_{n,k} < \beta_{n,k} < d_{n,k}$ such that $\sum_k (\beta_{n,k} - \alpha_{n,k}) < (\frac{2}{3})^n$ and $\sum_k (\varphi(\beta_{n,k}) - \varphi(\alpha_{n,k})) > \frac{1}{2}$. Since $(\frac{2}{3})^n \to 0$, absolute continuity fails for $\varepsilon = \frac{1}{2}$.
Key Insight: The increase of φ lies on intervals with arbitrarily small total length.

Proposition 3.5.8. *Lipschitz, Absolutely Continuous, and BV Classes*
Let $[a,b]$ be nondegenerate, and let $\mathcal{F}_{\mathrm{Lip}}$ denote the Lipschitz functions on $[a,b]$.
(i) $\mathcal{F}_{\mathrm{Lip}} \subsetneq AC([a,b]) \subsetneq BV([a,b])$.
(ii) For $\mathcal{C} \in \{\mathcal{F}_{\mathrm{Lip}}, AC([a,b]), BV([a,b])\}$, $F, G \in \mathcal{C}$ and $\alpha, \beta \in \mathbb{R}$ imply $\alpha F + \beta G \in \mathcal{C}$.
(iii) If $F \in \mathcal{C}$ for some $\mathcal{C} \in \{\mathcal{F}_{\mathrm{Lip}}, AC([a,b]), BV([a,b])\}$, then $T_F(x) := V_a^x(F)$ lies in $\mathcal{C}$.

Proof.
(i) If F is L-Lipschitz, then $\sum_j |F(d_j) - F(c_j)| \le L \sum_j (d_j - c_j)$, so $F \in AC([a,b])$.
Corollary 3.4.11(i) gives $AC([a,b]) \subseteq BV([a,b])$.
Strictness: $x \mapsto \sqrt{\frac{x-a}{b-a}}$ lies in $AC([a,b]) \setminus \mathcal{F}_{\mathrm{Lip}}$, and $x \mapsto \varphi(\frac{x-a}{b-a})$, with φ Cantor–Lebesgue, lies in $BV([a,b]) \setminus AC([a,b])$ because φ is nondecreasing and its Cantor-stage intervals have total length $(\frac{2}{3})^n \to 0$ but total φ-increase 1.
(ii) If F, G are Lipschitz with constants L_F, L_G, then $\alpha F + \beta G$ is Lipschitz with constant $|\alpha| L_F + |\beta| L_G$.
If $F, G \in AC([a,b])$, the interval criterion gives $\alpha F + \beta G \in AC([a,b])$.
If $F, G \in BV([a,b])$, then $V(\alpha F + \beta G, P) \le |\alpha| V(F,P) + |\beta| V(G,P)$, so $V_a^b(\alpha F + \beta G) < +\infty$.
(iii) If F is L-Lipschitz, then $T_F(v) - T_F(u) = V_u^v(F) \le L(v-u)$.
If $F \in AC([a,b])$, Proposition 3.5.1(i) gives $T_F \in AC([a,b])$.
If $F \in BV([a,b])$, then T_F is nondecreasing and $V_a^b(T_F) = T_F(b) - T_F(a) = V_a^b(F) < +\infty$.

Structural Commentary: $\mathcal{F}_{\mathrm{Lip}} \subsetneq AC \subsetneq BV$ is a strict control hierarchy.
Key Insight: $\sqrt{\cdot}$ breaks Lipschitz; Cantor mass breaks absolute continuity. □

Proposition 3.5.9. *Algebra and Safe Composition*
Let $F, G \in AC([a,b])$.
(i) For $\alpha, \beta \in \mathbb{R}$, $\alpha F + \beta G \in AC([a,b])$.
(ii) $FG \in AC([a,b])$.
(iii) If $\Phi : \mathbb{R} \to \mathbb{R}$ is Lipschitz, then $\Phi \circ G \in AC([a,b])$.
(iv) If G is strictly monotone and $\Phi \in AC(J)$ on a compact interval $J \supseteq G([a,b])$, then $\Phi \circ G \in AC([a,b])$.

Proof.
(i) For disjoint (c_k, d_k), $\sum_k |(\alpha F + \beta G)(d_k) - (\alpha F + \beta G)(c_k)| \le |\alpha| \sum_k |F(d_k) - F(c_k)| + |\beta| \sum_k |G(d_k) - G(c_k)|$. Thus the right side is $< \varepsilon$ whenever $\sum_k (d_k - c_k) < \delta$ for a common AC scale of F, G, QED.
(ii) Let $|F| \le M_F$ and $|G| \le M_G$. For $\Delta F_k := F(d_k) - F(c_k)$ and $\Delta G_k := G(d_k) - G(c_k)$, $|F(d_k)G(d_k) - F(c_k)G(c_k)| \le M_F |\Delta G_k| + M_G |\Delta F_k|$. Choose a common AC scale with $\sum_k |\Delta F_k| < \frac{\varepsilon}{2(1+M_G)}$ and $\sum_k |\Delta G_k| < \frac{\varepsilon}{2(1+M_F)}$; then $\sum_k |F(d_k)G(d_k) - F(c_k)G(c_k)| < \varepsilon$.
(iii) If Φ is L-Lipschitz, then $\sum_k |\Phi(G(d_k)) - \Phi(G(c_k))| \le L \sum_k |G(d_k) - G(c_k)|$.
Choose the AC scale of G for $\frac{\varepsilon}{L}$ if $L > 0$; the case $L = 0$ is trivial.
(iv) Suppose G is strictly increasing. Choose $\eta > 0$ from $AC(\Phi)$ for ε and $\delta > 0$ from $AC(G)$ for η.
If $\sum_k (d_k - c_k) < \delta$, then $\sum_k (G(d_k) - G(c_k)) < \eta$.
Since $(G(c_k), G(d_k))$ are disjoint, $\sum_k |\Phi(G(d_k)) - \Phi(G(c_k))| < \varepsilon$.
If G is strictly decreasing, replace $(G(c_k), G(d_k))$ by $(G(d_k), G(c_k))$.

Structural Commentary: AC is stable under algebra and controlled composition.
Key Insight: Lipschitz bounds sizes; monotonicity preserves disjoint intervals. □

Example 3.5.10. *Absolutely Continuous Composition Can Fail*
Define $f, g : [-1,1] \to \mathbb{R}$ by $f(x) := \operatorname{sgn}(x) |x|^{\frac{1}{3}}$, $g(0) := 0$, and $g(x) := x^2 \cos \frac{\pi}{2x}$ for $x \ne 0$. Then:
(i) $f, g \in AC([-1,1])$.
(ii) $f \circ g \notin BV([-1,1])$, hence $f \circ g \notin AC([-1,1])$.

Proof.
(i) Let $h(t) := \frac{1}{3} |t|^{-\frac{2}{3}} \mathbf{1}_{t \ne 0}$. Then $h \in L^1([-1,1])$ and $f(x) = \int_0^x h \, dm$, so $f \in AC([-1,1])$.
For $x \ne 0$, $g'(x) = 2x \cos \frac{\pi}{2x} + \frac{\pi}{2} \sin \frac{\pi}{2x}$, hence $|g'| \le 2 + \frac{\pi}{2}$ off 0.
Together with $|g(x)| \le x^2$, this gives g Lipschitz, so $g \in AC([-1,1])$.
(ii) For $k \ge 1$, $g(\frac{1}{2k-1}) = 0$ and $g(\frac{1}{2k}) = \frac{(-1)^k}{4k^2}$. With $P_n := \{0\} \cup \{\frac{1}{j} : 1 \le j \le 2n\}$,
$V(f \circ g, P_n) \ge \sum_{k=1}^{n} \left| f(g(\frac{1}{2k})) - f(g(\frac{1}{2k-1})) \right| = 4^{-\frac{1}{3}} \sum_{k=1}^{n} k^{-\frac{2}{3}} \to +\infty$. Thus $f \circ g \notin BV([-1,1])$.

Key Insight: The cube root amplifies the inner oscillations until variation diverges. □

Definition 3.5.11. *Singular Bounded-Variation Function*
A function $S \in BV([a,b])$ is *singular* if $S' = 0$ a.e. on $[a,b]$.

Theorem 3.5.12. *Lebesgue Decomposition of a BV Function*
Let $F \in BV([a,b])$. Define $G(x) := F(a) + \int_a^x F'\,dm$, $H(x) := F(x) - G(x)$.

(i) $G \in AC([a,b])$ and $G' = F'$ a.e.
(ii) $H \in BV([a,b])$, $H' = 0$ a.e., $H(a) = 0$, and $F = G + H$.
(iii) If $F = G_1 + H_1$ with $G_1 \in AC([a,b])$, $H_1' = 0$ a.e., and $H_1(a) = 0$, then $G_1 = G$ and $H_1 = H$.

Proof.

(i) By Corollary 3.4.12, $F' \in \mathscr{L}^1([a,b])$. By Theorem 3.3.11, $G \in AC([a,b])$ and $G' = F'$ a.e.
(ii) Since $F, G \in BV([a,b])$, $H = F - G \in BV([a,b])$.
Moreover, $H' = F' - G' = 0$ a.e., $H(a) = 0$, and $F = G + H$.
(iii) If $F = G_1 + H_1$ is another normalized decomposition, then $G_1 - G = H - H_1$ is absolutely continuous, has derivative 0 a.e., and vanishes at a. By Theorem 3.5.3, $G_1 - G = 0$, hence $G_1 = G$ and $H_1 = H$.

Structural Commentary: A BV function splits into an L^1-density part and a derivative-invisible singular part.
Key Insight: Integrating the a.e. derivative separates the absolutely continuous and singular parts. □

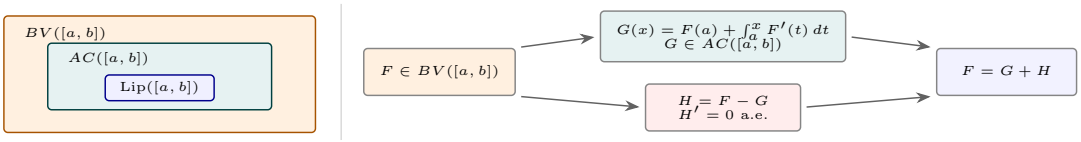

Figure 212: Lip $\subsetneq AC \subsetneq BV$, and each $F \in BV$ decomposes as $F = G + H$ with $G \in AC$ and $H' = 0$ a.e.

Corollary 3.5.13. *Absolutely Continuous Singular Functions Are Constant*

(i) If $F \in AC([a,b])$ and $F' = 0$ a.e., then F is constant.
(ii) The Cantor–Lebesgue function is nonconstant and singular.
(iii) The Cantor–Lebesgue function is not absolutely continuous.

Proof.

(i) By Theorem 3.5.3, $F(y) - F(x) = \int_x^y F'\,dm = 0$.
(ii) The function φ is nondecreasing, hence in $BV([0,1])$, and $\varphi' = 0$ on the full-measure set $[0,1] \setminus P$ by Proposition 8.1.2. Since $\varphi(0) = 0$ and $\varphi(1) = 1$, it is nonconstant.
(iii) If $\varphi \in AC([0,1])$, then $\varphi' = 0$ a.e. by (ii), so (i) gives φ constant, contradicting $\varphi(0) = 0 \neq 1 = \varphi(1)$.

Structural Commentary: The fundamental theorem makes absolute continuity exclude nonconstant singularity.
Key Insight: Derivative-invisible increase can occur in BV but not in absolute continuity. □

3.6 Nikodym Metric and Setwise Measure Limits

The Nikodym metric turns measurable sets modulo μ-null symmetric difference into a complete metric space. This lets Baire category control setwise limits of absolutely continuous measures.

Definition 3.6.1. *Setwise Convergence and Uniform Absolute Continuity*
Let $(X, \mathcal{M})$ be a measurable space.

(i) For $A, B \in \mathcal{M}$, $A \triangle B := (A \setminus B) \cup (B \setminus A)$.
(ii) Finite measures ν_n *converge setwise* to $\nu : \mathcal{M} \to [0, +\infty]$ iff $\nu_n(E) \to \nu(E)$ for every $E \in \mathcal{M}$.
(iii) For $\nu_n \ll \mu$ for all n, (ν_n) is *uniformly absolutely continuous* w.r.t. μ iff
$\forall \varepsilon > 0\ \exists \delta > 0$: $\mu(E) < \delta \Rightarrow \sup_n \nu_n(E) < \varepsilon$ for all $E \in \mathcal{M}$.

Lemma 3.6.2. *Nikodym Symmetric-Difference Calculus*
For $A, B, C \in \mathcal{M}$ and a finite measure ν:

(i) $A \triangle C \subseteq (A \triangle B) \cup (B \triangle C)$.
(ii) $|\nu(A) - \nu(B)| \leq \nu(A \triangle B)$.

Proof.

(i) If $x \in A \triangle C$, then $\mathbf{1}_A(x) \neq \mathbf{1}_C(x)$. Hence $\mathbf{1}_A(x) \neq \mathbf{1}_B(x)$ or $\mathbf{1}_B(x) \neq \mathbf{1}_C(x)$, so $x \in (A \triangle B) \cup (B \triangle C)$.
(ii) Since $\nu(A) - \nu(B) = \nu(A \setminus B) - \nu(B \setminus A)$, $|\nu(A) - \nu(B)| \leq \nu(A \setminus B) + \nu(B \setminus A) = \nu(A \triangle B)$.

Structural Commentary: Set inclusion gives the triangle inequality; disjoint differences give the mass bound.
Key Insight: Nikodym distance measures exactly the part where two measurable sets disagree. □

Definition 3.6.3. *Nikodym Metric Space*
Let $(X, \mathcal{M}, \mu)$ be a finite measure space.

(i) *Null equivalence*: $A \sim_\mu B \Leftrightarrow \mu(A \triangle B) = 0$.
(ii) *Quotient space*: $\mathcal{M}_\mu := \mathcal{M}/\!\sim_\mu$, with class notation $[A] \in \mathcal{M}_\mu$.
(iii) *Metric*: $\rho_\mu([A],[B]) := \mu(A \triangle B)$.

By Lemma 3.6.2 and Proposition 3.1.12, ρ_μ is a well-defined metric on $\mathcal{M}_\mu$.

Proposition 3.6.4. *Nikodym Pseudometric*
Let $E \subseteq \mathbb{R}$ be Lebesgue measurable with $m(E) < \infty$, let X be the collection of Lebesgue measurable subsets of E, and for $A, B \in X$ set $A \triangle B := (A \setminus B) \cup (B \setminus A)$ and $\rho(A,B) := m(A \triangle B)$. Define $A \sim_\rho B$ iff $\rho(A,B) = 0$.

(i) ρ is a pseudometric on X.

(ii) $\widetilde{\rho}([A],[B]) := \rho(A,B)$ *is a metric on* $X/\!\sim_\rho$.
(iii) *For all* $A, B \in X$, $\rho(A,B) = \int_E |\mathbf{1}_A - \mathbf{1}_B|\, dm$.

Proof.

(i) For $A, B, C \in X$, $A\Delta B \subseteq E$, $A\Delta A = \emptyset$, $A\Delta B = B\Delta A$, and $A\Delta C \subseteq (A\Delta B) \cup (B\Delta C)$.
Hence $0 \le \rho(A,B) \le m(E) < \infty$, $\rho(A,A) = 0$, $\rho(A,B) = \rho(B,A)$, and $\rho(A,C) \le \rho(A,B) + \rho(B,C)$.
(ii) By (i), ρ is a pseudometric and $A \sim_\rho B \iff \rho(A,B) = 0$.
Proposition 3.1.12 gives that $\widetilde{\rho}([A],[B]) := \rho(A,B)$ is a metric on $X/\!\sim_\rho$.
(iii) For $t \in E$, $|\mathbf{1}_A(t) - \mathbf{1}_B(t)| = \mathbf{1}_{A\Delta B}(t)$; integrating gives $\int_E |\mathbf{1}_A - \mathbf{1}_B|\, dm = m(A\Delta B) = \rho(A,B)$.

Structural Commentary: Symmetric difference measures set disagreement.
Key Insight: Quotienting null disagreement gives definiteness. □

Theorem 3.6.5. *Completeness of the Nikodym Metric*
If $(X, \mathcal{M}, \mu)$ *is a finite measure space, then* $(\mathcal{M}_\mu, \rho_\mu)$ *is complete.*

Proof. Let (A_n) be ρ_μ-Cauchy. Choose $n_k \uparrow \infty$ with $\rho_\mu(A_{n_{k+1}}, A_{n_k}) < 2^{-k}$, and set $D_k := A_{n_{k+1}} \triangle A_{n_k}$.
Since $\mu(\bigcup_{k\ge N} D_k) \le \sum_{k\ge N} 2^{-k} \to 0$, $N_0 := \bigcap_N \bigcup_{k\ge N} D_k$ is null. Put $A := \bigcup_N \bigcap_{k\ge N} A_{n_k}$.
Then $A_{n_k} \triangle A \subseteq N_0 \cup \bigcup_{j\ge k} D_j$, so $\rho_\mu(A_{n_k}, A) \le \sum_{j\ge k} 2^{-j} \to 0$. Since (A_n) is Cauchy, $\rho_\mu(A_n, A) \to 0$.

Structural Commentary: Summable jumps give an a.e. eventual set limit.
Key Insight: Summable symmetric differences confine infinitely changing membership to a null set. □

Proposition 3.6.6. *Absolutely Continuous Measures Are Nikodym-Continuous*
Let $(X, \mathcal{M}, \mu)$ *be finite, let* ν *be a finite measure with* $\nu \ll \mu$, *and define* $\Phi_\nu([E]) := \nu(E)$.
(i) $\Phi_\nu : \mathcal{M}_\mu \to \mathbb{R}$ *is well-defined.*
(ii) Φ_ν *is uniformly continuous.*

Proof.

(i) If $A \sim_\mu B$, then $\mu(A\triangle B) = 0$, hence $\nu(A\triangle B) = 0$ and $\nu(A) = \nu(B)$.
(ii) By Lemma 3.6.2, $|\nu(A) - \nu(B)| \le \nu(A\triangle B)$. Given $\varepsilon > 0$, choose $\delta > 0$ by Lemma 3.1.14 such that $\mu(E) < \delta$ implies $\nu(E) < \varepsilon$.
Thus $\rho_\mu(A,B) < \delta$ implies $|\Phi_\nu(A) - \Phi_\nu(B)| < \varepsilon$.

Structural Commentary: Null-set identification defines the map; absolute continuity controls its modulus.
Key Insight: Absolute continuity converts small Nikodym distance into small change of mass. □

Proposition 3.6.7. *Uniform Absolute Continuity and Radon–Nikodym Derivatives*
Let $(X, \mathcal{M}, \mu)$ *be finite, let* (ν_n) *be finite measures with* $\nu_n \ll \mu$, *and set* $f_n = \frac{d\nu_n}{d\mu}$. *The following are equivalent.*

(i) (ν_n) *is uniformly absolutely continuous with respect to* μ.
(ii) *The functions* $\Phi_{\nu_n} : \mathcal{M}_\mu \to \mathbb{R}$ *are uniformly equicontinuous.*
(iii) *The functions* Φ_{ν_n} *are equicontinuous at* $\emptyset$.
(iv) $\{f_n : n \ge 1\}$ *is uniformly integrable:* $\forall \varepsilon > 0\ \exists \delta > 0\ \forall E \in \mathcal{M}$, $\mu(E) < \delta \Rightarrow \sup_n \int_E f_n\, d\mu < \varepsilon$.

Proof.

(i) $\Rightarrow$ *(ii)* Given $\varepsilon > 0$, choose $\delta > 0$ with $\mu(E) < \delta \Rightarrow \sup_n \nu_n(E) < \varepsilon$.
If $\rho_\mu(A,B) = \mu(A\triangle B) < \delta$, then $|\Phi_{\nu_n}(A) - \Phi_{\nu_n}(B)| = |\nu_n(A) - \nu_n(B)| \le \nu_n(A\triangle B) < \varepsilon$ uniformly in n.
(ii) $\Rightarrow$ *(iii)* Given $\varepsilon > 0$, uniform equicontinuity gives $\delta > 0$ such that
$\rho_\mu(A,B) < \delta \Rightarrow \sup_n |\Phi_{\nu_n}(A) - \Phi_{\nu_n}(B)| < \varepsilon$. With $B = \emptyset$, this is equicontinuity at $\emptyset$.
(iii) $\Rightarrow$ *(i)* Given $\varepsilon > 0$, choose $\delta > 0$ such that $\rho_\mu(E,\emptyset) < \delta \Rightarrow \sup_n |\Phi_{\nu_n}(E) - \Phi_{\nu_n}(\emptyset)| < \varepsilon$.
Since $\rho_\mu(E,\emptyset) = \mu(E)$ and $\Phi_{\nu_n}(\emptyset) = 0$, $\mu(E) < \delta \Rightarrow \sup_n \nu_n(E) < \varepsilon$.
(i) $\Leftrightarrow$ *(iv)* For $E \in \mathcal{M}$, $\nu_n(E) = \int_E f_n\, d\mu$. Thus $\sup_n \nu_n(E) < \varepsilon \Leftrightarrow \sup_n \int_E f_n\, d\mu < \varepsilon$ for every small-μ set E.

Structural Commentary: Uniform AC of ν_n equals uniform integrability of f_n.
Key Insight: Radon–Nikodym turns set bounds into integral bounds. □

Theorem 3.6.8. *Setwise Limits under Uniform Absolute Continuity*
Let $(X, \mathcal{M}, \mu)$ *be finite, let* ν_n *be finite measures with* $\nu_n \ll_{\mathrm{u}} \mu$, $\sup_n \nu_n(X) < +\infty$, *and* $\nu_n(E) \to \nu(E)\ \forall E \in \mathcal{M}$.

(i) ν *is a finite measure.*
(ii) $\nu \ll \mu$.

Proof.

(i) Since $\nu(X) = \lim_n \nu_n(X) \le \sup_n \nu_n(X)$, ν is finite-valued. Finite additivity passes to the pointwise limit.
For pairwise disjoint (E_k), set $E := \bigcup_k E_k$ and $R_N := \bigcup_{k>N} E_k$.
Given $\varepsilon > 0$, uniform absolute continuity and $\mu(R_N) \downarrow 0$ give $\nu_n(R_N) < \varepsilon\ \forall n$ and all sufficiently large N, hence $\nu(R_N) \le \varepsilon$.
Therefore $\nu(E) = \sum_{k=1}^{N} \nu(E_k) + \nu(R_N) \to \sum_k \nu(E_k)$.
(ii) If $\mu(A) = 0$, then for every $\varepsilon > 0$, uniform absolute continuity gives $\sup_n \nu_n(A) < \varepsilon$.
Passing to the setwise limit, $\nu(A) \le \varepsilon\ \forall \varepsilon > 0$, hence $\nu(A) = 0$.

Structural Commentary: Uniform tail control yields countable additivity and preserves the null ideal.
Key Insight: Uniform absolute continuity makes the tail of any disjoint union uniformly small. □

Lemma 3.6.9. *One-Point Equicontinuity Spreads*
Let $(X, \mathcal{M}, \mu)$ be finite, and let (ν_n) be finite measures with $\nu_n \ll \mu$.
If the maps Φ_{ν_n} are equicontinuous at one point $E_0 \in \mathcal{M}_\mu$, then they are uniformly equicontinuous on $\mathcal{M}_\mu$.

Proof. Fix $\varepsilon > 0$ and choose $\delta > 0$ so that $\rho_\mu(E, E_0) < \delta$ implies $\sup_n |\nu_n(E) - \nu_n(E_0)| < \frac{\varepsilon}{2}$.
If $\mu(C) < \delta$, then both $E_0 \setminus C$ and $E_0 \cup (C \setminus E_0)$ are within δ of E_0, so $\nu_n(C \cap E_0) < \frac{\varepsilon}{2}$, $\nu_n(C \setminus E_0) < \frac{\varepsilon}{2}$ $\forall n$.
Hence $\sup_n \nu_n(C) < \varepsilon$. Taking $C = A \triangle B$ gives $\sup_n |\nu_n(A) - \nu_n(B)| < \varepsilon$ whenever $\rho_\mu(A, B) < \delta$.
Structural Commentary: Split a small set into its portions inside and outside the equicontinuity base point.
Key Insight: Smallness near one set controls both the part inside it and the part outside it. □

Method 3.6.10. *Baire Mechanism for Vitali–Hahn–Saks*
Regard each absolutely continuous measure ν_n as $\Phi_{\nu_n} : \mathcal{M}_\mu \to \mathbb{R}$, $\Phi_{\nu_n}(E) := \nu_n(E)$.
(i) *Translate*: Setwise convergence becomes pointwise convergence of (Φ_{ν_n}).
(ii) *Apply Baire*: Completeness of $\mathcal{M}_\mu$ supplies a point of equicontinuity.
(iii) *Spread*: Lemma 3.6.9 upgrades one-point equicontinuity to uniform equicontinuity.
(iv) *Return to measures*: Proposition 3.6.7 converts uniform equicontinuity into uniform absolute continuity.

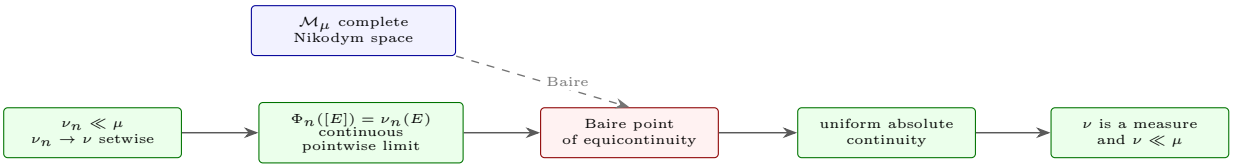

Figure 213: Vitali–Hahn–Saks mechanism: setwise convergence becomes pointwise convergence on $\mathcal{M}_\mu$; Baire gives uniform absolute continuity.

Theorem 3.6.11. *Vitali–Hahn–Saks Theorem*
Let $(X, \mathcal{M}, \mu)$ be finite, and let (ν_n) be finite measures with $\nu_n \ll \mu$, $\sup_n \nu_n(X) < +\infty$, and $\nu_n \to \nu$ setwise.

(i) (ν_n) is uniformly absolutely continuous with respect to μ.
(ii) ν is a finite measure.
(iii) $\nu \ll \mu$.

Proof.
(i) Set $\Phi_n([E]) := \nu_n(E)$. By Proposition 3.6.6, each Φ_n is continuous on complete $\mathcal{M}_\mu$.
If $A \sim_\mu B$, then $\nu_n(A) = \nu_n(B)$ $\forall n$, hence $\nu(A) = \nu(B)$.
Thus $\Phi([E]) := \nu(E)$ is well-defined and $\Phi_n \to \Phi$ pointwise. Since $|\Phi_n([E])| \le \sup_n \nu_n(X)$ and $\nu_n(E) \to \nu(E)$, Φ is real-valued.
Theorem 5.1.34 gives an equicontinuity point $E_0 \in \mathcal{M}_\mu$ for (Φ_n).
Lemma 3.6.9 gives uniform equicontinuity on $\mathcal{M}_\mu$, and Proposition 3.6.7 gives $\nu_n \ll_{\mathrm{u}} \mu$.
(ii) By (i), $\nu_n \ll_{\mathrm{u}} \mu$; Theorem 3.6.8(i) gives that ν is a finite measure.
(iii) By (i), $\nu_n \ll_{\mathrm{u}} \mu$; Theorem 3.6.8(ii) gives $\nu \ll \mu$.
Structural Commentary: Baire gives one equicontinuity point; Nikodym calculus spreads it.
Key Insight: Setwise convergence plus bounded total mass forces uniform null-set control. □

Corollary 3.6.12. *Nikodym Bounded Setwise Limit Theorem*
If finite measures (ν_n) on $(X, \mathcal{M})$ converge setwise to ν and $\sup_n \nu_n(X) < +\infty$, then ν is finite.

Proof. Define $\mu(E) := \sum_{n=1}^{\infty} 2^{-n} \nu_n(E)$. Then μ is a finite measure by countable additivity of nonnegative series, and $\nu_n \ll \mu$ $\forall n$ because $2^{-n}\nu_n \le \mu$. Thus ν is a finite measure by Theorem 3.6.11(ii).
Structural Commentary: A summable mixture places the sequence under one finite dominating measure.
Key Insight: A summable mixture builds one finite measure that dominates the whole sequence. □

4 L^p Spaces and Modes of Convergence

4.1 L^p Spaces

Lebesgue spaces turn integrability into normed linear geometry. The essential point is that an integral norm cannot distinguish functions that differ only on null sets, so the actual vectors are almost-everywhere equivalence classes. Their bounded linear functionals are themselves represented by integration against functions in the conjugate space.

Definition 4.1.1. *Norms and Seminorms*
Let $\mathcal{V}$ be a vector space over $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.
(i) A *seminorm* is $N : \mathcal{V} \to [0, \infty)$ with $N(\alpha v) = |\alpha| N(v)$ and $N(u + v) \le N(u) + N(v)$ $\forall u, v \in \mathcal{V}$, $\alpha \in \mathbb{F}$.
(ii) A *norm* is a seminorm with $N(v) = 0 \iff v = 0$. A norm N induces $d_N(u, v) := N(u - v)$.

Example 4.1.2. *Norms and Seminorms Before Quotienting*
(i) On $\mathbb{F}^n$, $\|u\|_p := (\sum_{j=1}^{n} |u_j|^p)^{\frac{1}{p}}$ for $1 \le p < \infty$ and $\|u\|_\infty := \max_{1 \le j \le n} |u_j|$ are norms.
Minkowski gives $\|u + v\|_p \le \|u\|_p + \|v\|_p$.

(ii) On sequences, $\ell^p := \{a : \sum_n |a_n|^p < +\infty\}$ with $\|a\|_p := (\sum_n |a_n|^p)^{\frac{1}{p}}$.
$\ell^\infty := \{a : \sup_n |a_n| < +\infty\}$ with $\|a\|_\infty := \sup_n |a_n|$.

(iii) On $B(X)$, $\|f\|_\infty := \sup_{x\in X} |f(x)|$ is a norm. On $C[0,1]$, $N_0(f) := |f(0)|$ and $N_1(f) := \sup_{0\le x\le \frac{1}{2}} |f(x)|$ are seminorms. On $C^1[a,b]$, $N_D(f) := \sup_{a\le x\le b} |f'(x)|$ is a seminorm with kernel the constant functions.

Key Insight: Seminorms become norms after quotienting out their zero directions.

Remark 4.1.3. *Integral Norm on Continuous Functions*
On $C[0,1]$, $N(f) := \int_0^1 |f(x)|\,dx$ is a norm: if $f(x_0) \neq 0$, continuity gives $N(f) > 0$. It is not complete, since continuous ramps can be Cauchy in N and converge in L^1 to a discontinuous step function.

Definition 4.1.4. *L^p Spaces and Mean Convergence*
Let $(X, \mathcal{M}, \mu)$ be a measure space.

(i) For $1 \le p < \infty$, the *p-integrable class* is $\mathscr{L}^p(\mu) := \{f : X \to \mathbb{F} : f \text{ measurable}, \int_X |f|^p\,d\mu < +\infty\}$.

(ii) The *L^p space* and *L^p norm* are $L^p(\mu) := \mathscr{L}^p(\mu)/=_{\text{a.e.}}$ and $\|f\|_p := (\int_X |f|^p\,d\mu)^{\frac{1}{p}}$.

(iii) *L^p convergence*, or *mean convergence of order p*, means $f_n \to f \iff \|f_n - f\|_p \to 0$.
L^p-Cauchy means $\|f_m - f_n\|_p \to 0$ as $m, n \to \infty$.

(iv) *Essentially bounded* means $|f| \le M$ a.e. for some $M < +\infty$; $L^\infty(\mu)$ is the a.e.-quotient of such functions, with *essential sup norm* $\|f\|_\infty := \inf\{M \ge 0 : |f| \le M \text{ a.e.}\} = \inf_{\mu(N)=0} \sup_{x\in X\setminus N} |f(x)|$.

Proposition 4.1.5. *L^1 as a Quotient of a Seminorm*
On $\mathscr{L}^1(\mu)$ set $N_\mu(f) := \int_X |f|\,d\mu$.

(i) N_μ is a seminorm.
(ii) $N_\mu(f) = 0 \iff f = 0$ a.e.
(iii) $L^1(\mu) := \mathscr{L}^1(\mu)/=_{\text{a.e.}}$ is normed by $\|[f]\|_1 := \int_X |f|\,d\mu$; write f for $[f]$.

Proof.

(i) If $f, g \in \mathscr{L}^1(\mu)$ and $a, b \in \mathbb{R}$, then $|af + bg| \le |a|\,|f| + |b|\,|g| \in \mathscr{L}^1(\mu)$, so $\mathscr{L}^1(\mu)$ is linear. Also $N_\mu(af) = |a|\,N_\mu(f)$ and $N_\mu(f+g) \le N_\mu(f) + N_\mu(g)$.
(ii) ($\Rightarrow$) If $N_\mu(f) = 0$, set $E_n := \{|f| \ge \frac{1}{n}\}$. Then $\frac{1}{n}\mu(E_n) \le \int_{E_n} |f|\,d\mu \le N_\mu(f) = 0$, $\{f \neq 0\} = \bigcup_n E_n$ null.
(ii) ($\Leftarrow$) If $f = 0$ a.e., then $|f| = 0$ a.e., hence $N_\mu(f) = 0$.
(iii) If $f = g$ a.e., then $|f| = |g|$ a.e. and $\int_X |f|\,d\mu = \int_X |g|\,d\mu$, so $\|[f]\|_1$ is well defined. The seminorm axioms descend from (i), and $\|[f]\|_1 = 0 \Rightarrow f = 0$ a.e. by (ii), hence $[f] = [0]$.

Structural Commentary: The seminorm kernel is exactly the a.e.-zero functions.
Key Insight: Quotient by null differences before calling the integral a norm. □

Definition 4.1.6. *Complex Integrals and L^2*

(i) For $f = u + iv$, *complex measurability* means measurability of u, v.
(ii) On $E \in \mathcal{M}$, *complex integrability* means $u, v \in \mathscr{L}^1(\mu)$ on E; set $\int_E f\,d\mu := \int_E u\,d\mu + i\int_E v\,d\mu$.
(iii) $L^2(\mu)$: complex measurable f satisfying $\int_X |f|^2\,d\mu < +\infty$, modulo a.e. equality; $\|f\|_2^2 := \int_X |f|^2\,d\mu$.
(iv) The *L^2 inner product* is $\langle f, g\rangle_{L^2} := \int_X f\overline{g}\,d\mu$; it induces $\|f\|_2$.

Proposition 4.1.7. *Complex L^1 and Dominated Convergence*
The following statements hold.

(i) For complex measurable f on E, f is integrable $\iff |f| \in \mathscr{L}^1(\mu)$ on E; then $\left|\int_E f\,d\mu\right| \le \int_E |f|\,d\mu$.
(ii) If $f_n \to f$ a.e. on E and $|f_n| \le g \in \mathscr{L}^1(\mu)$, then f is integrable and $\int_E f\,d\mu = \lim_n \int_E f_n\,d\mu$.

Proof.

(i) ($\Rightarrow$) Write $f = u + iv$. If $u, v \in \mathscr{L}^1$, then $|f| \le |u| + |v|$, so $|f| \in \mathscr{L}^1$.
(i) ($\Leftarrow$) If $|f| \in \mathscr{L}^1$, then $|u|, |v| \le |f|$, so $u, v \in \mathscr{L}^1$ and f is integrable.
If $\int_E f\,d\mu = re^{i\theta}$ and $h = e^{-i\theta}f$, then $\left|\int_E f\,d\mu\right| = r = \operatorname{Re}\int_E h\,d\mu = \int_E \operatorname{Re} h\,d\mu \le \int_E |h|\,d\mu = \int_E |f|\,d\mu$.
(ii) Write $f_n = u_n + iv_n$ and $f = u + iv$. Since $|u_n|, |v_n| \le g$ and $u_n \to u$, $v_n \to v$ a.e., real DCT gives $\int_E u_n\,d\mu \to \int_E u\,d\mu$ and $\int_E v_n\,d\mu \to \int_E v\,d\mu$; hence the complex identity.

Structural Commentary: Complex integration is two real integrals.
Key Insight: Rotate the integral to make its value real and nonnegative before applying the real inequality. □

Theorem 4.1.8. *L^2 Geometry*
For $f, g \in L^2(\mu)$, the following hold.

(i) Schwarz: $fg \in L^1(\mu)$ and $\int_X |fg|\,d\mu \le \|f\|_2\,\|g\|_2$.
(ii) Minkowski: $f + g \in L^2(\mu)$ and $\|f+g\|_2 \le \|f\|_2 + \|g\|_2$.
(iii) Completeness: modulo equality a.e., $(L^2(\mu), \|\cdot\|_2)$ is complete.

Proof.

(i) Since $2|fg| \le |f|^2 + |g|^2$, $fg \in L^1(\mu)$.
For $\lambda \in \mathbb{R}$, $0 \le Q(\lambda) := \int_X (|f| + \lambda|g|)^2\,d\mu = \|f\|_2^2 + 2\lambda\int_X |fg|\,d\mu + \lambda^2\|g\|_2^2$; hence $\Delta(Q) \le 0$.
(ii) By (i), $\|f+g\|_2^2 \le \int_X (|f| + |g|)^2\,d\mu \le (\|f\|_2 + \|g\|_2)^2$.

(iii) Let (f_n) be Cauchy. Choose $n_k \uparrow \infty$ with $\|f_{n_{k+1}} - f_{n_k}\|_2 \le 2^{-k}$, and set $h_N := \sum_{k<N} |f_{n_{k+1}} - f_{n_k}|$.

Then $\|h_N\|_2 \le \sum_{k<N} 2^{-k}$, so Fatou gives $h := \lim_N h_N \in L^2$ and $f_{n_k} \to f$ a.e. for some f.

For fixed n, Fatou gives $\|f - f_n\|_2 \le \liminf_k \|f_{n_k} - f_n\|_2$; the Cauchy property sends the right side to 0.

Structural Commentary: Schwarz and Minkowski supply geometry; rapid subsequences prove completeness.
Key Insight: Positivity of the integral transfers Euclidean quadratic estimates to function classes. □

Example 4.1.9. *Mazur Homeomorphism Between L^1 and L^2*
Let $E \subseteq \mathbb{R}$ be Lebesgue measurable. Define $\Phi(f) := \operatorname{sgn}(f)\,|f|^{\frac{1}{2}}$ on $L^1(E)$ and $\Psi(g) := \operatorname{sgn}(g)\,|g|^2$ on $L^2(E)$.
Then $\Phi : L^1(E) \to L^2(E)$ is a homeomorphism with inverse $\Psi : L^2(E) \to L^1(E)$.

Proof. $|\Phi(f)|^2 = |f|$ and $|\Psi(g)| = |g|^2$, so the maps are well-defined; pointwise $\Psi\Phi = \mathrm{id}_{L^1}$ and $\Phi\Psi = \mathrm{id}_{L^2}$.
For $a, b \in \mathbb{R}$, $\left|\operatorname{sgn}(a)\,|a|^{\frac{1}{2}} - \operatorname{sgn}(b)\,|b|^{\frac{1}{2}}\right|^2 \le 2\,|a-b|$, hence $\|\Phi(f) - \Phi(h)\|_2^2 \le 2\,\|f-h\|_1$.
Also $\left|\operatorname{sgn}(a)\,|a|^2 - \operatorname{sgn}(b)\,|b|^2\right| \le 2\,|a-b|\,(|a|+|b|)$, so $\|\Psi(g) - \Psi(k)\|_1 \le 2\,\|g-k\|_2\,(\|g\|_2 + \|k\|_2)$ by Cauchy–Schwarz. Thus Φ and Ψ are continuous.
Key Insight: Nonlinear power maps can homeomorphically identify different L^p norm topologies. □

Definition 4.1.10. *Conjugate Indices*
For $p, q \in (1, \infty)$, p and q are *conjugate indices* if $p^{-1} + q^{-1} = 1$, equivalently $p + q = pq$.
The unique self-conjugate index is $p = q = 2$.

Lemma 4.1.11. *Young's Inequality*
If $A, B \ge 0$, $1 < p < \infty$, and $p^{-1} + q^{-1} = 1$, then:
(i) $AB \le \frac{A^p}{p} + \frac{B^q}{q}$;
(ii) equality holds iff $A^p = B^q$.

Proof.
(i) If $A, B > 0$, set $\alpha := \frac{1}{p}$ and $t := \frac{A^p}{B^q}$. Since $q^{-1} = 1 - \alpha$, weighted AM–GM gives $t^\alpha \le \alpha t + 1 - \alpha$.
Multiplying by B^q yields $AB \le \frac{A^p}{p} + \frac{B^q}{q}$. If $AB = 0$, the inequality is immediate.
(ii) For $A, B > 0$, equality in weighted AM–GM is $t = 1$, i.e. $A^p = B^q$.
If $AB = 0$, equality in (i) holds iff $A = B = 0$, again equivalent to $A^p = B^q$.
Structural Commentary: Young's inequality is weighted AM–GM in conjugate exponents.
Key Insight: Rescale to A^p and B^q, then use convexity. □

Theorem 4.1.12. *Hölder and Minkowski for Sequence Spaces*
Let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.
(i) If $p, q > 1$ and $p^{-1} + q^{-1} = 1$, then $\mathbf{x} \in \ell^p(\mathbb{F})$, $\mathbf{y} \in \ell^q(\mathbb{F})$ imply $\sum_{n\ge1} |x_n y_n| \le \|\mathbf{x}\|_p\,\|\mathbf{y}\|_q$.
(ii) If $1 \le p < \infty$ and $\mathbf{x}, \mathbf{y} \in \ell^p(\mathbb{F})$, then $\mathbf{x} + \mathbf{y} \in \ell^p(\mathbb{F})$ and $\|\mathbf{x}+\mathbf{y}\|_p \le \|\mathbf{x}\|_p + \|\mathbf{y}\|_p$.

Proof.
(i) If $\|\mathbf{x}\|_p\,\|\mathbf{y}\|_q = 0$, the claim is immediate.
Otherwise set $X := \|\mathbf{x}\|_p$, $Y := \|\mathbf{y}\|_q$, $u_n := |x_n|/X$, and $v_n := |y_n|/Y$. Young's inequality gives $u_n v_n \le u_n^p/p + v_n^q/q$; summing over $1 \le n \le N$ and letting $N \to \infty$ gives $\sum_{n\ge1} |x_n y_n| \le XY$.
(ii) For $p = 1$, apply $|x_n + y_n| \le |x_n| + |y_n|$ and sum. For $p > 1$, put $s_N := (\sum_{n=1}^N |x_n + y_n|^p)^{1/p}$. If $s_N = 0$, the bound is trivial; if $s_N > 0$, then $\sum_{n=1}^N |x_n + y_n|^p \le \sum_{n=1}^N (|x_n| + |y_n|)\,|x_n + y_n|^{p-1} \le (\|\mathbf{x}\|_p + \|\mathbf{y}\|_p) s_N^{p-1}$ by (i), so $s_N \le \|\mathbf{x}\|_p + \|\mathbf{y}\|_p$. Let $N \to \infty$.
Structural Commentary: Hölder controls products; Minkowski controls sums.
Key Insight: The metric property of ℓ^p is exactly Minkowski's inequality. □

Example 4.1.13. *Sequence Spaces as Vector Spaces*
Over $\mathbb{C}$, the sequence spaces $c_0 = \{(z_n) : z_n \to 0\}$, $\ell^\infty = \{(z_n) : \sup_n |z_n| < \infty\}$, and, for $1 \le p < \infty$, $\ell^p = \left\{(z_n) : \sum_{n=1}^{\infty} |z_n|^p < \infty\right\}$ are vector spaces under componentwise operations; for ℓ^p, closure under addition follows from Minkowski's inequality.

Example 4.1.14. *Function and Sequence Metric Spaces*
Let $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.
(i) On $C_{\mathbb{F}}[a,b]$, $d_\infty(f,g) := \sup_{t\in[a,b]} |f(t) - g(t)|$ and $d_1(f,g) := \int_a^b |f(t) - g(t)|\,dt$ are metrics.
Definiteness of d_1 uses continuity.
(ii) On $\ell^\infty(\mathbb{F})$, $d_\infty(\mathbf{x}, \mathbf{y}) := \sup_{n\ge1} |x_n - y_n|$ is a metric.
(iii) For $1 \le p < \infty$, $d_p(\mathbf{x}, \mathbf{y}) := \|\mathbf{x} - \mathbf{y}\|_p = (\sum_{n\ge1} |x_n - y_n|^p)^{1/p}$ is a metric on $\ell^p(\mathbb{F})$ by Theorem 4.1.12.
Structural Commentary: Norm estimates produce metrics on function and sequence spaces.
Key Insight: Infinite-dimensional examples require estimates, not just coordinate formulas.

Theorem 4.1.15. *Hölder's Inequality*
Let $1 < p < \infty$, $p^{-1} + q^{-1} = 1$, $f \in L^p(\mu)$, and $g \in L^q(\mu)$.
(i) $fg \in L^1(\mu)$.
(ii) $\|fg\|_1 \le \|f\|_p\,\|g\|_q$.

Proof. If $\|f\|_p\,\|g\|_q = 0$, then $f = 0$ a.e. or $g = 0$ a.e., so both claims hold.
Assume $\|f\|_p\,\|g\|_q > 0$ and set $A := \frac{|f|}{\|f\|_p}$, $B := \frac{|g|}{\|g\|_q}$. Young gives $\frac{|fg|}{\|f\|_p\|g\|_q} \le \frac{A^p}{p} + \frac{B^q}{q}$.
(i) Since $\int A^p\,d\mu = \int B^q\,d\mu = 1$, the majorant $\frac{A^p}{p} + \frac{B^q}{q}$ lies in $L^1(\mu)$; hence $fg \in L^1(\mu)$.

(ii) Integrating the displayed inequality gives $\frac{\|fg\|_1}{\|f\|_p\|g\|_q} \le \frac{1}{p}\int A^p\,d\mu + \frac{1}{q}\int B^q\,d\mu = p^{-1}+q^{-1} = 1$.

Structural Commentary: Normalize both factors to unit L^p and L^q size.
Key Insight: Products are controlled by conjugate powers. □

Corollary 4.1.16. *Cauchy–Bunyakovsky–Schwarz in L^2*
If $f, g \in L^2(\mu)$, then:
(i) $fg \in L^1(\mu)$;
(ii) $\left|\int_X fg\,d\mu\right| \le \int_X |fg|\,d\mu \le \|f\|_2\,\|g\|_2$.

Proof.
(i) Since $2^{-1}+2^{-1}=1$, Theorem 4.1.15(i) gives $fg \in L^1(\mu)$.
(ii) Theorem 4.1.15(ii) gives $\int_X |fg|\,d\mu = \|fg\|_1 \le \|f\|_2\,\|g\|_2$, and $\left|\int_X fg\,d\mu\right| \le \int_X |fg|\,d\mu$.

Structural Commentary: Hölder at $p=q=2$ is Cauchy–Schwarz.
Key Insight: Pair two L^2 factors through $2^{-1}+2^{-1}=1$. □

Theorem 4.1.17. *Minkowski's Inequality*
If $1 \le p < \infty$ and $f, h \in L^p(\mu)$, then:
(i) $f+h \in L^p(\mu)$;
(ii) $\|f+h\|_p \le \|f\|_p + \|h\|_p$.

Proof. For $p=1$, integrate $|f+h| \le |f|+|h|$. Let $p>1$ and $q := \frac{p}{p-1}$.
(i) Since $|f+h|^p \le 2^{p-1}(|f|^p+|h|^p)$, $f+h \in L^p(\mu)$. Also $|f+h|^{p-1} \in L^q(\mu)$ because $(p-1)q = p$.
(ii) Pointwise, $|f+h|^p \le (|f|+|h|)\,|f+h|^{p-1}$.
By Hölder, $\|f+h\|_p^p \le (\|f\|_p + \|h\|_p)\left\||f+h|^{p-1}\right\|_q = (\|f\|_p+\|h\|_p)\,\|f+h\|_p^{p-1}$.
If $\|f+h\|_p > 0$, divide by $\|f+h\|_p^{p-1}$; otherwise the claim is trivial.

Structural Commentary: Hölder turns the pointwise triangle inequality into a norm triangle inequality.
Key Insight: Minkowski is exactly the closure and triangle estimate for L^p. □

Theorem 4.1.18. *L^p Is Normed*
For $1 \le p < \infty$, $(L^p(\mu), \|\cdot\|_p)$ is a normed linear space.

Proof.
(i) If $f = f'$ and $g = g'$ a.e., then $\alpha f + \beta g = \alpha f' + \beta g'$ a.e..
Hence pointwise operations descend to $L^p(\mu)$. Minkowski gives $\alpha f + \beta g \in L^p(\mu)$.
(ii) $\|\alpha f\|_p^p = \int_X |\alpha f|^p\,d\mu = |\alpha|^p\,\|f\|_p^p$, so $\|\alpha f\|_p = |\alpha|\,\|f\|_p$.
(iii) $\|f\|_p = 0 \Rightarrow \int_X |f|^p\,d\mu = 0 \Rightarrow f = 0$ a.e.; hence $[f] = 0$ in $L^p(\mu)$.
(iv) Minkowski gives $\|f+g\|_p \le \|f\|_p + \|g\|_p$.

Structural Commentary: Quotienting by a.e. equality turns pointwise operations into vector-space operations.
Key Insight: Minkowski supplies the nontrivial norm axiom. □

Definition 4.1.19. *Completeness Language*
Let $(V, \|\cdot\|)$ be a normed space.
(i) *Complete*: V is complete iff every Cauchy sequence $(x_n) \subset V$ has $x \in V$ with $\|x_n - x\| \to 0$.
(ii) *Banach*: A Banach space is a complete normed space.
(iii) *L^p criterion*: $L^p(\mu)$ is complete iff every L^p-Cauchy sequence converges in $\|\cdot\|_p$.

Lemma 4.1.20. *Convergent Implies Cauchy*
If $f_n \to f$ in $L^p(\mu)$, then (f_n) is Cauchy in $L^p(\mu)$.

Proof. Given $\varepsilon > 0$, choose N so $n \ge N$ implies $\|f_n - f\|_p < \frac{\varepsilon}{2}$.
Then $m, n \ge N$ gives $\|f_m - f_n\|_p \le \|f_m - f\|_p + \|f - f_n\|_p < \varepsilon$ by Minkowski.
Structural Commentary: A convergent sequence has uniformly small tails around its limit.
Key Insight: Use the common limit as the bridge between two tails. □

Definition 4.1.21. *Rapidly Cauchy Sequence*
Let $(V, \|\cdot\|)$ be a normed space. A sequence $(x_k) \subset V$ is *rapidly Cauchy* if $\exists (\varepsilon_k) \subset (0, +\infty)$ such that:
(i) $\sum_{k=1}^{\infty} \varepsilon_k < +\infty$.
(ii) $\|x_{k+1} - x_k\| \le \varepsilon_k^2$ for every $k \ge 1$.

Proposition 4.1.22. *Rapidly Cauchy Subsequences*
In a normed space, the following hold.
(i) Every rapidly Cauchy sequence is Cauchy.
(ii) Every Cauchy sequence has a rapidly Cauchy subsequence.

Proof.
(i) Let (x_k) be rapidly Cauchy with witnesses (ε_k). For $m > n$, $\|x_m - x_n\| \le \sum_{j=n}^{m-1} \|x_{j+1} - x_j\| \le \sum_{j=n}^{\infty} \varepsilon_j^2$.
Since $\sum_j \varepsilon_j < +\infty$, eventually $\varepsilon_j \le 1$, so $\sum_{j=n}^{\infty} \varepsilon_j^2 \le \sum_{j=n}^{\infty} \varepsilon_j \to 0$.
(ii) Let (x_n) be Cauchy. Choose $n_1 < n_2 < \cdots$ such that $m, n \ge n_k \Rightarrow \|x_m - x_n\| \le 4^{-k}$.
Set $y_k := x_{n_k}$ and $\varepsilon_k := 2^{-k}$. Then $\sum_k \varepsilon_k < +\infty$ and $\|y_{k+1} - y_k\| \le 4^{-k} = \varepsilon_k^2$, so (y_k) is rapidly Cauchy.

Structural Commentary: A Cauchy tail contains a summably controlled thread.
Key Insight: Replace arbitrary tail control by a geometric subsequence. □

Theorem 4.1.23. *Riesz–Fischer Completeness Theorem*
For $1 \le p < \infty$, the following hold.

(i) Completeness: $(L^p(\mu), \|\cdot\|_p)$ is complete.
(ii) A.E. subsequence: if $f_n \to f$ in $L^p(\mu)$, then some subsequence converges to a representative of f a.e.

Proof.

(i) Let (f_n) be Cauchy. Choose $g_k = f_{n_k}$ with $\|g_{k+1} - g_k\|_p \le 4^{-k}$. Set $G_N := |g_1| + \sum_{k<N} |g_{k+1} - g_k|$.
By Minkowski, $\|G_N\|_p \le \|g_1\|_p + \sum_{k<N} 4^{-k} \le \|g_1\|_p + \frac{1}{3}$; Fatou gives $G := \lim_N G_N \in L^p$.
The series $h := g_1 + \sum_k (g_{k+1} - g_k)$ converges a.e. with $|h| \le G$ and $g_k \to h$ a.e.
Since $|g_k - h| \le 2G$, DCT gives $\|g_k - h\|_p \to 0$. Given $\varepsilon > 0$, choose k with $\|g_k - h\|_p < \frac{\varepsilon}{2}$ and then N with $n \ge N \Rightarrow \|f_n - g_k\|_p < \frac{\varepsilon}{2}$; hence $\|f_n - h\|_p \to 0$.
(ii) If $f_n \to f$ in L^p, then (f_n) is Cauchy. Applying (i) gives a subsequence $f_{n_k} \to h$ a.e. and in L^p.
Since also $f_{n_k} \to f$ in L^p, uniqueness in normed space gives $[h] = f$ in L^p, so h is a representative of f.

Structural Commentary: A rapid subsequence converges a.e.; DCT gives norm convergence.
Key Insight: Fatou finds the pointwise limit, dominated convergence brings it back to L^p. □

Proposition 4.1.24. *Essential Supremum Test*
If $f \in L^\infty(\mu)$, then:

(i) $|f| \le \|f\|_\infty$ a.e.;
(ii) $A < \|f\|_\infty \Rightarrow \mu(\{|f| > A\}) > 0$.

Proof.

(i) Let $M := \|f\|_\infty$. For each k, $N_k := \{|f| > M + \frac{1}{k}\}$ is null. On $X \setminus \bigcup_k N_k$, $|f| \le M + \frac{1}{k}$ $\forall k$, hence $|f| \le M$.
(ii) If $A < M$ and $\mu(\{|f| > A\}) = 0$, then $|f| \le A$ a.e., so A is an essential upper bound. Contradiction.

Structural Commentary: The essential supremum is the least a.e. upper bound.
Key Insight: The sharp bound cannot be lowered on a full-measure set. □

Theorem 4.1.25. *L^∞ Is Banach*
$(L^\infty(\mu), \|\cdot\|_\infty)$ is a Banach space.

Proof.

(i) Pointwise operations descend modulo a.e. equality, and $\|\alpha f\|_\infty = |\alpha| \|f\|_\infty$. Proposition 4.1.24(i) gives definiteness; outside the union of two null sets, $|f + g| \le \|f\|_\infty + \|g\|_\infty$, hence $\|f + g\|_\infty \le \|f\|_\infty + \|g\|_\infty$.
(ii) Let (f_n) be L^∞-Cauchy. For each m, n, choose null N_{mn} with $|f_m - f_n| \le \|f_m - f_n\|_\infty$ on $X \setminus N_{mn}$, and set $N := \bigcup_{m,n} N_{mn}$.
On $X \setminus N$, (f_n) is uniformly Cauchy, hence converges uniformly to a measurable f.
(iii) The uniform convergence off N gives $\|f_n - f\|_\infty \to 0$.
For fixed n_0, $|f| \le |f_{n_0}| + \sup_{n \ge n_0} \|f_n - f_{n_0}\|_\infty$ a.e.; hence $f \in L^\infty(\mu)$.

Structural Commentary: Completeness is uniform convergence off one null set.
Key Insight: Essential bounds become ordinary uniform bounds off a common null set. □

Proposition 4.1.26. *Simple Approximation, Support, and Tails*
Let $1 \le p < \infty$ and $f \in L^p(\mu)$.

(i) Simple measurable functions are dense in $L^p(\mu)$; also in $L^\infty(\mu)$ for $\|\cdot\|_\infty$.
(ii) $\{|f| > 0\}$ is σ-finite.
(iii) For $E_n := \{|f| \ge n\}$, $\mu(E_n) \to 0$.
(iv) $\forall \varepsilon > 0$ $\exists E_\varepsilon \in \mathcal{M}$ with $\mu(E_\varepsilon) < +\infty$ such that $F \cap E_\varepsilon = \emptyset$ implies $\|f \mathbf{1}_F\|_p < \varepsilon$.

Proof.

(i) Choose simple $s_n \to f$ a.e. with $|s_n| \le |f|$ in the real case; treat real and imaginary parts separately in the complex case. Then $|f - s_n|^p \le 2^p |f|^p$, so DCT gives $\|f - s_n\|_p \to 0$.
For $f \in L^\infty$, discard null N with $|f| \le \|f\|_\infty + \eta$ on $X \setminus N$, then quantize that bounded range.
(ii) Put $A_k := \{|f| \ge \frac{1}{k}\}$. Then $\mu(A_k) \le k^p \|f\|_p^p < +\infty$ and $\{|f| > 0\} = \bigcup_k A_k$.
(iii) $n^p \mu(E_n) \le \int_{E_n} |f|^p \, d\mu \le \|f\|_p^p$, hence $\mu(E_n) \le n^{-p} \|f\|_p^p \to 0$.
(iv) With A_k as in (ii), $A_k \uparrow \{|f| > 0\}$ and $|f|^p \mathbf{1}_{X \setminus A_k} \to 0$ a.e. DCT gives $\int_{X \setminus A_k} |f|^p \, d\mu \to 0$.
Choose $E_\varepsilon = A_k$ with this integral $< \varepsilon^p$; if $F \cap E_\varepsilon = \emptyset$, then $\|f \mathbf{1}_F\|_p^p \le \int_{X \setminus E_\varepsilon} |f|^p \, d\mu < \varepsilon^p$.

Structural Commentary: L^p mass is simple-approximable and finite-piece capturable.
Key Insight: Integrability turns level sets into finite-measure exhaustions. □

Proposition 4.1.27. *Shell Criterion on Finite Measure Spaces*
Let $\mu(X) < +\infty$, f be measurable, and $E_n := \{n - 1 \le |f| < n\}$ for $n \ge 1$.
For $1 \le p < \infty$, $f \in L^p(\mu) \iff \sum_{n \ge 1} n^p \mu(E_n) < +\infty$.

Proof.

($\Rightarrow$) If $f \in L^p(\mu)$, then $\mu(E_1) \le \mu(X) < +\infty$ and, for $n \ge 2$, $n^p \mathbf{1}_{E_n} \le 2^p |f|^p \mathbf{1}_{E_n}$.
Thus $\sum_n n^p \mu(E_n) \le \mu(X) + 2^p \int_X |f|^p \, d\mu < +\infty$.

($\Leftarrow$) If $\sum_n n^p\mu(E_n) < +\infty$, then $|f|^p = \sum_n |f|^p \mathbf{1}_{E_n} \le \sum_n n^p \mathbf{1}_{E_n}$, hence $\int_X |f|^p \, d\mu < +\infty$.

Structural Commentary: The finite base shell handles small values; weighted shells control tails.
Key Insight: Shell weights characterize L^p mass. □

Proposition 4.1.28. *Inclusions, Interpolation, and Multipliers*

(i) If $\mu(X) < +\infty$ and $1 \le r \le p < \infty$, then $L^p(\mu) \subseteq L^r(\mu)$ and $\|f\|_r \le \|f\|_p \, \mu(X)^{\frac{1}{r}-\frac{1}{p}}$.
(ii) On $(\mathbb{N}, 2^{\mathbb{N}}, \#)$, $1 \le p \le s < \infty$ implies $\ell^p \subseteq \ell^s$ and $\|a\|_s \le \|a\|_p$.
(iii) If $1 \le p_1 < p_2 < \infty$ and $f \in L^{p_1}(\mu) \cap L^{p_2}(\mu)$, then $f \in L^p(\mu)$ for $p_1 \le p \le p_2$.
(iv) If $1 \le p \le \infty$, then $L^p(\mu) \cdot L^\infty(\mu) \subseteq L^p(\mu)$ and $\|fg\|_p \le \|f\|_p \|g\|_\infty$.
(v) $L^\infty(\mu) \subseteq L^1(\mu) \iff \mu(X) < +\infty$. If $\mu(X) = 1$, then $\|f\|_\infty = \lim_{p\to\infty} \|f\|_p$ for $f \in L^\infty(\mu)$.

Proof.

(i) For $r = p$, $L^p \subseteq L^p$ and the estimate reads $\|f\|_p \le \|f\|_p$, i.e. equality.
For $r < p$, Hölder applied to $|f|^r \cdot 1$ gives $\int_X |f|^r \, d\mu \le \|f\|_p^r \, \mu(X)^{1-\frac{r}{p}}$; take rth roots.
(ii) For $a \in \ell^p$, $\forall n$, $|a_n| \le \|a\|_p$, hence $\sum_n |a_n|^s \le \|a\|_p^{s-p} \sum_n |a_n|^p \le \|a\|_p^s$.
(iii) For $p \in [p_1, p_2]$, $|f|^p \le |f|^{p_1} \mathbf{1}_{\{|f|\le 1\}} + |f|^{p_2} \mathbf{1}_{\{|f|>1\}}$.
(iv) For $p < \infty$, $|fg|^p \le \|g\|_\infty^p \, |f|^p$ a.e.; for $p = \infty$, $|fg| \le \|f\|_\infty \|g\|_\infty$ a.e.
(v) ($\Rightarrow$) If $L^\infty(\mu) \subseteq L^1(\mu)$, then $\mathbf{1}_X \in L^\infty(\mu)$ lies in $L^1(\mu)$, so $\mu(X) = \int_X \mathbf{1}_X \, d\mu < +\infty$.
(v) ($\Leftarrow$) If $\mu(X) < +\infty$ and $f \in L^\infty(\mu)$, then $\int_X |f| \, d\mu \le \|f\|_\infty \, \mu(X) < +\infty$. If $\mu(X) = 1$, then $\|f\|_p \le \|f\|_\infty$.
For $A < \|f\|_\infty$, $\mu(\{|f| > A\}) > 0$ and $\|f\|_p \ge A\mu(\{|f| > A\})^{\frac{1}{p}} \to A$. Let $A \uparrow \|f\|_\infty$.

Structural Commentary: Inclusions depend on domain size and pointwise bounds.
Key Insight: Check whether size comes from the function values or from the measure of the domain. □

Example 4.1.29. *Membership Models*

(i) On $(\mathbb{N}, 2^{\mathbb{N}}, \#)$, $a_n = \frac{1}{n}$ satisfies $\|a\|_p^p = \sum_{n\ge 1} n^{-p}$; hence $a \in \ell^p \iff p > 1$, while $a \in \ell^\infty \setminus \ell^1$.
(ii) On $\mathbb{N}$ with $\lambda(\{n\}) = n^{-2}$, $\lambda(\mathbb{N}) < +\infty$ and $f(n) = n^{\frac{1}{p_0}}$ satisfies $\int_{\mathbb{N}} |f|^p \, d\lambda = \sum_{n\ge 1} n^{\frac{p}{p_0}-2}$.
Hence $f \in L^p(\lambda) \iff 1 \le p < p_0$. In particular, $f(n) = \sqrt{n}$ gives $p_0 = 2$.
(iii) On $(0, \infty)$, $f(x) = x^{-\frac{1}{2}}(1 + |\log x|)^{-1}$ gives $\int_0^\infty |f|^p \, dx = \int_{-\infty}^\infty e^{(1-\frac{p}{2})t}(1 + |t|)^{-p} \, dt$ under $x = e^t$.

Structural Commentary: L^p membership reduces to series and endpoint tests.
Key Insight: Different ends impose different p-conditions.

Proposition 4.1.30. *Hölder Dual Norm Attainment*
Let $1 < p < \infty$, $p^{-1} + q^{-1} = 1$, and let $f \in L^p(\mu)$ be real-valued.

(i) $\sup_{\|g\|_q \le 1} \left|\int_X fg \, d\mu\right| = \|f\|_p$.
(ii) If $f \ne 0$, the supremum is attained by $g_0 = \|f\|_p^{-\frac{p}{q}} \operatorname{sign}(f) \, |f|^{p-1}$.

Proof.

(i) For $\|g\|_q \le 1$, Hölder gives $\left|\int_X fg \, d\mu\right| \le \|f\|_p \|g\|_q \le \|f\|_p$.
If $f = 0$ this is sharp; if $f \ne 0$, item (ii) gives an admissible g_0 with $\int_X fg_0 \, d\mu = \|f\|_p$.
(ii) Since $(p-1)q = p$, $\|g_0\|_q^q = \|f\|_p^{-p} \int_X |f|^p \, d\mu = 1$ and $\int_X fg_0 \, d\mu = \|f\|_p^{-\frac{p}{q}} \int_X |f|^p \, d\mu = \|f\|_p$.

Structural Commentary: Equality in Hölder is obtained by matching the conjugate powers.
Key Insight: The L^q test function points in the power direction of f. □

Definition 4.1.31. *Bounded Linear Functionals on L^p*

(i) A *linear functional* on real $L^p(\mu)$ is a linear map $G : L^p(\mu) \to \mathbb{R}$.
(ii) G is *bounded* if $\exists M < +\infty$ such that $\forall f \in L^p(\mu)$, $|G(f)| \le M \|f\|_p$.
(iii) The *operator norm* is $\|G\| := \sup\{|G(f)| : f \in L^p(\mu), \ \|f\|_p \le 1\}$.
(iv) G is *positive* if $f \ge 0$ a.e. implies $G(f) \ge 0$.

Lemma 4.1.32. *Positive Split of a Bounded Functional*
Let $1 \le p < +\infty$ and $G \in (L^p(\mu))^*_{\mathbb{R}}$. Then $G = G^+ - G^-$ for positive bounded linear functionals $G^\pm$.

Proof. For $f \ge 0$, set $G^+(f) := \sup\{G(g) : 0 \le g \le f\}$.
This is finite since $|G(g)| \le \|G\| \|g\|_p \le \|G\| \|f\|_p$, and positive homogeneity is immediate.
For $f_1, f_2 \ge 0$, $G^+(f_1) + G^+(f_2) \le G^+(f_1 + f_2)$; conversely, if $0 \le h \le f_1 + f_2$, set $h_1 = (h - f_2)^+$ and $h_2 = h - h_1$, so $h = h_1 + h_2$ with $0 \le h_j \le f_j$, hence $G(h) \le G^+(f_1) + G^+(f_2)$.
Thus G^+ is additive on the positive cone. Extend by $G^+(f) = G^+(f^+) - G^+(f^-)$; then G^+ is positive, linear, and bounded. Let $G^- = G^+ - G$. Since $G^+(f) \ge G(f)$ for $f \ge 0$, G^- is positive and bounded.
Structural Commentary: Function-lattice functionals split into positive parts.
Key Insight: Split any competitor $h \le f_1 + f_2$ into the portions assigned to f_1 and f_2. □

Theorem 4.1.33. *Riesz Representation for L^1*
Let $(X, \mathcal{M}, \mu)$ be σ-finite and $G \in (L^1(\mu))^*_{\mathbb{R}}$.

(i) $\exists g \in L^\infty(\mu)$ such that $\forall f \in L^1(\mu)$, $G(f) = \int_X fg \, d\mu$.
(ii) $\|G\| = \|g\|_\infty$.

(iii) If G is positive, then $g \geq 0$ a.e.

Proof.

(i) First let $\mu(X) < +\infty$ and $G \geq 0$. Set $\lambda(E) := G(\mathbf{1}_E)$. Finite additivity is linearity; if $E_n \uparrow E$, then $\mathbf{1}_{E_n} \to \mathbf{1}_E$ in L^1, hence $\lambda(E_n) \to \lambda(E)$. Thus λ is finite, and $\lambda \ll \mu$ since $\mu(E) = 0$ gives $\mathbf{1}_E = 0$ in L^1. Radon–Nikodym gives $g \geq 0$ with $\lambda(E) = \int_E g \, d\mu$, so simple functions are represented.
By (ii), $g \in L^\infty$, hence L^1-density of simple functions extends the identity to all $f \in L^1$. For σ-finite μ, apply the finite case to $f \mapsto G(f\mathbf{1}_{X_n})$ on $X_n \uparrow X$, $\mu(X_n) < +\infty$, and patch densities on overlaps. For general G, use the positive split $G = G^+ - G^-$ and subtract the two densities.

(ii) The pairing estimate gives $\|G\| \leq \|g\|_\infty$. Conversely, if $A > \|G\|$ and $E \subseteq \{|g| > A\}$ has $\mu(E) < +\infty$, then with $f = \operatorname{sign}(g)\mathbf{1}_E$, $A\mu(E) < \int_E |g| \, d\mu = G(f) \leq \|G\| \, \mu(E)$, so $\mu(E) = 0$.
A σ-finite exhaustion gives $\forall A > \|G\|$, $\mu(\{|g| > A\}) = 0$, hence $\|g\|_\infty \leq \|G\|$.

(iii) If G is positive and $B = \{g < 0\}$, then $\forall E \subseteq B$ of finite measure, $0 \leq G(\mathbf{1}_E) = \int_E g \, d\mu \leq 0$ only if $\int_E (-g) \, d\mu = 0$. Hence $\mu(E) = 0$ on $\{g < -\frac{1}{k}\}$ $\forall k$, and a σ-finite exhaustion gives $\mu(B) = 0$.

Structural Commentary: A bounded functional on L^1 is integration against an essentially bounded density.
Key Insight: Indicators give a measure; Radon–Nikodym gives the density. □

Theorem 4.1.34. *Riesz Representation for L^p, $1 < p < +\infty$*
Let $(X, \mathcal{M}, \mu)$ be any measure space, $1 < p < +\infty$, $q = \frac{p}{p-1}$, and $G \in (L^p(\mu))^*_{\mathbb{R}}$.

(i) Representation: $\exists g \in L^q(\mu)$ such that $\forall f \in L^p(\mu)$, $G(f) = \int_X fg \, d\mu$.
(ii) Norm: every representing g satisfies $\|G\| = \|g\|_q$.
(iii) Uniqueness: if $g, h \in L^q(\mu)$ represent G, then $g = h$ a.e.

Proof.

(i) Finite μ: for $G \geq 0$, set $\lambda(E) := G(\mathbf{1}_E)$. Since $E_n \uparrow E \Rightarrow \mathbf{1}_{E_n} \to \mathbf{1}_E$ in L^p, λ is finite.
Since $\mu(E) = 0 \Rightarrow \mathbf{1}_E = 0$ in L^p, $\lambda \ll \mu$. Let $g = \frac{d\lambda}{d\mu}$.
By simple approximation, $G(\phi) = \int_X \phi g \, d\mu$ for bounded ϕ.
For $g_m := g \wedge m$, $\int_X g_m^q \, d\mu \leq G(g_m^{q-1}) \leq \|G\| \, (\int_X g_m^q \, d\mu)^{1/p}$; hence $g \in L^q$, by L^p-density $G(f) = \int_X fg \, d\mu$.
General finite G follows from $G = G^+ - G^-$. For σ-finite μ, choose $X_n \uparrow X$, $\mu(X_n) < +\infty$, represent $G_n : u \mapsto G(\tilde{u})$ by g_n, and patch the compatible g_n to g.
Since $\|g_n\|_q = \|G_n\| \leq \|G\|$, by MCT $g \in L^q$; $f\mathbf{1}_{X_n} \to f$ in $L^p \Rightarrow G(f) = \int_X fg \, d\mu$.
For arbitrary μ, choose $\|f_n\|_p = 1$, $G(f_n) \to \|G\|$, and $X_0 := \bigcup_{n,k} \{|f_n| > 1/k\}$.
If $E \subseteq X \setminus X_0$, $\mu(E) < +\infty$, and $a = G(\mathbf{1}_E)$, then $G(f_n) \pm ta \leq \|G\| \, (1 + t^p \mu(E))^{1/p}$; after $n \to \infty$ and $t \downarrow 0$, $a = 0$. Thus G vanishes off X_0; represent on X_0 and extend by 0.

(ii) For representing g, by Hölder, $\|G\| \leq \|g\|_q$; by Proposition 4.1.30, $\|g\|_q = \sup_{\|f\|_p \leq 1} \left| \int_X fg \, d\mu \right| \leq \|G\|$.

(iii) If g, h represent G, then $k := g - h$ satisfies $\int_X fk \, d\mu = 0$ $\forall f \in L^p(\mu)$.
By Proposition 4.1.30 applied to $k \in L^q(\mu)$ with exponents q, p, $\|k\|_q = 0$; hence $g = h$ a.e.

Structural Commentary: For $1 < p < \infty$, every bounded functional comes from the conjugate space L^q.
Key Insight: Localize to σ-finite support, then patch. □

Definition 4.1.35. *Bounded Finitely Additive Measures*
Let $(X, \mathcal{M}, \mu)$ be a measure space.
For $E \in \mathcal{M}$, let $\Pi(E)$ be the finite families $(E_1, \ldots, E_n)$ with $E_k \in \mathcal{M}$, $E_k \subseteq E$, and $E_i \cap E_j = \emptyset$ for $i \neq j$.
For $\nu : \mathcal{M} \to \mathbb{R}$, set $|\nu|_{\mathrm{fa}}(E) := \sup_{(E_k) \in \Pi(E)} \sum_k |\nu(E_k)|$ and $\|\nu\|_{\mathrm{var}} := |\nu|_{\mathrm{fa}}(X)$.

Define $\mathrm{BFA}(X, \mathcal{M}, \mu)$ as the set of $\nu : \mathcal{M} \to \mathbb{R}$ satisfying:

(i) *Finite additivity*: $\nu(\emptyset) = 0$ and $\nu(\bigsqcup_{k=1}^n E_k) = \sum_{k=1}^n \nu(E_k)$.
(ii) *Null compatibility*: $\mu(E) = 0 \Rightarrow \nu(E) = 0$.
(iii) *Bounded variation*: $\|\nu\|_{\mathrm{var}} < +\infty$.

Key Insight: BFA requires finite additivity, null compatibility, and finite variation, not countable additivity.

Theorem 4.1.36. *Kantorovitch Representation for $(L^\infty)^*$*
Let $(X, \mathcal{M}, \mu)$ be a measure space.

For $\nu \in \mathrm{BFA}(X, \mathcal{M}, \mu)$ and simple $\varphi = \sum_{k=1}^n c_k \mathbf{1}_{E_k}$ over a finite measurable partition, set $I_\nu(\varphi) := \sum_{k=1}^n c_k \nu(E_k)$.

(i) Extension: I_ν descends uniquely to $T_\nu \in (L^\infty(\mu))^*_{\mathbb{R}}$.
(ii) Isometry: $\|T_\nu\| = \|\nu\|_{\mathrm{var}}$.
(iii) Surjectivity: if $S \in (L^\infty(\mu))^*_{\mathbb{R}}$ and $\nu_S(E) := S(\mathbf{1}_E)$, then $\nu_S \in \mathrm{BFA}(X, \mathcal{M}, \mu)$ and $S = T_{\nu_S}$.

Thus $\nu \mapsto T_\nu$ is an isometric isomorphism $\mathrm{BFA}(X, \mathcal{M}, \mu) \cong (L^\infty(\mu))^*_{\mathbb{R}}$.

Proof.

(i) Refinement and finite additivity make I_ν well defined.
For simple φ, discard $N = \{|\varphi| > \|\varphi\|_\infty\}$; since $|\nu|_{\mathrm{fa}}(N) = 0$, $|I_\nu(\varphi)| \leq \|\varphi\|_\infty \|\nu\|_{\mathrm{var}}$.
Hence uniform simple approximation extends I_ν to bounded measurable f.
If $\operatorname{supp} f \subseteq N$ and $\mu(N) = 0$, then $|\nu|_{\mathrm{fa}}(N) = 0$, so $I_\nu(f) = 0$; therefore the extension depends only on the L^∞ class and defines T_ν with $\|T_\nu\| \leq \|\nu\|_{\mathrm{var}}$.

(ii) For $(E_k) \in \Pi(X)$, set $c_k := \operatorname{sign}(\nu(E_k))$ and $\varphi := \sum_k c_k \mathbf{1}_{E_k}$.
Then $\|\varphi\|_\infty \leq 1$ and $\sum_k |\nu(E_k)| = T_\nu(\varphi) \leq \|T_\nu\|$.
Supremizing over $\Pi(X)$ gives $\|\nu\|_{\mathrm{var}} \leq \|T_\nu\|$, and item (i) gives equality.

(iii) For $S \in (L^\infty(\mu))^*_{\mathbb{R}}$, $\nu_S(\emptyset) = 0$ and finite additivity follow from linearity.
If $\mu(E) = 0$, then $\mathbf{1}_E = 0$ in L^∞, so $\nu_S(E) = 0$.
For $(E_k) \in \Pi(X)$, with $c_k = \operatorname{sign}(\nu_S(E_k))$ and $\varphi = \sum_k c_k \mathbf{1}_{E_k}$, $\sum_k |\nu_S(E_k)| = S(\varphi) \le \|S\|$.
Hence $\nu_S \in \mathrm{BFA}(X, \mathcal{M}, \mu)$. Since S and T_{ν_S} agree on simple functions, uniform simple density gives $S = T_{\nu_S}$.

Structural Commentary: Simple extensions give T_ν; indicators recover ν.
Key Insight: Finite additivity supplies the full L^∞ dual. □

Proposition 4.1.37. *The Countably Additive Part*
For $g \in L^1(\mu)$, set $\nu_g(E) := \int_E g\, d\mu$.
(i) $\nu_g \in \mathrm{BFA}(X, \mathcal{M}, \mu)$.
(ii) $\|\nu_g\|_{\mathrm{var}} = \|g\|_1$.
(iii) $T_{\nu_g}(f) = \int_X fg\, d\mu$ for $f \in L^\infty(\mu)$; hence $L^1(\mu)$ embeds isometrically into $(L^\infty(\mu))^*$.

Proof.
(i) For disjoint $E_1, \dots, E_n$, $\nu_g(\bigsqcup_k E_k) = \sum_k \nu_g(E_k)$ by finite additivity of the integral, and
$\mu(E) = 0 \Rightarrow \nu_g(E) = 0$. Also, for $(E_k) \in \Pi(X)$, $\sum_k |\nu_g(E_k)| \le \sum_k \int_{E_k} |g|\, d\mu \le \|g\|_1$, so $\nu_g \in \mathrm{BFA}(X, \mathcal{M}, \mu)$.
(ii) Corollary 3.1.7 gives $\|\nu_g\|_{\mathrm{var}} = |\nu_g|(X)$, and Theorem 3.1.9 gives $|\nu_g|(X) = \int_X |g|\, d\mu = \|g\|_1$.
(iii) If $f = \sum_k c_k \mathbf{1}_{E_k}$ is simple, then $T_{\nu_g}(f) = \sum_k c_k \nu_g(E_k) = \int_X fg\, d\mu$.
For $f \in L^\infty(\mu)$, choose simple $f_n \to f$ uniformly; then $T_{\nu_g}(f_n) \to T_{\nu_g}(f)$ and $\int_X f_n g\, d\mu \to \int_X fg\, d\mu$.

Structural Commentary: Variation fixes the norm; simple approximation extends the pairing.
Key Insight: Countably additive representatives are exactly the familiar L^1 integral pairings. □

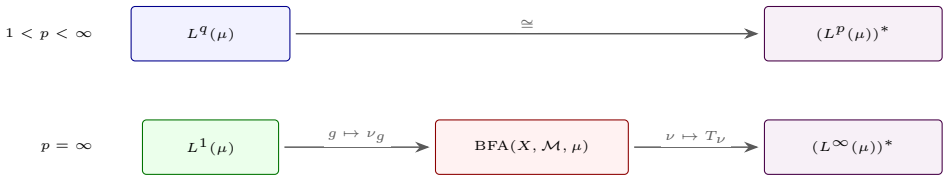

Figure 214: $L^q(\mu) \cong (L^p(\mu))^*$ for $1 < p < \infty$; $L^1(\mu)$ is the countably additive part of BFA $\cong (L^\infty(\mu))^*$.

Remark 4.1.38. *L^2 Riesz Gives Another Radon–Nikodym Route*
Let λ, μ be finite and $\lambda \ll \mu$. Put $\rho = \lambda + \mu$ and $G(h) := \int h\, d\lambda$ on $L^2(\rho)$.
If $G(h) = \int hg\, d\rho$, indicator tests give $0 \le g \le 1$ ρ-a.e. and $\mu(\{g = 1\}) = 0$.
Since $\int h(1-g)\, d\lambda = \int hg\, d\mu$, take $E_N = E \cap \{1 - g \ge \frac{1}{N}\}$ and $h = \frac{\mathbf{1}_{E_N}}{1-g} \in L^2(\rho)$ to get $\lambda(E_N) = \int_{E_N} \frac{g}{1-g}\, d\mu$. Let $N \to \infty$ by monotone convergence and $\lambda \ll \mu$: $\lambda(E) = \int_E \frac{g}{1-g}\, d\mu$.
Key Insight: Riesz representation on $L^2(\lambda + \mu)$ encodes the density in the ratio $\frac{g}{1-g}$.

Lemma 4.1.39. *Absolute Continuity of L^p Mass*
For $1 \le p < \infty$ and $f \in L^p(\mu)$, $\forall \varepsilon > 0\, \exists \delta > 0$ such that $\mu(E) < \delta$ implies $\|f\mathbf{1}_E\|_p < \varepsilon$.

Proof. Let $h = |f|^p \in L^1$. Choose $M > 0$ with $\int_{\{h > M\}} h\, d\mu < \frac{\varepsilon^p}{2}$, and set $\delta = \frac{\varepsilon^p}{2M}$.
If $\mu(E) < \delta$, then $\|f\mathbf{1}_E\|_p^p = \int_E h\, d\mu \le M\mu(E) + \int_{\{h > M\}} h\, d\mu < \varepsilon^p$.
Structural Commentary: L^p mass is absolutely continuous with respect to measure.
Key Insight: Truncate the tail; small measure controls the bounded part. □

Proposition 4.1.40. *Local Mass Limits for L^p Cauchy Sequences*
For $1 \le p < \infty$ and $f_n \in L^p(\mu)$, set $\beta_n(E) := \|f_n \mathbf{1}_E\|_p$ for $E \in \mathcal{M}$. The following hold.
(i) $|\beta_n(E) - \beta_m(E)| \le \|f_n - f_m\|_p$ for $E \in \mathcal{M}$.
(ii) If (f_n) is L^p-Cauchy, then $\forall E \in \mathcal{M}$, $\beta(E) := \lim_n \beta_n(E)$ exists.

Proof.
(i) Since $f_n \mathbf{1}_E = f_m \mathbf{1}_E + (f_n - f_m)\mathbf{1}_E$, $\beta_n(E) - \beta_m(E) \le \|f_n - f_m\|_p$.
Interchanging m, n gives $\beta_m(E) - \beta_n(E) \le \|f_n - f_m\|_p$; hence $|\beta_n(E) - \beta_m(E)| \le \|f_n - f_m\|_p$.
(ii) Fix $E \in \mathcal{M}$ and $\varepsilon > 0$. Choose N such that $m, n \ge N \Rightarrow \|f_n - f_m\|_p < \varepsilon$.
Then item (i) gives $|\beta_n(E) - \beta_m(E)| < \varepsilon$, so $(\beta_n(E))$ converges in $\mathbb{R}$.

Structural Commentary: Restricting to E is a 1-Lipschitz operation on L^p mass.
Key Insight: Local mass inherits global Cauchy control. □

Proposition 4.1.41. *Uniform Local Mass Control for L^p Cauchy Sequences*
Let $1 \le p < \infty$, f_n be L^p-Cauchy, and $\beta_n(E) := \|f_n \mathbf{1}_E\|_p$. Then $\forall \varepsilon > 0$:
(i) $\exists E_\varepsilon \in \mathcal{M}$ with $\mu(E_\varepsilon) < +\infty$ such that $F \cap E_\varepsilon = \emptyset$ implies $\sup_n \beta_n(F) < \varepsilon$;
(ii) $\exists \delta > 0$ such that $\mu(E) < \delta$ implies $\sup_n \beta_n(E) < \varepsilon$.

Proof. Choose N so $n \geq N$ implies $\|f_n - f_N\|_p < \frac{\varepsilon}{3}$.

(i) Choose finite-measure E_j for $1 \leq j \leq N$ with $F \cap E_j = \emptyset \Rightarrow \beta_j(F) < \frac{\varepsilon}{3}$, and set $E_\varepsilon = \bigcup_{j \leq N} E_j$.
For $n \leq N$ this works; for $n > N$, $\beta_n(F) \leq \|f_n - f_N\|_p + \beta_N(F) < \varepsilon$.

(ii) Choose $\delta_j > 0$ for $1 \leq j \leq N$ with $\mu(E) < \delta_j \Rightarrow \beta_j(E) < \frac{\varepsilon}{3}$, and set $\delta = \min_{j \leq N} \delta_j$.
For $n \leq N$ this works; for $n > N$, $\beta_n(E) \leq \|f_n - f_N\|_p + \beta_N(E) < \varepsilon$.

Structural Commentary: Cauchy families are uniformly tight and absolutely continuous.
Key Insight: Control finitely many early terms directly and the tail by Cauchy closeness. □

Method 4.1.42. *Lebesgue Proof Patterns*

(i) *Approximate*: for $f \geq 0$, use $s \in \mathcal{S}^+(f)$ and $\int_E f\, d\mu = \sup_{s \in \mathcal{S}^+(f)} \mathcal{I}_E(s)$.
(ii) *Promote*: prove for $\mathbf{1}_A$, extend to $s = \sum_i c_i \mathbf{1}_{A_i}$, then pass through $s_n \uparrow f$.
(iii) *Ignore null sets*: if $f \sim_{\text{a.e.}} g$ on E, replace f by g inside integrals over measurable $A \subseteq E$.
(iv) *Split signs*: use $f = f^+ - f^-$ and $h = u + iv$.
(v) *Exchange limits*: reduce Fatou and dominated convergence to $0 \leq f_n \uparrow f$.
(vi) *Slice*: prove boxes first; use regularity and null slices to pass to products and Fubini.

Key Insight: Reduce to simple functions, monotone convergence, null sets, and product boxes.

4.2 Modes of Convergence

Throughout this subsection $(X, \mathcal{M}, \mu)$ is a fixed measure space and, unless otherwise stated, functions are real-valued and measurable. The point is not to rank convergence modes linearly, but to know which hypotheses convert one mode into another.

Definition 4.2.1. *Pointwise, Uniform, and Almost-Everywhere Convergence*
Let (f_n) and f be functions on X.

(i) $f_n \to f$ *pointwise* if $\forall x \in X$, $\varepsilon > 0$, $\exists N(\varepsilon, x)$ s.t. $n \geq N(\varepsilon, x)$ implies $|f_n(x) - f(x)| < \varepsilon$.
(ii) $f_n \to f$ *uniformly* if $\forall \varepsilon > 0$ $\exists N(\varepsilon)$ s.t. $n \geq N(\varepsilon)$ implies $|f_n(x) - f(x)| < \varepsilon$ $\forall x \in X$.
(iii) $f_n \to f$ *almost everywhere* if $\exists A \in \mathcal{M}$ with $\mu(A) = 0$ s.t. $\forall x \in X \setminus A$, $\varepsilon > 0$, $\exists N(\varepsilon, x)$ s.t. $n \geq N(\varepsilon, x)$ implies $|f_n(x) - f(x)| < \varepsilon$.

Proposition 4.2.2. *First Implications and First Failures*
Let $f_n, f : X \to \mathbb{R}$.

(i) $f_n \rightrightarrows f \Rightarrow f_n \to f$ pointwise $\Rightarrow f_n \to f$ a.e.; converses fail.
(ii) $|X| < +\infty$ and $f_n \to f$ pointwise $\Rightarrow f_n \rightrightarrows f$.
(iii) $\mu(A) = 0 \Rightarrow A = \emptyset$ and $f_n \to f$ a.e. $\Rightarrow f_n \to f$ pointwise.

Proof.

(i) If $f_n \rightrightarrows f$, then $\forall \varepsilon > 0$ $\exists N_\varepsilon$ such that $\forall n \geq N_\varepsilon$ $\forall x \in X$, $|f_n(x) - f(x)| < \varepsilon$; hence pointwise convergence with $N(\varepsilon, x) = N_\varepsilon$.
Pointwise convergence is a.e. convergence with $A = \emptyset$.
Conversely, on $([0,1], \lambda)$, $x^n \to \mathbf{1}_{\{1\}}$ pointwise but not uniformly, and $\mathbf{1}_{\{0\}} \to 0$ a.e. but not pointwise.
(ii) If X is finite and $f_n \to f$ pointwise, then $\forall \varepsilon > 0$ $\forall x \in X$, choose $N(\varepsilon, x)$.
Set $N_\varepsilon = \max_{x \in X} N(\varepsilon, x)$; then $\forall n \geq N_\varepsilon$ $\forall x \in X$, $|f_n(x) - f(x)| < \varepsilon$, so $f_n \rightrightarrows f$.
(iii) If $f_n \to f$ a.e., then $\exists A \in \mathcal{M}$ with $\mu(A) = 0$ and $\forall x \in X \setminus A$, $f_n(x) \to f(x)$.
Since every null set is empty, $A = \emptyset$, so $f_n \to f$ pointwise.

Structural Commentary: Uniformity is bounded x-dependence of $N(\varepsilon, x)$.
Key Insight: Uniformity controls indices; a.e. convergence controls null exceptions. □

Proposition 4.2.3. *Uniform Convergence Gives L^p Convergence on Finite Measure Spaces*
Let $1 \leq p < \infty$, $\mu(X) < +\infty$, and $f_n \in L^p(\mu)$. If $f_n \rightrightarrows f$ on X, then $f \in L^p(\mu)$ and $\|f_n - f\|_p \to 0$.

Proof. For $\varepsilon > 0$, choose N with $n \geq N \Rightarrow |f_n - f| \leq \varepsilon$ on X.
Then $n \geq N \Rightarrow \|f_n - f\|_p \leq (\int_X \varepsilon^p\, d\mu)^{\frac{1}{p}} = \varepsilon \mu(X)^{\frac{1}{p}}$, so $\|f_n - f\|_p \to 0$.
Taking $\varepsilon = 1$, choose n_0 with $|f_{n_0} - f| \leq 1$ on X; hence $f - f_{n_0} \in L^p(\mu)$ and $f = f_{n_0} + (f - f_{n_0}) \in L^p(\mu)$.

Structural Commentary: Uniform error becomes L^p error after multiplication by $\mu(X)^{\frac{1}{p}}$.
Key Insight: Finite measure converts a pointwise sup-bound into an integral bound. □

Theorem 4.2.4. *Dominated Almost-Everywhere Convergence Gives L^p Convergence*
Let $1 \leq p < \infty$, $f_n \in L^p(\mu)$, and $f_n \to f$ a.e. Suppose $\exists g \in L^p(\mu)$ such that $\forall n$, $|f_n| \leq g$ a.e.

(i) $f \in L^p(\mu)$.
(ii) $\|f_n - f\|_p \to 0$.

Proof.

(i) Choose $N \in \mathcal{M}$ with $\mu(N) = 0$ such that on $X \setminus N$, $f_n \to f$ and $|f_n| \leq g$ $\forall n$.
Then $|f| \leq g$ a.e., so $|f|^p \leq g^p \in \mathscr{L}^1(\mu)$.
(ii) Since $|f_n - f|^p \to 0$ a.e. and $|f_n - f|^p \leq (2g)^p \in \mathscr{L}^1(\mu)$ a.e.,
Theorem 1.3.7 yields $\|f_n - f\|_p^p = \int_X |f_n - f|^p\, d\mu \to 0$.

Structural Commentary: Apply ordinary dominated convergence to the pth-power error.
Key Insight: A single L^p envelope controls both membership of the limit and convergence in mean. □

Corollary 4.2.5. *Uniform Boundedness on Finite Measure Spaces*
Let $\mu(X) < +\infty$, $0 \leq K < +\infty$, and $f_n \to f$ a.e. Assume $\forall n$, $|f_n| \leq K$ a.e. Then for every $1 \leq p < \infty$:

(i) $f \in L^p(\mu)$.

(ii) $\|f_n - f\|_p \to 0$.

Proof. Fix $1 \le p < \infty$ and set $g := K\mathbf{1}_X$. Then $\int_X g^p \, d\mu = K^p \mu(X) < +\infty$, so $g \in L^p(\mu)$ and $|f_n| \le g$ a.e.
(i) Since $f_n \to f$ a.e. and $|f_n| \le g \in L^p(\mu)$ a.e., Theorem 4.2.4(i) gives $f \in L^p(\mu)$.
(ii) The same hypotheses and Theorem 4.2.4(ii) give $\|f_n - f\|_p \to 0$.
Structural Commentary: Finite measure turns a uniform a.e. bound into an L^p envelope.
Key Insight: Bounded a.e. convergence on finite measure is dominated convergence. □

Example 4.2.6. *Uniform Need Not Imply L^p on Infinite Measure*
On $(\mathbb{R}, \mathcal{B}(\mathbb{R}), \lambda)$, fix $1 \le p < \infty$ and set $f_n := n^{-\frac{1}{p}} \mathbf{1}_{[0,n]}$. Then $\|f_n\|_\infty = n^{-\frac{1}{p}} \to 0$, so $f_n \rightrightarrows 0$.
However $\|f_n\|_p^p = \int_0^n n^{-1} \, d\lambda = 1$, hence $\|f_n\|_p \not\to 0$.
Structural Commentary: The support grows exactly enough to preserve L^p mass.
Key Insight: Uniform smallness alone does not control integrals on infinite measure spaces.

Example 4.2.7. *Almost Everywhere and In-Measure Need Not Imply L^p*
On $[0,1]$ with Lebesgue measure, set $f_n := n\mathbf{1}_{[\frac{1}{n}, \frac{2}{n}]}$.
$\forall x \in [0,1]$, $x \in [\frac{1}{n}, \frac{2}{n}]$ for only finitely many n, hence $f_n(x) \to 0$.
If $\alpha > 0$ and $n \ge \alpha$, then $\lambda\{|f_n| \ge \alpha\} = \frac{1}{n} \to 0$, so $f_n \to 0$ in measure.
Yet for $1 \le p < \infty$, $\|f_n\|_p^p = n^p \lambda([\frac{1}{n}, \frac{2}{n}]) = n^{p-1} \not\to 0$.
Given $\delta > 0$, choose $0 < \eta < \delta$; on $[0,1] \setminus [0, \eta]$, $\forall n > \frac{2}{\eta}$, $f_n = 0$, so $f_n \to 0$ almost uniformly.
Thus a.e., in-measure, and almost-uniform convergence do not imply L^p convergence.

Theorem 4.2.8. *Pointwise A.E. Convergence Plus Norms*
Let $1 \le p < \infty$, $f_n, f \in L^p(\mu)$, $f_n \to f$ a.e. Then $f_n \to f$ in $L^p(\mu)$ iff $\lim_{n\to\infty} \int_X |f_n|^p \, d\mu = \int_X |f|^p \, d\mu$.

Proof.
($\Rightarrow$) If $\|f_n - f\|_p \to 0$, then $\left| \|f_n\|_p - \|f\|_p \right| \le \|f_n - f\|_p$, hence $\int_X |f_n|^p \, d\mu = \|f_n\|_p^p \to \|f\|_p^p = \int_X |f|^p \, d\mu$.
($\Leftarrow$) Assume $\int_X |f_n|^p \, d\mu \to \int_X |f|^p \, d\mu$. Set $h_n := \frac{|f_n|^p + |f|^p}{2} - \left| \frac{f_n - f}{2} \right|^p \ge 0$ by convexity.
Since $h_n \to |f|^p$ a.e., Fatou gives $\int_X |f|^p \, d\mu \le \liminf_n \int_X h_n \, d\mu = \int_X |f|^p \, d\mu - 2^{-p} \limsup_n \int_X |f_n - f|^p \, d\mu$.
Thus $\limsup_n \|f_n - f\|_p^p \le 0$, so $f_n \to f$ in $L^p(\mu)$.
Structural Commentary: A.e. convergence identifies the limit; p-mass convergence prevents loss.
Key Insight: Fatou applied to the convexity defect forces the error norm to vanish. □

Definition 4.2.9. *Convergence and Cauchy Convergence in Measure*
Let (f_n) be measurable functions on X.
(i) $f_n \to f$ *in measure* if $\forall \alpha > 0$, $\mu\{x \in X : |f_n(x) - f(x)| \ge \alpha\} \to 0$.
(ii) (f_n) is *Cauchy in measure* if $\forall \alpha > 0$, $\mu\{x \in X : |f_m(x) - f_n(x)| \ge \alpha\} \to 0$ as $m, n \to \infty$.
The same definitions result with $>$ in place of $\ge$.

Proposition 4.2.10. *L^p Convergence Implies Convergence in Measure*
Let $1 \le p < \infty$. If $\|f_n - f\|_p \to 0$, then $f_n \to f$ in measure.

Proof. For $\alpha > 0$, set $E_n(\alpha) := \{|f_n - f| \ge \alpha\}$.
Since $\|f_n - f\|_p^p \ge \int_{E_n(\alpha)} |f_n - f|^p \, d\mu \ge \alpha^p \mu(E_n(\alpha))$, $\mu(E_n(\alpha)) \le \alpha^{-p} \|f_n - f\|_p^p \to 0$.
Structural Commentary: Large-error sets are controlled by the integral of the pth-power error.
Key Insight: This is Chebyshev's inequality in deterministic measure form. □

Example 4.2.11. *L^p Convergence Without Pointwise Convergence*
Let $X = [0,1]$ with Lebesgue measure and list $I_{m,k} := [\frac{k-1}{m}, \frac{k}{m}]$, $1 \le k \le m$, row by row in m.
Let $f_n := \mathbf{1}_{I_n}$, where I_n is the nth interval. If I_n lies in row $m(n)$, then $m(n) \to \infty$ and
$\|f_n\|_p^p = \lambda(I_n) = \frac{1}{m(n)} \to 0$; hence $f_n \to 0$ in L^p, therefore in measure by Proposition 4.2.10.
$\forall x \in [0,1]$, every row contains some $I_{m,k}$ with $x \in I_{m,k}$, giving a subsequence with value 1 at x; for infinitely many rows, some $I_{m,k}$ omits x, giving a subsequence with value 0 at x. Thus $(f_n(x))$ converges nowhere.
The subfamily $I_{m,2} = [\frac{1}{m}, \frac{2}{m}]$, $m \ge 2$, gives a subsequence converging pointwise to 0 on all of X.

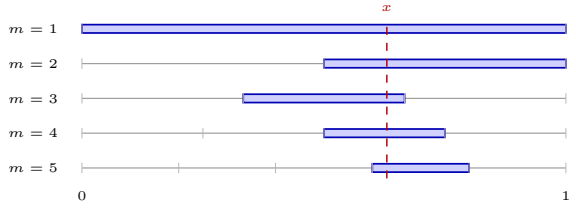

Figure 215: In each row, one shrinking typewriter interval contains the fixed point x.

Theorem 4.2.12. *Riesz Subsequence Principle for Convergence in Measure*
If (f_n) is Cauchy in measure, then there exist a subsequence (g_k) and a measurable f such that:
(i) $g_k \to f$ *a.e.*
(ii) $g_k \to f$ *in measure.*

(iii) $\forall \varepsilon > 0\ \exists E \in \mathcal{M}$ *with* $\mu(E) < \varepsilon$ *such that* $g_k \to f$ *uniformly on* $X \setminus E$.

Proof.

(i) Choose $n_1 < n_2 < \cdots$ so that $m, n \geq n_k \Rightarrow \mu\{|f_m - f_n| \geq \frac{1}{2^k}\} < \frac{1}{2^k}$, and set $g_k := f_{n_k}$.
For $E_k := \{|g_{k+1} - g_k| \geq \frac{1}{2^k}\}$, $\mu(E_k) < \frac{1}{2^k}$. Set $F_k := \bigcup_{j=k}^{\infty} E_j$. Then $F_k \downarrow$, $\mu(F_k) \leq \sum_{j=k}^{\infty} \frac{1}{2^j} = \frac{1}{2^{k-1}}$.
For $i > j \geq k$, $x \notin F_k$, $|g_i(x) - g_j(x)| \leq \sum_{r=j}^{i-1} |g_{r+1}(x) - g_r(x)| < \frac{1}{2^{j-1}}$.
Hence (g_j) is uniformly Cauchy on $X \setminus F_k$ $\forall k$.
Let $F := \bigcap_k F_k$, so $\mu(F) = 0$. Define $f = \lim_j g_j$ on $X \setminus F$, $f = 0$ on F. f is measurable, $g_j \to f$ a.e.

(ii) Letting $i \to \infty$ gives $j \geq k$, $x \notin F_k \Rightarrow |f(x) - g_j(x)| \leq \frac{1}{2^{j-1}} \leq \frac{1}{2^{k-1}}$. Given $\alpha, \varepsilon > 0$, choose k with $\frac{1}{2^{k-1}} < \alpha$ and $\mu(F_k) < \varepsilon$; then $j \geq k \Rightarrow \{|f - g_j| \geq \alpha\} \subseteq F_k$, so $g_j \to f$ in measure.

(iii) Given $\varepsilon > 0$, choose k with $\mu(F_k) < \varepsilon$.
The estimate in (ii) gives $\sup_{x \in X \setminus F_k} |f(x) - g_j(x)| \leq \frac{1}{2^{j-1}} \to 0$, so $g_j \to f$ uniformly on $X \setminus F_k$.

Structural Commentary: Cauchy in measure lets us select summably small exceptional sets.
Key Insight: Outside the tail union of exceptional sets, the subsequence is uniformly Cauchy. □

Corollary 4.2.13. *Completeness for Convergence in Measure*
(f_n) *is Cauchy in measure iff* $\exists f$ *measurable with* $f_n \to f$ *in measure.*

Proof.

(⇒) If (f_n) is Cauchy in measure, then $f_{n_k} \to f$ in measure for some measurable f by Theorem 4.2.12.
For $\alpha > 0$, $\{|f_n - f| \geq \alpha\} \subseteq \{|f_n - f_{n_k}| \geq \frac{\alpha}{2}\} \cup \{|f_{n_k} - f| \geq \frac{\alpha}{2}\}$.
Choose k large, then n large, to get $f_n \to f$ in measure.

(⇐) For $\alpha > 0$, $\{|f_m - f_n| \geq \alpha\} \subseteq \{|f_m - f| \geq \frac{\alpha}{2}\} \cup \{|f_n - f| \geq \frac{\alpha}{2}\}$.
Hence $\mu\{|f_m - f_n| \geq \alpha\} \to 0$ as $m, n \to \infty$.

Structural Commentary: The subsequential in-measure limit attracts the whole Cauchy sequence.
Key Insight: Convergence in measure is complete after measurable limits are admitted. □

Corollary 4.2.14. *Uniqueness for Convergence in Measure*
If $f_n \to f$ *and* $f_n \to g$ *in measure, then* $f = g$ *a.e.*

Proof. For $\alpha > 0$, $\{|f - g| \geq \alpha\} \subseteq \{|f - f_n| \geq \frac{\alpha}{2}\} \cup \{|f_n - g| \geq \frac{\alpha}{2}\}$, so $\mu\{|f - g| \geq \alpha\} = 0$.
Hence $\mu\{|f - g| > 0\} = 0$ and $f = g$ a.e.
Structural Commentary: Two in-measure limits cannot differ on a positive-measure set.
Key Insight: In-measure limits are unique modulo null sets. □

Corollary 4.2.15. *In-Measure Limits Have A.E. Subsequences*
If $f_n \to f$ *in measure, then some subsequence* f_{n_k} *converges to* f *a.e.*

Proof. Since $f_n \to f$ in measure, (f_n) is Cauchy in measure.
Choose a subsequence $f_{n_k} \to h$ a.e. and in measure by Theorem 4.2.12.
Then $h = f$ a.e. by Corollary 4.2.14; after enlarging the exceptional null set, $f_{n_k} \to f$ a.e.
Structural Commentary: Convergence in measure contains an almost-everywhere convergent subsequence.
Key Insight: Select a Cauchy-in-measure subsequence, then identify its limit by uniqueness. □

Proposition 4.2.16. *Subsequence and Indicator Consequences*

(i) $f_n \to f$ *in measure* ⇒ *every subsequence* $f_{n_k} \to f$ *in measure; if* (f_n) *is Cauchy in measure, then every* (f_{n_k}) *is Cauchy in measure.*
(ii) If $\|f_n - f\|_p \to 0$ *and* $\|f_{n_k} - g\|_p \to 0$, *then* $f = g$ *a.e.*
(iii) If $f_n = \mathbf{1}_{E_n}$ *and* $\|f_n - f\|_p \to 0$, *then* $f = \mathbf{1}_E$ *a.e. for some* $E \in \mathcal{M}$.

Proof.

(i) For $\alpha > 0$, $\mu\{|f_{n_k} - f| \geq \alpha\} \to 0$ since $n_k \to \infty$; the Cauchy claim is identical with $m_k, n_\ell \to \infty$.

(ii) $f_n \to f$ and $f_{n_k} \to g$ in measure by Proposition 4.2.10; also $f_{n_k} \to f$ in measure by (i).
Thus $f = g$ a.e. by Corollary 4.2.14.

(iii) By Proposition 4.2.10 and Theorem 4.2.12, some $f_{n_k} \to f$ a.e.
Since $f_{n_k} \in \{0, 1\}$, $f \in \{0, 1\}$ a.e.; with $E := \{f = 1\}$, $E \in \mathcal{M}$ and $f = \mathbf{1}_E$ a.e.

Structural Commentary: Subsequence permanence and a.e. uniqueness transfer mode limits to representatives.
Key Insight: In-measure subsequences preserve limits; indicator limits remain indicators a.e. □

Proposition 4.2.17. *Algebra of Convergence in Measure on Finite Measure Spaces*
Let $(X, \mathcal{M}, \mu)$ *satisfy* $\mu(X) < +\infty$. *All functions below are measurable and finite-valued a.e.*

(i) If $f_n \to f$ *and* $g_n \to g$ *in measure, then* $\forall a, b \in \mathbb{R}$, $af_n + bg_n \to af + bg$ *in measure.*
(ii) If $u_n \to 0$ *in measure and* h *is measurable and finite-valued a.e., then* $hu_n \to 0$ *in measure.*
(iii) If $f_n \to f$ *and* $g_n \to g$ *in measure, then* $f_n g_n \to fg$ *in measure.*
(iv) If $f_n \to f$ *in measure, then* $f_n^2 \to f^2$ *in measure.*

Proof.

(i) Fix $\alpha > 0$. Since $\{|a(f_n - f) + b(g_n - g)| \geq \alpha\} \subseteq \{|a(f_n - f)| \geq \frac{\alpha}{2}\} \cup \{|b(g_n - g)| \geq \frac{\alpha}{2}\}$, the measure of the right-hand side tends to 0 by convergence in measure of f_n and g_n.

(ii) Fix $\alpha, \eta > 0$. Since h is finite a.e. and $\mu(X) < +\infty$, choose $M > 0$ with $\mu\{|h| > M\} < \eta$.
Then $\{|hu_n| \geq \alpha\} \subseteq \{|h| > M\} \cup \{|u_n| \geq \frac{\alpha}{M}\}$, so $\limsup_n \mu\{|hu_n| \geq \alpha\} \leq \eta$. Let $\eta \downarrow 0$.

(iii) Set $u_n := f_n - f$ and $v_n := g_n - g$. Then $u_n, v_n \to 0$ in measure and $f_n g_n - fg = fv_n + gu_n + u_n v_n$. By (ii), $fv_n \to 0$ and $gu_n \to 0$ in measure. For $\alpha > 0$, $\{|u_n v_n| \geq \alpha\} \subseteq \{|u_n| \geq \sqrt{\alpha}\} \cup \{|v_n| \geq \sqrt{\alpha}\}$, so $u_n v_n \to 0$ in measure. Apply (i) to the three summands.
(iv) Apply (iii) with $g_n = f_n$ and $g = f$.

Structural Commentary: Finite measure makes finite measurable multipliers harmless after truncation.
Key Insight: Products split into fixed-multiplier errors and a product of two small-in-measure errors. □

Theorem 4.2.18. *Dominated Convergence in Measure Gives L^p Convergence*
Let $1 \leq p < \infty$, $f_n \in L^p(\mu)$, $f_n \to f$ in measure, and $|f_n| \leq g$ a.e. for some $g \in L^p(\mu)$. Then:
(i) $f \in L^p(\mu)$;
(ii) $\|f_n - f\|_p \to 0$.

Proof. Since $f_n \to f$ in measure, (f_n) is Cauchy in measure.

(i) By Theorem 4.2.12, some subsequence (u_j) satisfies $u_j \to h$ a.e. and in measure; $h = f$ a.e. by Corollary 4.2.14. Since $|u_j| \leq g$ a.e., $f \in L^p(\mu)$ by Theorem 4.2.4.
(ii) If norm convergence fails, then $\exists \varepsilon > 0$ and a subsequence (g_k) with $\|g_k - f\|_p \geq \varepsilon$. The argument in (i) produces a subsubsequence (h_j) with $h_j \to f$ a.e.; then $\|h_j - f\|_p \to 0$ by Theorem 4.2.4, a contradiction.

Structural Commentary: Reduce convergence in measure to almost-everywhere convergence along a subsequence.
Key Insight: Domination turns every in-measure subsequence into an L^p-convergent subsubsequence. □

Lemma 4.2.19. *Almost Uniform Cauchy Sequences Have Almost Uniform Limits*
If (f_n) is almost uniformly Cauchy, then $\exists f$ measurable such that $f_n \to f$ almost uniformly and a.e.

Proof. Choose $E_k \in \mathcal{M}$ with $\mu(E_k) < 2^{-k}$ and (f_n) uniformly Cauchy on $X \setminus E_k$. Set $F_k := \bigcup_{j=k}^{\infty} E_j$ and $F := \bigcap_k F_k$; then $F_k \downarrow$, $\mu(F_k) < 2^{-(k-1)}$, $\mu(F) = 0$, and (f_n) is uniformly Cauchy on $X \setminus F_k$. By Theorem 7.1.7, f_n has a uniform limit on each $X \setminus F_k$; these limits agree on overlaps, so define measurable f on $X \setminus F$, and set $f = 0$ on F. Hence $f_n \to f$ a.e. and uniformly on each $X \setminus F_k$; since $\mu(F_k) \to 0$, $f_n \to f$ almost uniformly.
Structural Commentary: Tail unions convert many small exceptional sets into nested uniform domains.
Key Insight: Almost uniform Cauchy means uniformly Cauchy after discarding a tail-small exceptional set. □

Theorem 4.2.20. *Almost Uniform Convergence and Convergence in Measure*
The following hold.
(i) If $f_n \to f$ almost uniformly, then $f_n \to f$ in measure.
(ii) If $f_n \to f$ in measure, then $\exists (f_{n_k})$ with $f_{n_k} \to f$ almost uniformly.

Proof.
(i) If $f_n \rightrightarrows f$ on $X \setminus E_\delta$ with $\mu(E_\delta) < \delta$, then $\forall \alpha > 0$ and sufficiently large n, $\{|f_n - f| \geq \alpha\} \subseteq E_\delta$. Thus $\limsup_n \mu\{|f_n - f| \geq \alpha\} \leq \delta$, and let $\delta \downarrow 0$.
(ii) Convergence in measure makes (f_n) Cauchy in measure. Choose $f_{n_k} \to h$ almost uniformly and in measure by Theorem 4.2.12. Uniqueness gives $h = f$ a.e.; absorb $\{h \neq f\}$ into the exceptional sets.

Structural Commentary: Almost uniform convergence is uniform convergence off arbitrarily small sets.
Key Insight: Convergence in measure always hides an almost-uniform subsequence. □

Corollary 4.2.21. *Finite-Measure Almost-Everywhere Convergence Implies In-Measure Convergence*
If $\mu(X) < +\infty$ and $f_n \to f$ a.e., with f_n, f finite-valued off a null set, then $f_n \to f$ in measure.

Proof. By Theorem 1.6.3, $f_n \to f$ almost uniformly; hence $f_n \to f$ in measure by Theorem 4.2.20.
Structural Commentary: Finite measure upgrades a.e. convergence through almost uniform convergence.
Key Insight: On finite measure spaces, a.e. convergence implies in-measure convergence. □

Corollary 4.2.22. *Finite-Measure Subsequence Test for Convergence in Measure*
Let $(X, \mathcal{M}, \mu)$ satisfy $\mu(X) < +\infty$, and let $f_n, f : X \to \overline{\mathbb{R}}$ be measurable and finite-valued a.e.
Then $f_n \to f$ in measure iff every subsequence of (f_n) has a further subsequence converging to f a.e.

Proof.
($\Rightarrow$) If $f_n \to f$ in measure, then every subsequence also converges to f in measure by Proposition 4.2.16. Choose a further subsequence converging to f a.e. by Corollary 4.2.15.
($\Leftarrow$) Suppose $f_n \not\to f$ in measure. Then $\exists \alpha, \varepsilon > 0$ and subsequence (f_{n_k}) with $\mu\{|f_{n_k} - f| \geq \alpha\} \geq \varepsilon$ $\forall k$. But some $f_{n_{k_j}} \to f$ a.e., hence in measure by Corollary 4.2.21, contradicting the uniform lower bound.

Structural Commentary: Subsequence tests characterize in-measure convergence.
Key Insight: Nonconvergence leaves a bad subsequence. □

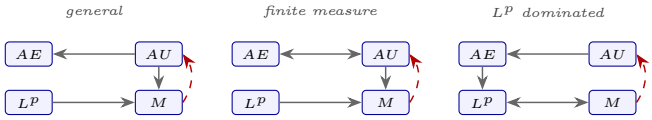

Figure 216: Modes of convergence in three settings: solid arrows are implications; dashed arrows yield convergent subsequences.

Method 4.2.23. *Counterexample Dictionary*

(i) On $(\mathbb{R},\lambda)$, $f_n = n^{-\frac{1}{p}}\mathbf{1}_{[0,n]}$ satisfies $f_n \rightrightarrows 0$ but $\|f_n\|_p = 1$.
(ii) On $([0,1],\lambda)$, $f_n = n\mathbf{1}_{[\frac{1}{n},\frac{2}{n}]}$ satisfies $f_n \to 0$ a.e., in measure, almost uniformly, but $\|f_n\|_p^p = n^{p-1} \nrightarrow 0$.
(iii) Typewriter intervals on $[0,1]$: if $f_n = \mathbf{1}_{I_n}$ and $\lambda(I_n) \to 0$ rowwise, then $\|f_n\|_p \to 0$ and $f_n \to 0$ in measure, but $(f_n(x))$ converges nowhere.
(iv) On $(\mathbb{R},\lambda)$, $f_n = \mathbf{1}_{[n,n+1]}$ satisfies $f_n \to 0$ pointwise but $\forall n,\ \lambda\{|f_n| \geq \frac{1}{2}\} = 1$, so $f_n \nrightarrow 0$ in measure.
(v) On $(\mathbb{R},\lambda)$, $f_n = \mathbf{1}_{[n,n+1]}$ is not almost uniformly convergent to 0: if $\lambda(E) < 1$ and $f_n \rightrightarrows 0$ on $\mathbb{R}\setminus E$, then $[n,n+1] \subseteq E$ for sufficiently large n, impossible.

Proposition 4.2.24. *An Integral Metric for Convergence in Measure on Finite Measure Spaces*
Let $\mu(X) < +\infty$ and $r(h) := \int_X |h|\,(1+|h|)^{-1}\,d\mu$. Then $f_n \to f$ in measure iff $r(f_n - f) \to 0$.

Proof.
($\Rightarrow$) Set $h_n := f_n - f$. For $\eta > 0$ and $A_n := \{|h_n| \geq \eta\}$, $r(h_n) \leq \mu(A_n) + \eta\mu(X)$. Let $n \to \infty$, then $\eta \downarrow 0$.
($\Leftarrow$) For $\alpha > 0$, $\alpha(1+\alpha)^{-1}\mathbf{1}_{\{|h_n|\geq\alpha\}} \leq |h_n|\,(1+|h_n|)^{-1}$, hence $\mu\{|h_n| \geq \alpha\} \leq (1+\alpha)\alpha^{-1} r(h_n) \to 0$.
Structural Commentary: The bounded error transform metrizes convergence in measure on finite measure spaces.
Key Insight: Small integral of the bounded error transform is equivalent to small large-error sets. □

Corollary 4.2.25. *Fatou and Dominated Convergence with In-Measure Hypotheses*
(i) $f_n \geq 0$ and $f_n \to f$ in measure $\Rightarrow \int_X f\,d\mu \leq \liminf_n \int_X f_n\,d\mu$.
(ii) $f_n \to f$ in measure and $|f_n| \leq g \in \mathscr{L}^1(\mu) \Rightarrow \int_X f_n\,d\mu \to \int_X f\,d\mu$.

Proof.
(i) Choose f_{n_k} with $\int f_{n_k}\,d\mu \to \liminf_n \int f_n\,d\mu$. By Theorem 4.2.12 and uniqueness, some $f_{n_{k_j}} \to f$ a.e.
Fatou gives $\int f\,d\mu \leq \liminf_j \int f_{n_{k_j}}\,d\mu = \liminf_n \int f_n\,d\mu$.
(ii) By Theorem 4.2.18 with $p=1$, $\|f_n - f\|_1 \to 0$, hence $\left|\int_X (f_n - f)\,d\mu\right| \leq \|f_n - f\|_1 \to 0$.
Structural Commentary: In-measure hypotheses reduce to a.e. subsequences or L^1 convergence.
Key Insight: Fatou and DCT survive convergence in measure through subsequences and domination. □

The next criterion packages the local mass controls needed to reverse convergence in measure into norm convergence.

Theorem 4.2.26. *Vitali Convergence Criterion for L^p*
Let $1 \leq p < \infty$, $f_n \in L^p(\mu)$, and let f be measurable. Consider the following conditions.
(i) $f \in L^p(\mu)$ and $\|f_n - f\|_p \to 0$.
(ii) $f_n \to f$ in measure.
(iii) $\forall \varepsilon > 0\ \exists E_\varepsilon \in \mathcal{M}$ with $\mu(E_\varepsilon) < +\infty$ such that $F \cap E_\varepsilon = \emptyset \Rightarrow \sup_n \int_F |f_n|^p\,d\mu < \varepsilon^p$.
(iv) $\forall \varepsilon > 0\ \exists \delta(\varepsilon) > 0$ such that $\mu(E) < \delta(\varepsilon) \Rightarrow \sup_n \int_E |f_n|^p\,d\mu < \varepsilon^p$.
Precisely, (i) is equivalent to the conjunction of (ii)–(iv).

Proof.
(i) Assume (i). Then (ii) holds by Proposition 4.2.10, and (f_n) is L^p-Cauchy. Conditions (iii)–(iv) follow from Proposition 4.1.41 after raising its norm bounds to the pth power.
(ii) Assume (ii)–(iv). Fix $\eta > 0$, choose E_η from (iii) and $\delta(\eta)$ from (iv), and put $F = X \setminus E_\eta$.
Then $\|(f_n - f_m)\mathbf{1}_F\|_p \leq \|f_n\mathbf{1}_F\|_p + \|f_m\mathbf{1}_F\|_p < 2\eta$.
If $\mu(E_\eta) > 0$, set $\alpha := \eta\mu(E_\eta)^{-\frac{1}{p}}$ and $H_{nm} := E_\eta \cap \{|f_n - f_m| \geq \alpha\}$.
By (ii), (f_n) is Cauchy in measure, so $\mu(H_{nm}) < \delta(\eta)$ for large m,n. On $E_\eta \setminus H_{nm}$, $|f_n - f_m| < \alpha$; on H_{nm}, use $|f_n - f_m| \leq |f_n| + |f_m|$. Hence $\|(f_n - f_m)\mathbf{1}_{E_\eta}\|_p \leq \alpha\mu(E_\eta)^{\frac{1}{p}} + \|f_n\mathbf{1}_{H_{nm}}\|_p + \|f_m\mathbf{1}_{H_{nm}}\|_p < 3\eta$ by (iv). If $\mu(E_\eta) = 0$, the E_η term is 0.
Thus $\|f_n - f_m\|_p < 5\eta$ eventually, so (f_n) is L^p-Cauchy.
By Riesz–Fischer, $f_n \to h$ in L^p; by Proposition 4.2.10 and Corollary 4.2.14, $h = f$ a.e., so (i) holds.
Structural Commentary: Vitali = in-measure convergence + tightness + uniform small-set control.
Key Insight: Tightness and small-set control convert in-measure convergence into an L^p Cauchy estimate. □

4.3 Composition and Convergence Modes

Proposition 4.3.1. *Composition and Pointwise Modes*
Let $\varphi : \mathbb{R} \to \mathbb{R}$.
(i) φ continuous, $f_n \to f$ a.e. $\Rightarrow \varphi \circ f_n \to \varphi \circ f$ a.e.
(ii) φ uniformly continuous preserves uniform, a.u., and in-measure convergence.
(iii) If φ is discontinuous, composition need not preserve a.e. convergence.
(iv) Non-uniform continuity can destroy uniform, even in-measure, convergence.

Proof.
(i) Outside a null set, $f_n(x) \to f(x)$; continuity gives $\varphi(f_n(x)) \to \varphi(f(x))$.
(ii) Given $\varepsilon > 0$, choose $\delta > 0$ with $|s-t| < \delta \Rightarrow |\varphi(s) - \varphi(t)| < \varepsilon$. Uniform and almost-uniform convergence use $\sup|f_n - f| < \delta$ on X or $X \setminus E_\eta$; in measure, $\{|\varphi(f_n) - \varphi(f)| \geq \varepsilon\} \subseteq \{|f_n - f| \geq \delta\}$.
(iii) If φ is discontinuous at a, choose $t_n \to a$ and $\alpha > 0$ with $|\varphi(t_n) - \varphi(a)| \geq \alpha$.
On $X = \{*\}$, $f_n(*) = t_n \to a = f(*)$, but $\varphi(f_n(*)) \nrightarrow \varphi(f(*))$.
(iv) If φ is not uniformly continuous, choose a_n, b_n with $|a_n - b_n| \to 0$ and $|\varphi(a_n) - \varphi(b_n)| \geq \alpha > 0$.
On $(\mathbb{N},\#)$, set $f(k) = b_k$ and $f_n(k) = a_n$ for $k = n$, $f_n(k) = b_k$ for $k \neq n$.
Then $\|f_n - f\|_\infty \to 0$, but $\forall n,\ \#\{|\varphi(f_n) - \varphi(f)| \geq \alpha\} = 1$.

Structural Commentary: Continuity is pointwise; uniform continuity gives one global δ.
Key Insight: Composition needs the same uniformity as the convergence mode. □

Proposition 4.3.2. *Composition and Convergence in Measure*
Let $f_n, f : X \to \mathbb{R}$ be measurable with $f_n \to f$ in measure, and let $\varphi : \mathbb{R} \to \mathbb{R}$.

(i) If φ is uniformly continuous, then $\forall \varepsilon > 0$, $\mu\{|\varphi(f_n) - \varphi(f)| \geq \varepsilon\} \to 0$.
(ii) If $\mu(X) < +\infty$ and φ is continuous, then $\forall \varepsilon > 0$, $\mu\{|\varphi(f_n) - \varphi(f)| \geq \varepsilon\} \to 0$.

Proof.

(i) Fix $\varepsilon > 0$ and choose $\delta > 0$ with $|s - t| < \delta \Rightarrow |\varphi(s) - \varphi(t)| < \varepsilon$.
Then $\{|\varphi(f_n) - \varphi(f)| \geq \varepsilon\} \subseteq \{|f_n - f| \geq \delta\}$, so the measures tend to 0.

(ii) Fix $\varepsilon, \eta > 0$. Since $\mu(X) < +\infty$ and f is finite-valued, choose M with $\mu\{|f| > M\} < \eta$. Uniform continuity of φ on $[-M-1, M+1]$ gives $0 < \delta < 1$ such that $s, t \in [-M-1, M+1]$ and $|s - t| < \delta \Rightarrow |\varphi(s) - \varphi(t)| < \varepsilon$. Hence $\{|\varphi(f_n) - \varphi(f)| \geq \varepsilon\} \subseteq \{|f| > M\} \cup \{|f_n - f| \geq \delta\}$, so $\limsup_n \mu\{|\varphi(f_n) - \varphi(f)| \geq \varepsilon\} \leq \eta \downarrow 0$.

Structural Commentary: Use global uniformity, or truncate to a bounded range.
Key Insight: On finite measure spaces, measurable finite-valued functions are almost bounded. □

Example 4.3.3. *Continuity Alone Is Not Enough on Infinite Measure*
On $(\mathbb{R}, \mathcal{B}(\mathbb{R}), \lambda)$, set $f(x) = x$, $f_n(x) = x + \frac{1}{n}$, and $\varphi(t) = t^2$.
Then $\|f_n - f\|_\infty = \frac{1}{n} \to 0$, hence $f_n \rightrightarrows f$ and $f_n \to f$ in measure.
However $\varphi(f_n) - \varphi(f) = \frac{2x}{n} + \frac{1}{n^2}$; for $E_n := \{|\varphi(f_n) - \varphi(f)| \geq 1\}$, $[\frac{n}{2}, +\infty) \subseteq E_n$, so $\lambda(E_n) = +\infty$.
Thus $\varphi \circ f_n \not\to \varphi \circ f$ in measure.

Proposition 4.3.4. *Growth Conditions for L^p Composition*
Let $1 \leq p < \infty$, let $\varphi : \mathbb{R} \to \mathbb{R}$ be measurable, and let $f_n, f : X \to \mathbb{R}$ be measurable.

(i) If $\exists A, B \geq 0$ such that $\forall t$, $|\varphi(t)| \leq A|t| + B$, $\mu(X) < +\infty$, and $f \in L^p(\mu)$, then $\varphi \circ f \in L^p(\mu)$.
(ii) If $\exists A \geq 0$ such that $\forall t$, $|\varphi(t)| \leq A|t|$, and $f \in L^p(\mu)$, then $\varphi \circ f \in L^p(\mu)$.
(iii) If $\mu(X) < +\infty$, φ is uniformly continuous, $f_n, f \in L^p(\mu)$, and $\|f_n - f\|_p \to 0$, then $\|\varphi \circ f_n - \varphi \circ f\|_p \to 0$.
(iv) If φ is Lipschitz, $\varphi(0) = 0$, $f_n, f \in L^p(\mu)$, and $\|f_n - f\|_p \to 0$, then $\|\varphi \circ f_n - \varphi \circ f\|_p \to 0$.

Proof.

(i) $|\varphi(f)|^p \leq 2^{p-1}(A^p |f|^p + B^p)$, so $\|\varphi \circ f\|_p^p \leq 2^{p-1}(A^p \|f\|_p^p + B^p \mu(X)) < +\infty$.

(ii) $|\varphi(f)|^p \leq A^p |f|^p$, so $\|\varphi \circ f\|_p \leq A \|f\|_p < +\infty$.

(iii) Uniform continuity gives constants $C, D \geq 0$ with $|\varphi(t)| \leq C|t| + D$ and $|\varphi(s) - \varphi(t)| \leq C|s - t| + D$.
Hence all compositions lie in L^p by (i). Let $h_n := |f_n - f|$.
Given $\eta > 0$, choose $\delta > 0$ with $|s - t| < \delta \Rightarrow |\varphi(s) - \varphi(t)| < \eta$ and set $H_n := \{h_n \geq \delta\}$.
Then $\int_X |\varphi(f_n) - \varphi(f)|^p \, d\mu \leq \eta^p \mu(X) + 2^{p-1} \int_{H_n} (C^p h_n^p + D^p) \, d\mu$.
Since $\int h_n^p \, d\mu \to 0$ and $\mu(H_n) \leq \delta^{-p} \int h_n^p \, d\mu \to 0$, take $\limsup_n$ and then $\eta \downarrow 0$.

(iv) If L is Lipschitz, $|\varphi(f)| \leq L|f|$ and $\|\varphi \circ f_n - \varphi \circ f\|_p \leq L \|f_n - f\|_p \to 0$.

Structural Commentary: Growth gives membership; continuity estimates transfer L^p convergence.
Key Insight: Finite measure makes small uniform errors integrable; Lipschitz bounds give norm control. □

Example 4.3.5. *Uniform Continuity Does Not Suffice on Infinite Measure*
On $(\mathbb{R}, \lambda)$, fix $1 \leq p < \infty$, set $f = 0$, $f_n := n^{-1} \mathbf{1}_{[0, n^{\frac{p}{2}}]}$, and $\varphi(t) := \sqrt{|t|}$.
Then φ is uniformly continuous, $\varphi(0) = 0$, $\|f_n - f\|_p^p = n^{-\frac{p}{2}} \to 0$, but $\forall n$, $\|\varphi \circ f_n - \varphi \circ f\|_p^p = 1$.
Thus uniform continuity need not preserve L^p convergence on infinite measure spaces.

Lemma 4.3.6. *L^p Convergence Allows Continuous Composition in Measure*
Let $1 \leq p < \infty$, $f_n, f \in L^p(\mu)$, $\|f_n - f\|_p \to 0$, and let $\varphi : \mathbb{R} \to \mathbb{R}$ be continuous.
Then $\varphi \circ f_n \to \varphi \circ f$ in measure.

Proof. Fix $\alpha, \eta > 0$. Choose M with $\mu\{|f| > M\} < \eta$. By uniform continuity of φ on $[-M-1, M+1]$, choose $0 < \delta < 1$ such that $s, t \in [-M-1, M+1]$ and $|s - t| < \delta \Rightarrow |\varphi(s) - \varphi(t)| < \alpha$.
Then $\{|\varphi(f_n) - \varphi(f)| \geq \alpha\} \subseteq \{|f| > M\} \cup \{|f_n - f| \geq \delta\}$, so $\limsup_n \mu\{|\varphi(f_n) - \varphi(f)| \geq \alpha\} \leq \eta$. Let $\eta \downarrow 0$.

Structural Commentary: L^p convergence localizes to a large bounded range where continuity is uniform.
Key Insight: Norm convergence gives in-measure control; bounded-range continuity transfers it. □

Theorem 4.3.7. *Composition Growth Criteria in L^p*
Let $1 \leq p < \infty$ and let $\varphi : \mathbb{R} \to \mathbb{R}$ be continuous.

(i) If $\mu(X) < +\infty$ and $\exists K > 0$ such that $|\varphi(t)| \leq K|t|$ for $|t| \geq K$, then $f \in L^p(\mu) \Rightarrow \varphi \circ f \in L^p(\mu)$.
(ii) Under (i), if $f_n, f \in L^p(\mu)$ and $\|f_n - f\|_p \to 0$, then $\|\varphi \circ f_n - \varphi \circ f\|_p \to 0$.
(iii) If $\exists K \geq 0$ such that $\forall t$, $|\varphi(t)| \leq K|t|$, then $f \in L^p(\mu) \Rightarrow \varphi \circ f \in L^p(\mu)$ on any measure space.
(iv) Under (iii), if $f_n, f \in L^p(\mu)$ and $\|f_n - f\|_p \to 0$, then $\|\varphi \circ f_n - \varphi \circ f\|_p \to 0$ on any measure space.

Proof.

(i) Let $M := \sup_{|t| \leq K} |\varphi(t)|$, $C := K + M$. Then $\forall t$, $|\varphi(t)| \leq C(1 + |t|)$; hence $|\varphi(f)|^p \leq 2^{p-1} C^p (1 + |f|^p) \in L^1(\mu)$.

(ii) Let C be as in (i). Then $\varphi \circ f_n \to \varphi \circ f$ in measure by Lemma 4.3.6.
Since (f_n) is L^p-Cauchy, Proposition 4.1.41 and the growth bound from (i) supply the finite-tail and small-set estimates. Thus $\|\varphi \circ f_n - \varphi \circ f\|_p \to 0$ by Theorem 4.2.26.

(iii) $|\varphi(f)|^p \leq K^p |f|^p \in L^1(\mu)$.

(iv) $\varphi \circ f_n \to \varphi \circ f$ in measure by Lemma 4.3.6. Since (f_n) is L^p-Cauchy and $|\varphi(f_n)|^p \le K^p |f_n|^p$, the finite-tail and small-set estimates for $(\varphi \circ f_n)$ follow from Proposition 4.1.41.
Thus $\|\varphi \circ f_n - \varphi \circ f\|_p \to 0$ by Theorem 4.2.26.

Structural Commentary: Local growth needs finite measure; global growth does not.
Key Insight: Vitali converts in-measure composition plus inherited mass control into L^p convergence. □

Method 4.3.8. *Atomic Counterexamples for Composition Growth*

(i) If finite-measure tail growth fails, choose $|t_n| \ge n$ with $|\varphi(t_n)| > n^2 |t_n|$. On $\mathbb{N}$, set $\mu(\{n\}) = (n^2 |t_n|^p)^{-1}$ and $f(n) = t_n$. Then $\mu(\mathbb{N}) < +\infty$, $\int |f|^p \, d\mu = \sum_n n^{-2} < +\infty$, but $\int |\varphi(f)|^p \, d\mu \ge \sum_n n^{2p-2} = +\infty$.

(ii) If the same tail growth fails, choose $|t_n| \ge n$ with $|\varphi(t_n) - \varphi(0)| \ge n |t_n|$. With $\mu(\{n\}) = (n^p |t_n|^p)^{-1}$, $f = 0$, and $f_n = t_n \mathbf{1}_{\{n\}}$, one has $\mu(\mathbb{N}) < +\infty$, $\|f_n - f\|_p = \frac{1}{n} \to 0$, but $\|\varphi \circ f_n - \varphi \circ f\|_p \ge 1$.

(iii) If global linear growth fails and $\varphi(0) = 0$, the constructions in (i)–(ii), without requiring $\mu(\mathbb{N}) < +\infty$, give membership and convergence counterexamples on arbitrary measure spaces.

(iv) If $\varphi(0) \ne 0$, then on $(\mathbb{N}, \#)$, $0 \in L^p$ but $\varphi \circ 0$ is a nonzero constant and hence not in L^p; the constant sequence $f_n = 0$ gives the convergence failure.

4.4 Uniform Integrability and Vitali Convergence

Uniform integrability is the L^1 condition that rules out concentration of mass on tiny sets. On infinite-measure spaces it must be paired with tightness, which rules out mass escaping to remote finite-measure tails.

Lemma 4.4.1. *Finite-Measure Lebesgue Sets Have Small Pieces*
Let $E \in \mathcal{L}^1$, $m(E) < +\infty$, and $\delta > 0$. Then $\exists E_1, \dots, E_N \in \mathcal{L}^1$ such that:

(i) $E_i \cap E_j = \emptyset$ *for* $i \ne j$.

(ii) $E = \bigsqcup_{k=1}^{N} E_k$.

(iii) $m(E_k) < \delta$ *for* $1 \le k \le N$.

Proof. Choose n_0 with $T := E \setminus [-n_0, n_0]$ and $m(T) < \delta$. Partition $[-n_0, n_0]$ into finitely many disjoint intervals I_j with $m(I_j) < \delta$, and let (E_k) be the nonempty sets among T and $E \cap I_j$.

(i) Since $T \cap [-n_0, n_0] = \emptyset$ and the I_j are disjoint, the E_k are pairwise disjoint.

(ii) $E = T \bigsqcup (E \cap [-n_0, n_0]) = T \bigsqcup \bigsqcup_j (E \cap I_j) = \bigsqcup_{k=1}^{N} E_k$.

(iii) $m(T) < \delta$ and $m(E \cap I_j) \le m(I_j) < \delta$.

Structural Commentary: Finite measure gives a small tail T; a fine partition makes $E \setminus T$ small-piece.
Key Insight: One small tail plus a fine finite grid gives a finite small-piece decomposition. □

Proposition 4.4.2. *L^1 Absolute Continuity on Small Sets*
Let $E \in \mathcal{L}^1$, let $\mathcal{L}^1_E = \{A \in \mathcal{L}^1 : A \subseteq E\}$, let $m_E = m|_{\mathcal{L}^1_E}$, and let $f : E \to \mathbb{R}$ be measurable.
Consider the condition $(*)$: $\forall \varepsilon > 0 \; \exists \delta > 0$ such that $A \in \mathcal{L}^1_E$ and $m(A) < \delta$ imply $\int_A |f| \, dm < \varepsilon$.

(i) If $f \in L^1(m_E)$, then $(*)$ holds.
(ii) If $m(E) < +\infty$ and $(*)$ holds, then $f \in L^1(m_E)$.

Proof.

(i) Since $f \in L^1(m_E)$, Lemma 4.1.39 on $(E, \mathcal{L}^1_E, m_E)$ with $p = 1$ gives $\forall \varepsilon > 0 \; \exists \delta > 0$ such that $A \in \mathcal{L}^1_E$ and $m_E(A) < \delta$ imply $\int_A |f| \, dm_E < \varepsilon$. Since $m_E(A) = m(A)$ and $\int_A |f| \, dm_E = \int_A |f| \, dm$, $(*)$ holds.

(ii) Choose $\delta > 0$ from $(*)$ with $\varepsilon = 1$. By Lemma 4.4.1, write $E = \bigsqcup_{k=1}^{N} E_k$ with $E_k \in \mathcal{L}^1_E$ and $m(E_k) < \delta$. Then $(*)$ gives $\int_{E_k} |f| \, dm < 1$ for each k, hence $\int_E |f| \, dm = \sum_{k=1}^{N} \int_{E_k} |f| \, dm < N < +\infty$.

Structural Commentary: L^1 gives small-set control; finite partitions recover L^1.
Key Insight: A finite small-piece decomposition turns local integral bounds into one global finite integral. □

Definition 4.4.3. *Uniform Integrability and Tightness*
Let $\mathcal{F}$ be a family of measurable functions $h : X \to \mathbb{R}$ on $(X, \mathcal{M}, \mu)$.

(i) $\mathcal{F}$ is *uniformly integrable* on X if $\forall \varepsilon > 0 \, \exists \delta > 0$ such that $A \in \mathcal{M}$ and $\mu(A) < \delta$ imply $\sup_{h \in \mathcal{F}} \int_A |h| \, d\mu < \varepsilon$.

(ii) $\mathcal{F}$ is *tight* on X if $\forall \varepsilon > 0 \, \exists X_\varepsilon \in \mathcal{M}$ with $\mu(X_\varepsilon) < +\infty$ and $\sup_{h \in \mathcal{F}} \int_{X \setminus X_\varepsilon} |h| \, d\mu < \varepsilon$.

On finite measure spaces, tightness is automatic by taking $X_\varepsilon = X$.
Key Insight: UI controls mass on small A; tightness controls mass on $X \setminus X_\varepsilon$.

Example 4.4.4. *Concentration versus Escape*

(i) *Concentration*: on $(0, 1)$, $u_n := n \mathbf{1}_{(0, \frac{1}{n})}$. For every $\delta > 0$, choose $n > \delta^{-1}$ and $A_n = (0, \frac{1}{n})$.
Then $m(A_n) < \delta$ but $\int_{A_n} u_n \, dm = 1$, so (u_n) is not uniformly integrable.

(ii) *Escape*: on $\mathbb{R}$, let $I_n := (n, n+1)$ and $v_n := \mathbf{1}_{I_n}$. Since $\int_A v_n \, dm \le m(A)$, (v_n) is uniformly integrable.
If $m(E_0) < +\infty$ and $\sup_n \int_{\mathbb{R} \setminus E_0} v_n \, dm < \frac{1}{2}$, then $m(E_0 \cap I_n) > \frac{1}{2}$ for all n, contradiction.

Structural Commentary: Concentration occurs even on $m(X) < +\infty$; escape is an $m(X) = +\infty$ obstruction.
Key Insight: Uniform integrability controls small-set mass; tightness keeps mass in finite-measure cores.

Proposition 4.4.5. *Basic Sources of Uniform Integrability and Tightness*
Let $(X, \mathcal{M}, \mu)$ be a measure space.

(i) If $0 \le g \in L^1(\mu)$ and $\forall h \in \mathcal{F}$, $|h| \le g$ a.e., then $\mathcal{F}$ is uniformly integrable and tight.
(ii) If $f_1, \dots, f_N \in L^1(\mu)$, then $\{f_1, \dots, f_N\}$ is uniformly integrable and tight.

Proof. Let $\varepsilon > 0$.

(i) Choose $\delta > 0$ with $\mu(A) < \delta \Rightarrow \int_A g \, d\mu < \varepsilon$ by Lemma 4.1.39; hence $\sup_{h \in \mathcal{F}} \int_A |h| \, d\mu < \varepsilon$.
Choose finite-measure X_ε with $\int_{X \setminus X_\varepsilon} g \, d\mu < \varepsilon$ by Proposition 1.3.22; hence $\sup_{h \in \mathcal{F}} \int_{X \setminus X_\varepsilon} |h| \, d\mu < \varepsilon$.

(ii) For each j, apply (i) to $\{f_j\}$ with ε: choose $\delta_j > 0$ such that $\mu(A) < \delta_j \Rightarrow \int_A |f_j| \, d\mu < \varepsilon$, and choose $X_{\varepsilon,j}$ with $\mu(X_{\varepsilon,j}) < +\infty$ and $\int_{X \setminus X_{\varepsilon,j}} |f_j| \, d\mu < \varepsilon$. Set $\delta := \min_{1 \le j \le N} \delta_j$ and $X_\varepsilon := \bigcup_{j=1}^{N} X_{\varepsilon,j}$.
Then $\mu(A) < \delta \Rightarrow \sup_j \int_A |f_j| \, d\mu < \varepsilon$, while $\mu(X_\varepsilon) < +\infty$ and $\sup_j \int_{X \setminus X_\varepsilon} |f_j| \, d\mu < \varepsilon$.

Structural Commentary: An envelope gives common bounds; finite families use $\min_j \delta_j$ and $\bigcup_j X_{\varepsilon,j}$.

Key Insight: Domination gives uniform estimates; finite families allow minima and finite unions. □

Corollary 4.4.6. *L^p-Bounded Families Are Uniformly Integrable*
Let $1 < p < \infty$, q conjugate to p. If $\mathcal{F} \subseteq L^p(\mu)$ and $\forall h \in \mathcal{F}$, $\|h\|_p \le M$, then $\mathcal{F}$ is uniformly integrable.

Proof. If $M = 0$, every $h \in \mathcal{F}$ vanishes a.e. and the claim is immediate. Else, for measurable A with $\mu(A) < +\infty$,
by Hölder's inequality, $\int_A |h| \, d\mu = \int_X |h| \, \mathbf{1}_A \, d\mu \le \|h\|_p \, \|\mathbf{1}_A\|_q \le M \mu(A)^{\frac{1}{q}}$.
Given $\varepsilon > 0$, take $\delta = (\frac{\varepsilon}{M})^q$. Then $\mu(A) < \delta$ implies $\sup_{h \in \mathcal{F}} \int_A |h| \, d\mu < \varepsilon$.

Structural Commentary: Apply Hölder to $h\mathbf{1}_A$ and choose one measure threshold for the whole family.
Key Insight: Hölder converts a uniform L^p bound into uniform small-set L^1 control. □

Proposition 4.4.7. *Uniform Integrability by Large-Value Tails*
Let $(X, \mathcal{M}, \mu)$ be a finite measure space and let (f_n) be bounded in $L^1(\mu)$. The following are equivalent.

(i) (f_n) is uniformly integrable.
(ii) $\forall \varepsilon > 0 \ \exists M > 0 : \ \sup_n \int_{\{|f_n| \ge M\}} |f_n| \, d\mu < \varepsilon$.

Proof. Let $C = \sup_n \|f_n\|_1 < +\infty$.

($\Rightarrow$) Given $\varepsilon > 0$, choose $\delta > 0$ from uniform integrability and $M > C/\delta$.
By Chebyshev, $\mu(\{|f_n| \ge M\}) \le M^{-1} \|f_n\|_1 \le C/M < \delta$, so $\sup_n \int_{\{|f_n| \ge M\}} |f_n| \, d\mu < \varepsilon$.

($\Leftarrow$) Given $\varepsilon > 0$, choose $M > 0$ with $\sup_n \int_{\{|f_n| \ge M\}} |f_n| \, d\mu < \frac{\varepsilon}{2}$ and set $\delta := \frac{\varepsilon}{2M}$.
If $\mu(A) < \delta$, then $\int_A |f_n| \, d\mu \le \int_{\{|f_n| \ge M\}} |f_n| \, d\mu + M\mu(A) < \varepsilon$.

Structural Commentary: Chebyshev shrinks tails; truncation recovers UI.
Key Insight: UI iff large tails vanish uniformly. □

Theorem 4.4.8. *Vitali Convergence for L^1 Families*
Let $(X, \mathcal{M}, \mu)$ be a measure space, let $f_n \in L^1(\mu)$, let $f : X \to \mathbb{R}$ be measurable, and assume $f_n \to f$ a.e.

(i) If $\mu(X) < +\infty$ and $\{f_n : n \ge 1\}$ is uniformly integrable, then $f \in L^1(\mu)$ and $\|f_n - f\|_1 \to 0$.
(ii) If $\{f_n : n \ge 1\}$ is uniformly integrable and tight, then $f \in L^1(\mu)$ and $\|f_n - f\|_1 \to 0$.
(iii) Under either hypothesis, $\int_X f_n \, d\mu \to \int_X f \, d\mu$.

Proof.

(i) Since $\mu(X) < +\infty$ and $f_n \to f$ a.e., $f_n \to f$ in measure by Corollary 4.2.21. Uniform integrability is the small-set hypothesis of Theorem 4.2.26 with $p = 1$; the finite-tail hypothesis holds with $E_\varepsilon = X$, QED.

(ii) Fix $\alpha, \eta > 0$ and set $B_n^\alpha := \{|f_n - f| \ge \alpha\}$.
By tightness, choose $X_0 \in \mathcal{M}$ with $\mu(X_0) < +\infty$, $\sup_n \int_{X \setminus X_0} |f_n| \, d\mu < \frac{\alpha\eta}{4}$. By Fatou, $\int_{X \setminus X_0} |f| \, d\mu \le \frac{\alpha\eta}{4}$.
Then $\alpha\mu(B_n^\alpha \cap (X \setminus X_0)) \le \int_{X \setminus X_0} (|f_n| + |f|) \, d\mu < \frac{\alpha\eta}{2}$. Since $f_n \to f$ a.e. on finite X_0, $\mu(B_n^\alpha \cap X_0) < \frac{\eta}{2}$ eventually by Corollary 4.2.21. Thus $\mu(B_n^\alpha) < \eta$ eventually, so $f_n \to f$ in measure.
By Theorem 4.2.26 with $p = 1$, using uniform integrability and tightness, $f \in L^1(\mu)$ and $\|f_n - f\|_1 \to 0$.

(iii) In either case, $\left|\int_X f_n \, d\mu - \int_X f \, d\mu\right| = \left|\int_X (f_n - f) \, d\mu\right| \le \|f_n - f\|_1 \to 0$.

Structural Commentary: Tightness gives finite cores; UI upgrades in-measure convergence to L^1.
Key Insight: Uniform integrability prevents concentration; tightness prevents escape. □

Corollary 4.4.9. *Nonnegative Integral Vanishing Criterion*
Let $f_n \in L^1(\mu)$ with $f_n \ge 0$ a.e. The following are equivalent.

(i) $\int_X f_n \, d\mu \to 0$.
(ii) $\|f_n\|_1 \to 0$.
(iii) $f_n \to 0$ in measure, and $\{f_n : n \ge 1\}$ is uniformly integrable and tight.

Proof.

(i) $\Rightarrow$ (ii) Since $f_n \ge 0$, $\|f_n\|_1 = \int_X f_n \, d\mu \to 0$.

(ii) $\Rightarrow$ (iii) By Theorem 4.2.26 with $p = 1$ and limit 0, $\|f_n\|_1 \to 0$ implies $f_n \to 0$ in measure,
$\forall \varepsilon > 0 \ \exists E_\varepsilon \in \mathcal{M}$ with $\mu(E_\varepsilon) < +\infty$ and $F \cap E_\varepsilon = \emptyset \Rightarrow \sup_n \int_F f_n \, d\mu < \varepsilon$,
and $\forall \varepsilon > 0 \ \exists \delta > 0$ with $\mu(A) < \delta \Rightarrow \sup_n \int_A f_n \, d\mu < \varepsilon$; hence tightness and uniform integrability.

(iii) $\Rightarrow$ *(i)* Condition (iii) is hypotheses (ii)–(iv) of Theorem 4.2.26 with $p = 1$ and limit 0, so $\|f_n\|_1 \to 0$.
Since $f_n \geq 0$, $\int_X f_n \, d\mu = \|f_n\|_1 \to 0$.

Structural Commentary: For nonnegative functions, integral convergence to zero is L^1 convergence to zero.
Key Insight: Vitali's conditions characterize when nonnegative mass vanishes. □

Corollary 4.4.10. *Domination Gives Tail and Small-Set Control*
Let $1 \leq p < \infty$, $g \in L^p(\mu)$, and $\forall n$, $|f_n| \leq g$ a.e. Then $\forall \varepsilon > 0$:
(i) $\exists E_\varepsilon \in \mathcal{M}$ *with* $\mu(E_\varepsilon) < +\infty$ *such that* $F \cap E_\varepsilon = \emptyset \Rightarrow \sup_n \int_F |f_n|^p \, d\mu < \varepsilon^p$.
(ii) $\exists \delta(\varepsilon) > 0$ *such that* $\mu(E) < \delta(\varepsilon) \Rightarrow \sup_n \int_E |f_n|^p \, d\mu < \varepsilon^p$.

Proof.
(i) Choose E_ε with $\mu(E_\varepsilon) < +\infty$ and $F \cap E_\varepsilon = \emptyset \Rightarrow \int_F |g|^p \, d\mu < \varepsilon^p$ by Proposition 4.1.26.
Since $|f_n|^p \leq |g|^p$ a.e., $\sup_n \int_F |f_n|^p \, d\mu < \varepsilon^p$.
(ii) Choose $\delta(\varepsilon) > 0$ with $\mu(E) < \delta(\varepsilon) \Rightarrow \int_E |g|^p \, d\mu < \varepsilon^p$ by Lemma 4.1.39.
Since $|f_n|^p \leq |g|^p$ a.e., $\sup_n \int_E |f_n|^p \, d\mu < \varepsilon^p$.

Structural Commentary: One L^p envelope supplies both tail tightness and small-set control.
Key Insight: Domination transfers both estimates from g to every f_n. □

4.5 Approximation and Separability in L^p

Approximation results explain why L^p spaces are large enough to contain rough measurable functions but still small enough to be controlled by countable data when $p < \infty$. The guiding pattern is to localize the L^p mass, approximate measurable atoms by elementary sets, and then code the elementary sets with rational parameters.

Definition 4.5.1. *Dense Subsets and Separable Normed Spaces*
Let $A \subseteq B$ be subsets of a normed space $(V, \|\cdot\|)$.
(i) A is *dense in* B if $\forall b \in B \; \forall \varepsilon > 0 \; \exists a \in A$ with $\|a - b\| < \varepsilon$.
(ii) V is *separable* if it has a countable dense subset.
Equivalently, A is dense in B iff every $b \in B$ is the norm-limit of a sequence from A.

Example 4.5.2. *Sequence-Space Separability*
(i) $\ell^\infty(\mathbf{F})$ is not separable. The set $\{0,1\}^{\mathbb{N}}$ is uncountable, and $s \neq t$ gives $d_\infty(s,t) = 1$; the balls $B_{1/3}(s)$ are pairwise disjoint, so no countable dense set can meet all of them.
(ii) For $1 \leq p < \infty$, $\ell^p(\mathbf{F})$ is separable. Let D be the countable set of finite-support sequences with rational coordinates, using rational real and imaginary parts if $\mathbf{F} = \mathbb{C}$.
For $x \in \ell^p$ and $\varepsilon > 0$, choose N with $\sum_{n>N} |x_n|^p < (\varepsilon/2)^p$, then choose $y \in D$ with support in $\{1, \ldots, N\}$ and $\sum_{n=1}^N |x_n - y_n|^p < (\varepsilon/2)^p$. Thus $\|x - y\|_p < \varepsilon$.

Structural Commentary: Separability is the existence of a countable set meeting every nonempty open ball.
Key Insight: Finite rational data are dense in ℓ^p, while ℓ^∞ contains an uncountable 1-separated set.

Theorem 4.5.3. *Separability and C_c Density in L^p*
Let $E \subseteq \mathbb{R}$ be Lebesgue measurable and let $1 \leq p < \infty$.
If $C_c(E)$ denotes restrictions to E of continuous functions on $\mathbb{R}$ with bounded support, then:
(i) $L^p(E)$ is separable;
(ii) $C_c(E)$ is dense in $L^p(E)$.

Proof.
(i) Let $\mathbb{F}_0 := \mathbb{Q}$ if real, $\mathbb{F}_0 := \mathbb{Q} + i\mathbb{Q}$ if complex. Let $\mathcal{D} := \operatorname{span}_{\mathbb{F}_0}\{\mathbf{1}_{E \cap (r,s)} : r, s \in \mathbb{Q}, \; r < s\}$.
Then $\mathcal{D}$ is countable. Extend $f \in L^p(E)$ by 0 to $\tilde{f} \in L^p(\mathbb{R})$.
By Proposition 4.1.26, it suffices to approximate $s = \sum_{\ell=1}^M a_\ell \mathbf{1}_{A_\ell}$ with $m(A_\ell) < +\infty$.
For each ℓ, Corollary 6.2.4 and rational endpoint perturbation give a finite union V_ℓ of rational open intervals with $m(A_\ell \triangle V_\ell)$ small, hence $\|\mathbf{1}_{E \cap A_\ell} - \mathbf{1}_{E \cap V_\ell}\|_p \leq m(A_\ell \triangle V_\ell)^{1/p}$. Approximate a_ℓ by $q_\ell \in \mathbb{F}_0$; then $\sum_{\ell=1}^M q_\ell \mathbf{1}_{E \cap V_\ell} \in \mathcal{D}$ approximates f arbitrarily well. Hence $L^p(E)$ is separable.
(ii) For rational $r < s$ and $0 < \eta < \frac{s-r}{2}$, choose $\psi_\eta \in C_c(\mathbb{R})$ with $0 \leq \psi_\eta \leq 1$, $\psi_\eta = 1$ on $[r + \eta, s - \eta]$, and $\psi_\eta = 0$ on $\mathbb{R} \setminus (r, s)$. Then $\|\psi_\eta|_E - \mathbf{1}_{E \cap (r,s)}\|_p^p \leq m((r, r+\eta) \cup (s - \eta, s)) \leq 2\eta \to 0$.
Thus each generator of $\mathcal{D}$ lies in $\overline{C_c(E)}^{L^p(E)}$; by finite linearity and (i), $C_c(E)$ is dense in $L^p(E)$.

Structural Commentary: Finite-measure atoms reduce to rational intervals, then to continuous cutoffs.
Key Insight: Countable rational steps lie in $\overline{C_c(E)}^{L^p(E)}$. □

Remark 4.5.4. *L^1 Does Not Exhaust the Dual of L^∞*
Let $I = [a,b]$ with $a < b$, and let $\iota : L^1(I) \to (L^\infty(I))^*$ be $\iota(g)(f) := \int_I fg \, dm$. The map ι from Proposition 4.1.37 is not onto. If ι were onto, then $(L^\infty(I))^*$ would be separable by Theorem 4.5.3.
Let (Φ_n) be dense in its unit sphere and choose $u_n \in L^\infty(I)$ with $\|u_n\|_\infty = 1$ and $|\Phi_n(u_n)| > \frac{1}{2}$.
If $Y := \overline{\operatorname{span}}\{u_n : n \geq 1\} \neq L^\infty(I)$, Hahn–Banach gives $\Phi \in (L^\infty(I))^*$ with $\|\Phi\| = 1$ and $\Phi|_Y = 0$.
Choosing n with $\|\Phi - \Phi_n\| < \frac{1}{4}$ gives $|\Phi_n(u_n)| < \frac{1}{4}$, a contradiction. Hence $L^\infty(I)$ would be separable.
But $v_t := \mathbf{1}_{[a,t]}$ satisfies $\|v_t - v_s\|_\infty = 1$ for $s < t$, an uncountable separated family, so $L^\infty(I)$ is not separable.

Example 4.5.5. *L^∞ on an Interval Need Not Be Separable*
Let $I = [a, b]$ with $a < b$. For $t \in I$, set $u_t := \mathbf{1}_{[a,t]}$. If $s < t$, then $\|u_t - u_s\|_\infty = 1$, since $u_t - u_s = \mathbf{1}_{(s,t]}$ a.e.
Thus $\{B(u_t, \frac{1}{3}) : t \in I\}$ is pairwise disjoint. If countable $D \subseteq L^\infty(I)$ were dense, choose $d_t \in D \cap B(u_t, \frac{1}{3})$ for each $t \in I$; disjointness makes $t \mapsto d_t$ injective, impossible. Hence $L^\infty(I)$ is not separable.
Key Insight: Uncountably many distance-1 indicators preclude countable density.

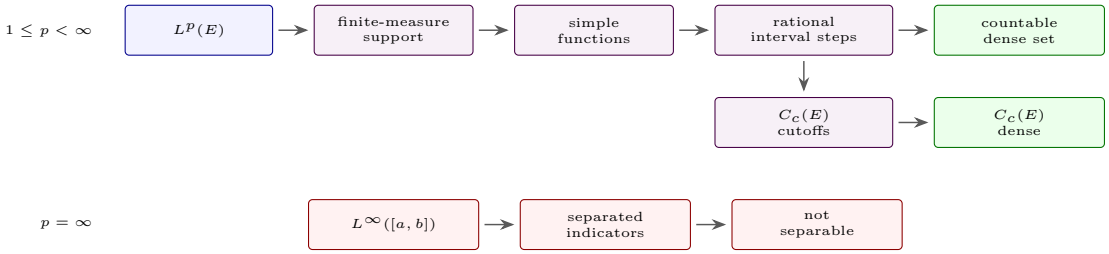

Figure 217: For $1 \le p < \infty$, rational interval steps and $C_c(E)$ are dense in $L^p(E)$; $L^\infty([a, b])$ is nonseparable.

4.6 Weak Convergence in L^p

Weak convergence in L^p keeps only the scalar information detected by conjugate functions. For $1 < p < +\infty$, reflexivity turns boundedness into weak subsequential compactness; at $p = 1$, bounded mass can still concentrate and destroy weak compactness unless uniform integrability is imposed.

Theorem 4.6.1. *L^p Weak Convergence by Dual Tests*
Let $(X, \mathcal{M}, \mu)$ be a measure space, $1 < p < +\infty$, $q = \frac{p}{p-1}$, $(f_n) \subseteq L^p(\mu)$, and $f \in L^p(\mu)$, all real-valued.
Then $f_n \rightharpoonup f$ in $L^p(\mu)$ iff $\int_X f_n g \, d\mu \to \int_X fg \, d\mu$ for all $g \in L^q(\mu)$.

Proof.
($\Rightarrow$) For $g \in L^q(\mu)$, $\Lambda_g(h) := \int_X hg \, d\mu$ is in $(L^p(\mu))^*$ by Holder.
Hence $f_n \rightharpoonup f$ implies $\int_X f_n g \, d\mu = \Lambda_g(f_n) \to \Lambda_g(f) = \int_X fg \, d\mu$.
($\Leftarrow$) Let $\Lambda \in (L^p(\mu))^*$. By Theorem 4.1.34, choose $g \in L^q(\mu)$ with $\Lambda(h) = \int_X hg \, d\mu \ \forall h \in L^p(\mu)$.
The assumed integral test yields $\Lambda(f_n) \to \Lambda(f)$, hence $f_n \rightharpoonup f$.

Structural Commentary: Dual tests are exactly L^q pairings.
Key Insight: Weak convergence in L^p is conjugate-function testing. □

Proposition 4.6.2. *Weak Limits and Norm Lower Semicontinuity*
Let $(X, \mathcal{M}, \mu)$ be a measure space, $1 < p < +\infty$, $(f_n) \subseteq L^p(\mu)$, and $f_n \rightharpoonup f$ in real $L^p(\mu)$. Then:
(i) $\sup_n \|f_n\|_p < +\infty$;
(ii) if $f_n \rightharpoonup h$ in $L^p(\mu)$, then $h = f$ in $L^p(\mu)$;
(iii) $\|f\|_p \le \liminf_{n\to\infty} \|f_n\|_p$.

Proof.
(i) By Proposition 6.1.4 applied to $u_n = f_n$ in $L^p(\mu)$, $f_n \rightharpoonup f$ implies $\sup_n \|f_n\|_p < +\infty$.
(ii) Let $q = \frac{p}{p-1}$, $f_n \rightharpoonup h$. For $g \in L^q(\mu)$, by Theorem 4.6.1, $\int_X (f - h)g \, d\mu = \lim_n \int_X f_n g \, d\mu - \lim_n \int_X f_n g \, d\mu = 0$.
By Proposition 4.1.30, $\|f - h\|_p = 0$, so $h = f$ in $L^p(\mu)$.
(iii) By Proposition 6.1.4, $u \mapsto \|u\|_p$ is weakly lower semicontinuous on $L^p(\mu)$;
with $u_n = f_n$ and $u = f$, $\|f\|_p \le \liminf_{n\to\infty} \|f_n\|_p$.

Structural Commentary: General weak facts handle bounds; L^q tests force uniqueness.
Key Insight: Weak limits are norm-controlled and conjugate-tested. □

Theorem 4.6.3. *Reflexivity of L^p, $1 < p < +\infty$*
Let $(X, \mathcal{M}, \mu)$ be σ-finite, $1 < p < +\infty$, $q = \frac{p}{p-1}$, and $Jf(\Phi) := \Phi(f)$.
For $r \in \{p, q\}$ with conjugate r', set $T_r u \in (L^{r'}(\mu))^*$ by $(T_r u)(v) := \int_X uv \, d\mu$. Then:
(i) T_p and T_q are isometric isomorphisms;
(ii) $J : L^p(\mu) \to (L^p(\mu))^{**}$ is onto; hence real $L^p(\mu)$ is reflexive.

Proof.
(i) By Theorem 4.1.34, $T_p : L^p(\mu) \to (L^q(\mu))^*$ and $T_q : L^q(\mu) \to (L^p(\mu))^*$ are isometric isomorphisms.
(ii) Let $S \in (L^p(\mu))^{**}$. Since $S \circ T_q \in (L^q(\mu))^*$, by (i), $f \in L^p(\mu)$, $S(T_q g) = (T_p f)(g) = \int_X fg \, d\mu \ \forall g \in L^q(\mu)$.
For $\Phi \in (L^p(\mu))^*$, by (i) $\Phi = T_q g$; $S(\Phi) = S(T_q g) = \int_X fg \, d\mu = \Phi(f) = Jf(\Phi)$. Hence $S = Jf$, J is onto.

Structural Commentary: Represent both dual layers by conjugate pairings.
Key Insight: Every bidual functional is evaluation at an L^p function. □

Definition 4.6.4. *Weak Sequential Compactness*
Let $\mathcal{X}$ be a normed space and $K \subseteq \mathcal{X}$.
Then K is *weakly sequentially compact* if every $(x_n) \subseteq K$ admits $n_k \uparrow \infty$ and $x \in K$ with $x_{n_k} \rightharpoonup x$ in $\mathcal{X}$.

Theorem 4.6.5. *Riesz Weak Compactness Theorem*
Let $(X, \mathcal{M}, \mu)$ be σ-finite, $1 < p < +\infty$, $q = \frac{p}{p-1}$, and $(f_n) \subseteq L^p(\mu)$ be real-valued with $M := \sup_n \|f_n\|_p < +\infty$.
Then there exist $n_k \uparrow \infty$ and $f \in L^p(\mu)$ such that:
(i) $f_{n_k} \rightharpoonup f$ in $L^p(\mu)$;
(ii) $\int_X f_{n_k} g \, d\mu \to \int_X fg \, d\mu$ for all $g \in L^q(\mu)$.

Proof. Set $B_M := \{h \in L^p(\mu) : \|h\|_p \le M\}$. By Theorem 4.6.3, $L^p(\mu)$ is reflexive; hence B_M is weakly compact. By Eberlein–Smulian, B_M is weakly sequentially compact.
(i) Since $(f_n) \subseteq B_M$ and B_M is weakly sequentially compact, $\exists n_k \uparrow \infty$ and $f \in B_M$ with $f_{n_k} \rightharpoonup f$ in $L^p(\mu)$.
(ii) From (i) and Theorem 4.6.1, $\forall g \in L^q(\mu)$, $\int_X f_{n_k} g \, d\mu \to \int_X fg \, d\mu$.
Structural Commentary: Reflexive bounded balls are weakly sequentially compact.
Key Insight: Bounded L^p sequences have conjugate-test convergent subsequences. □

Corollary 4.6.6. *The L^p Unit Ball Is Weakly Sequentially Compact*
Let $(X, \mathcal{M}, \mu)$ be σ-finite, $1 < p < +\infty$, and $B_p := \{f \in L^p(\mu) : \|f\|_p \le 1\}$.
Then B_p is weakly sequentially compact in $L^p(\mu)$.

Proof. Let $(f_n) \subseteq B_p$. By Theorem 4.6.5, $\exists n_k \uparrow \infty$ and $f \in L^p(\mu)$ with $f_{n_k} \rightharpoonup f$.
By Proposition 4.6.2, $\|f\|_p \le \liminf_{k\to\infty} \|f_{n_k}\|_p \le 1$, so $f \in B_p$.
Structural Commentary: Weak limits stay in B_p by lower semicontinuity.
Key Insight: Closed norm balls are weakly sequentially closed. □

Theorem 4.6.7. *Radon–Riesz Principle*
Let $(X, \mathcal{M}, \mu)$ be a measure space, $1 < p < +\infty$, $(f_n) \subseteq L^p(\mu)$, and $f \in L^p(\mu)$, all real-valued.
Then $f_n \rightharpoonup f$ and $\|f_n\|_p \to \|f\|_p$ iff $\|f_n - f\|_p \to 0$.

Proof.
($\Rightarrow$) If $\|f\|_p = 0$, then $\|f_n - f\|_p \le \|f_n\|_p + \|f\|_p \to 0$. Let $a := \|f\|_p > 0$.
Otherwise, after subsequences, $\|f_n - f\|_p \ge \varepsilon > 0$ and, with $a_n := \|f_n\|_p$, $u_n := \frac{f_n}{a_n}$, $u := \frac{f}{a}$, one has $u_n \rightharpoonup u$, $\|u_n\|_p = \|u\|_p = 1$, and $\|u_n - u\|_p \ge \eta > 0$. By uniform convexity, $\left\|\frac{u_n+u}{2}\right\|_p \le 1 - \delta$.
Since $\frac{u_n+u}{2} \rightharpoonup u$, weak lower semicontinuity implies $1 = \|u\|_p \le \liminf_n \left\|\frac{u_n+u}{2}\right\|_p \le 1 - \delta$, contradiction.
($\Leftarrow$) Assume $\|f_n - f\|_p \to 0$. Then $\left|\|f_n\|_p - \|f\|_p\right| \le \|f_n - f\|_p \to 0$.
For $\Lambda \in (L^p(\mu))^*$, $|\Lambda(f_n) - \Lambda(f)| \le \|\Lambda\| \, \|f_n - f\|_p \to 0$, hence $f_n \rightharpoonup f$.
Structural Commentary: Uniform convexity turns weak lower semicontinuity into strong convergence.
Key Insight: Weak direction plus norm size fixes the vector. □

Remark 4.6.8. *L^2 Proof of Radon–Riesz*
For $p = 2$, $f_n \rightharpoonup f$ in $L^2(\mu)$, $\|f_n\|_2 \to \|f\|_2$. Then $\int_X f_n f \, d\mu \to \|f\|_2^2$,
$\|f_n - f\|_2^2 = \|f_n\|_2^2 - 2\int_X f_n f \, d\mu + \|f\|_2^2 \to 0$. The converse follows from norm convergence in $L^2(\mu)$.
Key Insight: Weak convergence fixes the cross term.

Corollary 4.6.9. *Strong Subsequence Criterion*
Let $(X, \mathcal{M}, \mu)$ be a measure space, $1 < p < +\infty$, $(f_n) \subseteq L^p(\mu)$, and $f_n \rightharpoonup f$ in real $L^p(\mu)$.
Then $\exists n_k \uparrow \infty$ with $\|f_{n_k} - f\|_p \to 0$ iff $\|f\|_p = \liminf_{n\to\infty} \|f_n\|_p$.

Proof. Set $L := \liminf_{n\to\infty} \|f_n\|_p$.
($\Rightarrow$) If $\|f_{n_k} - f\|_p \to 0$, then $\|f_{n_k}\|_p \to \|f\|_p$.
Since $L \le \lim_k \|f_{n_k}\|_p = \|f\|_p$ and, by Proposition 4.6.2, $\|f\|_p \le L$, one has $L = \|f\|_p$.
($\Leftarrow$) Assume $L = \|f\|_p$. Choose $n_k \uparrow \infty$ with $\|f_{n_k}\|_p \to L$.
Since $f_{n_k} \rightharpoonup f$ and $\|f_{n_k}\|_p \to \|f\|_p$, Theorem 4.6.7 implies $\|f_{n_k} - f\|_p \to 0$.
Structural Commentary: Match the liminf subsequence to Radon–Riesz.
Key Insight: Strong subsequences occur exactly when no norm is lost. □

Theorem 4.6.10. *Dunford–Pettis Criterion in L^1*
Let $(X, \mathcal{M}, \mu)$ be a finite measure space and let (f_n) be bounded in $L^1(\mu)$. The following are equivalent.
(i) (f_n) is uniformly integrable.
(ii) $\forall (f_{n_k}) \subseteq (f_n)$ $\exists (f_{n_{k_j}}) \subseteq (f_{n_k})$ converging weakly in $L^1(\mu)$.

Proof.
($\Rightarrow$) Let (u_j) be a subsequence of (f_n), set $C := \sup_j \|u_j\|_1$, and put $T_m(t) := (-m) \vee (t \wedge m)$.
By Proposition 4.4.7, $\sup_j \|u_j - T_m(u_j)\|_1 \to 0$. For fixed m and sign $\pm$, $\left\|T_m(u_j^{\pm})\right\|_2^2 \le m \left\|u_j^{\pm}\right\|_1 \le mC$.
By bounded Hilbert weak subsequence extraction and diagonalization over $(m, \pm)$, pass to a subsequence, still (u_j), such that $\int_E T_m(u_j^{\pm}) \, d\mu$ converges for every $E \in \mathcal{M}$ and $m \in \mathbb{N}$. Set $\nu_j^{\pm}(E) := \int_E u_j^{\pm} \, d\mu$.
For r, s, m and $E \in \mathcal{M}$, $\left|\nu_r^{\pm}(E) - \nu_s^{\pm}(E)\right| \le \left|\int_E (T_m(u_r^{\pm}) - T_m(u_s^{\pm})) \, d\mu\right| + 2\sup_j \left\|u_j^{\pm} - T_m(u_j^{\pm})\right\|_1$.
Hence $(\nu_j^{\pm}(E))_j$ is Cauchy. Put $\nu^{\pm}(E) := \lim_j \nu_j^{\pm}(E)$.
By Theorem 3.6.11, $\nu^{\pm}$ are finite measures and $\nu^{\pm} \ll \mu$. Write $h^{\pm} = \frac{d\nu^{\pm}}{d\mu}$ and $h := h^+ - h^- \in L^1(\mu)$.
Then $\int_X \varphi u_j \, d\mu \to \int_X \varphi h \, d\mu$ for simple φ; by Lemma 1.1.14 and $\sup_j \|u_j\|_1 + \|h\|_1 < +\infty$, the convergence holds for every $\varphi \in L^\infty(\mu)$. Thus $u_j \rightharpoonup h$ in $L^1(\mu)$.

($\Leftarrow$) Suppose (f_n) is not uniformly integrable. Since finite subfamilies are uniformly integrable by Proposition 4.4.5(ii), choose a subsequence (u_j) and sets $A_j \in \mathcal{M}$ with $\mu(A_j) \to 0$ and $\int_{A_j} |u_j|\, d\mu \geq \varepsilon_0 > 0$.

By (ii), some (u_{j_ℓ}) converges weakly in $L^1(\mu)$ to u. Set $\eta_\ell(E) := \int_E u_{j_\ell}\, d\mu$ and $\eta(E) := \int_E u\, d\mu$.
Then $\eta_\ell(E) \to \eta(E)$ for every $E \in \mathcal{M}$, and $\sup_\ell |\eta_\ell|(X) = \sup_\ell \|u_{j_\ell}\|_1 < +\infty$ by Theorem 3.1.9.
The signed form of Theorem 3.6.11 implies $\eta_\ell \ll_u \mu$ in variation:
$\forall \varepsilon > 0\ \exists \delta > 0$ such that $\mu(A) < \delta \Rightarrow \sup_\ell |\eta_\ell|(A) < \varepsilon$. Since $|\eta_\ell|(A) = \int_A |u_{j_\ell}|\, d\mu$, the subsequence (u_{j_ℓ}) is uniformly integrable, contradicting $\int_{A_{j_\ell}} |u_{j_\ell}|\, d\mu \geq \varepsilon_0$ and $\mu(A_{j_\ell}) \to 0$.

Structural Commentary: Truncate, pass to setwise limits, apply VHS.
Key Insight: UI is weak sequential compactness in finite L^1. □

Corollary 4.6.11. *Dominated L^1 Families Have Weak Subsequences*
Let $(X, \mathcal{M}, \mu)$ be finite. If $g \in L^1(\mu)$, $\forall n\, |f_n| \leq g$ a.e., then (f_n) has subsequence that converges weakly in $L^1(\mu)$.

Proof. Since $|f_n| \leq g$ a.e., $\|f_n\|_1 \leq \|g\|_1\ \forall n$, (f_n) is bounded in $L^1(\mu)$. By Proposition 4.4.5(i), $\{f_n : n \geq 1\}$ is uniformly integrable. Theorem 4.6.10, $(i) \Rightarrow (ii)$, yields a weakly convergent subsequence.
Structural Commentary: Domination verifies Dunford–Pettis through a common integrable envelope.
Key Insight: One L^1 envelope prevents concentration throughout the sequence. □

Corollary 4.6.12. *Bounded L^p Families Are Weakly Compact in L^1*
Let $(X, \mathcal{M}, \mu)$ be finite, let $1 < p < +\infty$, and let (f_n) be bounded in $L^p(\mu)$.
Then (f_n) has a subsequence that converges weakly in $L^1(\mu)$.

Proof. Let q be conjugate to p and $M := \sup_n \|f_n\|_p < +\infty$. By Hölder, $\|f_n\|_1 \leq M\mu(X)^{\frac{1}{q}}\ \forall n$, so (f_n) is bounded in $L^1(\mu)$. By Corollary 4.4.6, $\{f_n : n \geq 1\}$ is uniformly integrable.
Hence Theorem 4.6.10, $(i) \Rightarrow (ii)$, yields a weakly convergent subsequence in $L^1(\mu)$.
Structural Commentary: Hölder gives L^1 boundedness, uniform integrability before Dunford–Pettis is applied.
Key Insight: On finite measure spaces, an L^p bound with $p > 1$ rules out L^1 concentration. □

Example 4.6.13. *A Bounded L^1 Sequence with No Weakly Convergent Subsequence*
In $L^1[0,1]$, $I_n = [0, \frac{1}{n}]$ $f_n = n\mathbf{1}_{I_n}$. Then $\|f_n\|_1 = 1\ \forall n$, and no subsequence of (f_n) converges weakly in $L^1[0,1]$.

Proof. Assume $f_{n_k} \rightharpoonup f$ in $L^1[0,1]$. For $0 < c < d \leq 1$, $\mathbf{1}_{[c,d]} \in L^\infty[0,1]$ and $[c,d] \cap I_{n_k} = \varnothing$ for k large.
Hence $\int_c^d f\, dm = \lim_{k\to\infty} \int_c^d f_{n_k}\, dm = 0$. Thus $f = 0$ a.e. on $(0,1]$.
Testing by $\mathbf{1}_{[0,1]}$ yields $0 = \int_0^1 f\, dm = \lim_{k\to\infty} \int_0^1 f_{n_k}\, dm = 1$, contradiction.
Key Insight: Unit mass concentrates on shrinking supports. □

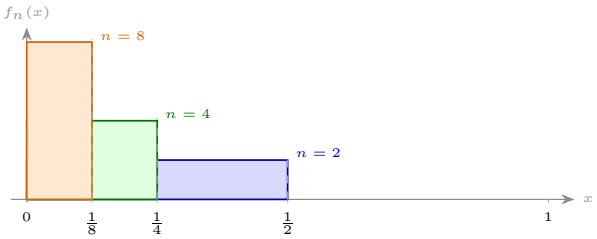

Figure 218: $f_n = n\mathbf{1}_{[0,\frac{1}{n}]}$: unit L^1 mass on shrinking support.

Remark 4.6.14. *Endpoint Failure and Uniform Integrability*
For $f_n = n\mathbf{1}_{[0,\frac{1}{n}]} \in L^1[0,1]$, $\|f_n\|_1 = 1$ but $\int_{\{f_n > R\}} f_n\, dm = 1$ whenever $n > R$.
Hence (f_n) is not uniformly integrable; the $p = 1$ failure is concentration, not lack of boundedness.

Theorem 4.6.15. *Banach–Saks Theorem*
Let $(X, \mathcal{M}, \mu)$ be a measure space, $1 < p < +\infty$, $(f_n) \subseteq L^p(\mu)$, and $f_n \rightharpoonup f$ in real $L^p(\mu)$.
Then $\exists n_k \uparrow \infty$ such that, with $A_k := \frac{1}{k}\sum_{j=1}^k f_{n_j}$, $\|A_k - f\|_p \to 0$.

Proof. Set $h_n := f_n - f$. Then $h_n \rightharpoonup 0$ and $\sup_n \|h_n\|_p < +\infty$ by Proposition 4.6.2.
Since real $L^p(\mu)$ is uniformly convex, by the selection lemma there is $n_k \uparrow \infty$ with $\left\|\frac{1}{k}\sum_{j=1}^k h_{n_j}\right\|_p \to 0$.
Since $\frac{1}{k}\sum_{j=1}^k h_{n_j} = A_k - f$, $\|A_k - f\|_p \to 0$.
Structural Commentary: Reduce to weakly null; select Cesaro means by uniform convexity.
Key Insight: Convex averaging turns weak nullity into norm decay. □

Remark 4.6.16. *The L^2 Selection Estimate*
For $p = 2$, replace f_n by $f_n - f$ and assume $f_n \rightharpoonup 0$ in $L^2(\mu)$ with $\|f_n\|_2^2 \leq M$. Set $n_1 = 1$ and $S_k := \sum_{j=1}^k f_{n_j}$.

(i) Given S_k, choose $n_{k+1} > n_k$ so that $\left|\int_X S_k f_{n_{k+1}}\, d\mu\right| \leq 1$.
(ii) Then $\|S_{k+1}\|_2^2 = \|S_k\|_2^2 + 2\int_X S_k f_{n_{k+1}}\, d\mu + \|f_{n_{k+1}}\|_2^2 \leq \|S_k\|_2^2 + 2 + M$.
(iii) Hence $\|S_k/k\|_2^2 \leq \frac{2+M}{k}$ by induction.

Thus $S_k/k \to 0$ in $L^2(\mu)$.
Key Insight: Weak convergence makes new terms nearly orthogonal to old sums.

Definition 4.6.17. *Closed Convex Sets and Convex Functionals*
Let C be a subset of a normed space $\mathcal{X}$.

(i) C is *convex* if $\lambda f + (1-\lambda)g \in C$ whenever $f, g \in C$ and $0 \le \lambda \le 1$.
(ii) C is *closed* if every strongly convergent sequence in C has its limit in C.
(iii) A real-valued functional $T : C \to \mathbb{R}$ is *continuous* if $f_n \to f$ strongly in C implies $T(f_n) \to T(f)$.
(iv) If C is convex, then T is *convex* if $T(\lambda f + (1-\lambda)g) \le \lambda T(f) + (1-\lambda)T(g)$ $\forall f, g \in C$ and $0 \le \lambda \le 1$.

Example 4.6.18. *Basic Closed Convex Sets in L^p*
Let $E \subseteq \mathbb{R}$ be measurable and $1 \le p < +\infty$.

(i) If $g \in L^p(E)$ and $g \ge 0$ a.e., then $C_g := \{f \in L^p(E) : |f| \le g \text{ a.e.}\}$ is closed and convex.
(ii) $B := \{f \in L^p(E) : \|f\|_p \le 1\}$ is closed and convex.

Proof.

(i) If $f, h \in C_g$ and $0 \le \lambda \le 1$, then $|\lambda f + (1-\lambda)h| \le \lambda |f| + (1-\lambda)|h| \le g$ a.e., so C_g is convex.
If $f_n \in C_g$ and $f_n \to f$ in $L^p(E)$, choose $f_{n_k} \to f$ a.e. by Theorem 4.1.23; then $|f| \le g$ a.e., so $f \in C_g$.
(ii) If $f, h \in B$ and $0 \le \lambda \le 1$, then by Minkowski, $\|\lambda f + (1-\lambda)h\|_p \le \lambda \|f\|_p + (1-\lambda)\|h\|_p \le 1$.
If $f_n \in B$ and $f_n \to f$ in $L^p(E)$, then $\|f\|_p \le \|f - f_n\|_p + \|f_n\|_p \le \|f - f_n\|_p + 1$, hence $\|f\|_p \le 1$.

Key Insight: Norm limits preserve a.e. bounds and norm bounds. □

Lemma 4.6.19. *Weak Limits and Convex Lower Semicontinuity*
Let $E \subseteq \mathbb{R}$ be measurable, $1 < p < +\infty$, $C \subseteq L^p(E)$ closed, bounded, and convex.
Let $T : C \to \mathbb{R}$ be continuous and convex. If $(f_n) \subseteq C$ and $f_n \rightharpoonup f$ in $L^p(E)$, then, with $\alpha := \liminf_{n\to\infty} T(f_n)$:

(i) $f \in C$;
(ii) $T(f) \le \alpha$.

Proof.

(i) By Theorem 4.6.15, choose $n_k \uparrow \infty$ with $a_k := \frac{1}{k}\sum_{j=1}^{k} f_{n_j} \to f$ in $L^p(E)$.
Since $a_k \in \operatorname{co}\{f_{n_1}, \dots, f_{n_k}\} \subseteq C$ and C is closed, $f \in C$.
(ii) Choose $m_k \uparrow \infty$ with $T(f_{m_k}) \to \alpha$.

By Theorem 4.6.15, choose $g_j := f_{m_{k_j}}$ such that $b_k := \frac{1}{k}\sum_{j=1}^{k} g_j \to f$ in $L^p(E)$.

Then $b_k \in C$ and $T(g_j) \to \alpha$; by continuity and convexity, $T(f) = \lim_k T(b_k) \le \lim_k \frac{1}{k}\sum_{j=1}^{k} T(g_j) = \alpha$.

Structural Commentary: Banach–Saks supplies strong convex averages; convexity transfers the liminf.
Key Insight: Weak limits inherit closed convex constraints and convex lsc. □

Theorem 4.6.20. *Direct Method for Convex Functionals on L^p*
Let $E \subseteq \mathbb{R}$ be measurable, $1 < p < +\infty$, $C \subseteq L^p(E)$ nonempty, closed, bounded, and convex.
Let $T : C \to \mathbb{R}$ be continuous and convex. Then $\exists f_0 \in C$ such that $T(f_0) = \inf_{h\in C} T(h)$.

Proof.

(i) If $\inf_C T = -\infty$, choose $f_n \in C$ with $T(f_n) \to -\infty$.
Since C is bounded, by Theorem 4.6.5, $\exists n_k \uparrow \infty$ and $f \in L^p(E)$ with $f_{n_k} \rightharpoonup f$.
By Lemma 4.6.19, $f \in C$ and $T(f) \le \liminf_k T(f_{n_k}) = -\infty$, contradicting $T : C \to \mathbb{R}$. Thus $\inf_C T > -\infty$.
(ii) Let $c := \inf_C T$ and choose $f_n \in C$ with $T(f_n) \to c$.
Since C is bounded, by Theorem 4.6.5, $\exists n_k \uparrow \infty$ and $f_0 \in L^p(E)$ with $f_{n_k} \rightharpoonup f_0$.
By Lemma 4.6.19, $f_0 \in C$ and $T(f_0) \le \liminf_k T(f_{n_k}) = c$. Since $c \le T(f_0)$, $T(f_0) = c$.

Structural Commentary: Weak compactness supplies a limit; convex lsc keeps the infimum.
Key Insight: Direct method equals compactness plus lower semicontinuity. □

Corollary 4.6.21. *Integral Convex Functionals Have Unit-Ball Minimizers*
Let $\mu(E) < +\infty$, $1 < p < +\infty$, and $\varphi : \mathbb{R} \to \mathbb{R}$ be continuous convex with $|\varphi(s)| \le c_1 + c_2|s|^p$ for some $c_1, c_2 \ge 0$. Set $B := \{f \in L^p(E) : \|f\|_p \le 1\}$ and $T(f) := \int_E \varphi(f)\,dm$. Then:

(i) $T : B \to \mathbb{R}$ is continuous and convex;
(ii) $\exists f_0 \in B$ such that $T(f_0) = \min_{f\in B} T(f)$.

Proof.

(i) For $f \in B$, $|\varphi(f)| \le c_1 + c_2|f|^p \in L^1(E)$, so $T(f) \in \mathbb{R}$.
Convexity of φ implies $T(\lambda f + (1-\lambda)h) \le \lambda T(f) + (1-\lambda)T(h)$ for $f, h \in B$, $0 \le \lambda \le 1$.
If $f_n \to f$ in $L^p(E)$, every subsequence admits $f_{n_k} \to f$ a.e. with $|f_{n_k}| \le g$ for some $g \in L^p(E)$.
Then $|\varphi(f_{n_k})| \le c_1 + c_2 g^p \in L^1(E)$, so by dominated convergence $T(f_{n_k}) \to T(f)$.
By the subsequence criterion, $T(f_n) \to T(f)$.
(ii) The set B is nonempty, bounded, convex by Minkowski, and closed since $f_n \in B$, $f_n \to f$ in $L^p(E)$ imply $\|f\|_p \le \liminf_n \|f_n\|_p \le 1$.
By Theorem 4.6.20, $\exists f_0 \in B$ with $T(f_0) = \min_{f\in B} T(f)$.

Structural Commentary: p-growth ⇒ continuity; direct method ⇒ attainment.
Key Insight: Growth converts strong L^p convergence to dominated convergence. □

5 Banach and Hilbert Spaces

5.1 Normed and Banach Spaces

Normed spaces make vector spaces metric; Banach spaces add completeness. This is the setting for infinite series, fixed points, bounded linear maps, and operator norms.

Definition 5.1.1. *Normed and Banach Spaces*
Let $\mathcal{X}$ be a vector space over $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$.

(i) *Norm*: $\|\cdot\| : \mathcal{X} \to [0,\infty)$; $\|x\| = 0 \iff x = 0$, $\|\lambda x\| = |\lambda| \, \|x\|$; $\|x + y\| \le \|x\| + \|y\|$ for $x, y \in \mathcal{X}$, $\lambda \in \mathbb{F}$.
(ii) *Normed space*: $(\mathcal{X}, \|\cdot\|)$ carries the metric $d(x, y) := \|x - y\|$.
(iii) *Banach space*: $(\mathcal{X}, \|\cdot\|)$ is complete in the norm metric.

Definition 5.1.2. *Basic Normed-Space Geometry*
Let $\mathcal{X}$ be a normed space.

(i) *Open unit ball*: $B_{\mathcal{X}} := \{x \in \mathcal{X} : \|x\| < 1\}$.
(ii) *Closed unit ball*: $\overline{B}_{\mathcal{X}} := \{x \in \mathcal{X} : \|x\| \le 1\}$.
(iii) *Unit vector*: $x \in \mathcal{X}$ satisfies $\|x\| = 1$.
(iv) *Minkowski sum*: $A + B := \{a + b : a \in A,\ b \in B\}$ for nonempty $A, B \subseteq \mathcal{X}$.
(v) *Scalar multiple*: $\lambda A := \{\lambda a : a \in A\}$ for nonempty $A \subseteq \mathcal{X}$ and $\lambda \in \mathbb{F}$.
(vi) *Closed linear span*: $\operatorname{cspan}(S) := \overline{\operatorname{span}(S)}$ for $S \subseteq \mathcal{X}$.
(vii) *Equivalent norms*: $\|\cdot\|_1 \sim \|\cdot\|_2$ iff $\exists c_1, c_2 > 0$ such that $\forall x \in \mathcal{X}$, $c_1 \|x\|_1 \le \|x\|_2 \le c_2 \|x\|_1$.

Proposition 5.1.3. *Linear Operations, Closed Spans, and Equivalent Norms*
Let $\mathcal{X}$ be a normed space.

(i) The norm map $x \mapsto \|x\|$, addition $\mathcal{X} \times \mathcal{X} \to \mathcal{X}$, and scalar multiplication $\mathbb{F} \times \mathcal{X} \to \mathcal{X}$ are continuous.
(ii) If $M \le \mathcal{X}$, then $\overline{M} \le \mathcal{X}$; for $S \subseteq \mathcal{X}$, $\operatorname{cspan}(S)$ is the least closed subspace containing S.
(iii) Equivalent norms have the same convergent and Cauchy sequences, topology, and compact sets.

Proof.

(i) $|\|x\| - \|y\|| \le \|x - y\|$, so $x \mapsto \|x\|$ is 1-Lipschitz.
Also $\|(x + h) + (y + k) - (x + y)\| \le \|h\| + \|k\|$, so addition is continuous.
If $\lambda_n \to \lambda$ and $x_n \to x$, then $\|\lambda_n x_n - \lambda x\| \le |\lambda_n| \, \|x_n - x\| + |\lambda_n - \lambda| \, \|x\| \to 0$, since (λ_n) is bounded.
(ii) Let $x, y \in \overline{M}$ and choose $x_n, y_n \in M$ with $x_n \to x$, $y_n \to y$.
For $\alpha, \beta \in \mathbb{F}$, $\alpha x_n + \beta y_n \in M$ and $\alpha x_n + \beta y_n \to \alpha x + \beta y$ by (i); hence $\overline{M} \le \mathcal{X}$.
If C is closed, $C \le \mathcal{X}$, and $S \subseteq C$, then $\operatorname{span}(S) \subseteq C$, so $\operatorname{cspan}(S) = \overline{\operatorname{span}(S)} \subseteq C$.
(iii) If $c \|z\|_1 \le \|z\|_2 \le C \|z\|_1$ for all $z \in \mathcal{X}$, then $B_1(x, \frac{\varepsilon}{C}) \subseteq B_2(x, \varepsilon) \subseteq B_1(x, \frac{\varepsilon}{c})$. Thus the topologies agree, the identity maps are bi-Lipschitz, convergent and Cauchy sequences agree, and compact sets agree.

Structural Commentary: Norms turn the algebraic operations into continuous operations.
Key Insight: Closing a subspace preserves linearity because linear combinations commute with limits. □

Definition 5.1.4. *Bounded Linear Maps and Operator Norm*
Let $\mathcal{X}, \mathcal{Y}$ be normed spaces and let $T : \mathcal{X} \to \mathcal{Y}$ be linear.

(i) *Bounded*: $\exists C \ge 0$ such that $\forall x \in \mathcal{X}$, $\|Tx\|_{\mathcal{Y}} \le C \|x\|_{\mathcal{X}}$.
(ii) *Operator norm*: $\|T\|_{\mathrm{op}} := \sup_{\|x\|_{\mathcal{X}} \le 1} \|Tx\|_{\mathcal{Y}} = \sup_{x \ne 0} \frac{\|Tx\|_{\mathcal{Y}}}{\|x\|_{\mathcal{X}}}$.
(iii) *Operator space*: $\mathcal{L}(\mathcal{X}, \mathcal{Y}) := \{T : \mathcal{X} \to \mathcal{Y} : T \text{ is bounded and linear}\}$ and $\mathcal{L}(\mathcal{X}) := \mathcal{L}(\mathcal{X}, \mathcal{X})$.

Theorem 5.1.5. *Bounded Equals Continuous for Linear Maps*
For a linear map $T : \mathcal{X} \to \mathcal{Y}$ between normed spaces, the following are equivalent:

(i) T is bounded.
(ii) T is continuous at 0.
(iii) T is continuous everywhere.

Proof.

(i) $\Rightarrow$ *(iii)* If T is bounded, then $\|Tx - Ty\| \le \|T\|_{\mathrm{op}} \|x - y\|$ for $x, y \in \mathcal{X}$; hence T is Lipschitz.
(iii) $\Rightarrow$ *(ii)* Since $0 \in \mathcal{X}$, continuity on $\mathcal{X}$ implies continuity at 0.
(ii) $\Rightarrow$ *(i)* Choose $\delta > 0$ with $\|z\| < \delta \Rightarrow \|Tz\| < 1$. For $x \ne 0$, set $z := \frac{\delta x}{2\|x\|}$.
Then $\|z\| < \delta$ and $\|Tx\| = \frac{2\|x\|}{\delta} \|Tz\| \le \frac{2}{\delta} \|x\|$. Thus $\|T\|_{\mathrm{op}} \le \frac{2}{\delta}$.

Structural Commentary: Continuity at 0 rescales to a global operator bound.
Key Insight: Linear continuity is boundedness. □

Theorem 5.1.6. *Bounded Operators Form a Banach Space*
Let $\mathcal{X}, \mathcal{Y}$ be normed spaces.

(i) $\mathcal{L}(\mathcal{X}, \mathcal{Y})$ is normed by $\|\cdot\|_{op}$ under pointwise operations.
(ii) If $\mathcal{Y}$ is Banach, then $\mathcal{L}(\mathcal{X}, \mathcal{Y})$ is Banach.

Proof.

(i) If $S, T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$ and $\alpha, \beta \in \mathbb{F}$, then $\|(\alpha S + \beta T)x\| \le (|\alpha| \, \|S\|_{\mathrm{op}} + |\beta| \, \|T\|_{\mathrm{op}}) \|x\|$, so $\alpha S + \beta T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$.
Also $\|\alpha T\|_{\mathrm{op}} = |\alpha| \, \|T\|_{\mathrm{op}}$, $\|S + T\|_{\mathrm{op}} \le \|S\|_{\mathrm{op}} + \|T\|_{\mathrm{op}}$, and $\|T\|_{\mathrm{op}} = 0 \Rightarrow Tx = 0$ for all $x \in \mathcal{X}$.

(ii) Assume $\mathcal{Y}$ is Banach and let (T_n) be Cauchy in $\|\cdot\|_{\text{op}}$.
For each $x \in \mathcal{X}$, $\|T_n x - T_m x\| \le \|T_n - T_m\|_{\text{op}} \|x\|$, so define $Tx := \lim_n T_n x$.
Then $T(\alpha x + \beta y) = \alpha Tx + \beta Ty$. Given $\varepsilon > 0$, choose N with $\|T_n - T_m\|_{\text{op}} < \varepsilon$ for $m, n \ge N$.
Letting $m \to \infty$ gives $\|(T_n - T)x\| \le \varepsilon \|x\|$, so $\|T_n - T\|_{\text{op}} \le \varepsilon$.
Hence $T_N - T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$, $T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$, and $T_n \to T$.

Structural Commentary: Pointwise limits are linear; operator-norm Cauchy control is uniform in x.
Key Insight: Completeness of $\mathcal{Y}$ lifts to $\mathcal{L}(\mathcal{X}, \mathcal{Y})$. □

Corollary 5.1.7. *Neumann Series*
Let $\mathcal{X}$ be Banach and let $T \in \mathcal{L}(\mathcal{X})$ satisfy $\|T\|_{op} < 1$.

Then $I - T$ has bounded inverse, with Neumann series converging in $\mathcal{L}(\mathcal{X})$: $(I - T)^{-1} = \sum_{n=0}^{\infty} T^n$.

Proof. Let $S_N := \sum_{n=0}^{N} T^n$. For $M > N$, $\|S_M - S_N\|_{\text{op}} \le \sum_{n=N+1}^{M} \|T\|_{\text{op}}^n \le \frac{\|T\|_{\text{op}}^{N+1}}{1 - \|T\|_{\text{op}}} \to 0$, so $S_N \to S \in \mathcal{L}(\mathcal{X})$.
Since $(I - T)S_N = I - T^{N+1} = S_N(I - T)$ and $\|T^{N+1}\|_{\text{op}} \le \|T\|_{\text{op}}^{N+1} \to 0$.
Passing to the limit gives $(I - T)S = S(I - T) = I$.
Structural Commentary: Operator-norm convergence turns the geometric identity into an inverse.
Key Insight: If $\|T\|_{\text{op}} < 1$, then $\sum T^n = (I - T)^{-1}$. □

Proposition 5.1.8. *Quotient Norm and Quotient Map*
Let $M \le \mathcal{X}$ be closed, let $\mathcal{X}/M := \{x + M : x \in \mathcal{X}\}$, and let $q : \mathcal{X} \to \mathcal{X}/M$ be $q(x) := x + M$.
Set $\|x + M\|_{\mathcal{X}/M} := \inf_{m \in M} \|x - m\|$.

(i) $\|\cdot\|_{\mathcal{X}/M}$ is a norm on $\mathcal{X}/M$.
(ii) q is continuous with $\|q\|_{op} \le 1$.
(iii) $\forall x \in \mathcal{X}$ and $r > 0$, $q(B_r(x)) = B_r(qx)$.
(iv) q is open.

Proof.
(i) If $x' = x + m_0$ with $m_0 \in M$, then $\inf_{m \in M} \|x' - m\| = \inf_{m \in M} \|x - m\|$, so the formula is well defined.
Also $\|x + M\| = 0 \iff x \in \overline{M} = M$. For $\alpha \neq 0$,
$\|\alpha(x + M)\| = \inf_{m \in M} \|\alpha x - m\| = |\alpha| \inf_{m \in M} \|x - \alpha^{-1} m\| = |\alpha| \|x + M\|$; $\alpha = 0$ is trivial.
For $m, n \in M$, $\|(x + y) - (m + n)\| \le \|x - m\| + \|y - n\|$; take infima.
(ii) Since $\|q(x)\| \le \|x - 0\| = \|x\|$, $q \in \mathcal{L}(\mathcal{X}, \mathcal{X}/M)$ and $\|q\|_{\text{op}} \le 1$.
(iii) If $z \in B_r(x)$, then $\|qz - qx\| \le \|z - x\| < r$, so $q(B_r(x)) \subseteq B_r(qx)$. Conversely, if $\eta = qz$ and $\|\eta - qx\| < r$, choose $m \in M$ with $\|z - x - m\| < r$; then $z - m \in B_r(x)$ and $q(z - m) = \eta$.
(iv) If $U \subseteq \mathcal{X}$ is open and $y \in q(U)$, choose $x \in U$ with $qx = y$ and $r > 0$ with $B_r(x) \subseteq U$.
By (iii), $B_r(y) = q(B_r(x)) \subseteq q(U)$; hence $q(U)$ is open.

Structural Commentary: Quotient norm is distance to the closed subspace M.
Key Insight: Closedness makes zero distance equivalent to membership. □

Theorem 5.1.9. *Banach Quotients*
If M is a closed linear subspace of a Banach space $\mathcal{X}$, then $\mathcal{X}/M$ is Banach in the quotient norm.

Proof. Let (ξ_n) be Cauchy in $\mathcal{X}/M$. Choose $n_1 < n_2 < \cdots$ with $\|\xi_{n_{k+1}} - \xi_{n_k}\| < 2^{-k}$ and choose $u_k \in \mathcal{X}$ with $q(u_k) = \xi_{n_{k+1}} - \xi_{n_k}$, $\|u_k\| < 2^{-k}$. Since $\sum_k \|u_k\| < +\infty$ and $\mathcal{X}$ is Banach, $u := \sum_{k \ge 1} u_k$ exists.
For $K \ge 1$, $\xi_{n_K} = \xi_{n_1} + q(\sum_{k<K} u_k) \to \xi_{n_1} + q(u)$.
Since (ξ_n) is Cauchy and has a convergent subsequence, $\xi_n \to \xi_{n_1} + q(u)$.
Structural Commentary: Rapid quotient increments lift to an absolutely convergent series.
Key Insight: A Cauchy sequence with a convergent subsequence converges. □

Proposition 5.1.10. *Operator Factor through the Kernel Quotient*
Let $T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$, set $M := \ker T$, and let $\widetilde{T} : \mathcal{X}/M \to \mathcal{Y}$ be induced by Theorem 2.2.12.

(i) $\widetilde{T}$ is bounded.
(ii) $\|\widetilde{T}\|_{op} = \|T\|_{op}$.

Proof. Since $q(x) = q(y) \iff x - y \in M = \ker T$, the formula $\widetilde{T}(qx) := Tx$ is well defined and $T = \widetilde{T}q$.
For $m \in M$, $\|\widetilde{T}(qx)\| = \|Tx\| = \|T(x - m)\| \le \|T\|_{\text{op}} \|x - m\|$; taking $\inf_{m \in M}$ gives $\|\widetilde{T}(qx)\| \le \|T\|_{\text{op}} \|qx\|$.

(i) The estimate gives $\widetilde{T} \in \mathcal{L}(\mathcal{X}/M, \mathcal{Y})$.
(ii) The estimate gives $\|\widetilde{T}\|_{\text{op}} \le \|T\|_{\text{op}}$. Since $T = \widetilde{T}q$ and $\|q\|_{\text{op}} \le 1$, $\|T\|_{\text{op}} \le \|\widetilde{T}\|_{\text{op}} \|q\|_{\text{op}} \le \|\widetilde{T}\|_{\text{op}}$.

Structural Commentary: Collapsing $\ker T$ makes T descend without changing its norm.
Key Insight: The quotient infimum is taken over exactly the invisible directions of T. □

Example 5.1.11. *Standard Banach Space Examples*
Standard Banach spaces include the following canonical examples.

(i) If S is a set and $B(S) := \{f : S \to \mathbb{F} : \|f\|_\infty < +\infty\}$, then $(B(S), \|\cdot\|_\infty)$ is Banach.
(ii) $\ell^\infty := \{x = (x_n) : \sup_n |x_n| < +\infty\}$ is Banach under $\|x\|_\infty := \sup_n |x_n|$.

(iii) For $1 \le p < \infty$, $\ell^p := \{x = (x_n) : \sum_n |x_n|^p < +\infty\}$ is Banach under $\|x\|_p := (\sum_n |x_n|^p)^{1/p}$.
(iv) For a measure space $(X, \mathcal{M}, \mu)$ and $1 \le p \le \infty$, $L^p(\mu)$ is Banach.
(v) $L^2(\mu)$ is Hilbert with $\langle f, g\rangle := \int_X f\overline{g}\, d\mu$.

Example 5.1.12. *Completeness of ℓ^∞ and ℓ^p*
For $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, $(\ell^\infty(\mathbb{F}), \|\cdot\|_\infty)$ and $(\ell^p(\mathbb{F}), \|\cdot\|_p)$, $1 \le p < \infty$, are complete.

Proof. For ℓ^∞, let $\mathbf{x}^{(n)} = (x_j^{(n)})_j$ be Cauchy. Then $x_j^{(n)} \to y_j \in \mathbb{F}$ for each j.
If $\|\mathbf{x}^{(n)} - \mathbf{x}^{(m)}\|_\infty < \varepsilon$ for $m, n \ge N$, then $|x_j^{(n)} - y_j| \le \varepsilon$ for all j, so $\|\mathbf{x}^{(n)} - \mathbf{y}\|_\infty \le \varepsilon$.
Taking $n = N$ gives $\mathbf{y} \in \ell^\infty$, hence $\mathbf{x}^{(n)} \to \mathbf{y}$.
For ℓ^p, let $\mathbf{x}^{(n)}$ be Cauchy and define $\mathbf{y} = (y_j)$ by coordinatewise limits.
If $\|\mathbf{x}^{(n)} - \mathbf{x}^{(m)}\|_p < \varepsilon$ for $m, n \ge N$, then for each r, $\sum_{j=1}^r |x_j^{(n)} - y_j|^p = \lim_{m\to\infty} \sum_{j=1}^r |x_j^{(n)} - x_j^{(m)}|^p \le \varepsilon^p$.
Letting $r \to \infty$ gives $\|\mathbf{x}^{(n)} - \mathbf{y}\|_p \le \varepsilon$ for $n \ge N$. Taking $n = N$ gives $\mathbf{y} \in \ell^p$, hence $\mathbf{x}^{(n)} \to \mathbf{y}$.
Structural Commentary: Completeness of scalar coordinates combines with uniform tail control.
Key Insight: Norm-Cauchy control keeps coordinatewise limits inside the space. □

Example 5.1.13. *Two Metrics on $C[0,1]$*
For $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$, $C_\mathbb{F} := C([0,1], \mathbb{F})$ is complete under $d_\infty(f,g) := \sup_{x\in[0,1]} |f(x) - g(x)|$ by Theorem 8.1.1, but not under $d_1(f,g) := \int_0^1 |f(x) - g(x)|\, dx$.

Proof. For $n \ge 2$, define $f_n \in C_\mathbb{F}$ by

$$f_n(x) := \begin{cases} 0, & 0 \le x \le \frac{1}{2}, \\ n(x - \frac{1}{2}), & \frac{1}{2} \le x \le \frac{1}{2} + \frac{1}{n}, \\ 1, & \frac{1}{2} + \frac{1}{n} \le x \le 1. \end{cases}$$

Let $s := \mathbf{1}_{(1/2,1]}$. Then $d_1(f_n, s) = 1/(2n)$, hence (f_n) is d_1-Cauchy. If $f_n \to g \in C_\mathbb{F}$ in d_1, then $d_1(g, s) = 0$, so $g = s$ a.e. Continuity forces $g = 0$ on $[0, 1/2]$ and $g = 1$ on $(1/2, 1]$, impossible at $1/2$.
Structural Commentary: The integral metric permits a continuous ramp to collapse to a jump.
Key Insight: Supremum control preserves continuity; integral control can miss jumps. □

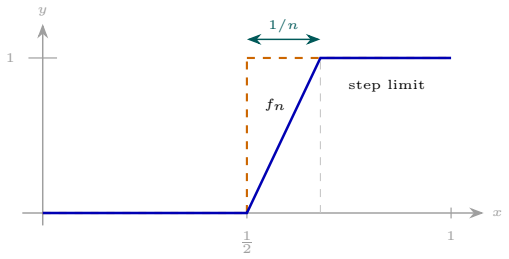

Figure 219: The continuous ramps f_n converge in the integral metric to a discontinuous step function.

Theorem 5.1.14. *Finite-Dimensional Normed Spaces*
Let $\mathcal{X}$ be a finite-dimensional normed space.
(i) $\mathcal{X}$ is Banach.
(ii) Every subspace of $\mathcal{X}$ is closed.
(iii) $\overline{B}_\mathcal{X}$ is compact.

Proof. Choose a basis $e_1, \dots, e_n$ and set $A : \mathbb{F}^n \to \mathcal{X}$, $Aa := \sum_{i=1}^n a_i e_i$.
Then A is linear bijective and $\|Aa\| \le \sum_i |a_i|\, \|e_i\| \le C\, \|a\|_2$.
Since $a \mapsto \|Aa\|$ is continuous, positive on $\{a : \|a\|_2 = 1\}$, $\exists c > 0$ with $c\, \|a\|_2 \le \|Aa\| \le C\, \|a\|_2$ $\forall a \in \mathbb{F}^n$.
(i) If (x_k) is Cauchy in $\mathcal{X}$, then $a_k := A^{-1}x_k$ is Cauchy in $\mathbb{F}^n$ by $c\, \|a_k - a_\ell\|_2 \le \|x_k - x_\ell\|$.
Since $\mathbb{F}^n$ is complete, $a_k \to a$, hence $x_k \to Aa$.
(ii) If $M \le \mathcal{X}$, then M is finite-dimensional, hence Banach by (i). If $x_k \in M$ and $x_k \to x$ in $\mathcal{X}$, then (x_k) converges in M to some $y \in M$; uniqueness of limits gives $x = y \in M$. Thus M is closed.
(iii) Since $\overline{B}_\mathcal{X} \subseteq A(\overline{B}_2(0, \frac{1}{c}))$ and $A^{-1}(\overline{B}_\mathcal{X})$ is closed in the compact Euclidean ball $\overline{B}_2(0, \frac{1}{c})$, $A^{-1}(\overline{B}_\mathcal{X})$ is compact; continuity of A gives compactness of $\overline{B}_\mathcal{X}$.
Structural Commentary: The coordinate map is a bi-Lipschitz linear isomorphism.
Key Insight: Finite-dimensional normed spaces inherit completeness and compactness from $\mathbb{F}^n$. □

Theorem 5.1.15. *Riesz Lemma*
Let M be a closed proper linear subspace of a normed space $\mathcal{X}$.
Then $\forall \varepsilon \in (0,1)$ $\exists u \in \mathcal{X}$ such that $\|u\| = 1$ and $\forall m \in M$, $\|u - m\| > 1 - \varepsilon$.

Proof. Choose $x \in \mathcal{X} \setminus M$ and set $d := \inf_{m\in M} \|x - m\|$. Since M is closed, $d > 0$.
Choose $m_0 \in M$ with $d \le \|x - m_0\| < \frac{d}{1-\varepsilon}$ and set $u := \frac{x - m_0}{\|x - m_0\|}$.
Then $\|u\| = 1$. For $m \in M$, $m_0 + \|x - m_0\|\, m \in M$, so $\|u - m\| = \frac{\|x - (m_0 + \|x - m_0\| m)\|}{\|x - m_0\|} \ge \frac{d}{\|x - m_0\|} > 1 - \varepsilon$.

Structural Commentary: A positive distance to M survives normalization.
Key Insight: Normalize an almost-minimizer of $\operatorname{dist}(x, M)$. □

Corollary 5.1.16. *Compact Unit Balls Characterize Finite Dimension*
For a normed space $\mathcal{X}$, $\overline{B}_{\mathcal{X}}$ is compact iff $\dim \mathcal{X} < \infty$.

Proof.
($\Leftarrow$) If $\dim \mathcal{X} < \infty$, then $\overline{B}_{\mathcal{X}}$ is compact by Theorem 5.1.14(iii).
($\Rightarrow$) Suppose $\dim \mathcal{X} = \infty$. Choose $x_1 \in \mathcal{X}$ with $\|x_1\| = 1$. Given $x_1, \dots, x_n$, set $M_n := \operatorname{span}\{x_1, \dots, x_n\}$.
Then M_n is finite-dimensional, closed, and proper, so Theorem 5.1.15 with $\varepsilon = \frac{1}{2}$ gives $x_{n+1} \in \mathcal{X}$ with $\|x_{n+1}\| = 1$ and $\operatorname{dist}(x_{n+1}, M_n) > \frac{1}{2}$. Since $x_i \in M_n$ for $i \le n$, $\|x_{n+1} - x_i\| > \frac{1}{2}$.
Thus $(x_n) \subseteq \overline{B}_{\mathcal{X}}$ has no Cauchy subsequence, so $\overline{B}_{\mathcal{X}}$ is not compact.
Structural Commentary: Riesz iteration builds a separated sequence in $\overline{B}_{\mathcal{X}}$.
Key Insight: Compact unit ball forces finite dimension. □

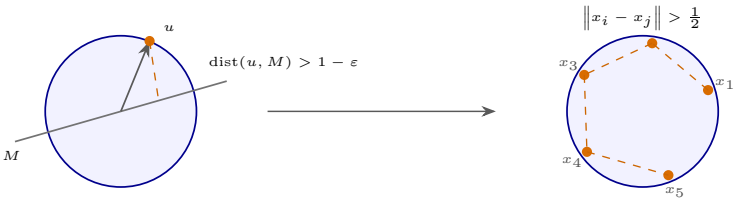

Figure 220: Riesz iteration: $M_n = \operatorname{span}\{x_1, \dots, x_n\}$, $\operatorname{dist}(x_{n+1}, M_n) > \frac{1}{2} \Rightarrow \|x_i - x_j\| > \frac{1}{2}$ $(i \neq j)$; hence no Cauchy subsequence in $\overline{B}_{\mathcal{X}}$.

5.2 Hilbert Spaces

Hilbert spaces are complete inner-product spaces. They extend the orthogonal geometry of Definition 1.1.3 to function and sequence spaces, supporting projection, Fourier expansion, and Riesz representation.

Definition 5.2.1. *Hilbert Space*
Let $\mathcal{H}$ be an inner-product space.
(i) *Hilbert space*: $\mathcal{H}$ is complete in the norm $\|x\| := \sqrt{\langle x, x \rangle}$.
(ii) *Orthonormal family*: $(e_i)_{i \in I} \subseteq \mathcal{H}$ satisfies $\forall i, j \in I$, $\langle e_i, e_j \rangle = \delta_{ij}$.

Proposition 5.2.2. *Continuity of the Inner Product*
Let $\mathcal{V}$ be an inner-product space, let $(x_n), (y_n) \subseteq \mathcal{V}$, and let $x, y \in \mathcal{V}$.
(i) $x_n \to x \Longrightarrow \|x_n\| \to \|x\|$.
(ii) $x_n \to x$ and $y_n \to y \Longrightarrow \langle x_n, y_n \rangle \to \langle x, y \rangle$.

Proof.
(i) $|\|x_n\| - \|x\|| \le \|x_n - x\| \to 0$, hence $\|x_n\| \to \|x\|$.
(ii) Since (y_n) is bounded, choose $M < \infty$ with $\|y_n\| \le M$.
Cauchy–Schwarz gives $\left|\langle x_n, y_n \rangle - \langle x, y \rangle\right| \le M \|x_n - x\| + \|x\| \|y_n - y\| \to 0$.
Structural Commentary: Cauchy–Schwarz turns norm convergence in either coordinate into scalar convergence.
Key Insight: Inner products are continuous because their errors are controlled by products of norms. □

Theorem 5.2.3. *Hilbert Completion*
Let $\mathcal{V}$ be an inner-product space.
(i) $\exists (\widehat{\mathcal{V}}, J)$ such that $\widehat{\mathcal{V}}$ is Hilbert, $J : \mathcal{V} \to \widehat{\mathcal{V}}$ is a linear isometry, and $\overline{J(\mathcal{V})} = \widehat{\mathcal{V}}$.
(ii) If $(\mathcal{K}, I)$ also satisfies (i), then $\exists! U : \widehat{\mathcal{V}} \to \mathcal{K}$ a surjective linear isometry with $U \circ J = I$.

Proof.
(i) Let $C(\mathcal{V})$ be the Cauchy sequences, set $(x_n) \sim (y_n) \iff \|x_n - y_n\| \to 0$, and define $\widehat{\mathcal{V}} := C(\mathcal{V})/\sim$.
Set $[x_n] + [y_n] := [x_n + y_n]$, $a[x_n] := [ax_n]$, $Jx := [(x)]$, and $\langle [x_n], [y_n] \rangle_{\widehat{\mathcal{V}}} := \lim_{n \to \infty} \langle x_n, y_n \rangle_{\mathcal{V}}$.
If $(x_n), (y_n)$ are bounded by M, then $\left|\langle x_n, y_n \rangle - \langle x_m, y_m \rangle\right| \le M \|y_n - y_m\| + M \|x_n - x_m\| \to 0$.
The same estimate for equivalent representatives makes the limit well defined.
Also $\|[x_n] - [y_n]\| = \lim_n \|x_n - y_n\|$, the metric-completion norm; hence $\widehat{\mathcal{V}}$ is Hilbert and $\overline{J(\mathcal{V})} = \widehat{\mathcal{V}}$.
(ii) Since $(\widehat{\mathcal{V}}, J)$ and $(\mathcal{K}, I)$ are metric completions of $\mathcal{V}$, there is a unique surjective isometry $U : \widehat{\mathcal{V}} \to \mathcal{K}$ with $U \circ J = I$. For $x, y \in \mathcal{V}$ and $a, b \in \mathbb{F}$, $U(aJx + bJy) = U(J(ax + by)) = I(ax + by) = aUJx + bUJy$; by density and continuity, U is linear. Since $\|Uz - Uw\| = \|z - w\|$, polarization gives $\langle Uz, Uw \rangle_{\mathcal{K}} = \langle z, w \rangle_{\widehat{\mathcal{V}}}$.
Structural Commentary: Complete the metric first, then recover the inner product by taking limits.
Key Insight: Cauchy–Schwarz makes the lifted inner product well defined. □

Theorem 5.2.4. *Complete, Closed, and Finite-Dimensional Subspaces*
Let $\mathcal{S}$ be a subspace of an inner-product space $\mathcal{V}$.
(i) If $\mathcal{S}$ is complete in the inherited metric, then $\mathcal{S}$ is closed in $\mathcal{V}$.
(ii) If $\mathcal{V}$ is Hilbert, then $\mathcal{S}$ is Hilbert if and only if $\mathcal{S}$ is closed.
(iii) If $\mathcal{S}$ is finite-dimensional, then $\mathcal{S}$ is complete and closed in $\mathcal{V}$.

Proof.

(i) Let $v \in \overline{\mathcal{S}}$ and choose $s_n \in \mathcal{S}$ with $s_n \to v$ in $\mathcal{V}$. Then (s_n) is Cauchy in $\mathcal{S}$, so $s_n \to s \in \mathcal{S}$ by completeness. Uniqueness of limits gives $v = s$, hence $\overline{\mathcal{S}} = \mathcal{S}$.

(ii) Assume $\mathcal{V}$ Hilbert. If $\mathcal{S}$ is closed and $(s_n) \subseteq \mathcal{S}$ is Cauchy, then $s_n \to v \in \mathcal{V}$ and $v \in \mathcal{S}$, so $\mathcal{S}$ is complete. Conversely, if $\mathcal{S}$ is Hilbert, then $\mathcal{S}$ is complete, hence closed by (i).

(iii) Let $\dim \mathcal{S} = m$ and choose an orthonormal basis $e_1, \dots, e_m$.

If (s_n) is Cauchy in $\mathcal{S}$ and $s_n = \sum_{j=1}^{m} a_{n,j} e_j$, then $|a_{n,j} - a_{k,j}| = |\langle s_n - s_k, e_j \rangle| \le \|s_n - s_k\|$.

Thus $a_{n,j} \to a_j \in \mathbb{F}$ for each j, and $s_n \to s := \sum_{j=1}^{m} a_j e_j \in \mathcal{S}$. Hence $\mathcal{S}$ is complete, so closed by (i).

Structural Commentary: In a complete ambient space, closed subspaces are exactly complete subspaces.
Key Insight: Finite orthonormal coordinates reduce completeness to $\mathbb{F}^m$. □

Definition 5.2.5. *Series in an Inner-Product Space*
Let $(x_k) \subseteq \mathcal{V}$.

(i) The *partial sums* are $s_n := \sum_{k=1}^{n} x_k$.

(ii) The *series* $\sum_{k=1}^{\infty} x_k$ *converges* to $s \in \mathcal{V}$ iff $s_n \to s$.

(iii) The series is *absolutely convergent* iff $\sum_{k=1}^{\infty} \|x_k\| < \infty$.

Theorem 5.2.6. *Completeness via Absolutely Convergent Series*
$\mathcal{V}$ is complete $\iff$ every series $\sum_{k=1}^{\infty} x_k$ in $\mathcal{V}$ with $\sum_{k=1}^{\infty} \|x_k\| < \infty$ converges in $\mathcal{V}$.

Proof.

($\Rightarrow$) Let $s_n := \sum_{k=1}^{n} x_k$ and assume $\sum_k \|x_k\| < +\infty$. For $n > m$, $\|s_n - s_m\| \le \sum_{k=m+1}^{n} \|x_k\| \to 0$ as $m, n \to \infty$. Thus (s_n) is Cauchy, hence convergent by completeness.

($\Leftarrow$) Let (x_n) be Cauchy. Let $N_1 < N_2 < \cdots$ such that $i, j \ge N_k \Rightarrow \|x_i - x_j\| < 2^{-k}$, $y_k := x_{N_{k+1}} - x_{N_k}$. Then $\sum_k \|y_k\| \le \sum_k 2^{-k} < +\infty$, so $\sum_k y_k$ converges. Since $x_{N_m} = x_{N_1} + \sum_{k<m} y_k$, the subsequence (x_{N_m}) converges; because (x_n) is Cauchy, (x_n) converges.

Structural Commentary: Absolute tails make partial sums Cauchy; Cauchy tails contain summable increments.
Key Insight: Completeness is summability of norm-controlled series. □

Example 5.2.7. *ℓ^2 and the Parallelogram Test*
Let $\ell^2 := \{x = (x_n) : \sum_{n=1}^{\infty} |x_n|^2 < \infty\}$. With $\langle x, y \rangle := \sum_{n=1}^{\infty} x_n \overline{y_n}$ and $\|x\|_2 = \langle x, x \rangle^{\frac{1}{2}}$, Cauchy coordinate limits and finite-set estimates give completeness, so ℓ^2 is Hilbert.
For $p \neq 2$, $\|\cdot\|_p$ is not inner-product-induced: with $x = (1, 1, 0, \dots)$ and $y = (1, -1, 0, \dots)$,

$\|x + y\|_p^2 + \|x - y\|_p^2 = 8$ while $2\|x\|_p^2 + 2\|y\|_p^2 = 4 \cdot 2^{\frac{2}{p}}$, so the parallelogram identity holds only for $p = 2$.
Structural Commentary: Completeness alone does not make a Banach space Hilbert.
Key Insight: The parallelogram identity detects whether a norm really came from an inner product.

Example 5.2.8. *The Supremum Norm Is Not Hilbertian*
For $a < b$, $C([a, b], \mathbb{F})$ with $\|h\|_\infty := \sup_{t \in [a,b]} |h(t)|$ is Banach but not Hilbertian: take $f(t) = 1$ and $g(t) = \frac{t-a}{b-a}$, so $\|f\|_\infty = \|g\|_\infty = 1$, $\|f + g\|_\infty = 2$, $\|f - g\|_\infty = 1$, and $\|f + g\|_\infty^2 + \|f - g\|_\infty^2 = 5 \neq 4 = 2\|f\|_\infty^2 + 2\|g\|_\infty^2$, violating the parallelogram identity.
Structural Commentary: Banach need not mean Hilbert.
Key Insight: One failed parallelogram identity rules out every possible inner product inducing the norm.

Theorem 5.2.9. *Hilbert Projection Theorem*
Let $C \subseteq \mathcal{H}$ be nonempty, closed, and convex. Then $\forall x \in \mathcal{H}$ $\exists! p \in C$ such that $\|x - p\| = \inf_{q \in C} \|x - q\|$.

Proof. Let $d := \inf_{q \in C} \|x - q\|$, $q_n \in C$, $\|x - q_n\| \to d$. Since $\frac{q_n + q_m}{2} \in C$, by parallelogram identity,

$\|q_n - q_m\|^2 = 2\|x - q_n\|^2 + 2\|x - q_m\|^2 - 4\left\|x - \frac{q_n + q_m}{2}\right\|^2 \le 2\|x - q_n\|^2 + 2\|x - q_m\|^2 - 4d^2 \to 0.$

Thus (q_n) is Cauchy. Hence $q_n \to p \in \mathcal{H}$; closedness gives $p \in C$, and $\|x - p\| = d$.
If $p_1, p_2 \in C$ both minimize, the same identity gives $\|p_1 - p_2\|^2 \le 2d^2 + 2d^2 - 4d^2 = 0$.
Structural Commentary: Convexity and parallelogram force minimizing sequences to converge in C.
Key Insight: Midpoint minimality turns near minimizers into a Cauchy sequence. □

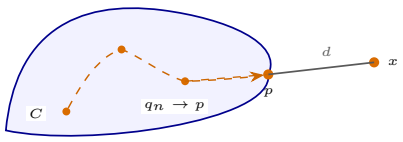

Figure 221: Hilbert projection: $q_n \in C$, $\|x - q_n\| \to d = \operatorname{dist}(x, C) \Rightarrow q_n \to p \in C$ and $\|x - p\| = d$.

Corollary 5.2.10. *Orthogonal Projection onto a Closed Subspace*
Let $M \leq \mathcal{H}$ be closed.

(i) $\forall x \in \mathcal{H}\ \exists! p \in M$ *such that* $x - p \in M^\perp$.
(ii) $\mathcal{H} = M \odot M^\perp$.

Proof.

(i) By Theorem 5.2.9, choose the unique $p \in M$ minimizing $\|x - p\|$, and set $r := x - p$.
For $y \in M$ and $t \in \mathbb{R}$, $p + ty \in M$, so $0 \leq \|r - ty\|^2 - \|r\|^2 = -2t \operatorname{Re}\langle r, y\rangle + t^2 \|y\|^2$.
Thus $\operatorname{Re}\langle r, y\rangle = 0$; over $\mathbb{C}$, replace y by iy to get $\operatorname{Im}\langle r, y\rangle = 0$. Hence $r \in M^\perp$.
If $x = p_1 + r_1 = p_2 + r_2$ with $p_i \in M$, $r_i \in M^\perp$, then $p_1 - p_2 = r_2 - r_1 \in M \cap M^\perp = \{0\}$.
(ii) By (i), each $x \in \mathcal{H}$ has $x = p + r$ with $p \in M$, $r \in M^\perp$, so $\mathcal{H} = M + M^\perp$.
Since $M \cap M^\perp = \{0\}$, the sum is direct: $\mathcal{H} = M \odot M^\perp$.

Structural Commentary: Nearest points are characterized by orthogonal residuals.
Key Insight: Every vector splits uniquely into M and $M^\perp$ parts. □

Definition 5.2.11. *Closed Linear Span and Total Sets*
For $A \subseteq \mathcal{H}$:

(i) *Closed linear span*: $\operatorname{cspan}(A) := \overline{\operatorname{span}(A)}$.
(ii) *Total*: A is total in $\mathcal{H}$ iff $\operatorname{cspan}(A) = \mathcal{H}$.

Theorem 5.2.12. *Double Orthogonal Complements in Hilbert Spaces*
Let $\mathcal{H}$ be a Hilbert space.

(i) $\forall A \subseteq \mathcal{H}$, $\operatorname{cspan}(A) = A^{\perp\perp}$.
(ii) $\forall \mathcal{S} \leq \mathcal{H}$, $\overline{\mathcal{S}} = \mathcal{S}^{\perp\perp}$.
(iii) $\forall \mathcal{K} \leq \mathcal{H}$, $\mathcal{K}$ *closed* $\iff \mathcal{K} = \mathcal{K}^{\perp\perp}$.
(iv) $\forall A \subseteq \mathcal{H}$, $\operatorname{span}(A)$ *dense in* $\mathcal{H} \iff A^\perp = \{\mathbf{0}\}$.

Proof.

(i) Let $B := \operatorname{cspan}(A)$. Since $A \subseteq B$, $B^\perp \subseteq A^\perp$. If $y \in A^\perp$, by $y \perp \operatorname{span}(A)$, continuity of $z \mapsto \langle z, y\rangle$, $y \perp B$, so $A^\perp = B^\perp$. By Corollary 5.2.10, $\mathcal{H} = B \odot B^\perp$; $B^{\perp\perp} = B$. Therefore $A^{\perp\perp} = B^{\perp\perp} = B = \operatorname{cspan}(A)$.
(ii) With $A = \mathcal{S}$ in (i), $\mathcal{S}^{\perp\perp} = \operatorname{cspan}(\mathcal{S}) = \overline{\operatorname{span}(\mathcal{S})} = \overline{\mathcal{S}}$.
(iii) By (ii), $\mathcal{K}^{\perp\perp} = \overline{\mathcal{K}}$; thus $\mathcal{K} = \mathcal{K}^{\perp\perp} \iff \mathcal{K} = \overline{\mathcal{K}} \iff \mathcal{K}$ is closed.
(iv) By (i), $\operatorname{span}(A)$ is dense $\iff A^{\perp\perp} = \mathcal{H}$. If $A^\perp = \{\mathbf{0}\}$, then $A^{\perp\perp} = \{\mathbf{0}\}^\perp = \mathcal{H}$.
Conversely, if $A^{\perp\perp} = \mathcal{H}$ and $y \in A^\perp$, then $y \in A^{\perp\perp}$, so $\|y\|^2 = \langle y, y\rangle = 0$; hence $A^\perp = \{\mathbf{0}\}$.

Structural Commentary: Double orthogonal complement equals closed linear span.
Key Insight: Missing closed-span directions are exactly nonzero orthogonal vectors. □

Example 5.2.13. *Completeness Is Needed for Double Complements*
Let $\mathcal{V} := c_{00}(\mathbb{N}; \mathbb{R}) \subseteq \ell^2$ with inherited inner product, $Lx := \sum_{n=1}^{\infty} \frac{x_n}{n}$, and $\mathcal{K} := \ker L$.

Then $|Lx| \leq \|x\|_2 \left(\sum_{n=1}^{\infty} n^{-2}\right)^{\frac{1}{2}}$, so L is continuous and $\mathcal{K}$ is a closed subspace of $\mathcal{V}$.

If $y \in \mathcal{K}^\perp$, then $e_1 - ne_n \in \mathcal{K}$ for $n \geq 2$, hence $0 = \langle y, e_1 - ne_n\rangle = y_1 - ny_n$.
Since $y \in c_{00}$, choose $n \geq 2$ with $y_n = 0$, so $y_1 = 0$ and then $\forall n,\ y_n = 0$.
Thus $\mathcal{K}^\perp = \{\mathbf{0}\}$ and $\mathcal{K}^{\perp\perp} = \mathcal{V}$. But $e_1 \notin \mathcal{K}$, hence $\mathcal{K} \neq \mathcal{V} = \mathcal{K}^{\perp\perp}$.
Structural Commentary: Closedness need not recover double complements without completeness.
Key Insight: The identity $\mathcal{K} = \mathcal{K}^{\perp\perp}$ is genuinely Hilbert-space geometry.

Perspective 5.2.14. *Hilbert and Hamel Basis Caution*
In Hilbert-space theory, an *orthonormal basis* usually means a complete orthonormal family: vectors are recovered by convergent Fourier expansion, not necessarily by finite linear combinations.
A *Hamel basis* is a vector-space basis and is much stronger in infinite dimension.
For example, the standard $(\mathbf{e}_j)$ in $\ell^2(\mathbb{F})$ is a complete orthonormal family, but $\operatorname{span}\{\mathbf{e}_j : j \geq 1\} = \mathbb{F}^{(\mathbb{N})} \subsetneq \ell^2(\mathbb{F})$.

Definition 5.2.15. *Hilbert Basis*

(i) A *Hilbert basis*, or complete orthonormal family, is a maximal orthonormal set under inclusion.
(ii) A *Hamel basis* is a vector-space basis.
(iii) Here *orthonormal basis* means Hilbert basis outside finite-dimensional Hamel context.

Proposition 5.2.16. *Finite Hilbert Bases Are Hamel Bases*
Let $\mathcal{O} = \{\mathbf{e}_1, \ldots, \mathbf{e}_m\}$ be orthonormal in $\mathcal{V}$ and set $W = \operatorname{span}(\mathcal{O})$.
Then $\mathcal{O}$ is a Hilbert basis $\iff W = \mathcal{V} \iff \mathcal{O}$ is an orthonormal Hamel basis.

Proof. Since $\mathcal{O}$ is orthonormal, it is linearly independent; hence $W = \mathcal{V} \iff \mathcal{O}$ is an orthonormal Hamel basis.
It remains to show maximality $\iff W = \mathcal{V}$.

($\Rightarrow$) Suppose $\mathcal{O}$ is maximal orthonormal and $W \neq \mathcal{V}$. Choose $\mathbf{v} \notin W$ and set $\mathbf{u} := \mathbf{v} - \sum_{j=1}^{m} \langle \mathbf{v}, \mathbf{e}_j\rangle\, \mathbf{e}_j$.

Then $\langle \mathbf{u}, \mathbf{e}_i\rangle = 0$ for $1 \leq i \leq m$, and $\mathbf{u} \neq \mathbf{0}$ since $\mathbf{v} \notin W$.
Thus $\mathcal{O} \cup \{\mathbf{u}/\|\mathbf{u}\|\}$ is orthonormal, contradiction. Hence $W = \mathcal{V}$.

($\Leftarrow$) Suppose $W = \mathcal{V}$. If $\mathbf{w} \perp \mathcal{O}$, write $\mathbf{w} = \sum_{j=1}^{m} a_j \mathbf{e}_j$. Then $a_j = \langle \mathbf{w}, \mathbf{e}_j\rangle = 0$ for every j, so $\mathbf{w} = \mathbf{0}$.

Hence no nonzero vector can be adjoined orthogonally to $\mathcal{O}$; $\mathcal{O}$ is maximal orthonormal.

Structural Commentary: In finite orthonormal families, maximality equals spanning.
Key Insight: Any missing vector has a nonzero orthogonal residual. □

Example 5.2.17. *A Hilbert Basis Need Not Be a Hamel Basis*
In $\ell^2(\mathbb{F})$, let $\mathbf{e}_j = (0,\dots,0,1,0,\dots)$. Then $\{\mathbf{e}_j : j \geq 1\}$ is orthonormal and maximal, since $\forall j,\ \mathbf{x} \perp \mathbf{e}_j$ implies $\forall j,\ x_j = \langle \mathbf{x}, \mathbf{e}_j \rangle = 0$. Its finite span is $\mathbb{F}^{(\mathbb{N})} \subsetneq \ell^2(\mathbb{F})$, so it is a Hilbert basis but not a Hamel basis.

Theorem 5.2.18. *Hilbert Basis Characterizations*
Let $\mathcal{O} \subseteq \mathcal{H}$ be orthonormal. The following are equivalent:

(i) $\mathcal{O}$ *is maximal orthonormal.*
(ii) $\mathcal{O}^\perp = \{\mathbf{0}\}$.
(iii) $\operatorname{cspan}(\mathcal{O}) = \mathcal{H}$.

Proof.

(*i*) $\Rightarrow$ (*ii*) If $0 \neq v \in \mathcal{O}^\perp$, then $\mathcal{O} \cup \{v/\|v\|\}$ is orthonormal, contradicting maximality. Hence $\mathcal{O}^\perp = \{\mathbf{0}\}$.
(*ii*) $\Rightarrow$ (*iii*) By Theorem 5.2.12, $\operatorname{cspan}(\mathcal{O}) = \mathcal{O}^{\perp\perp} = (\mathcal{O}^\perp)^\perp = \{\mathbf{0}\}^\perp = \mathcal{H}$.
(*iii*) $\Rightarrow$ (*i*) If $\mathcal{O} \subsetneq \mathcal{O} \cup \{u\}$ is orthonormal with $\|u\| = 1$, then $u \in \mathcal{O}^\perp$.
By (iii) and Theorem 5.2.12(iv), $\mathcal{O}^\perp = \{\mathbf{0}\}$, contradiction. Thus $\mathcal{O}$ is maximal orthonormal.

Structural Commentary: Maximality, trivial orthogonal complement, and closed span are equivalent.
Key Insight: A Hilbert basis is total, not necessarily Hamel. □

Definition 5.2.19. *Arbitrary Sums in a Hilbert Space*
Let $(x_k)_{k\in K} \subseteq \mathcal{H}$.

(i) *Finite partial sums*: $\mathcal{F}(K) := \{J \subseteq K : |J| < \infty\}$, ordered by $\subseteq$, and $s_J := \sum_{k\in J} x_k$.
(ii) *Arbitrary convergence*: $\sum_{k\in K} x_k = x \iff \forall \varepsilon > 0\, \exists S \in \mathcal{F}(K)\, \forall T \in \mathcal{F}(K) : S \subseteq T \Rightarrow \|s_T - x\| \leq \varepsilon$.
(iii) *Nonnegative scalar sum*: for $(a_k)_{k\in K} \subseteq [0,\infty)$, $\sum_{k\in K} a_k < \infty \iff \sup_{J\in\mathcal{F}(K)} \sum_{k\in J} a_k < \infty$.

Proposition 5.2.20. *Basic Properties of Arbitrary Sums*
Let $(x_k)_{k\in K}, (y_k)_{k\in K} \subseteq \mathcal{H}$ satisfy $\sum_{k\in K} x_k = x$ and $\sum_{k\in K} y_k = y$.

(i) $\forall a, b \in \mathbb{F},\ \sum_{k\in K} (ax_k + by_k) = ax + by$.
(ii) $\forall z \in \mathcal{H},\ \sum_{k\in K} \langle x_k, z\rangle = \langle x, z\rangle$.
(iii) $\forall z \in \mathcal{H},\ \sum_{k\in K} \langle z, x_k\rangle = \langle z, x\rangle$.

Proof. For $J \in \mathcal{F}(K)$, set $s_J := \sum_{k\in J} x_k$ and $t_J := \sum_{k\in J} y_k$.

(i) Since $s_J \to x$ and $t_J \to y$, $as_J + bt_J \to ax + by$.
(ii) For $z \in \mathcal{H}$ and $J \in \mathcal{F}(K)$, $\sum_{k\in J} \langle x_k, z\rangle = \langle s_J, z\rangle$; since $s_J \to x$, Proposition 5.2.2 gives $\langle s_J, z\rangle \to \langle x, z\rangle$.
(iii) For $z \in \mathcal{H}$ and $J \in \mathcal{F}(K)$, $\sum_{k\in J} \langle z, x_k\rangle = \langle z, s_J\rangle$; since $s_J \to x$, Proposition 5.2.2 gives $\langle z, s_J\rangle \to \langle z, x\rangle$.

Structural Commentary: Arbitrary sums are ordinary finite sums plus a convergence net.
Key Insight: Once the vector sum converges, continuous linear tests may pass through the sum. □

Theorem 5.2.21. *Arbitrary Orthonormal Sums*
Let $(u_k)_{k\in K} \subseteq \mathcal{H}$ be orthonormal.

(i) For $(r_k)_{k\in K} \subseteq \mathbb{F}$, $\sum_{k\in K} r_k u_k$ converges iff $\sup_{J\in\mathcal{F}(K)} \sum_{k\in J} |r_k|^2 < \infty$.
(ii) Under the conditions in (i), $\left\| \sum_{k\in K} r_k u_k \right\|^2 = \sum_{k\in K} |r_k|^2$.
(iii) $\forall (x_k)_{k\in K} \subseteq \mathcal{H}$, $\sum_{k\in K} x_k$ convergent implies $|\{k \in K : x_k \neq \mathbf{0}\}| \leq \aleph_0$.

Proof.

(*i*) ($\Rightarrow$) Let $s_J := \sum_{k\in J} r_k u_k$. If $s_J \to x$, choose $S \in \mathcal{F}(K)$ with $S \subseteq T \Rightarrow \|s_T - x\| \leq 1$.
For $J \in \mathcal{F}(K)$, $\sum_{k\in J} |r_k|^2 \leq \|s_{J\cup S}\|^2 \leq (\|x\| + 1)^2$.
(*i*) ($\Leftarrow$) Let $M := \sup_{J\in\mathcal{F}(K)} \sum_{k\in J} |r_k|^2 < +\infty$. Given $\varepsilon > 0$, choose $S \in \mathcal{F}(K)$ with $M - \sum_{k\in S} |r_k|^2 < \varepsilon^2$.
If $S \subseteq J, L$, then $\|s_J - s_L\|^2 = \sum_{k\in J\triangle L} |r_k|^2 \leq \sum_{k\in (J\cup L)\setminus S} |r_k|^2 < \varepsilon^2$.
Thus (s_J) is Cauchy, hence converges in $\mathcal{H}$.
(*ii*) If $s_J \to s := \sum_{k\in K} r_k u_k$, then $\|s\|^2 = \lim_J \|s_J\|^2 = \sup_{J\in\mathcal{F}(K)} \sum_{k\in J} |r_k|^2 = \sum_{k\in K} |r_k|^2$.
(*iii*) If $s_J := \sum_{k\in J} x_k$ converges, then (s_J) is Cauchy.
For each $n \geq 1$, choose $I_n \in \mathcal{F}(K)$ such that $I_n \subseteq J, L \Rightarrow \|s_J - s_L\| \leq \frac{1}{n}$.
Then $F \in \mathcal{F}(K \setminus I_n)$ implies $\left\| \sum_{k\in F} x_k \right\| = \|s_{I_n\cup F} - s_{I_n}\| \leq \frac{1}{n}$.
With $I := \bigcup_{n\geq 1} I_n$, I is countable; if $k \notin I$, then $\|x_k\| \leq \frac{1}{n}$ for all n, so $x_k = \mathbf{0}$.

Structural Commentary: Orthonormal finite sums turn net tails into square-sum tails.
Key Insight: Convergent arbitrary sums have countable support. □

Theorem 5.2.22. *Fourier Expansion in a Hilbert Space*
Let $\mathcal{O} = (u_k)_{k\in K} \subseteq \mathcal{H}$ be orthonormal. For $x \in \mathcal{H}$, set $\widehat{x}_{\mathcal{O}} := \sum_{k\in K} \langle x, u_k\rangle\, u_k$.

(i) $\widehat{x}_{\mathcal{O}}$ converges in $\mathcal{H}$.
(ii) $\|\widehat{x}_{\mathcal{O}}\|^2 = \sum_{k\in K} \left|\langle x, u_k\rangle\right|^2 \le \|x\|^2$.
(iii) $\widehat{x}_{\mathcal{O}}$ is the unique minimizer of $\|x - y\|$ over $y \in \operatorname{cspan}(\mathcal{O})$.
(iv) $\|\widehat{x}_{\mathcal{O}}\| = \|x\| \iff x \in \operatorname{cspan}(\mathcal{O})$.

Proof.
(i) For $J \in \mathcal{F}(K)$, finite Bessel gives $\sum_{k\in J} \left|\langle x, u_k\rangle\right|^2 \le \|x\|^2$.
Hence $\sup_J \sum_{k\in J} \left|\langle x, u_k\rangle\right|^2 < +\infty$, so $\sum_{k\in K} \langle x, u_k\rangle\, u_k$ converges by Theorem 5.2.21(i).
(ii) Theorem 5.2.21(ii) gives $\|\widehat{x}_{\mathcal{O}}\|^2 = \sum_{k\in K} \left|\langle x, u_k\rangle\right|^2$; finite Bessel gives the inequality $\sum_{k\in K} \left|\langle x, u_k\rangle\right|^2 \le \|x\|^2$.
(iii) For $i \in K$, Proposition 5.2.20 gives $\langle \widehat{x}_{\mathcal{O}}, u_i\rangle = \sum_{k\in K} \langle x, u_k\rangle\, \langle u_k, u_i\rangle = \langle x, u_i\rangle$, so $r := x - \widehat{x}_{\mathcal{O}} \perp \mathcal{O}$.
By continuity, $r \perp M := \operatorname{cspan}(\mathcal{O})$. For $y \in M$, $x - y = r + (\widehat{x}_{\mathcal{O}} - y)$ orthogonally,
so $\|x - y\|^2 = \|r\|^2 + \|\widehat{x}_{\mathcal{O}} - y\|^2 \ge \|r\|^2 = \|x - \widehat{x}_{\mathcal{O}}\|^2$, with equality iff $y = \widehat{x}_{\mathcal{O}}$.
(iv) ($\Rightarrow$) As $x = \widehat{x}_{\mathcal{O}} + r$ orthogonally, $\|x\|^2 = \|\widehat{x}_{\mathcal{O}}\|^2 + \|r\|^2$. If $\|\widehat{x}_{\mathcal{O}}\| = \|x\|$, then $r = 0$, $x = \widehat{x}_{\mathcal{O}} \in \operatorname{cspan}(\mathcal{O})$.
(iv) ($\Leftarrow$) If $x \in \operatorname{cspan}(\mathcal{O})$, the minimizer of $\|x - y\|$ over $y \in \operatorname{cspan}(\mathcal{O})$ is x; by (iii), $\widehat{x}_{\mathcal{O}} = x$, $\|\widehat{x}_{\mathcal{O}}\| = \|x\|$.
Structural Commentary: Fourier expansion is orthogonal projection onto $\operatorname{cspan}(\mathcal{O})$.
Key Insight: Bessel bounds the coefficients; completeness sums them. □

Corollary 5.2.23. *Parseval Characterization of Hilbert Bases*
For an orthonormal family $\mathcal{O} = \{u_k : k \in K\}$ in $\mathcal{H}$, the following are equivalent:

(i) $\mathcal{O}$ is a Hilbert basis.
(ii) $\forall x \in \mathcal{H}$, $x = \sum_{k\in K} \langle x, u_k\rangle\, u_k$.
(iii) $\forall x, y \in \mathcal{H}$, Parseval's identity $\langle x, y\rangle = \sum_{k\in K} \langle x, u_k\rangle\, \overline{\langle y, u_k\rangle}$ holds.
(iv) $\forall x \in \mathcal{H}$, $\|x\|^2 = \sum_{k\in K} \left|\langle x, u_k\rangle\right|^2$.

Proof.
(i) $\Rightarrow$ (ii) By Theorem 5.2.18, $\operatorname{cspan}(\mathcal{O}) = \mathcal{H}$. For $x \in \mathcal{H}$, both x and $\widehat{x}_{\mathcal{O}}$ minimize $\|x - y\|$ over $y \in \operatorname{cspan}(\mathcal{O})$.
By uniqueness in Theorem 5.2.22(iii), $x = \widehat{x}_{\mathcal{O}} = \sum_{k\in K} \langle x, u_k\rangle\, u_k$.
(ii) $\Rightarrow$ (iii) For $x, y \in \mathcal{H}$, (ii) and Proposition 5.2.20 give $\langle x, y\rangle = \sum_{k\in K} \langle x, u_k\rangle\, \langle u_k, y\rangle = \sum_{k\in K} \langle x, u_k\rangle\, \overline{\langle y, u_k\rangle}$.
(iii) $\Rightarrow$ (iv) Put $y = x$: $\|x\|^2 = \langle x, x\rangle = \sum_{k\in K} \langle x, u_k\rangle\, \overline{\langle x, u_k\rangle} = \sum_{k\in K} \left|\langle x, u_k\rangle\right|^2$.
(iv) $\Rightarrow$ (i) By Theorem 5.2.22(ii), (iv) gives $\|\widehat{x}_{\mathcal{O}}\| = \|x\|$ for every $x \in \mathcal{H}$.
By Theorem 5.2.22(iv), $x \in \operatorname{cspan}(\mathcal{O})$ for every x, so $\operatorname{cspan}(\mathcal{O}) = \mathcal{H}$. Theorem 5.2.18 gives (i).
Structural Commentary: Totality, Fourier expansion, Parseval, and norm equality are equivalent.
Key Insight: Parseval preserves all Hilbert geometry. □

Theorem 5.2.24. *Existence and Cardinality of Hilbert Bases*
Let $\mathcal{H}$ be a Hilbert space.

(i) $\mathcal{H}$ admits a Hilbert basis.
(ii) If $\mathcal{B}, \mathcal{C}$ are Hilbert bases of $\mathcal{H}$, then $|\mathcal{B}| = |\mathcal{C}|$.

Proof.
(i) Let $\mathfrak{O}$ be the orthonormal subsets of $\mathcal{H}$, ordered by $\subseteq$. Chains in $\mathfrak{O}$ have orthonormal unions, so Principle 6.1.3 gives maximal $\mathcal{O} \in \mathfrak{O}$; by Theorem 5.2.18, $\mathcal{O}$ is a Hilbert basis.
(ii) Let $\mathcal{B} = \{b_i : i \in I\}$ and $\mathcal{C} = \{c_j : j \in J\}$ be Hilbert bases.
If $|I| < \infty$, Proposition 5.2.16 gives $\dim \mathcal{H} = |I|$; orthonormality gives $|J| \le \dim \mathcal{H}$, hence $|J| < \infty$, and Proposition 5.2.16 gives $|J| = \dim \mathcal{H}$. The case $|J| < \infty$ is symmetric.
Assume I, J infinite. For $i \in I$, set $J_i := \{j \in J : \langle b_i, c_j\rangle \neq 0\}$. By Theorem 5.2.21(iii), $|J_i| \le \aleph_0$.
Since $\mathcal{B}^\perp = \{\mathbf{0}\}$, $j \notin \bigcup_{i\in I} J_i$ is impossible; hence $J = \bigcup_{i\in I} J_i$ and $|J| \le \sum_{i\in I} |J_i| \le \aleph_0\, |I| = |I|$.
Symmetry gives $|I| \le |J|$; Theorem 6.2.3 gives $|I| = |J|$.
Structural Commentary: Zorn gives existence; countable coordinate supports compare cardinalities.
Key Insight: Hilbert-basis size is intrinsic. □

Definition 5.2.25. *Hilbert Dimension*
For a Hilbert space $\mathcal{H}$ with Hilbert basis $\mathcal{B}$, define $\operatorname{hdim}(\mathcal{H}) := |\mathcal{B}|$; this is well defined by Theorem 5.2.24.

Proposition 5.2.26. *The Hilbert Space $\ell^2(K)$*
Let K be a set and set $\ell^2(K) := \{f : K \to \mathbb{F} : \sum_{k\in K} |f(k)|^2 < \infty\}$.

(i) $\ell^2(K)$ is Hilbert under $\langle f, g\rangle := \sum_{k\in K} f(k)\overline{g(k)}$.
(ii) The coordinate family $(\delta_k)_{k\in K}$ is a Hilbert basis of $\ell^2(K)$.

Proof.

(i) For $f, g \in \ell^2(K)$ and finite $F \subseteq K$, $\sum_{k\in F} \left|f(k)\overline{g(k)}\right| \le (\sum_{k\in F} |f(k)|^2)^{1/2}(\sum_{k\in F} |g(k)|^2)^{1/2} \le \|f\|_2 \|g\|_2$, so $\langle f, g\rangle$ is well defined. If (f_n) is Cauchy, then $|f_m(k) - f_n(k)| \le \|f_m - f_n\|_2$ for each k, so set $f(k) := \lim_n f_n(k)$.
Given $\varepsilon > 0$, choose N with $\|f_m - f_n\|_2 < \varepsilon$ for $m, n \ge N$.
Then for finite $F \subseteq K$ and $n \ge N$, $\sum_{k\in F} |f(k) - f_n(k)|^2 = \lim_m \sum_{k\in F} |f_m(k) - f_n(k)|^2 \le \varepsilon^2$.
Hence $f - f_n \in \ell^2(K)$, $\|f - f_n\|_2 \le \varepsilon$, $f \in \ell^2(K)$, and $f_n \to f$.

(ii) $\langle \delta_j, \delta_k\rangle = \mathbf{1}_{\{j=k\}}$. If $f \perp \delta_k$ for every $k \in K$, then $f(k) = \langle f, \delta_k\rangle = 0$ for every k, so $(\delta_k)_{k\in K}^{\perp} = \{\mathbf{0}\}$.
By Theorem 5.2.18, $(\delta_k)_{k\in K}$ is a Hilbert basis.

Structural Commentary: Coordinatewise limits and uniform finite-subset bounds prove completeness.
Key Insight: Square-summability is precisely the norm condition for arbitrary orthogonal coordinates. □

Corollary 5.2.27. *Classification by Hilbert Dimension*
For Hilbert spaces $\mathcal{H}_1, \mathcal{H}_2$, $\mathcal{H}_1 \cong_{\text{iso}} \mathcal{H}_2$ iff $\operatorname{hdim}(\mathcal{H}_1) = \operatorname{hdim}(\mathcal{H}_2)$.

Proof.

(⇒) Let $U : \mathcal{H}_1 \to \mathcal{H}_2$ be a surjective linear isometry and let $\mathcal{B}$ be a Hilbert basis of $\mathcal{H}_1$.
Then $U\mathcal{B}$ is orthonormal and $\operatorname{cspan}(U\mathcal{B}) = U(\operatorname{cspan}\mathcal{B}) = \mathcal{H}_2$.
Thus $U\mathcal{B}$ is a Hilbert basis and $\operatorname{hdim}(\mathcal{H}_1) = |\mathcal{B}| = |U\mathcal{B}| = \operatorname{hdim}(\mathcal{H}_2)$.

(⇐) Let $\operatorname{hdim}(\mathcal{H}_1) = \operatorname{hdim}(\mathcal{H}_2) = |I|$, and choose Hilbert bases $(b_i)_{i\in I}$ and $(c_i)_{i\in I}$.
Define $\Phi_1 x := (i \mapsto \langle x, b_i\rangle)$ and $\Phi_2 y := (i \mapsto \langle y, c_i\rangle)$. By Corollary 5.2.23, $\|\Phi_1 x\|_2 = \|x\|$, $\|\Phi_2 y\|_2 = \|y\|$.
If $a = (a_i) \in \ell^2(I)$, then $\sum_{i\in I} a_i b_i$ and $\sum_{i\in I} a_i c_i$ converge by Theorem 5.2.21, with images a under Φ_1 and Φ_2.
Hence $U := \Phi_2^{-1}\Phi_1 : \mathcal{H}_1 \to \mathcal{H}_2$ is a surjective linear isometry.

Structural Commentary: Map both spaces isometrically onto the same coordinate model.
Key Insight: Hilbert spaces are classified by the number of orthogonal coordinate directions. □

Corollary 5.2.28. *Separable Hilbert Spaces*
$\mathcal{H}$ separable $\iff \operatorname{hdim}(\mathcal{H}) \le \aleph_0$.

Proof.

(⇒) Let $D \subseteq \mathcal{H}$ be countable dense and let $\mathcal{O}$ be a Hilbert basis. $\forall u \in \mathcal{O}$, choose $d_u \in D$ with $\|u - d_u\| < \frac{1}{3}$.
If $u \ne v$ and $d_u = d_v$, then $\sqrt{2} = \|u - v\| \le \|u - d_u\| + \|d_v - v\| < \frac{2}{3}$, impossible.
Hence $u \mapsto d_u$ injects $\mathcal{O}$ into D, so $\operatorname{hdim}(\mathcal{H}) = |\mathcal{O}| \le \aleph_0$.

(⇐) Let $\mathcal{O}$ be a Hilbert basis with $|\mathcal{O}| \le \aleph_0$. The finite $\mathbb{Q}$-span of $\mathcal{O}$ over $\mathbb{R}$, respectively finite $(\mathbb{Q} + i\mathbb{Q})$-span over $\mathbb{C}$, is countable and dense in $\operatorname{cspan}(\mathcal{O}) = \mathcal{H}$.

Structural Commentary: Countable bases and countable dense sets force each other.
Key Insight: Separability of a Hilbert space is exactly countability of its orthogonal coordinate directions. □

Corollary 5.2.29. *Infinite Hilbert Bases Are Not Hamel Bases*
If $\operatorname{hdim}(\mathcal{H})$ is infinite, no Hilbert basis of $\mathcal{H}$ is a Hamel basis.

Proof. Let $\mathcal{O}$ be Hilbert basis, choose distinct $u_n \in \mathcal{O}$.
Since $\sum_n 4^{-n} < \infty$, $x := \sum_n 2^{-n} u_n \in \mathcal{H}$ by Theorem 5.2.21.

For every n, continuity of $\langle \cdot, u_n\rangle$ gives $\langle x, u_n\rangle = 2^{-n} \ne 0$. If $\mathcal{O}$ were Hamel, then $x = \sum_{j=1}^{N} a_j v_j$ with $v_j \in \mathcal{O}$; choosing n with $u_n \notin \{v_1, \dots, v_N\}$ gives $\langle x, u_n\rangle = 0$, contradiction.
Structural Commentary: Infinite Hilbert coordinates allow square-summable infinite expansions.
Key Insight: A Hilbert basis spans by limits, while a Hamel basis spans by finite sums. □

Perspective 5.2.30. *Bounded Functionals*
Here $\mathcal{H}^* = \mathcal{L}(\mathcal{H}, \mathbb{F})$ by Definition 5.1.4 and Theorem 5.1.5.

Proposition 5.2.31. *Operator Norm Algebra*
Let $S, T \in \mathcal{L}(\mathcal{H})$ and $a \in \mathbb{F}$.

(i) $\|aT\|_{op} = |a| \|T\|_{op}$.
(ii) $\|S + T\|_{op} \le \|S\|_{op} + \|T\|_{op}$.
(iii) $\|ST\|_{op} \le \|S\|_{op} \|T\|_{op}$.
(iv) $\mathcal{L}(\mathcal{H})$ is a normed algebra under composition.

Proof.

(i) $\|aT\|_{\text{op}} = \sup_{\|x\|\le 1} \|aTx\| = |a| \sup_{\|x\|\le 1} \|Tx\| = |a| \|T\|_{\text{op}}$.

(ii) For $\|x\| \le 1$, $\|(S + T)x\| \le \|Sx\| + \|Tx\| \le \|S\|_{\text{op}} + \|T\|_{\text{op}}$; taking sup gives the claim.

(iii) For $\|x\| \le 1$, $\|STx\| \le \|S\|_{\text{op}} \|Tx\| \le \|S\|_{\text{op}} \|T\|_{\text{op}}$; taking sup gives the claim.

(iv) Items (i)–(ii), with $\|T\|_{\text{op}} = 0 \Rightarrow T = 0$, give a norm on $\mathcal{L}(\mathcal{H})$.
Item (iii) gives closure and submultiplicativity for associative composition.

Structural Commentary: Composition multiplies stretch bounds.
Key Insight: Bounded operators behave like matrices with a compatible norm. □

Theorem 5.2.32. *Riesz Representation for Hilbert Spaces*
For $\varphi \in \mathcal{H}^*$:

(i) $\exists! y \in \mathcal{H}$ *such that* $\forall x \in \mathcal{H}$, $\varphi(x) = \langle x, y\rangle$.

(ii) The representing vector satisfies $\|\varphi\|_{op} = \|y\|$.

Proof.

(i) If $\varphi = 0$, take $y = 0$. If $\varphi \neq 0$, set $M := \ker\varphi$, $a \notin M$, $a = p + u$, $p \in M$, $u \in M^{\perp}$ by Corollary 5.2.10.
Then $u \neq 0$ and $\varphi(u) = \varphi(a) \neq 0$. For $x \in \mathcal{H}$, $x - \frac{\varphi(x)}{\varphi(u)}u \in M$, hence $\langle x, u\rangle = \frac{\varphi(x)}{\varphi(u)}\|u\|^2$.
Thus $y := \overline{\varphi(u)}\,\|u\|^{-2}\,u$ satisfies $\varphi(x) = \langle x, y\rangle$ for every x.
If z also represents φ, then $\langle x, y - z\rangle = 0$ for every x; with $x = y - z$, $z = y$.

(ii) For every x, $|\varphi(x)| = \big|\langle x, y\rangle\big| \leq \|x\|\,\|y\|$, so $\|\varphi\|_{\mathrm{op}} \leq \|y\|$.
If $y \neq 0$, then $\|\varphi\|_{\mathrm{op}} \geq \frac{|\varphi(y)|}{\|y\|} = \|y\|$; if $y = 0$, both norms vanish.

Structural Commentary: The kernel is a hyperplane; its orthogonal direction represents the functional.
Key Insight: Bounded functionals are exactly inner products with fixed vectors. □

Corollary 5.2.33. *Riesz Identifies the Continuous Dual*
Define $R : \mathcal{H} \to \mathcal{H}^*$ *by* $Ry := (x \mapsto \langle x, y\rangle)$.

(i) R *is an isometric bijection.*
(ii) R *is conjugate-linear over* $\mathbb{C}$ *and linear over* $\mathbb{R}$.

Proof.

(i) For $y \in \mathcal{H}$, $|Ry(x)| = \big|\langle x, y\rangle\big| \leq \|x\|\,\|y\|$, so $Ry \in \mathcal{H}^*$. By Theorem 5.2.32, $\mathcal{H}^* = R(\mathcal{H})$ and $\|Ry\|_{\mathrm{op}} = \|y\|$.
If $Ry = Rz$, then $0 = \|R(y - z)\|_{\mathrm{op}} = \|y - z\|$; hence R is bijective and isometric.

(ii) For $x, y, z \in \mathcal{H}$ and $\alpha, \beta \in \mathbb{C}$, $R(\alpha y + \beta z)(x) = \langle x, \alpha y + \beta z\rangle = \overline{\alpha}Ry(x) + \overline{\beta}Rz(x)$.
Over $\mathbb{R}$, $R(\alpha y + \beta z) = \alpha Ry + \beta Rz$.

Structural Commentary: Continuous functionals are represented by vectors.
Key Insight: Riesz identifies $\mathcal{H}^*$ with $\mathcal{H}$, up to complex conjugation. □

Theorem 5.2.34. *Bounded Hilbert Adjoints*
Let $T \in \mathcal{L}(\mathcal{H})$.

(i) $\exists! T^* \in \mathcal{L}(\mathcal{H})$ *such that* $\forall u, v \in \mathcal{H}$, $\langle Tu, v\rangle = \langle u, T^*v\rangle$.
(ii) $\|T^*\|_{op} = \|T\|_{op}$.
(iii) $(T^*)^* = T$.

Proof.

(i) For $v \in \mathcal{H}$, set $\phi_v(u) := \langle Tu, v\rangle$. Since $|\phi_v(u)| \leq \|T\|_{\mathrm{op}}\,\|v\|\,\|u\|$, $\phi_v \in \mathcal{H}^*$.
By Theorem 5.2.32, $\exists! T^*v \in \mathcal{H}$ with $\phi_v(u) = \langle u, T^*v\rangle$ for every u.
For $\alpha, \beta \in \mathbb{F}$, $\phi_{\alpha v + \beta w} = \overline{\alpha}\phi_v + \overline{\beta}\phi_w$, so uniqueness gives $T^*(\alpha v + \beta w) = \alpha T^*v + \beta T^*w$.
Also $\|T^*v\| = \|\phi_v\|_{\mathrm{op}} \leq \|T\|_{\mathrm{op}}\,\|v\|$, hence $T^* \in \mathcal{L}(\mathcal{H})$.
If A also satisfies the adjoint identity, then $\langle u, (T^* - A)v\rangle = 0$ for every u, v, so $A = T^*$.

(ii) If $\mathcal{H} = \{\mathbf{0}\}$, immediate. Else $\|T\|_{\mathrm{op}} = \sup_{\|u\|=\|v\|=1}\big|\langle Tu, v\rangle\big| = \sup_{\|u\|=\|v\|=1}\big|\langle u, T^*v\rangle\big| = \|T^*\|_{\mathrm{op}}$.

(iii) For $u, v \in \mathcal{H}$, $\langle T^*u, v\rangle = \overline{\langle v, T^*u\rangle} = \overline{\langle Tv, u\rangle} = \langle u, Tv\rangle$.
Thus T satisfies the adjoint identity for T^*; by uniqueness, $(T^*)^* = T$.

Structural Commentary: Riesz turns the scalar tests induced by an operator back into vectors.
Key Insight: The adjoint is the dual action transported through the Hilbert-space Riesz map. □

Corollary 5.2.35. *Hilbert Adjoint Algebra Identities*
Let $S, T \in \mathcal{L}(\mathcal{H})$ *and* $a \in \mathbb{F}$.

(i) $(aS + T)^* = \overline{a}S^* + T^*$.
(ii) $(ST)^* = T^*S^*$.

Proof.

(i) For $u, v \in \mathcal{H}$, $\langle (aS + T)u, v\rangle = a\langle Su, v\rangle + \langle Tu, v\rangle = \langle u, \overline{a}S^*v + T^*v\rangle$.
Uniqueness of adjoints gives $(aS + T)^* = \overline{a}S^* + T^*$.

(ii) For $u, v \in \mathcal{H}$, $\langle STu, v\rangle = \langle Tu, S^*v\rangle = \langle u, T^*S^*v\rangle$; uniqueness gives $(ST)^* = T^*S^*$.

Structural Commentary: Move each operator across one inner product and invoke adjoint uniqueness.
Key Insight: Taking adjoints reverses composition and conjugates scalars. □

Definition 5.2.36. *Self-Adjoint, Nonnegative, and Coercive Operators*
Let $T \in \mathcal{L}(\mathcal{H})$.

(i) *Self-adjoint*: $T = T^*$.
(ii) *Nonnegative*: $T = T^*$ and $\forall h \in \mathcal{H}$, $\langle Th, h\rangle \geq 0$; write $T \geq 0$.
(iii) *Coercive*: if $\mathcal{H}$ is real, $\exists c > 0$ such that $\forall h \in \mathcal{H}$, $\langle Th, h\rangle \geq c\,\|h\|^2$.

Proposition 5.2.37. *Positive Order, Polarization, and Reducing Complements*
Let $\mathcal{H}$ *be a real Hilbert space.*

(i) If $T \geq 0$ *and* $S \in \mathcal{L}(\mathcal{H})$, *then* $S^*TS \geq 0$.
(ii) If $T \in \mathcal{L}(\mathcal{H})$ *is self-adjoint and* $Q_T(u) := \langle Tu, u\rangle$, *then* $\langle Tu, v\rangle = \frac{1}{4}\left[Q_T(u + v) - Q_T(u - v)\right]$.
(iii) If $T \in \mathcal{L}(\mathcal{H})$ *is self-adjoint and* $Q_T \equiv 0$, *then* $T = 0$.
(iv) If $T \in \mathcal{L}(\mathcal{H})$ *is self-adjoint and* $V \leq \mathcal{H}$ *satisfies* $T(V) \subseteq V$, *then* $T(V^{\perp}) \subseteq V^{\perp}$.

Proof.

(i) Since $T = T^*$, $(S^*TS)^* = S^*T^*S = S^*TS$. For $h \in \mathcal{H}$, $\langle S^*TSh, h\rangle = \langle TSh, Sh\rangle \geq 0$; hence $S^*TS \geq 0$.

(ii) For $u, v \in \mathcal{H}$, self-adjointness gives $Q_T(u \pm v) = Q_T(u) \pm 2\langle Tu, v\rangle + Q_T(v)$.
Subtracting gives $Q_T(u+v) - Q_T(u-v) = 4\langle Tu, v\rangle$.
(iii) By (ii), $\langle Tu, v\rangle = 0$ for all $u, v \in \mathcal{H}$; with $v = Tu$, $\|Tu\|^2 = 0$ for every u, so $T = 0$.
(iv) If $w \in V^\perp$ and $v \in V$, then $Tv \in V$ and $\langle Tw, v\rangle = \langle w, Tv\rangle = 0$; hence $Tw \in V^\perp$.

Structural Commentary: Adjoints transfer positivity and invariance; polarization recovers mixed terms.
Key Insight: For self-adjoint operators, the diagonal quadratic form controls the mixed inner products. □

Theorem 5.2.38. *Self-Adjoint Operator Norm from the Quadratic Form*
If $\mathcal{H}$ is real and $T \in \mathcal{L}(\mathcal{H})$ is self-adjoint, then $\|T\|_{op} = \sup_{\|u\|=1} \left|\langle Tu, u\rangle\right|$.

Proof. Let $\eta := \sup_{\|u\|=1} \left|\langle Tu, u\rangle\right|$. By Cauchy–Schwarz, $\eta \le \|T\|_{\mathrm{op}}$.
If $\eta = 0$, then $Q_T \equiv 0$ by scaling, so $T = 0$ by Proposition 5.2.37(iii).
Assume $\eta > 0$ and set $A_\pm := \eta I \pm T$. For $u \in \mathcal{H}$, $\left|\langle Tu, u\rangle\right| \le \eta \|u\|^2$, hence $\langle A_\pm u, u\rangle \ge 0$ and $A_\pm \ge 0$.
By Proposition 5.2.37(i), $A_+^* A_- A_+ \ge 0$ and $A_-^* A_+ A_- \ge 0$.
Since $A_\pm = A_\pm^*$ and $A_+A_- = A_-A_+ = \eta^2 I - T^2$, their sum is $2\eta(\eta^2 I - T^2) \ge 0$, so $\eta^2 I - T^2 \ge 0$.
Thus $\|Tu\|^2 = \langle T^2 u, u\rangle \le \eta^2 \|u\|^2$ for every u, hence $\|T\|_{\mathrm{op}} \le \eta$.
Structural Commentary: Self-adjointness lets order information about $\eta I \pm T$ control T^2.
Key Insight: A bounded self-adjoint operator is normed by its one-vector quadratic tests. □

Proposition 5.2.39. *Closed Range and the Adjoint Kernel*
If $T \in \mathcal{L}(\mathcal{H})$ has closed range, then $\mathcal{H} = \operatorname{range}(T) \odot \ker(T^*)$.

Proof. For $z \in \mathcal{H}$, $z \in \ker(T^*) \iff \forall u \in \mathcal{H},\ \langle u, T^* z\rangle = 0 \iff \forall u \in \mathcal{H},\ \langle Tu, z\rangle = 0 \iff z \in \operatorname{range}(T)^\perp$.
Thus $\ker(T^*) = \operatorname{range}(T)^\perp$, and Corollary 5.2.10 gives $\mathcal{H} = \operatorname{range}(T) \odot \ker(T^*)$ since $\operatorname{range}(T)$ is closed.
Structural Commentary: Identify the orthogonal complement of the range by moving T across the inner product.
Key Insight: The directions missed by T are exactly the vectors annihilated by T^*. □

Theorem 5.2.40. *Coercive Operators Are Invertible*
Let $\mathcal{H}$ be real and let $T \in \mathcal{L}(\mathcal{H})$ satisfy $\exists c > 0$ such that $\forall h \in \mathcal{H}$, $\langle Th, h\rangle \ge c\|h\|^2$.
(i) T is bijective.
(ii) $T^{-1} \in \mathcal{L}(\mathcal{H})$ and $\left\|T^{-1}\right\|_{op} \le c^{-1}$.

Proof. For $u \ne \mathbf{0}$, $c\|u\|^2 \le \langle Tu, u\rangle \le \|Tu\|\,\|u\|$, hence $\|Tu\| \ge c\|u\|$; the same holds for $u = \mathbf{0}$, so $\ker T = \{\mathbf{0}\}$.
If $Tu_n \to y$, then $\|u_n - u_m\| \le c^{-1}\|Tu_n - Tu_m\|$; hence $u_n \to u$ and $Tu = y$, so $\operatorname{range}(T)$ is closed.
Also $\langle T^* h, h\rangle = \langle Th, h\rangle \ge c\|h\|^2$, so $\ker(T^*) = \{\mathbf{0}\}$.
(i) By Proposition 5.2.39, $\mathcal{H} = \operatorname{range}(T) \odot \ker(T^*) = \operatorname{range}(T)$; with $\ker T = \{\mathbf{0}\}$, T is bijective.
(ii) For $y \in \mathcal{H}$, put $u = T^{-1}y$. Then $c\left\|T^{-1}y\right\| = c\|u\| \le \|Tu\| = \|y\|$, so $T^{-1} \in \mathcal{L}(\mathcal{H})$ and $\left\|T^{-1}\right\|_{\mathrm{op}} \le c^{-1}$.

Structural Commentary: Coercivity closes the range and kills both kernels; adjoint splitting gives surjectivity.
Key Insight: Coercivity supplies both a lower Lipschitz bound and, through the adjoint, surjectivity. □

Theorem 5.2.41. *Lax–Milgram Lemma*
Let $\mathcal{H}$ be a real Hilbert space and let $B : \mathcal{H} \times \mathcal{H} \to \mathbb{R}$ be bilinear.
Suppose there are constants $M, c > 0$ such that $|B(u,v)| \le M\|u\|\,\|v\|$ and $B(h,h) \ge c\|h\|^2$ $\forall u, v, h \in \mathcal{H}$.
Then $\forall \psi \in \mathcal{H}^*$ $\exists! h \in \mathcal{H}$ such that $\psi(u) = B(h, u)$ $(u \in \mathcal{H})$.

Proof. Let $R : \mathcal{H} \to \mathcal{H}^*$ be the real Riesz isometry, $Ry(u) = \langle u, y\rangle$, and define $S : \mathcal{H} \to \mathcal{H}^*$ by $Sh(u) = B(h, u)$. For $h, u \in \mathcal{H}$, $|Sh(u)| \le M\|h\|\,\|u\|$, hence $S \in \mathcal{L}(\mathcal{H}, \mathcal{H}^*)$.
Set $A := R^{-1}S \in \mathcal{L}(\mathcal{H})$. For $h \in \mathcal{H}$, $\langle Ah, h\rangle = \langle h, Ah\rangle = (RAh)(h) = Sh(h) = B(h,h) \ge c\|h\|^2$.
By Theorem 5.2.40, A is bijective, hence $S = RA$ is bijective.
For $\psi \in \mathcal{H}^*$, set $h := A^{-1}R^{-1}\psi$; then $\forall u \in \mathcal{H}$, $\psi(u) = (RAh)(u) = Sh(u) = B(h, u)$.
If h_1, h_2 solve this identity, then $S(h_1 - h_2) = 0$, so $h_1 = h_2$.
Structural Commentary: A coercive bilinear form is a Riesz-represented coercive operator in disguise.
Key Insight: Solving $B(h, \cdot) = \psi$ is solving an invertible operator equation after Riesz representation. □

Theorem 5.2.42. *Orthonormal Systems in L^2*
Let $(\phi_n)_{n\ge1} \subseteq L^2(\mu)$ be orthonormal, $\langle \phi_n, \phi_m\rangle = \delta_{nm}$, and $c_n(f) := \langle f, \phi_n\rangle = \int_X f\overline{\phi_n}\,d\mu$.

(i) $\forall f \in L^2(\mu)$, $\sum_{n=1}^{\infty} |c_n(f)|^2 \le \|f\|_2^2$.

(ii) If $(c_n) \in \ell^2$, then $s_N := \sum_{k=1}^{N} c_k \phi_k$ converges in $L^2(\mu)$.

(iii) If (ϕ_n) is complete, then $\forall f \in L^2(\mu)$, $\|f\|_2^2 = \sum_{n=1}^{\infty} |c_n(f)|^2$.

Proof.

(i) Set $s_N(f) := \sum_{k=1}^{N} c_k(f)\phi_k$. Finite orthonormality gives $\|f - s_N(f)\|_2^2 = \|f\|_2^2 - \sum_{k=1}^{N} |c_k(f)|^2 \ge 0$.
Monotone convergence of the partial sums yields $\sum_{n=1}^{\infty} |c_n(f)|^2 \le \|f\|_2^2$.

(ii) If $m < N$, then $\|s_N - s_m\|_2^2 = \sum_{k=m+1}^{N} |c_k|^2$. Since $(c_n) \in \ell^2$, (s_N) is Cauchy.
By completeness, $\exists g \in L^2(\mu)$ with $s_N \to g$.

(iii) Assume (ϕ_n) is complete. By (i), $(c_n(f)) \in \ell^2$; by (ii), $s_N(f) \to g$.
For fixed j, $\langle s_N(f), \phi_j\rangle = c_j(f)$ for $N \geq j$, hence $\langle f-g, \phi_j\rangle = c_j(f) - \lim_N \langle s_N(f), \phi_j\rangle = 0$.
Thus $f - g \perp \{\phi_j : j \geq 1\}$, so $f = g$; therefore $\|f\|_2^2 = \lim_N \|s_N(f)\|_2^2 = \sum_{n=1}^{\infty} |c_n(f)|^2$.

Structural Commentary: Complete orthonormal systems coordinatize L^2 by square-summable sequences.
Key Insight: Parseval is Pythagoras after passing from finite coordinates to an L^2 limit. □

Method 5.2.43. *Hilbert Space Proof Patterns*

(i) *Complete*: Cauchy tails, completions, and convergent subsequences force limits.
(ii) *Parallelogram*: test Hilbertian norms and make distance-minimizing sequences Cauchy.
(iii) *Project*: for closed M, write $x = p + r$, $p \in M$, $r \in M^\perp$.
(iv) *Separate*: density and equality via $M^\perp = \{\mathbf{0}\}$ and $M^{\perp\perp} = \overline{M}$.
(v) *Sum*: arbitrary convergence is net convergence over $\mathcal{F}(K)$; control finite tails.
(vi) *Expand*: orthonormal finite identities + Bessel bounds + completeness ⇒ Fourier expansions.
(vii) *Classify*: Hilbert bases give hdim, separability, and $\mathcal{H} \cong \ell^2(K)$.
(viii) *Dualize*: Riesz identifies $\mathcal{H}^*$ with $\mathcal{H}$, producing adjoints and coercive operator equations.

Key Insight: Hilbert-space arguments are finite orthogonal geometry plus completeness.

5.3 Core Functional Analytic Theorems

The core theorems explain why complete normed spaces behave rigidly under linear maps. Hahn–Banach supplies norm-preserving extensions, while Baire category turns pointwise control into uniform boundedness.

Theorem 5.3.1. *Hahn–Banach Extension Theorem*
Let $\mathcal{X}$ be a real normed space, $M \leq \mathcal{X}$, $p : \mathcal{X} \to \mathbb{R}$ sublinear, and $\varphi : M \to \mathbb{R}$ linear with $\varphi \leq p$ on M.

(i) If $x_0 \in \mathcal{X} \setminus M$ and $M_0 := M + \mathbb{R}x_0$, then $\exists \varphi_0 : M_0 \to \mathbb{R}$ linear such that $\varphi_0|_M = \varphi$ and $\varphi_0 \leq p$ on M_0.
(ii) $\exists \Phi : \mathcal{X} \to \mathbb{R}$ linear such that $\Phi|_M = \varphi$ and $\Phi \leq p$ on $\mathcal{X}$.

Proof.

(i) For $y, z \in M$, $\varphi(y) + \varphi(z) = \varphi(y+z) \leq p(y+z) \leq p(y - x_0) + p(z + x_0)$; $\varphi(y) - p(y - x_0) \leq p(z + x_0) - \varphi(z)$.
Set $a := \sup_{y \in M} (\varphi(y) - p(y - x_0))$, $b := \inf_{z \in M} (p(z + x_0) - \varphi(z))$. Then $-p(-x_0) \leq a \leq b \leq p(x_0)$; $\alpha \in [a, b]$.
Since $x_0 \notin M$, $y + tx_0$ has unique coordinates, so define $\varphi_0(y + tx_0) := \varphi(y) + t\alpha$.
If $t > 0$, then $\varphi_0(y + tx_0) = t(\varphi(y/t) + \alpha) \leq tp(y/t + x_0) = p(y + tx_0)$.
If $t < 0$, then $\varphi_0(y + tx_0) = (-t)(\varphi(y/(-t)) - \alpha) \leq (-t)p(y/(-t) - x_0) = p(y + tx_0)$.
If $t = 0$, domination is $\varphi \leq p$ on M.
(ii) Let $\mathscr{E}$ be (N, ψ), $M \leq N \leq \mathcal{X}$, $\psi : N \to \mathbb{R}$ linear, $\psi|_M = \varphi$, $\psi \leq p$ on N, ordered by extension.
Chains have upper bound $(\bigcup N_i, \psi_*)$, where $\psi_*|_{N_i} = \psi_i$, so Principle 6.1.3 gives maximal $(N_*, \psi_*) \in \mathscr{E}$.
If $N_* \neq \mathcal{X}$, choose $x_0 \in \mathcal{X} \setminus N_*$; by (i), ψ_* extends to $N_* + \mathbb{R}x_0$, contradiction. Thus $N_* = \mathcal{X}$ and $\Phi := \psi_*$.

Structural Commentary: Extend across one new direction while preserving domination, then use maximality.
Key Insight: Sublinearity leaves a nonempty interval of admissible values on each added direction. □

Corollary 5.3.2. *Norm-Preserving Extensions and Norming Functionals*
Let $\mathcal{X}$ be a normed space and let $M \subseteq \mathcal{X}$ be a linear subspace.

(i) A bounded linear functional $\varphi : M \to \mathbb{F}$ admits an extension $\Phi \in \mathcal{X}^*$ with $\|\Phi\|_{op} = \|\varphi\|_{op}$.
(ii) $\forall 0 \neq x \in \mathcal{X}$ $\exists \Phi \in \mathcal{X}^*$ such that $\|\Phi\|_{op} = 1$ and $\Phi(x) = \|x\|$.

Proof.

(i) If $\mathbb{F} = \mathbb{R}$, apply Theorem 5.3.1 with $p(u) := \|\varphi\|_{\mathrm{op}} \|u\|$ to get $\Phi|_M = \varphi$ and $\Phi \leq p$.
Since $-\Phi(u) = \Phi(-u) \leq p(u)$, $|\Phi(u)| \leq \|\varphi\|_{\mathrm{op}} \|u\| \forall u \in \mathcal{X}$, so $\|\Phi\|_{\mathrm{op}} \leq \|\varphi\|_{\mathrm{op}}$; restriction gives equality.
If $\mathbb{F} = \mathbb{C}$, apply the real case to $\operatorname{Re}\varphi$ and set $\Phi(u) := F(u) - iF(iu)$.
Then $\Phi|_M = \varphi$, Φ is complex-linear, and $|\Phi(u)| = \sup_{|\alpha|=1} F(\alpha u) \leq \|\varphi\|_{\mathrm{op}} \|u\|$, so again $\|\Phi\|_{\mathrm{op}} = \|\varphi\|_{\mathrm{op}}$.
(ii) Fix $0 \neq x \in \mathcal{X}$, put $M_x := \mathbb{F}x$, and define $\varphi_x(\lambda x) := \lambda \|x\|$.
Then $\|\varphi_x\|_{\mathrm{op}} = 1$ and $\varphi_x(x) = \|x\|$; by (i), choose $\Phi \in \mathcal{X}^*$ with $\Phi|_{M_x} = \varphi_x$ and $\|\Phi\|_{\mathrm{op}} = 1$.

Structural Commentary: Preserve the norm, then extend a one-dimensional norming functional.
Key Insight: Hahn–Banach continues a bounded scalar test without weakening its norm bound. □

Corollary 5.3.3. *Natural Embedding Is an Isometry*
For a normed space $\mathcal{X}$, the canonical map $J : \mathcal{X} \to \mathcal{X}^{**}$, $Jx(\Phi) = \Phi(x)$, satisfies $\|Jx\|_{op} = \|x\|$ $(x \in \mathcal{X})$.

Proof. $\forall \Phi \in \mathcal{X}^*$, $|Jx(\Phi)| = |\Phi(x)| \leq \|\Phi\|_{\mathrm{op}} \|x\|$, so $\|Jx\|_{\mathrm{op}} \leq \|x\|$. If $x \neq 0$, choose $\Phi \in \mathcal{X}^*$ with $\|\Phi\|_{\mathrm{op}} = 1$ and $\Phi(x) = \|x\|$ by Corollary 5.3.2; hence $\|Jx\|_{\mathrm{op}} \geq \|x\|$. The case $x = 0$ is immediate.
Structural Commentary: The upper bound is duality; a norming functional attains the matching lower bound.
Key Insight: The double dual records every vector without changing its norm. □

Example 5.3.4. *A Dominated Extension of the Limit Functional*
On real ℓ^∞, set $p((x_n)) := \limsup_{n\to\infty} x_n$. This functional is subadditive and positively homogeneous.
If $c \subseteq \ell^\infty$ is the subspace of convergent sequences and $L((x_n)) := \lim_{n\to\infty} x_n$, then $L \leq p$ on c.
By Theorem 5.3.1, L extends to a linear functional $\Lambda : \ell^\infty \to \mathbb{R}$ with $\Lambda(x) \leq \limsup_{n\to\infty} x_n$ $(x \in \ell^\infty)$.
This is the Hahn–Banach domination step behind limit-extension arguments on ℓ^∞.

Corollary 5.3.5. *Positive Riesz Representation on $C([a,b])$*
Let $J=[a,b]$ and let $G\in C(J)^*$ be positive, i.e. $f\ge 0$ on J implies $G(f)\ge 0$.

(i) $\exists\gamma:\mathcal{B}(\mathbb{R})\to[0,+\infty]$ *a finite Borel measure with* $\operatorname{supp}\gamma\subseteq J$ *and* $\forall f\in C(J)$, $G(f)=\int_J f\,d\gamma$.
(ii) $\|G\|_{op}=G(\mathbf{1}_J)=\gamma(J)$.

Proof.

(i) By Theorem 5.2.14, $\exists$ finite Radon μ on J such that $G(f)=\int_J f\,d\mu$ for $f\in C(J)$.
Define $\gamma(E):=\mu(E\cap J)$ for $E\in\mathcal{B}(\mathbb{R})$. Then $\gamma(\mathbb{R}\setminus J)=0$, so $\operatorname{supp}\gamma\subseteq J$, and $\int_J f\,d\gamma=\int_J f\,d\mu=G(f)$.
(ii) If $\|f\|_\infty\le 1$, then $\mathbf{1}_J\pm f\ge 0$, hence $-G(\mathbf{1}_J)\le G(f)\le G(\mathbf{1}_J)$ and $|G(f)|\le G(\mathbf{1}_J)$.
Thus $\|G\|_{\mathrm{op}}\le G(\mathbf{1}_J)$; taking $f=\mathbf{1}_J$ gives $\|G\|_{\mathrm{op}}\ge G(\mathbf{1}_J)$. Also $G(\mathbf{1}_J)=\int_J \mathbf{1}_J\,d\gamma=\gamma(J)$.

Structural Commentary: Specialize Riesz–Markov to the interval, then extend the measure by zero.
Key Insight: Positivity converts the order unit $\mathbf{1}_J$ into the exact dual norm. □

Corollary 5.3.6. *Signed Riesz Representation by a Charge*
Let $J=[a,b]$, and suppose $G\in C(J)^*$ admits $G=G^+-G^-$ with positive $G^\pm\in C(J)^*$.
Then $\exists\lambda:\mathcal{B}(\mathbb{R})\to\mathbb{R}$ a charge with $\operatorname{supp}\lambda\subseteq J$ and $\forall f\in C(J)$, $G(f)=\int_J f\,d\lambda$.

Proof. By Corollary 5.3.5, choose finite Borel measures $\gamma^\pm$ on $\mathbb{R}$ such that $\gamma^\pm(\mathbb{R}\setminus J)=0$ and $G^\pm(f)=\int_J f\,d\gamma^\pm$ for $f\in C(J)$. Define $\lambda(E):=\gamma^+(E)-\gamma^-(E)$ for $E\in\mathcal{B}(\mathbb{R})$.
Then λ is a charge, $\lambda(\mathbb{R}\setminus J)=0$, and for $f\in C(J)$, $G(f)=G^+(f)-G^-(f)=\int_J f\,d\gamma^+-\int_J f\,d\gamma^-=\int_J f\,d\lambda$.
Structural Commentary: Subtract the positive representing measures.
Key Insight: Signed representation is positive representation plus subtraction. □

Theorem 5.3.7. *Uniform Boundedness Principle*
Let $\mathcal{X}$ be Banach, $\mathcal{Y}$ normed. If $\mathcal{F}\subseteq\mathcal{L}(\mathcal{X},\mathcal{Y})$ pointwise bounded, $\forall x\in\mathcal{X}$, $\sup_{T\in\mathcal{F}}\|Tx\|<\infty$, then $\sup_{T\in\mathcal{F}}\|T\|_{op}<\infty$.

Proof. For $T\in\mathcal{F}$, $f_T(x):=\|Tx\|$ is continuous. Pointwise boundedness and Theorem 5.1.33 give $x_0\in\mathcal{X}$, $r>0$, and $C<\infty$ with $\sup_{T\in\mathcal{F}}\|Tz\|\le C$ for $z\in B(x_0,r)$. Set $M_0:=\sup_{T\in\mathcal{F}}\|Tx_0\|<\infty$.
If $\|y\|<r$, then $\sup_{T\in\mathcal{F}}\|Ty\|\le\sup_{T\in\mathcal{F}}\|T(x_0+y)\|+\sup_{T\in\mathcal{F}}\|Tx_0\|\le C+M_0$.
For $\|x\|=1$ and $0<t<r$, $t\sup_{T\in\mathcal{F}}\|Tx\|=\sup_{T\in\mathcal{F}}\|T(tx)\|\le C+M_0$. By $t\uparrow r$, $\sup_{T\in\mathcal{F}}\|T\|_{\mathrm{op}}\le\frac{C+M_0}{r}<\infty$.
Structural Commentary: Baire controls one ball; translation and scaling transfer control to the unit ball.
Key Insight: Baire and linearity turn pointwise bounds into one uniform operator bound. □

Corollary 5.3.8. *Banach–Steinhaus Pointwise Limit Theorem*
Let $\mathcal{X}$ be Banach, $\mathcal{Y}$ normed, $(T_n)\subseteq\mathcal{L}(\mathcal{X},\mathcal{Y})$. Suppose $\forall x\in\mathcal{X}$, T_nx converges in $\mathcal{Y}$, $Tx:=\lim_{n\to\infty}T_nx$.

(i) $\sup_n\|T_n\|_{op}<\infty$.
(ii) T *is linear.*
(iii) $T\in\mathcal{L}(\mathcal{X},\mathcal{Y})$ *and* $\|T\|_{op}\le\liminf_{n\to\infty}\|T_n\|_{op}$.

Proof.

(i) For each $x\in\mathcal{X}$, convergence of (T_nx) gives $\sup_n\|T_nx\|<\infty$; hence Theorem 5.3.7 gives $\sup_n\|T_n\|_{\mathrm{op}}<\infty$.
(ii) For $\alpha,\beta\in\mathbb{F}$ and $x,y\in\mathcal{X}$, $T(\alpha x+\beta y)=\lim_n T_n(\alpha x+\beta y)=\alpha Tx+\beta Ty$.
(iii) Let $L:=\liminf_n\|T_n\|_{\mathrm{op}}<\infty$. For $x\in\mathcal{X}$, $\|Tx\|=\lim_n\|T_nx\|\le L\|x\|$, so $T\in\mathcal{L}(\mathcal{X},\mathcal{Y})$ and $\|T\|_{\mathrm{op}}\le L$.

Structural Commentary: Uniform boundedness controls the family before taking its pointwise limit.
Key Insight: Completeness prevents the norms of pointwise-convergent operators from escaping. □

5.4 Open Mapping, Closed Graph, and Complemented Subspaces

The Baire-category principle has three operator-theoretic consequences that should be read together: closed range gives uniform preimage estimates, open maps are detected at the unit ball, and closed graphs force boundedness.

Theorem 5.4.1. *Closed Range Estimate*
Let $\mathcal{X},\mathcal{Y}$ be Banach spaces, let $T\in\mathcal{L}(\mathcal{X},\mathcal{Y})$, and set $\mathcal{R}:=T(\mathcal{X})$. The following are equivalent.

(i) $\mathcal{R}$ *is closed in* $\mathcal{Y}$.
(ii) $\exists M>0$ *such that* $\forall y\in\mathcal{R}$ $\exists x\in\mathcal{X}$ *with* $Tx=y$ *and* $\|x\|\le M\|y\|$.

Proof.

(ii) $\Rightarrow$ *(i)* Let $y\in\overline{\mathcal{R}}$. Choose $y_n\in\mathcal{R}$ with $y_n\to y$ and $\|y_n-y_{n-1}\|\le 2^{-n}$ for $n\ge 2$.
Pick $x_1,u_n\in\mathcal{X}$ with $Tx_1=y_1$, $Tu_n=y_n-y_{n-1}$, and $\|u_n\|\le M2^{-n}$.
Since $\sum_{n\ge2}\|u_n\|<\infty$, $x:=x_1+\sum_{n\ge2}u_n$ exists and $Tx=\lim_N y_N=y$, so $y\in\mathcal{R}$.

(i) $\Rightarrow$ *(ii)* If $\mathcal{R}=\{\mathbf{0}\}$, take $M=1$. Otherwise $\mathcal{R}$ is Banach and $\mathcal{R}=\bigcup_{n\ge1}n\,\overline{T(B_{\mathcal{X}})}^{\mathcal{R}}$.
By Baire and balanced convexity, $\exists c>0$ with $\overline{B}_{\mathcal{R}}\subseteq c\,\overline{T(B_{\mathcal{X}})}^{\mathcal{R}}$.
Thus each $0\ne r\in\mathcal{R}$ has $u\in\mathcal{X}$ with $\|u\|\le c\|r\|$ and $\|r-Tu\|\le\frac12\|r\|$.
For $y\ne0$, iterate from $r_0=y$ to get $r_k=r_{k-1}-Tu_k$, $\|r_k\|\le2^{-k}\|y\|$, and $\|u_k\|\le c2^{1-k}\|y\|$.
Then $x:=\sum_{k\ge1}u_k$ satisfies $Tx=y$ and $\|x\|\le2c\|y\|$. For $y=0$, take $x=0$.

Structural Commentary: Baire category turns surjectivity onto a closed range into uniform preimage control.
Key Insight: Closed range is equivalent to solving $Tx=y$ with a norm bound proportional to $\|y\|$. □

Proposition 5.4.2. *Relative Openness and Closed Range*
Let $\mathcal{X}, \mathcal{Y}$ be Banach spaces, $T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$.
Then $T : \mathcal{X} \to T(\mathcal{X})$ is open, for subspace topology on range, iff $T(\mathcal{X})$ closed in $\mathcal{Y}$.

Proof. Let $\mathcal{R} := T(\mathcal{X})$.

($\Rightarrow$) If $T : \mathcal{X} \to \mathcal{R}$ is open, then $\exists r > 0$ with $B_{\mathcal{R}}(0, r) \subseteq T(B_{\mathcal{X}})$.
For $0 \neq y \in \mathcal{R}$, choose $u \in B_{\mathcal{X}}$ with $Tu = \frac{r}{2\|y\|} y$, and set $x := \frac{2\|y\|}{r} u$.
Then $Tx = y$ and $\|x\| \leq \frac{2}{r} \|y\|$; for $y = 0$, take $x = 0$. By Theorem 5.4.1, $\mathcal{R}$ is closed.

($\Leftarrow$) If $\mathcal{R}$ is closed, then by Theorem 5.4.1, $\exists M > 0$ such that every $y \in \mathcal{R}$ has $x \in \mathcal{X}$ with $Tx = y$ and $\|x\| \leq M \|y\|$. Let $U \subseteq \mathcal{X}$ be open and $x_0 \in U$. Choose $\rho > 0$ with $x_0 + \rho B_{\mathcal{X}} \subseteq U$. If $z \in B_{\mathcal{R}}(Tx_0, \frac{\rho}{M})$, choose $h \in \mathcal{X}$ with $Th = z - Tx_0$ and $\|h\| < \rho$; then $z = T(x_0 + h) \in T(U)$. Thus $T(U)$ is open in $\mathcal{R}$.

Structural Commentary: For linear maps, openness is detected at the unit ball around the origin.
Key Insight: Relative openness is the topological form of uniform preimage control. □

Theorem 5.4.3. *Open Mapping Theorem*
Every surjective $T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$ between Banach spaces is open.

Proof. Since T is surjective, $T(\mathcal{X}) = \mathcal{Y}$, $\mathcal{Y}$ is closed in itself. By Proposition 5.4.2, $T : \mathcal{X} \to T(\mathcal{X}) = \mathcal{Y}$ open.
Structural Commentary: Surjectivity identifies the relative range with the codomain.
Key Insight: A Banach-space surjection has uniformly controlled preimages near the origin. □

Corollary 5.4.4. *Bounded Inverse Theorem*
If $T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$ is bijective between Banach spaces, then $T^{-1} \in \mathcal{L}(\mathcal{Y}, \mathcal{X})$.

Proof. Set $U := T^{-1} : \mathcal{Y} \to \mathcal{X}$. By Theorem 5.4.3, T is open: if $O \subseteq \mathcal{X}$ is open, then $U^{-1}(O) = T(O)$ is open in $\mathcal{Y}$. Thus U is continuous; since U is linear, Theorem 5.1.5 gives $U \in \mathcal{L}(\mathcal{Y}, \mathcal{X})$.
Structural Commentary: Openness of the forward bijection is continuity of the inverse.
Key Insight: Banach completeness prevents a bounded linear bijection from having an unbounded inverse. □

Corollary 5.4.5. *One-Sided Control of Banach Norms*
Let $\|\cdot\|_1$ and $\|\cdot\|_2$ be norms on $\mathcal{X}$ such that $(\mathcal{X}, \|\cdot\|_1)$ and $(\mathcal{X}, \|\cdot\|_2)$ are Banach.
Assume $\exists c > 0$ such that $\|x\|_2 \leq c \|x\|_1$ for all $x \in \mathcal{X}$.

(i) $\exists C > 0$ such that $\|x\|_1 \leq C \|x\|_2$ for all $x \in \mathcal{X}$.
(ii) $\|\cdot\|_1$ and $\|\cdot\|_2$ are equivalent.

Proof.

(i) Let $I : (\mathcal{X}, \|\cdot\|_1) \to (\mathcal{X}, \|\cdot\|_2)$ be the identity. Since $\|Ix\|_2 \leq c \|x\|_1$, $I \in \mathcal{L}$ and is bijective.
By Corollary 5.4.4, $I^{-1} \in \mathcal{L}$, hence $\exists C > 0$ such that $\|x\|_1 = \left\|I^{-1}x\right\|_1 \leq C \|x\|_2$.

(ii) For all $x \in \mathcal{X}$, $\|x\|_2 \leq c \|x\|_1$ by hypothesis and $\|x\|_1 \leq C \|x\|_2$ by (i).
Hence the identity maps between the two normed structures are Lipschitz.

Structural Commentary: Apply the bounded inverse theorem to the identity between the two normed structures.
Key Insight: Completeness upgrades one-sided norm control to two-sided equivalence. □

Definition 5.4.6. *Closed Operators and Closed Complements*
Let $\mathcal{X}, \mathcal{Y}$ be normed spaces.

(i) *Closed operator*: $T : \mathcal{X} \to \mathcal{Y}$ is linear and $\forall (x_n) \subseteq \mathcal{X}$, $x_n \to x$ and $Tx_n \to y$ imply $Tx = y$.
(ii) *Closed linear complement*: $W \leq \mathcal{X}$ satisfies $\mathcal{X} = V \oplus W$ and is closed.

Theorem 5.4.7. *Closed Graph Theorem*
Let $\mathcal{X}, \mathcal{Y}$ be Banach spaces and let $T : \mathcal{X} \to \mathcal{Y}$ be linear. Set $\Gamma(T) := \{(x, Tx) : x \in \mathcal{X}\}$.

(i) T is bounded iff T is closed.
(ii) T is closed iff $\Gamma(T)$ is closed in $\mathcal{X} \times \mathcal{Y}$.

Proof. On $\mathcal{X} \times \mathcal{Y}$, use $\|(x, y)\| := \|x\| + \|y\|$.

(i) ($\Rightarrow$) If T is bounded, $x_n \to x$ and $Tx_n \to y$ imply $Tx_n \to Tx$; hence $y = Tx$, so T is closed.
(i) ($\Leftarrow$) Assume T is closed and set $\|x\|_* := \|x\| + \|Tx\|$. If (x_n) is $\|\cdot\|_*$-Cauchy, then $x_n \to x$ in $\mathcal{X}$ and $Tx_n \to y$ in $\mathcal{Y}$; by closedness, $y = Tx$, so $x_n \to x$ in $\|\cdot\|_*$. Thus $(\mathcal{X}, \|\cdot\|_*)$ is Banach.
Since $\|x\| \leq \|x\|_*$, by Corollary 5.4.5, $\exists C > 0$ such that $\|x\|_* \leq C \|x\|$; hence $\|Tx\| \leq C \|x\|$.
(ii) ($\Rightarrow$) If T is closed and $(x_n, Tx_n) \to (x, y)$, then $x_n \to x$ and $Tx_n \to y$, so $y = Tx$ and $(x, y) \in \Gamma(T)$.
(ii) ($\Leftarrow$) If $\Gamma(T)$ is closed, $x_n \to x$, and $Tx_n \to y$, then $(x_n, Tx_n) \to (x, y) \in \Gamma(T)$; hence $y = Tx$.

Structural Commentary: The graph norm turns closedness of the graph into completeness.
Key Insight: Graph-norm completeness and domination force equivalence with the original norm. □

Theorem 5.4.8. *Closed Complements and Continuous Projections*
Let V be a closed subspace of a Banach space $\mathcal{X}$. The following are equivalent.

(i) $\exists W \leq \mathcal{X}$ closed such that $\mathcal{X} = V \oplus W$.
(ii) $\exists P \in \mathcal{L}(\mathcal{X})$ such that $P^2 = P$ and $P(\mathcal{X}) = V$.

Proof.

(i) $\Rightarrow$ *(ii)* Let $\mathcal{X} = V \oplus W$ with W closed, and define $P(v + w) := v$. Then $P^2 = P$ and $P(\mathcal{X}) = V$.
If $x_n \to x$ and $Px_n \to v$, then $v \in V$ and $(I - P)x_n \to x - v \in W$; by uniqueness in $V \oplus W$, $Px = v$.
Thus P is closed, so $P \in \mathcal{L}(\mathcal{X})$ by Theorem 5.4.7.

(ii) $\Rightarrow$ *(i)* Let $P \in \mathcal{L}(\mathcal{X})$ with $P^2 = P$ and $P(\mathcal{X}) = V$. By Proposition 2.4.2, $\mathcal{X} = V \oplus \ker P$.
Since $\ker P = P^{-1}(\{\mathbf{0}\})$ and P is continuous, $\ker P$ is closed.

Structural Commentary: Closed complementary coordinates are exactly bounded projection coordinates.
Key Insight: The Closed Graph Theorem converts algebraic splitting into continuous splitting. □

Theorem 5.4.9. *Complemented Ranges Are Closed*
Let $T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$ act between Banach spaces. If $\operatorname{range}(T)$ has a closed linear complement in $\mathcal{Y}$, then it is closed.

Proof. Set $\mathcal{R} := T(\mathcal{X})$, $\mathcal{Y} = \mathcal{R} \oplus Y_0$, Y_0 closed. Put $Z := \mathcal{X} \times Y_0$, $\|(x, y_0)\|_Z := \|x\| + \|y_0\|$, and $S : Z \to \mathcal{Y}$, $S(x, y_0) := Tx + y_0$. Then Z is Banach, $S \in \mathcal{L}(Z, \mathcal{Y})$, and $S(Z) = \mathcal{Y}$.
By Theorem 5.4.1, $\exists M > 0$ such that $\forall y \in \mathcal{Y}\ \exists (x, y_0) \in Z$: $y = Tx + y_0$ and $\|x\| + \|y_0\| \le M \|y\|$. If $y \in \mathcal{R}$, by direct-sum uniqueness $y_0 = 0$; $\forall y \in \mathcal{R}\ \exists x \in \mathcal{X}$: $Tx = y$, $\|x\| \le M \|y\|$. By Theorem 5.4.1, $\mathcal{R}$ closed.
Structural Commentary: A closed complement transfers preimage control to the range summand.
Key Insight: Complementability supplies the missing uniform preimage estimate for closed range. □

Corollary 5.4.10. *Finite-Codimensional Operator Ranges Are Closed*
Let $\mathcal{X}, \mathcal{Y}$ be Banach spaces and let $T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$. If $\operatorname{codim}_{\mathcal{Y}} T(\mathcal{X}) < \infty$, then $T(\mathcal{X})$ is closed.

Proof. Set $\mathcal{R} := T(\mathcal{X})$. Since $\operatorname{codim}_{\mathcal{Y}} \mathcal{R} < \infty$, choose $Y_0 \le \mathcal{Y}$ with $\mathcal{Y} = \mathcal{R} \oplus Y_0$ and $\dim Y_0 < \infty$.
By Theorem 5.1.14, Y_0 is closed; by Theorem 5.4.9, $\mathcal{R}$ is closed.
Structural Commentary: Finite codimension produces a finite-dimensional closed complement.
Key Insight: Only finitely many missing codomain directions force the operator range to be closed. □

6 Weak Topologies, Compact Operators, and Spectral Theory

6.1 Weak Topologies and Duality

Weak topologies replace norm control by scalar tests. They are usually too weak to preserve distances, but strong enough to expose compactness phenomena that are invisible in norm topology.

Definition 6.1.1. *Dual Space, Weak Topology, and Weak-* Topology*
For a normed space $\mathcal{X}$ over $\mathbb{F}$, its continuous dual is $\mathcal{X}^* := \mathcal{L}(\mathcal{X}, \mathbb{F})$.

(i) The *weak topology* on $\mathcal{X}$ is the weakest topology making $\varphi : \mathcal{X} \to \mathbb{F}$ continuous $\forall \varphi \in \mathcal{X}^*$.
(ii) The *weak-* topology* on $\mathcal{X}^*$ is the weakest topology making the evaluation $\varphi \mapsto \varphi(x)$ continuous $\forall x \in \mathcal{X}$.
(iii) The *strong topology* is the norm topology.

For $m \in \mathbb{N}$, $\varepsilon > 0$, $\varphi_\bullet = (\varphi_1, \dots, \varphi_m) \in (\mathcal{X}^*)^m$, and $x_\bullet = (x_1, \dots, x_m) \in \mathcal{X}^m$:

(i) Weak: $N(x; \varphi_\bullet; \varepsilon) := \{y \in \mathcal{X} : |\varphi_j(y - x)| < \varepsilon\ \forall j\}$.
(ii) Weak-*: $N_*(\varphi; x_\bullet; \varepsilon) := \{\psi \in \mathcal{X}^* : |(\psi - \varphi)(x_j)| < \varepsilon\ \forall j\}$.

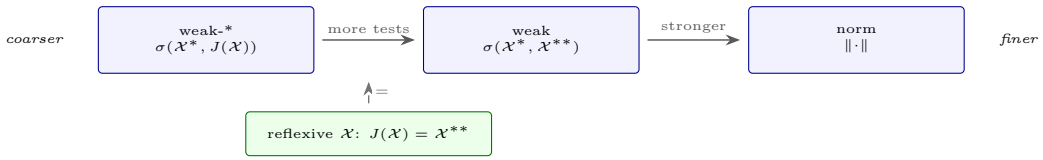

Figure 222: Topologies on $\mathcal{X}^*$: weak-* $\subseteq$ weak $\subseteq$ norm; reflexivity identifies the first two.

Definition 6.1.2. *Weak and Weak-* Convergence*

(i) $(x_n) \subseteq \mathcal{X}$ *converges weakly* to x, written $x_n \rightharpoonup x$, iff $\varphi(x_n) \to \varphi(x)\ \forall \varphi \in \mathcal{X}^*$.
(ii) $(\varphi_n) \subseteq \mathcal{X}^*$ *converges weak-** to $\varphi \in \mathcal{X}^*$ iff $\varphi_n(x) \to \varphi(x)\ \forall x \in \mathcal{X}$.

Proposition 6.1.3. *Strong Convergence Implies Weak Convergence*
If $x_n \to x$ in norm in a normed space $\mathcal{X}$, then $x_n \rightharpoonup x$.

Proof. $\forall \varphi \in \mathcal{X}^*$, $|\varphi(x_n) - \varphi(x)| = |\varphi(x_n - x)| \le \|\varphi\|_{\mathrm{op}} \|x_n - x\| \to 0$.
Structural Commentary: Apply an arbitrary bounded scalar test to the norm error.
Key Insight: Norm convergence controls every bounded linear test. □

Proposition 6.1.4. *Weakly Convergent Sequences Are Bounded*
If $x_n \rightharpoonup x$ in a normed space $\mathcal{X}$, then:

(i) $\sup_n \|x_n\| < +\infty$.
(ii) $\|x\| \le \liminf_{n \to \infty} \|x_n\|$.

Proof.

(i) $\forall \varphi \in \mathcal{X}^*$, the scalar sequence $(\varphi(x_n))$ is bounded. The space $\mathcal{X}^*$ is Banach by Theorem 5.1.6, so the Uniform Boundedness Principle, Theorem 5.3.7, applies to $Jx_n : \mathcal{X}^* \to \mathbb{F}$, $Jx_n(\varphi) := \varphi(x_n)$.
Since $\|Jx_n\|_{\mathrm{op}} = \|x_n\|$ by Corollary 5.3.3, the sequence is norm bounded.
(ii) If $x \neq 0$, choose $\varphi \in \mathcal{X}^*$ with $\|\varphi\|_{\mathrm{op}} = 1$ and $\varphi(x) = \|x\|$ by Corollary 5.3.2.
Then $\|x\| = \lim_{n \to \infty} |\varphi(x_n)| \le \liminf_{n \to \infty} \|x_n\|$. The case $x = 0$ is immediate.

Structural Commentary: Uniform boundedness proves (i); one norming functional proves (ii).
Key Insight: Scalar-test boundedness forces norm boundedness. □

Definition 6.1.5. *Reflexivity*
For a normed space $\mathcal{X}$, the canonical map $J : \mathcal{X} \to \mathcal{X}^{**}$ is defined by $Jx(\varphi) := \varphi(x)$.
A Banach space $\mathcal{X}$ is *reflexive* if $J(\mathcal{X}) = \mathcal{X}^{**}$.

Theorem 6.1.6. *Banach–Alaoglu Theorem*
For a normed space $\mathcal{X}$, the closed unit ball $\overline{B}_{\mathcal{X}^*}$ is weak- compact.*

Proof. Let $B := \overline{B}_{\mathcal{X}}$, $B^* := \overline{B}_{\mathcal{X}^*}$, and $D := \{a \in \mathbb{F} : |a| \le 1\}$. By Theorem 6.3.13, D^B is compact.
The injection $R : B^* \hookrightarrow D^B$, $R\varphi = \varphi|_B$, identifies $\sigma(\mathcal{X}^*, \mathcal{X})|_{B^*}$ with pointwise convergence on B.
Let $f \in \overline{R(B^*)} \subseteq D^B$. If $x_j \in B$, $a_j \in \mathbb{F}$, and $\sum_j a_j x_j \in B$, then $f(\sum_j a_j x_j) = \sum_j a_j f(x_j)$ by passage from the identities for $R\varphi$.
Define $\Phi(0) := 0$ and $\Phi(x) := \|x\| f(x/\|x\|)$ for $x \neq 0$.
Then Φ is linear, $|\Phi(x)| \le \|x\|$, and $R\Phi = f$; hence $R(B^*)$ is closed in D^B. Therefore B^* is weak-* compact.
Structural Commentary: $B^* \hookrightarrow D^B$; closed linear constraints plus Tychonoff give compactness.
Key Insight: Weak-* topology records precisely the coordinates used in Tychonoff compactness. □

Remark 6.1.7. *Compactness and Sequences*
Weak-* compactness need not be weak-* sequential compactness. For $\mathcal{X} = \ell^\infty$, let $\varphi_n(x) := x_n$.
Then $\varphi_n \in \overline{B}_{\mathcal{X}^*}$, but for any subsequence (n_k), choosing $x \in \ell^\infty$ with $x_{n_k} = (-1)^k$ makes $\varphi_{n_k}(x) = (-1)^k$, so no subsequence is weak-* convergent. Helly's theorem gives a sequential substitute when $\mathcal{X}$ is separable.

Theorem 6.1.8. *Helly Selection for Bounded Dual Sequences*
Let $\mathcal{X}$ be a separable normed space. If $(T_n) \subseteq \mathcal{X}^*$ and $\sup_n \|T_n\|_{op} < +\infty$, then $\exists$ a subsequence (T_{n_k}) and $T \in \mathcal{X}^*$ such that $\forall x \in \mathcal{X}$, $T_{n_k}(x) \to T(x)$.

Proof. Let $D = \{x_j : j \ge 1\} \subseteq \mathcal{X}$ be dense and set $M := \sup_n \|T_n\|_{\mathrm{op}}$.
If $M = 0$, take $T = 0$; assume $M > 0$. By diagonal extraction, choose (n_k) such that $T_{n_k} x_j$ converges $\forall j$.
For $x \in \mathcal{X}$ and $\varepsilon > 0$, choose j with $\|x - x_j\| < \varepsilon/(4M)$ and then k, ℓ large with $|T_{n_k} x_j - T_{n_\ell} x_j| < \varepsilon/2$.
Then $|T_{n_k} x - T_{n_\ell} x| \le 2M \|x - x_j\| + |T_{n_k} x_j - T_{n_\ell} x_j| < \varepsilon$, so $(T_{n_k} x)$ is Cauchy. Define $Tx := \lim_k T_{n_k} x$.
Linearity passes to limits, and $|Tx| \le M \|x\|$; hence $T \in \mathcal{X}^*$ and $T_{n_k} x \to Tx$ $\forall x \in \mathcal{X}$.
Structural Commentary: Diagonalize on dense D; use $M = \sup_n \|T_n\|_{\mathrm{op}}$ to extend D-limits to $\mathcal{X}$.
Key Insight: A countable dense set reduces pointwise convergence to diagonal convergence. □

Corollary 6.1.9. *Embedding into a Continuous Function Space*
For every normed space $\mathcal{X}$, $\exists$ compact Hausdorff K and a linear isometry $\Phi : \mathcal{X} \to C(K)$.

Proof. Let $K := \overline{B}_{\mathcal{X}^*}$ with the weak-* topology. By Theorem 6.1.6, K is compact; since evaluations separate points of K, K is Hausdorff. Define $\Phi : \mathcal{X} \to C(K)$ by $\Phi(x)(\varphi) := \varphi(x)$. Each $\Phi(x)$ is weak-* continuous, Φ is linear, and by Corollary 5.3.3, $\|\Phi(x)\|_\infty = \|x\|$.
Structural Commentary: $K = \overline{B}^{w^*}_{\mathcal{X}^*}$ turns scalar tests into compact coordinates.
Key Insight: Evaluation turns each vector into a continuous function without changing its norm. □

Proposition 6.1.10. *Natural Embedding and Weak Topologies*
For a normed space $\mathcal{X}$, the canonical map $J : \mathcal{X} \to \mathcal{X}^{**}$ is a homeomorphism $(\mathcal{X}, w) \to (J(\mathcal{X}), w^*|_{J(\mathcal{X})})$.

Proof. By Corollary 5.3.3, J is injective. Fix $x_0 \in \mathcal{X}$, $\varphi_\bullet = (\varphi_1, \dots, \varphi_m) \in (\mathcal{X}^*)^m$, and $\varepsilon > 0$.
Since $(Jx - Jx_0)(\varphi_j) = \varphi_j(x - x_0)$, $J^{-1}(N_*(Jx_0; \varphi_\bullet; \varepsilon) \cap J(\mathcal{X})) = N(x_0; \varphi_\bullet; \varepsilon)$.
Thus J and $J^{-1} : J(\mathcal{X}) \to \mathcal{X}$ are continuous.
Structural Commentary: Pullbacks of weak-* tests are weak tests.
Key Insight: J preserves precisely the scalar tests that define the weak topology. □

Theorem 6.1.11. *Kakutani's Weak Compactness Criterion*
For a Banach space $\mathcal{X}$, the following are equivalent.
(i) $\mathcal{X}$ is reflexive.
(ii) The closed unit ball $\overline{B}_{\mathcal{X}}$ is weakly compact.

Proof.
(*i*) $\Rightarrow$ (*ii*) If $J(\mathcal{X}) = \mathcal{X}^{**}$, then by Corollary 5.3.3, $J(\overline{B}_{\mathcal{X}}) = \overline{B}_{\mathcal{X}^{**}}$.
By Theorem 6.1.6 applied to $\mathcal{X}^*$, $\overline{B}_{\mathcal{X}^{**}}$ is weak-* compact. By Proposition 6.1.10, $\overline{B}_{\mathcal{X}}$ is weakly compact.
(*ii*) $\Rightarrow$ (*i*) By Proposition 6.1.10, $K := J(\overline{B}_{\mathcal{X}})$ is weak-* compact, hence weak-* closed, in $\mathcal{X}^{**}$.
If $F \in \overline{B}_{\mathcal{X}^{**}} \setminus K$, weak-* separation yields $\varphi \in \mathcal{X}^*$ with $\operatorname{Re} F(\varphi) > \sup_{\|x\| \le 1} \operatorname{Re} Jx(\varphi) = \|\varphi\|_{\mathrm{op}}$.
But $\operatorname{Re} F(\varphi) \le |F(\varphi)| \le \|F\|_{\mathrm{op}} \|\varphi\|_{\mathrm{op}} \le \|\varphi\|_{\mathrm{op}}$, a contradiction. Thus $\overline{B}_{\mathcal{X}^{**}} \subseteq K$.
For $F \in \mathcal{X}^{**}$ with $F \neq 0$, $F/\|F\|_{\mathrm{op}} \in K$, so $F \in J(\mathcal{X})$; hence $J(\mathcal{X}) = \mathcal{X}^{**}$.

Structural Commentary: Reflexivity identifies $J(\overline{B}_{\mathcal{X}})$ with $\overline{B}_{\mathcal{X}^{**}}$; weak-* separation forces the converse.
Key Insight: Reflexivity identifies the weak-* compact bidual ball with the embedded original ball. □

Corollary 6.1.12. *Closed Bounded Convex Sets in Reflexive Spaces*
Let $\mathcal{X}$ be reflexive Banach. If $C \subseteq \mathcal{X}$ is norm-closed, bounded, and convex, then C is weakly compact.

Proof. If $C = \emptyset$, the claim is trivial. Choose $r > 0$ with $C \subseteq r\overline{B}_{\mathcal{X}}$. By Theorem 6.1.11, $r\overline{B}_{\mathcal{X}}$ is weakly compact.
For $x_0 \notin C$, by Hahn–Banach separation, $\varphi \in \mathcal{X}^*$ and $\alpha \in \mathbb{R}$ with $\operatorname{Re}\varphi(x_0) > \alpha \ge \sup_{c \in C} \operatorname{Re}\varphi(c)$; hence $\{\operatorname{Re}\varphi > \alpha\}$ is weakly open, contains x_0, and misses C. Thus C is weakly closed, so C is weakly compact. *Structural Commentary*: $C \subseteq r\overline{B}_{\mathcal{X}}$ and C weakly closed inside a weakly compact ball.
Key Insight: Convex norm-closed sets remain closed when the topology is weakened to scalar tests. □

Theorem 6.1.13. *Goldstine's Theorem*
For a normed space $\mathcal{X}$, the weak- closure of $J(\overline{B}_{\mathcal{X}})$ in $\mathcal{X}^{**}$ is $\overline{B}_{\mathcal{X}^{**}}$.*

Proof. Set $C := \overline{J(\overline{B}_{\mathcal{X}})}^{\sigma(\mathcal{X}^{**},\mathcal{X}^{*})}$. J is isometric by Corollary 5.3.3, $\overline{B}_{\mathcal{X}^{**}} = \bigcap_{\varphi\in\overline{B}_{\mathcal{X}^{*}}}\{F\in\mathcal{X}^{**} : |F(\varphi)|\le 1\}$ is weak-* closed, hence $C\subseteq \overline{B}_{\mathcal{X}^{**}}$. Suppose $F\in\overline{B}_{\mathcal{X}^{**}}\setminus C$. By weak-* Hahn–Banach separation,
$\exists\varphi\in\mathcal{X}^{*}$ and $\alpha\in\mathbb{R}$ such that $\operatorname{Re}F(\varphi) > \alpha \ge \sup_{\|x\|\le 1}\operatorname{Re}Jx(\varphi) = \sup_{\|x\|\le 1}\operatorname{Re}\varphi(x) = \|\varphi\|_{\mathrm{op}}$.
But $\operatorname{Re}F(\varphi)\le |F(\varphi)|\le \|F\|_{\mathrm{op}}\|\varphi\|_{\mathrm{op}}\le \|\varphi\|_{\mathrm{op}}$, a contradiction. Hence $\overline{B}_{\mathcal{X}^{**}}\subseteq C$.
Structural Commentary: $J(\overline{B}_{\mathcal{X}})\subseteq \overline{B}_{\mathcal{X}^{**}}$; weak-* separation excludes $\overline{B}_{\mathcal{X}^{**}}\setminus C$.
Key Insight: $J(\overline{B}_{\mathcal{X}})$ is weak-* dense in $\overline{B}_{\mathcal{X}^{**}}$ even when $J\mathcal{X}\neq\mathcal{X}^{**}$. □

Theorem 6.1.14. *Eberlein–Smulian Theorem for Unit Balls*
Let $\mathcal{X}$ be Banach and set $B := \overline{B}_{\mathcal{X}}$. The following are equivalent:
(i) B is compact in $(\mathcal{X}, w)$.
(ii) Every $(x_n)\subseteq B$ has a subsequence $x_{n_k}\rightharpoonup x$ for some $x\in B$.

Proof. By Eberlein–Smulian, for bounded $A\subseteq\mathcal{X}$, A is relatively weakly compact iff every sequence in A has a weakly convergent subsequence with limit in $\overline{A}^{w}$. By Hahn–Banach separation, B is weakly closed, so $\overline{B}^{w} = B$.
$(i)\Rightarrow(ii)$ Apply the criterion with $A = B$.
$(ii)\Rightarrow(i)$ The criterion makes B relatively weakly compact; since $\overline{B}^{w} = B$, B is weakly compact.
Structural Commentary: For $B = \overline{B}_{\mathcal{X}}$, weak compactness $\iff$ weak subsequential compactness.
Key Insight: Weak compactness of B is sequence-detectable. □

Corollary 6.1.15. *Reflexive Unit-Ball Characterization*
Let $\mathcal{X}$ be Banach, set $B := \overline{B}_{\mathcal{X}}$, and let $J:\mathcal{X}\to\mathcal{X}^{**}$ be canonical. The following are equivalent:
(i) $J(\mathcal{X}) = \mathcal{X}^{**}$.
(ii) B is compact in $(\mathcal{X}, w)$.
(iii) Every $(x_n)\subseteq B$ has a subsequence $x_{n_k}\rightharpoonup x$ for some $x\in B$.

Proof.
$(i)\Rightarrow(ii)$ $J(\mathcal{X}) = \mathcal{X}^{**}\Rightarrow B$ is compact in $(\mathcal{X},w)$ by Theorem 6.1.11.
$(ii)\Rightarrow(iii)$ By Theorem 6.1.14, B weakly compact implies every $(x_n)\subseteq B$ has $x_{n_k}\rightharpoonup x\in B$.
$(iii)\Rightarrow(i)$ By Theorem 6.1.14, (iii) implies B weakly compact; by Theorem 6.1.11, $J(\mathcal{X}) = \mathcal{X}^{**}$.
Structural Commentary: $J(\mathcal{X}) = \mathcal{X}^{**}\iff B_w$ compact $\iff B_w$ subsequentially compact.
Key Insight: Reflexivity is unit-ball compactness. □

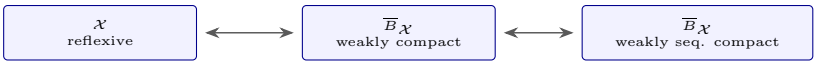

Figure 223: For Banach $\mathcal{X}$: $\mathcal{X}$ reflexive $\iff \overline{B}_{\mathcal{X}}$ weakly compact $\iff \overline{B}_{\mathcal{X}}$ weakly sequentially compact.

Proposition 6.1.16. *Hilbert Weak Convergence Tests*
Let $\mathcal{H}$ be a Hilbert space, let $(h_n),(u_n)\subseteq\mathcal{H}$, and let $h,u\in\mathcal{H}$.
(i) $h_n\rightharpoonup h$ if and only if $\forall u\in\mathcal{H}$, $\langle h_n,u\rangle\to\langle h,u\rangle$.
(ii) If $h_n\rightharpoonup h$ and $u_n\to u$ strongly, then $\langle h_n,u_n\rangle\to\langle h,u\rangle$.

Proof.
(i) $(\Rightarrow)$ For $u\in\mathcal{H}$, $\phi_u(x) := \langle x,u\rangle\in\mathcal{H}^{*}$, so $\langle h_n,u\rangle = \phi_u(h_n)\to\phi_u(h) = \langle h,u\rangle$.
(i) $(\Leftarrow)$ For $\phi\in\mathcal{H}^{*}$, $u_\phi\in\mathcal{H}$ with $\phi(x) = \langle x,u_\phi\rangle$ by Theorem 5.2.32; $\phi(h_n) = \langle h_n,u_\phi\rangle\to\langle h,u_\phi\rangle = \phi(h)$.
(ii) Let $C := \sup_n\|h_n\| < +\infty$ by Proposition 6.1.4(i).
Since $|\langle h_n,u_n\rangle - \langle h,u\rangle| \le C\|u_n-u\| + |\langle h_n-h,u\rangle|$, the limit is 0.
Structural Commentary: $\mathcal{H}^{*} = \{\langle\cdot,u\rangle : u\in\mathcal{H}\}$; boundedness controls $u_n - u$.
Key Insight: $h_n\rightharpoonup h\iff\langle h_n,u\rangle\to\langle h,u\rangle$ for all fixed $u\in\mathcal{H}$. □

Theorem 6.1.17. *Bounded Hilbert Sequences Have Weak Subsequences*
Let $\mathcal{H}$ be Hilbert and let $(h_n)\subseteq\mathcal{H}$ satisfy $C := \sup_n\|h_n\| < +\infty$. Then $\exists n_k\uparrow\infty$ and $h\in\mathcal{H}$ such that $h_{n_k}\rightharpoonup h$.

Proof. Set $M := \operatorname{cspan}\{h_n : n\ge 1\}$. Then M is a separable Hilbert space.
If $\dim M < +\infty$, then $C\overline{B}_M$ is compact by Theorem 5.1.14(iii); choose $h_{n_k}\to h\in M$ strongly, hence weakly.
Assume $\dim M = \infty$. Choose a Hilbert basis $(e_j)_{j\ge1}$ of M by Corollary 5.2.28.
Diagonalize so $\langle h_{n_k},e_j\rangle\to a_j\ \forall j$. For $m\ge1$, $\sum_{j=1}^{m}|a_j|^2 = \lim_k\sum_{j=1}^{m}|\langle h_{n_k},e_j\rangle|^2\le C^2$ by Theorem 5.2.22(ii).
Hence $a\in\ell^2$ and $h := \sum_j a_je_j\in M$ by Theorem 5.2.21(i). If $v\in\operatorname{span}\{e_j : j\ge1\}$, then $\langle h_{n_k}-h,v\rangle\to0$.
For $u\in M$, $\varepsilon>0$, $\|u-v\| < \varepsilon$ for v; then $\limsup_k|\langle h_{n_k}-h,u\rangle|\le(C+\|h\|)\varepsilon$, so $\langle h_{n_k}-h,u\rangle\to0$.
For $u\in\mathcal{H}$, write $u = P_Mu + u_\perp$, $u_\perp\in M^{\perp}$. Since $h_{n_k}-h\in M$, $\langle h_{n_k}-h,u\rangle = \langle h_{n_k}-h,P_Mu\rangle\to0$.
Thus $h_{n_k}\rightharpoonup h$ by Proposition 6.1.16.
Structural Commentary: Work in $M = \operatorname{cspan}\{h_n\}$; diagonal limits on (e_j) extend by $\overline{\operatorname{span}}\{e_j\} = M$ and $M^{\perp}$.
Key Insight: Bounded Hilbert sequences have countably coordinatized weak limits. □

Theorem 6.1.18. *Hilbert Spaces Are Reflexive*
For every Hilbert space $\mathcal{H}$, the canonical embedding $J:\mathcal{H}\to\mathcal{H}^{**}$ is onto.

Proof. Set $B := \overline{B}_{\mathcal{H}}$. If $(h_n)\subseteq B$, then by Theorem 6.1.17, $h_{n_k}\rightharpoonup h$ for some $h\in\mathcal{H}$.
By Proposition 6.1.4, $\|h\|\le\liminf_k\|h_{n_k}\|\le1$, so $h\in B$.
Thus B is weakly subsequentially compact, hence $J(\mathcal{H}) = \mathcal{H}^{**}$ by Corollary 6.1.15.
Structural Commentary: B_w subsequentially compact $\Longrightarrow J(\mathcal{H}) = \mathcal{H}^{**}$.
Key Insight: Hilbert coordinates make B_w sequence-compact. □

Theorem 6.1.19. *Banach–Saks Theorem in Hilbert Spaces*

Let $\mathcal{H}$ be Hilbert and let $h_n \rightharpoonup h$. Then $\exists n_k \uparrow \infty$ such that $\frac{1}{k}\sum_{j=1}^{k} h_{n_j} \to h$ strongly.

Proof. Replace h_n by $h_n - h$; let $h = 0$. Put $C := \sup_n \|h_n\|^2 < +\infty$.

Let $n_1 = 1$, $n_1 < \cdots < n_k$, $s_k := \sum_{j=1}^{k} h_{n_j}$; $n_{k+1} > n_k$ with $\left|\langle s_k, h_{n_{k+1}}\rangle\right| \le 1$, since $\langle s_k, h_n\rangle \to 0$.

Then $\|s_{k+1}\|^2 = \|s_k\|^2 + 2\operatorname{Re}\langle s_k, h_{n_{k+1}}\rangle + \|h_{n_{k+1}}\|^2 \le \|s_k\|^2 + C + 2$, so $\|s_k\|^2 \le (C+2)k$.

Hence $\left\|\frac{1}{k}s_k\right\|^2 \le \frac{C+2}{k} \to 0$. For the original sequence, $\frac{1}{k}\sum_{j=1}^{k} h_{n_j} = h + \frac{1}{k}\sum_{j=1}^{k}(h_{n_j} - h) \to h$.

Structural Commentary: Choose n_{k+1} so $\left|\langle s_k, h_{n_{k+1}}\rangle\right| \le 1$; then $\|s_k\|^2 = O(k)$.
Key Insight: Weak-null subsequences can have $o(k)$ Cesàro norm. □

Theorem 6.1.20. *Radon–Riesz Theorem in Hilbert Spaces*
Let $\mathcal{H}$ be Hilbert and let $h_n \rightharpoonup h$. Then $h_n \to h$ in norm iff $\|h_n\| \to \|h\|$.

Proof.
($\Rightarrow$) If $\|h_n - h\| \to 0$, then $|\|h_n\| - \|h\|| \le \|h_n - h\| \to 0$.
($\Leftarrow$) Since $h_n \rightharpoonup h$, $\langle h_n, h\rangle \to \|h\|^2$. If also $\|h_n\| \to \|h\|$, then $\|h_n - h\|^2 = \|h_n\|^2 - 2\operatorname{Re}\langle h_n, h\rangle + \|h\|^2 \to 0$.

Structural Commentary: Weak convergence fixes $\langle h_n, h\rangle$; norm convergence fixes $\|h_n\|^2$.
Key Insight: $\|h_n - h\|^2$ has no remaining term. □

Theorem 6.1.21. *Metrizing Weak Topologies on the Unit Ball*
Let $\mathcal{X}$ be normed, $W \le \mathcal{X}^*$ separable and point-separating $B := \overline{B}_{\mathcal{X}}$. Choose $(\varphi_k)_{k\ge1}$ dense in $W \cap \overline{B}_{\mathcal{X}^*}$. Then $\rho(u,v) := \sum_{k\ge1} 2^{-k}|\varphi_k(u-v)|$ is a metric on B inducing $\sigma(\mathcal{X}, W)|_B$.

Proof. For $u, v \in B$, $|\varphi_k(u-v)| \le 2$, hence $\rho(u,v) < +\infty$; symmetry and the triangle inequality are termwise.
If $\rho(u,v) = 0$, then $\varphi_k(u-v) = 0$ for all k; for $\psi \in W \setminus \{0\}$, density gives $\varphi_{k_j} \to \frac{\psi}{\|\psi\|}$, hence $\psi(u-v) = 0$.
Since W separates points, $u = v$, so ρ is a metric. Fix $u \in B$. It remains to compare neighborhoods at u.
($\Rightarrow$) Given $r > 0$, choose N with $\sum_{k>N} 2^{1-k} < \frac{r}{2}$ and $\delta > 0$ with $\delta \sum_{k\le N} 2^{-k} < \frac{r}{2}$.
Then $V := \{v \in B : |\varphi_k(v-u)| < \delta, 1 \le k \le N\}$ is a $\sigma(\mathcal{X}, W)|_B$-neighborhood of u.
By $v \in V$, $\rho(u,v) \le \delta \sum_{k\le N} 2^{-k} + \sum_{k>N} 2^{1-k} < r$, hence $V \subseteq B_\rho(u, r)$.
($\Leftarrow$) Let $U = \{v \in B : |\psi_j(v-u)| < \varepsilon, 1 \le j \le m\}$ with $\psi_j \in W$ and $\varepsilon > 0$. Put $K := \{j : \psi_j \ne 0\}$.
For $j \in K$, choose k_j with $\left\|\frac{\psi_j}{\|\psi_j\|} - \varphi_{k_j}\right\| < \frac{\varepsilon}{4\|\psi_j\|}$, then choose $r > 0$ with $2^{k_j} r < \frac{\varepsilon}{2\|\psi_j\|}$ $\forall j \in K$.
If $\rho(u,v) < r$, then $\left|\varphi_{k_j}(v-u)\right| < 2^{k_j} r$, $\|v-u\| \le 2$,
so $|\psi_j(v-u)| \le \|\psi_j\|\left|\varphi_{k_j}(v-u)\right| + \|\psi_j\|\left\|\frac{\psi_j}{\|\psi_j\|} - \varphi_{k_j}\right\|\|v-u\| < \varepsilon$ for $j \in K$.
For $j \notin K$, $\psi_j = 0$. Thus $B_\rho(u,r) \subseteq U$.
Therefore ρ induces $\sigma(\mathcal{X}, W)|_B$.
Structural Commentary: $\rho = \sum_{k\ge1} 2^{-k}|\varphi_k(\cdot)|$ metrizes the bounded test topology generated by W.
Key Insight: On B, dense countable tests determine all W-tests. □

Corollary 6.1.22. *Metrizability of Weak Unit Balls*
Let $\mathcal{X}$ be normed, write $B_{\mathcal{Y}} := \overline{B}_{\mathcal{Y}}$ for normed $\mathcal{Y}$, and let $J : \mathcal{X} \to \mathcal{X}^{**}$ be canonical.
(i) If $\mathcal{X}^*$ is separable, then $(B_{\mathcal{X}}, \sigma(\mathcal{X}, \mathcal{X}^*))$ is metrizable.
(ii) If $\mathcal{X}$ is separable, then $(B_{\mathcal{X}^*}, \sigma(\mathcal{X}^*, J(\mathcal{X})))$ is metrizable.
(iii) If $\mathcal{X}$ is reflexive Banach, then $(B_{\mathcal{X}}, \sigma(\mathcal{X}, \mathcal{X}^*))$ is metrizable iff $\mathcal{X}$ is separable.

Proof.
(i) $\mathcal{X}^*$ is separable and point-separating on $\mathcal{X}$: if $x \ne y$, then $\exists \varphi \in \mathcal{X}^*$ with $\varphi(x-y) \ne 0$.
Theorem 6.1.21 with $(\mathcal{Y}, W) = (\mathcal{X}, \mathcal{X}^*)$ metrizes $(B_{\mathcal{X}}, \sigma(\mathcal{X}, \mathcal{X}^*))$.
(ii) Since J is an isometry, $\mathcal{X}$ separable implies $J(\mathcal{X})$ separable.
If $\varphi \ne \psi$ in $\mathcal{X}^*$, choose $x \in \mathcal{X}$ with $(\varphi - \psi)(x) \ne 0$, hence $Jx(\varphi - \psi) \ne 0$, $J(\mathcal{X})$ point-separating on $\mathcal{X}^*$.
Theorem 6.1.21 with $(\mathcal{Y}, W) = (\mathcal{X}^*, J(\mathcal{X}))$ metrizes $(B_{\mathcal{X}^*}, \sigma(\mathcal{X}^*, J(\mathcal{X})))$.
(*iii*) ($\Rightarrow$) Let $B := B_{\mathcal{X}}$, B_w metrizable. By reflexivity, Theorem 6.1.11, B_w is compact metrizable, separable.
Choose countable $D \subseteq B$ with $\overline{D}^w = B$. Set $K := \overline{\operatorname{co} D}^{\|\cdot\|}$. If $K \ne B$, choose $x \in B \setminus K$.
Hahn–Banach gives $\varphi \in \mathcal{X}^*$ with $\operatorname{Re}\varphi(x) > \sup_{y\in K}\operatorname{Re}\varphi(y)$.
Since $D \subseteq K$ and $x \in \overline{D}^w$, weak continuity gives $\operatorname{Re}\varphi(x) \le \sup_{y\in K}\operatorname{Re}\varphi(y)$, contradiction.
Thus $B = K = \overline{\operatorname{co}_{\mathbb{Q}} D}^{\|\cdot\|}$; $\operatorname{co}_{\mathbb{Q}} D$ is countable, so B is norm separable, and $\mathcal{X} = \bigcup_{m\ge1} mB$ is separable.
(*iii*) ($\Leftarrow$) Assume $\mathcal{X}$ separable. By (ii), Theorem 6.1.6, $J(\mathcal{X}) = \mathcal{X}^{**}$, $B_{\mathcal{X}^*}$ compact metrizable in $\sigma(\mathcal{X}^*, \mathcal{X}^{**})$.
Pick countable dense $D \subseteq B_{\mathcal{X}^*}$. The ($\Rightarrow$) argument in $\mathcal{X}^*$ gives $B_{\mathcal{X}^*} = \overline{\operatorname{co}_{\mathbb{Q}} D}^{\|\cdot\|}$.
Since $\operatorname{co}_{\mathbb{Q}} D$ is countable, $B_{\mathcal{X}^*}$ is norm separable and $\mathcal{X}^* = \bigcup_{m\ge1} mB_{\mathcal{X}^*}$ is separable, so (i) applies.

Structural Commentary: W separable metrizes $B_{\sigma(\mathcal{X},W)}$; compact metrizable B_w yields $B = \overline{\operatorname{co}_{\mathbb{Q}} D}^{\|\cdot\|}$.
Key Insight: Reflexive $B_{\mathcal{X}}$ is weakly metrizable iff $\mathcal{X}$ is separable. □

Theorem 6.1.23. *Whole Weak Topologies Are Not Metrizable in Infinite Dimension*
Let $\mathcal{X}$ be Banach with $\dim \mathcal{X} = +\infty$.

(i) $(\mathcal{X}, \sigma(\mathcal{X}, \mathcal{X}^*))$ *is not metrizable.*
(ii) $(\mathcal{X}^*, \sigma(\mathcal{X}^*, J(\mathcal{X})))$ *is not metrizable.*

Proof.

(i) Suppose ρ metrizes $\sigma(\mathcal{X}, \mathcal{X}^*)$. $\forall n$, choose $U_n \subseteq B_\rho(0, \frac{1}{n})$ with $U_n = \{x : |\varphi_{n,j}(x)| < \varepsilon_n,\ 1 \le j \le m_n\}$.
Since $\bigcap_{j=1}^{m_n} \ker \varphi_{n,j} \neq \{0\}$, choose x_n in this kernel with $\|x_n\| = n$.
Then $x_n \in U_n$, so $\rho(x_n, 0) < \frac{1}{n}$ and $x_n \rightharpoonup 0$, contradicting Proposition 6.1.4(i).

(ii) Suppose ρ_* metrizes $\sigma(\mathcal{X}^*, J(\mathcal{X}))$. $\forall n$, choose finite-dim $M_n \le \mathcal{X}$ with $M_n^\perp := \{\varphi : \varphi|_{M_n} = 0\} \subseteq B_{\rho_*}(0, \frac{1}{n})$.
Choose $y_n \notin M_n$ and define ψ_n on $M_n + \operatorname{span}\{y_n\}$ by $\psi_n|_{M_n} = 0$ and $\psi_n(y_n) = 1$.
Extend ψ_n to $\mathcal{X}$ by Corollary 5.3.2(i), and rescale to $\varphi_n \in M_n^\perp$ with $\|\varphi_n\|_{\text{op}} = n$.
Then $\rho_*(\varphi_n, 0) < \frac{1}{n}$, so $\varphi_n \to 0$ weak-*. By Theorem 5.3.7, $(\|\varphi_n\|_{\text{op}})$ is bounded, a contradiction.

Structural Commentary: Finite tests leave nonzero kernels in $\mathcal{X}$ and nonzero annihilators in $\mathcal{X}^*$.
Key Insight: Metric convergence would force bounded norms; finite scalar tests cannot. □

Method 6.1.24. *Weak Compactness Proof Patterns*

(i) *Compactify*: replace $\|x\|$ by finite coordinates $(\varphi_1(x), \dots, \varphi_m(x))$.
(ii) *Embed*: use $J : \mathcal{X} \to \mathcal{X}^{**}$ and compare $\sigma(\mathcal{X}, \mathcal{X}^*)$ with $\sigma(\mathcal{X}^{**}, \mathcal{X}^*)|_{J(\mathcal{X})}$.
(iii) *Separate*: if $F \notin J(B)$, choose $\varphi \in \mathcal{X}^*$ separating F from $J(B)$.
(iv) *Metrize on balls*: for separable $W \le \mathcal{X}^*$, use $\rho(u, v) = \sum_{k \ge 1} 2^{-k} |\varphi_k(u - v)|$ on bounded B.
(v) *Hilbertize*: replace φ by $\langle \cdot, h \rangle$ and use orthogonal coordinates/projections.

Key Insight: Weak compactness is compactness for scalar coordinates $\varphi(x)$ on bounded sets.

6.2 Compact Operators

Compact operators carry bounded sets to relatively compact sets. Their spectral and solvability theory therefore resembles matrix theory inside infinite-dimensional spaces.

Definition 6.2.1. *Compact and Finite-Rank Operators*
Let $\mathcal{X}, \mathcal{Y}$ be normed spaces and let $T : \mathcal{X} \to \mathcal{Y}$ be linear.

(i) *Compact*: $\overline{T(B)}$ is compact in $\mathcal{Y}$ $\forall B \subseteq \mathcal{X}$ bounded.
(ii) *Finite rank*: $\dim \operatorname{range}(T) < \infty$.

Proposition 6.2.2. *Compactness Tests on Hilbert Spaces*
Let $\mathcal{H}$ be Hilbert, let $K \in \mathcal{L}(\mathcal{H})$, and set $B := \overline{B}_{\mathcal{H}}$. The following are equivalent:

(i) K *is compact.*
(ii) $K(B)$ *is totally bounded.*
(iii) Every bounded $(h_n) \subseteq \mathcal{H}$ has a subsequence (h_{n_j}) such that Kh_{n_j} converges in norm.

Proof. For bounded $E \subseteq \mathcal{H}$, choose $r > 0$ with $E \subseteq rB$; then $K(E) \subseteq K(rB) = rK(B)$.

(i) $\Rightarrow$ (ii) K compact $\Rightarrow$ $\overline{K(B)}$ compact $\Rightarrow$ $\overline{K(B)}$ totally bounded $\Rightarrow$ $K(B)$ totally bounded.
(ii) $\Rightarrow$ (iii) (h_n) bounded $\Rightarrow \exists r > 0$, $\{h_n : n \ge 1\} \subseteq rB$. Then $(Kh_n) \subseteq K(rB) = rK(B)$ with $rK(B)$ totally bounded, so $\exists (n_j)$ such that (Kh_{n_j}) is Cauchy; $\mathcal{H}$ complete $\Rightarrow \exists y \in \mathcal{H}$, $\|Kh_{n_j} - y\| \to 0$.
(iii) $\Rightarrow$ (i) Let $E \subseteq \mathcal{H}$ be bounded. If $K(E)$ is not totally bounded, then $\exists \varepsilon > 0$ and $(x_n) \subseteq E$ such that $n \neq m \Rightarrow \|Kx_n - Kx_m\| \ge \varepsilon$. By (iii), $\exists (n_j)$ and $y \in \mathcal{H}$ with $\|Kx_{n_j} - y\| \to 0$, contradiction. Hence $K(E)$ is totally bounded, so $\overline{K(E)}$ is totally bounded and complete; Theorem 4.1.34 gives $\overline{K(E)}$ compact.

Structural Commentary: $E \subseteq rB \Rightarrow K(E) \subseteq rK(B)$; $K(B)$ totally bounded $\Rightarrow (h_n) \subseteq rB \Rightarrow \exists (n_j) : (Kh_{n_j})$ Cauchy.
Key Insight: K compact iff K sends bounded sequences to norm-precompact sequences. □

Proposition 6.2.3. *Finite Rank Operators Are Compact*
Let $\mathcal{X}, \mathcal{Y}$ be normed, $T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$, $R := \operatorname{range}(T)$. If $\dim R < +\infty$, then T is compact.

Proof. Let $B \subseteq \mathcal{X}$ be bounded. Then $T(B) \subseteq R$ is bounded, so $\overline{T(B)}^{\,R}$ is compact by Theorem 5.1.14.
Since $R \le \mathcal{Y}$ is finite-dimensional, R is closed in $\mathcal{Y}$; hence $\overline{T(B)}^{\,\mathcal{Y}} = \overline{T(B)}^{\,R}$ is compact. Thus T is compact.
Structural Commentary: $T(B) \subseteq R$, $\dim R < +\infty$, and bounded subsets of R have compact closure.
Key Insight: Finite-dimensional range makes bounded images relatively compact. □

Theorem 6.2.4. *Norm Limits of Compact Operators*
Let $\mathcal{X}$ be normed, $\mathcal{Y}$ Banach, $T_n, T \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$. If each T_n compact and $\|T_n - T\|_{op} \to 0$, then T is compact.

Proof. Let $B \subseteq \mathcal{X}$ be bounded, $M > 0$, $\|x\| \le M$ for $x \in B$. For $\varepsilon > 0$, choose N with $\|T - T_N\|_{\text{op}} < \frac{\varepsilon}{2M}$.
Since $\overline{T_N(B)}$ is compact, choose $y_1, \dots, y_r \in \mathcal{Y}$ with $T_N(B) \subseteq \bigcup_{j=1}^r B_{\mathcal{Y}}(y_j, \frac{\varepsilon}{2})$.
Then $T(B) \subseteq \bigcup_{j=1}^r B_{\mathcal{Y}}(y_j, \varepsilon)$, so $T(B)$ is totally bounded. Since $\mathcal{Y}$ is complete, $\overline{T(B)}$ is compact; T is compact. *Structural Commentary*: $\|T - T_N\|_{\text{op}}$ transfers finite nets from $T_N(B)$ to $T(B)$ for bounded B.
Key Insight: Norm limits preserve relative compactness of bounded images. □

Proposition 6.2.5. *Compact Operators Form an Operator Ideal*
Let $\mathcal{W}, \mathcal{X}, \mathcal{Y}, \mathcal{Z}$ be normed spaces.

(i) If $K_1, \dots, K_m : \mathcal{X} \to \mathcal{Y}$ are compact, then $\sum_{j=1}^m K_j$ is compact.
(ii) If $K : \mathcal{X} \to \mathcal{Y}$ is compact, $A \in \mathcal{L}(\mathcal{Y}, \mathcal{Z})$, and $B \in \mathcal{L}(\mathcal{W}, \mathcal{X})$, then $AKB : \mathcal{W} \to \mathcal{Z}$ is compact.

Proof.

(i) Let $E \subseteq \mathcal{X}$ be bounded, $C_j := \overline{K_j(E)}$. Then each C_j is compact, and $\sum_{j=1}^{m} K_j(E) \subseteq \sigma(C_1 \times \cdots \times C_m)$ for the continuous map $\sigma(y_1, \ldots, y_m) := \sum_{j=1}^{m} y_j$. Thus $\sum_{j=1}^{m} K_j(E)$ is relatively compact.

(ii) Let $E \subseteq \mathcal{W}$ be bounded. Then $B(E)$ is bounded, $C := \overline{K(B(E))}$ is compact, and $AKB(E) \subseteq A(C)$. Since $A(C)$ is compact and closed in $\mathcal{Z}$, $\overline{AKB(E)} \subseteq A(C)$ is compact.

Structural Commentary: Products of compact image closures control sums; bounded precomposition and continuous postcomposition control AKB.
Key Insight: Compact operators form a two-sided ideal in $\mathcal{L}$. □

Example 6.2.6. *Diagonal Compact Operators*
Let $(e_k)_{k\geq 1}$ be a Hilbert basis of separable $\mathcal{H}$ and let $\lambda = (\lambda_k) \in \ell^\infty$ with $\lambda_k \to 0$.
For $h \in \mathcal{H}$, set $Th := \sum_{k=1}^{\infty} \lambda_k \langle h, e_k\rangle e_k$ and $T_N h := \sum_{k=1}^{N} \lambda_k \langle h, e_k\rangle e_k$.
By Parseval: $\sum_k |\lambda_k \langle h, e_k\rangle|^2 \leq \|\lambda\|_\infty^2 \|h\|^2 \Rightarrow T \in \mathcal{L}(\mathcal{H})$.
For $N \geq 1$, $\operatorname{range} T_N \subseteq \operatorname{span}\{e_1, \ldots, e_N\} \Rightarrow \operatorname{rank} T_N \leq N \Rightarrow T_N$ compact by Proposition 6.2.3.
Also $\|(T - T_N)h\|^2 = \sum_{k>N} |\lambda_k|^2 |\langle h, e_k\rangle|^2 \leq \sup_{k>N} |\lambda_k|^2 \|h\|^2 \Rightarrow \|T - T_N\|_{\text{op}} \leq \sup_{k>N} |\lambda_k| \to 0$.
Hence $T_N \to T$ in $\|\cdot\|_{\text{op}}$ and T is compact by Theorem 6.2.4.

Theorem 6.2.7. *Weak-to-Strong Characterization*
Let $\mathcal{H}$ be Hilbert, $K \in \mathcal{L}(\mathcal{H})$. Then K is compact iff $h_n \rightharpoonup h$ implies $\|Kh_n - Kh\| \to 0$ $\forall (h_n) \subseteq \mathcal{H}$ and $h \in \mathcal{H}$.

Proof.

($\Rightarrow$) Let $h_n \rightharpoonup h$. By Proposition 6.1.4(i), (h_n) bounded.
For every subsequence (n_j), By Proposition 6.2.2(iii), $\exists (j_\ell)$ and $y \in \mathcal{H}$ with $\left\|Kh_{n_{j_\ell}} - y\right\| \to 0$.
For $u \in \mathcal{H}$, $\langle y, u\rangle = \lim_\ell \left\langle Kh_{n_{j_\ell}}, u\right\rangle = \lim_\ell \left\langle h_{n_{j_\ell}}, K^* u\right\rangle = \langle h, K^* u\rangle = \langle Kh, u\rangle$, so $y = Kh$.
If $\|Kh_n - Kh\| \not\to 0$, then $\exists \varepsilon > 0$, (n_j) with $\left\|Kh_{n_j} - Kh\right\| \geq \varepsilon$, contradicting $\exists (j_\ell) : \left\|Kh_{n_{j_\ell}} - Kh\right\| \to 0$.

($\Leftarrow$) Let (h_n) be bounded. By Theorem 6.1.17, $\exists (n_j)$, $h \in \mathcal{H}$ with $h_{n_j} \rightharpoonup h$. By hypothesis, $\left\|Kh_{n_j} - Kh\right\| \to 0$.
Hence $\forall (h_n)$ bounded, $\exists (n_j)$ and $y \in \mathcal{H}$ with $\left\|Kh_{n_j} - y\right\| \to 0$; By Proposition 6.2.2(iii), K compact.

Structural Commentary: K compact, $h_n \rightharpoonup h \Rightarrow Kh_{n_{j_\ell}} \to y = Kh$; (h_n) bounded $\Rightarrow h_{n_j} \rightharpoonup h \Rightarrow Kh_{n_j} \to Kh$.
Key Insight: K compact iff $h_n \rightharpoonup h$ forces $Kh_n \to Kh$ in norm. □

Definition 6.2.8. *Orthogonal Projection Sequence*
Let $(e_k)_{k\geq 1}$ be a Hilbert basis for a separable Hilbert space $\mathcal{H}$.
The induced *orthogonal projection sequence* $(P_n)_{n\geq 1}$ is defined by:

(i) $P_n h := \sum_{k=1}^{n} \langle h, e_k\rangle e_k$ for $h \in \mathcal{H}$.
(ii) $\operatorname{range}(P_n) = \operatorname{span}\{e_1, \ldots, e_n\}$ and $\|P_n\|_{\text{op}} = 1$.
(iii) $P_n h \to h$ for every $h \in \mathcal{H}$.

Proposition 6.2.9. *Finite-Rank Approximation by Orthogonal Projections*
Let (P_n) be the orthogonal projection sequence induced by a Hilbert basis of a separable Hilbert space $\mathcal{H}$. For $T \in \mathcal{L}(\mathcal{H})$, T is compact iff $\|P_n T - T\|_{op} \to 0$.

Proof.

($\Rightarrow$) $B := \overline{B}_{\mathcal{H}}$, $C := \overline{T(B)}$; T compact $\Rightarrow C$ compact.
$\varepsilon > 0 \Rightarrow \exists y_1, \ldots, y_r \in C, N \in \mathbb{N} : C \subseteq \bigcup_{j=1}^{r} B_{\mathcal{H}}(y_j, \frac{\varepsilon}{3})$ and $n \geq N \Rightarrow \max_{1\leq j\leq r} \|(P_n - I)y_j\| < \frac{\varepsilon}{3}$.
Thus $n \geq N$, $x \in B \Rightarrow \exists j : \|Tx - y_j\| < \frac{\varepsilon}{3}$ and $\|(P_n T - T)x\| \leq \|Tx - y_j\| + \|(P_n - I)y_j\| + \|y_j - Tx\| < \varepsilon$.
Hence $\|P_n T - T\|_{\text{op}} = \sup_{x\in B} \|(P_n T - T)x\| \to 0$.

($\Leftarrow$) $\operatorname{range}(P_n T) \subseteq \operatorname{range}(P_n)$, $\dim \operatorname{range}(P_n) < \infty \Rightarrow P_n T$ compact by Proposition 6.2.3.
Also $P_n T \to T$ in $\|\cdot\|_{\text{op}}$; Theorem 6.2.4 $\Rightarrow T$ compact.

Structural Commentary: Compact $C = \overline{T(B)}$ upgrades $P_n y \to y$ to uniform convergence on C.
Key Insight: T compact iff finite-rank projections approximate T in operator norm. □

Corollary 6.2.10. *Finite-Rank Operators Are Dense in Compact Operators*
Let $\mathcal{H}$ be separable, and let $\mathcal{K}(\mathcal{H})$ and $\mathcal{F}(\mathcal{H})$ denote the compact and finite-rank operators in $\mathcal{L}(\mathcal{H})$.

(i) $\mathcal{K}(\mathcal{H})$ is a norm-closed linear subspace of $\mathcal{L}(\mathcal{H})$.
(ii) $\overline{\mathcal{F}(\mathcal{H})}^{\|\cdot\|_{op}} = \mathcal{K}(\mathcal{H})$.

Proof.

(i) Proposition 6.2.5: $K_1, K_2 \in \mathcal{K}(\mathcal{H})$, $\alpha, \beta \in \mathbb{F} \Rightarrow \alpha K_1 + \beta K_2 \in \mathcal{K}(\mathcal{H})$.
Theorem 6.2.4: $K_n \in \mathcal{K}(\mathcal{H})$, $\|K_n - K\|_{\text{op}} \to 0 \Rightarrow K \in \mathcal{K}(\mathcal{H})$.

(ii) ($\Rightarrow$) $\mathcal{F}(\mathcal{H}) \subseteq \mathcal{K}(\mathcal{H})$, (i) $\Rightarrow \overline{\mathcal{F}(\mathcal{H})}^{\|\cdot\|_{\text{op}}} \subseteq \mathcal{K}(\mathcal{H})$.

(ii) ($\Leftarrow$) $\dim \mathcal{H} < +\infty \Rightarrow \mathcal{F}(\mathcal{H}) = \mathcal{L}(\mathcal{H}) \supseteq \mathcal{K}(\mathcal{H})$. If $\dim \mathcal{H} = +\infty$,
take (P_n); $T \in \mathcal{K}(\mathcal{H}) \Rightarrow P_n T \in \mathcal{F}(\mathcal{H})$, $\|P_n T - T\|_{\text{op}} \to 0 \Rightarrow T \in \overline{\mathcal{F}(\mathcal{H})}^{\|\cdot\|_{\text{op}}}$ by Proposition 6.2.9.

Structural Commentary: $\mathcal{K}(\mathcal{H})$ is norm closed, and $P_nT \in \mathcal{F}(\mathcal{H})$ with $P_nT \to T$ for compact T.
Key Insight: On separable $\mathcal{H}$, $\mathcal{K}(\mathcal{H}) = \overline{\mathcal{F}(\mathcal{H})}^{\|\cdot\|_{\mathrm{op}}}$. □

Theorem 6.2.11. *Schauder's Theorem*
Let $\mathcal{H}$ be Hilbert. If $K \in \mathcal{L}(\mathcal{H})$ is compact, then K^* is compact.

Proof. ByTheorem 5.2.34,$K^* \in \mathcal{L}(\mathcal{H})$. By Theorem 6.2.7, it suffices to prove $h_n \rightharpoonup h \Rightarrow \|K^*(h_n - h)\| \to 0$.
Put $u_n := h_n - h$. Then $u_n \rightharpoonup 0$, $M := \sup_n \|u_n\| < \infty$, and $\forall v \in \mathcal{H}$, $\langle K^*u_n, v\rangle = \langle u_n, Kv\rangle \to 0$, so $K^*u_n \rightharpoonup 0$.
Compactness of K gives $\|KK^*u_n\| \to 0$, hence $0 \le \|K^*u_n\|^2 = \langle KK^*u_n, u_n\rangle \le M\|KK^*u_n\| \to 0$.
Structural Commentary: $u_n \rightharpoonup 0 \Rightarrow K^*u_n \rightharpoonup 0$, K compact $\Rightarrow KK^*u_n \to 0$; $\|K^*u_n\|^2 \le M\|KK^*u_n\|$.
Key Insight: $\|K^*u_n\|^2 = \langle KK^*u_n, u_n\rangle$. □

Proposition 6.2.12. *Injective Compact Perturbations of the Identity Are Onto*
Let $\mathcal{H}$ be Hilbert, let $K \in \mathcal{L}(\mathcal{H})$ be compact, and set $A := I + K$. If $\ker A = \{0\}$, then $A(\mathcal{H}) = \mathcal{H}$.

Proof.
(i) If $\inf_{\|h\|=1}\|Ah\| = 0$, choose $\|h_n\| = 1$, $Ah_n \to 0$. By Proposition 6.2.2(iii), $Kh_{n_j} \to y$,
hence $h_{n_j} = Ah_{n_j} - Kh_{n_j} \to -y := h$, $\|h\| = 1$, and $Ah = 0$, contradiction.
Thus $\exists c > 0 : \|Ah\| \ge c\|h\|\ \forall h \in \mathcal{H}$.
(ii) Fix $g \in \mathcal{H}$ and put $M := \mathrm{cspan}\{K^m g : m \ge 0\}$. Then $g \in M$, $K(M) \subseteq M$, and M is separable.
If $\dim M < +\infty$, then $A|_M : M \to M$ injective $\Rightarrow$ $A|_M$ surjective $\Rightarrow g \in A(\mathcal{H})$.
(iii) Assume $\dim M = +\infty$. Let (P_n) be projection sequence of Hilbert basis of M,
$H_n := P_n(M)$, $\dim H_n < +\infty$. By Proposition 6.2.9, $\|P_nK - K\|_{\mathrm{op}} \to 0$. Let N,
$n \ge N \Rightarrow \|P_nK - K\|_{\mathrm{op}} < \frac{c}{2}$. Then $n \ge N$, $h \in H_n \Rightarrow \|(I + P_nK)h\| \ge \|Ah\| - \|(P_nK - K)h\| \ge \frac{c}{2}\|h\|$, so $I + P_nK : H_n \to H_n$ injective $\Rightarrow$ surjective.
(iv) Choose $u_n \in H_n$ with $(I + P_nK)u_n = P_ng$. Then $\|u_n\| \le \frac{2}{c}\|P_ng\| \le \frac{2}{c}\|g\|$.
By Theorem 6.1.17, $u_{n_j} \rightharpoonup u$ for some subsequence.
By Theorem 6.2.7, $Ku_{n_j} \to Ku$, $\|P_{n_j}Ku_{n_j} - Ku_{n_j}\| \le \|P_{n_j}K - K\|_{\mathrm{op}}\|u_{n_j}\| \to 0$.
Since $P_{n_j}g \to g$, $u_{n_j} = P_{n_j}g - P_{n_j}Ku_{n_j} \to g - Ku$; by weak uniqueness $u = g - Ku$, hence $Au = g$.
Since $g \in \mathcal{H}$ was arbitrary, $A(\mathcal{H}) = \mathcal{H}$.
Structural Commentary: $\|Ah\| \ge c\|h\|$ and $(I + P_nK)u_n = P_ng \Rightarrow Au = g$.
Key Insight: Compactness removes approximate kernels and passes projected solutions to a true solution. □

Definition 6.2.13. *Fredholm Operator and Index*
Let $\mathcal{H}$ be a Hilbert space and let $T \in \mathcal{L}(\mathcal{H})$.
(i) *Fredholm*: $\mathrm{range}(T)$ is closed, $\dim\ker T < \infty$, and $\mathrm{codim}\,\mathrm{range}(T) < \infty$.
(ii) *Index*: $\mathrm{ind}\,T := \dim\ker T - \mathrm{codim}\,\mathrm{range}(T)$ when T is Fredholm.

Theorem 6.2.14. *Riesz–Schauder for Compact Perturbations of the Identity*
Let $\mathcal{H}$ be Hilbert, let $K \in \mathcal{L}(\mathcal{H})$ be compact, and set $A := I + K$. Then:
(i) $\dim\ker A < \infty$.
(ii) $\mathrm{range}(A)$ *is closed.*
(iii) $\mathrm{codim}\,\mathrm{range}(A) = \dim\ker(A^*) = \dim\ker A < \infty$.
(iv) A is Fredholm with $\mathrm{ind}\,A = 0$.
(v) A is injective iff it is surjective.

Proof.
(i) $\dim\ker A = +\infty \Rightarrow \exists(u_n) \subseteq \ker A$ with $\langle u_n, u_m\rangle = \delta_{nm}$.
Then $Ku_n = -u_n$ and $n \ne m \Rightarrow \|Ku_n - Ku_m\| = \sqrt{2}$, contradicting Proposition 6.2.2(iii).
(ii) Let $H_0 := (\ker A)^\perp$. If $\inf\{\|Ah\| : h \in H_0, \|h\| = 1\} = 0$, choose $h_n \in H_0$, $\|h_n\| = 1$, $Ah_n \to 0$.
By Proposition 6.2.2(iii), $Kh_{n_j} \to y$, so $h_{n_j} = Ah_{n_j} - Kh_{n_j} \to -y := h \in H_0$, $Ah = 0$.
Thus $h \in \ker A \cap H_0 = \{0\}$, contradiction. Hence $\exists c > 0 : \|Ah\| \ge c\|h\|$ on H_0.
Also $A(H_0) = A(\mathcal{H})$. If $Ah_n \to y$ with $h_n \in H_0$, then $\|h_n - h_m\| \le c^{-1}\|Ah_n - Ah_m\|$.
Thus $h_n \to h \in H_0$ and $Ah = y$; hence $\mathrm{range}(A)$ is closed.
(iii) By Theorem 6.2.11, K^* compact, so (i)–(ii) apply to $A^* = I + K^*$.
By Proposition 5.2.39, $\mathcal{H} = \mathrm{range}(A) \odot \ker(A^*)$, $\mathrm{codim}\,\mathrm{range}(A) = \dim\ker(A^*)$.
If $\dim\ker A < \dim\ker(A^*)$, choose injective $L : \ker A \to \ker(A^*)$ with $L(\ker A) \ne \ker(A^*)$, $F := LP_{\ker A}$.
Then $\mathrm{rank}\,F < +\infty$, $K + F$ compact. For $x = z + n$, $z \in H_0$, $n \in \ker A$,
$(A + F)x = Az + Ln \in \mathrm{range}(A) \odot L(\ker A)$; injectivity of L gives $\ker(A + F) = \{0\}$ and
$\mathrm{range}(A + F) = \mathrm{range}(A) \odot L(\ker A) \ne \mathcal{H}$, contradicting Proposition 6.2.12. Thus $\dim\ker A \ge \dim\ker(A^*)$.
Apply the same argument to A^* and use $(K^*)^* = K$ to get $\dim\ker A = \dim\ker(A^*)$.
(iv) (i)–(iii) give $\mathrm{range}(A)$ closed, $\dim\ker A < +\infty$, $\mathrm{codim}\,\mathrm{range}(A) < +\infty$.
Also $\dim\ker A = \mathrm{codim}\,\mathrm{range}(A)$; hence A is Fredholm and $\mathrm{ind}\,A = 0$.
(v) (iii) gives $\ker A = \{0\} \iff \mathrm{codim}\,\mathrm{range}(A) = 0 \iff \mathrm{range}(A) = \mathcal{H}$.
Structural Commentary: Compactness $\Rightarrow \dim\ker A < \infty$, $\mathrm{range}(A)$ closed; $F = LP_{\ker A} \Rightarrow \dim\ker A = \dim\ker(A^*)$.
Key Insight: For $A = I + K$ compactly perturbed, injectivity and surjectivity have the same finite defect. □

Corollary 6.2.15. *Fredholm Alternative*
Let $\mathcal{H}$ be Hilbert, let $K \in \mathcal{L}(\mathcal{H})$ be compact, let $\lambda \in \mathbb{F} \setminus \{0\}$, and set $T_\lambda := \lambda I - K$.
(i) $\mathrm{range}(T_\lambda) = \mathcal{H}$ *iff* $\ker T_\lambda = \{0\}$.
(ii) If the conditions in (i) hold, then $T_\lambda^{-1} \in \mathcal{L}(\mathcal{H})$.

Proof. Let $\widetilde{K} := -\lambda^{-1}K$; $\widetilde{K}$ compact, $T_\lambda = \lambda(I + \widetilde{K})$, $\ker T_\lambda = \ker(I + \widetilde{K})$, $\mathrm{range}(T_\lambda) = \mathcal{H}$ iff $\mathrm{range}(I + \widetilde{K}) = \mathcal{H}$.
(i) ($\Rightarrow$) $\mathrm{range}(T_\lambda) = \mathcal{H} \Rightarrow \mathrm{range}(I + \widetilde{K}) = \mathcal{H} \Rightarrow \ker(I + \widetilde{K}) = \{0\}$ by Theorem 6.2.14(v), hence $\ker T_\lambda = \{0\}$.

(*i*) ($\Leftarrow$) $\ker T_\lambda = \{0\} \Rightarrow \ker(I + \widetilde{K}) = \{0\} \Rightarrow \operatorname{range}(I + \widetilde{K}) = \mathcal{H}$ by Theorem 6.2.14(v), hence $\operatorname{range}(T_\lambda) = \mathcal{H}$.
(*ii*) (i) $\Rightarrow T_\lambda$ bijective; Corollary 5.4.4 $\Rightarrow T_\lambda^{-1} \in \mathcal{L}(\mathcal{H})$.

Structural Commentary: $T_\lambda = \lambda(I + \widetilde{K})$ with $\widetilde{K}$ compact; bijective T_λ has bounded inverse.
Key Insight: $\forall f$, $T_\lambda u = f$ is solvable iff $\ker T_\lambda = \{0\}$. □

Theorem 6.2.16. *Fredholm Index Zero as an Invertible Plus Compact Operator*
Let $\mathcal{H}$ be Hilbert and let $T \in \mathcal{L}(\mathcal{H})$. The following are equivalent:

(i) T is Fredholm and $\operatorname{ind} T = 0$.
(ii) $\exists S, K \in \mathcal{L}(\mathcal{H})$ such that $T = S + K$, S is invertible, and K is compact.

Proof.

(*i*) $\Rightarrow$ (*ii*) $N := \ker T$, $R := \operatorname{range}(T)$, $Z := \ker(T^*)$.
By Proposition 5.2.39, $\mathcal{H} = R \odot Z$ and $\dim Z = \operatorname{codim} R$. $\operatorname{ind} T = 0 \Rightarrow \dim N = \dim Z < +\infty$.
$A : N \to Z$ isomorphism, P_N orthogonal projection, $K := AP_N$, $S := T - K$.
Then $\operatorname{rank} K < +\infty \Rightarrow K$ compact and $T = S + K$. For $h = v + u$, $v \in N^\perp$, $u \in N$, $Sh = Tv - Au \in R \odot Z$ and $Sh = 0 \Rightarrow Tv = 0$, $Au = 0 \Rightarrow v = 0$, $u = 0$; hence $\ker S = \{0\}$.
Also $T(N^\perp) = R$, $A(N) = Z$, and $y = r + z \in R \odot Z \Rightarrow \exists v \in N^\perp, u \in N : Tv = r, Au = -z, S(v + u) = y$; hence $\operatorname{range} S = \mathcal{H}$ and $S^{-1} \in \mathcal{L}(\mathcal{H})$ by Corollary 5.4.4.
(*ii*) $\Rightarrow$ (*i*) $C := S^{-1}K$, $A := I + C$. By Proposition 6.2.5(ii), C is compact and $T = SA$.
By Theorem 6.2.14(iv), A is Fredholm, $\operatorname{ind} A = 0$. S isomorphism $\Rightarrow \ker T = \ker A$, $\operatorname{range} T = S(\operatorname{range} A)$, $\operatorname{codim} \operatorname{range} T = \operatorname{codim} \operatorname{range} A$. Hence T is Fredholm and $\operatorname{ind} T = 0$.

Structural Commentary: $K = AP_{\ker T}$ makes $S = T - K$ invertible; $T = S(I + C)$ with C compact.
Key Insight: $\operatorname{ind} T = 0$ iff T is invertible modulo compact operators. □

Corollary 6.2.17. *Index-Zero Fredholm Operators Are Closed under Composition*
Let $\mathcal{H}$ be Hilbert, $S, T \in \mathcal{L}(\mathcal{H})$ be Fredholm with $\operatorname{ind} S = \operatorname{ind} T = 0$. Then ST is Fredholm and $\operatorname{ind}(ST) = 0$.

Proof. By Theorem 6.2.16, $S = S_0 + K_S$, $T = T_0 + K_T$, with S_0, T_0 invertible and K_S, K_T compact.
Let $U := S_0T_0$, $C := S_0K_T + K_ST_0 + K_SK_T$. Then $ST = U + C$, U invertible, by Proposition 6.2.5, C compact.
Theorem 6.2.16 $\Rightarrow ST$ Fredholm and $\operatorname{ind}(ST) = 0$.
Structural Commentary: $(S_0 + K_S)(T_0 + K_T) = S_0T_0 + C$, $C \in \mathcal{K}(\mathcal{H})$.
Key Insight: Invertible modulo compact operators are closed under products. □

Corollary 6.2.18. *Compact Perturbations Preserve Index-Zero Fredholm Operators*
Let $\mathcal{H}$ be Hilbert and let $T, K \in \mathcal{L}(\mathcal{H})$. If T is Fredholm, $\operatorname{ind} T = 0$, and K is compact, then:

(i) $T + K$ is Fredholm.
(ii) $\operatorname{ind}(T + K) = 0$.

Proof. By Theorem 6.2.16, $T = S + C$, S invertible, C compact. Set $\widetilde{C} := C + K$.
By Proposition 6.2.5, $\widetilde{C} \in \mathcal{K}(\mathcal{H})$ and $T + K = S + \widetilde{C}$.

(i) $T + K = S + \widetilde{C}$, S invertible, $\widetilde{C}$ compact $\Rightarrow T + K$ Fredholm by Theorem 6.2.16.
(ii) $T + K = S + \widetilde{C}$, S invertible, $\widetilde{C}$ compact $\Rightarrow \operatorname{ind}(T + K) = 0$ by Theorem 6.2.16.

Structural Commentary: $T = S + C$, $K \in \mathcal{K}(\mathcal{H}) \Rightarrow T + K = S + \widetilde{C}$, $\widetilde{C} = C + K \in \mathcal{K}(\mathcal{H})$.
Key Insight: ind = 0 is stable under compact perturbation. □

6.3 Spectral Theory of Operators

For bounded operators, spectrum replaces the finite-dimensional eigenvalue list. The resolvent tracks invertibility, while the spectrum records every obstruction to it.

Definition 6.3.1. *Spectrum and Resolvent*
Let $\mathcal{X}$ be a complex Banach space and let $T \in \mathcal{L}(\mathcal{X})$.

(i) *Resolvent set*: $\rho(T) := \{\lambda \in \mathbb{C} : \lambda I - T$ is bijective and $(\lambda I - T)^{-1} \in \mathcal{L}(\mathcal{X})\}$.
(ii) *Spectrum*: $\sigma(T) := \mathbb{C} \setminus \rho(T)$.

Theorem 6.3.2. *Spectrum of a Complex Bounded Operator*
Let $\mathcal{X}$ be a nonzero complex Banach space and let $T \in \mathcal{L}(\mathcal{X})$. Then:

(i) $\sigma(T) \neq \varnothing$;
(ii) $\sigma(T)$ is compact in $\mathbb{C}$;
(iii) $\sigma(T) \subseteq \{\lambda \in \mathbb{C} : |\lambda| \leq \|T\|_{op}\}$.

Proof. For $\lambda \in \rho(T)$, $R(\lambda) := (\lambda I - T)^{-1}$. If $\mu \in \rho(T)$, $|\lambda - \mu| \, \|R(\mu)\|_{\mathrm{op}} < 1$; $\lambda I - T = (I + (\lambda - \mu)R(\mu))(\mu I - T)$.
By Corollary 5.1.7, $\lambda \in \rho(T)$, $R(\lambda) = R(\mu)(I + (\lambda - \mu)R(\mu))^{-1}$. If $|\lambda| > \|T\|_{\mathrm{op}}$, then $\lambda I - T = \lambda(I - \lambda^{-1}T)$.
By Corollary 5.1.7, $\lambda \in \rho(T)$ and $\|R(\lambda)\|_{\mathrm{op}} \leq (|\lambda| - \|T\|_{\mathrm{op}})^{-1}$.

(i) Suppose $\sigma(T) = \varnothing$. By the local Neumann formula above, $R : \mathbb{C} \to \mathcal{L}(\mathcal{X})$ is entire.
For $x \in \mathcal{X}$ and $\Phi \in \mathcal{X}^*$, $f_{x,\Phi}(\lambda) := \Phi(R(\lambda)x)$ is an entire scalar function. By the estimate above, $f_{x,\Phi}(\lambda) \to 0$ as $|\lambda| \to +\infty$, and continuity bounds $f_{x,\Phi}$ on compact disks. By Liouville's theorem, $f_{x,\Phi} = 0$. By Corollary 5.3.3, bounded linear functionals separate points, so $R(0) = 0$, contradicting $(-T)R(0) = I$ on the nonzero space $\mathcal{X}$.
(ii) By the local Neumann formula, $\rho(T)$ is open, so $\sigma(T)$ is closed in $\mathbb{C}$.
By outside-disk formula, $\sigma(T) \subseteq \{\lambda \in \mathbb{C} : |\lambda| \leq \|T\|_{\mathrm{op}}\}$, hence $\sigma(T)$ is bounded. Thus $\sigma(T)$ is compact.
(iii) If $|\lambda| > \|T\|_{\mathrm{op}}$, then the outside-disk condition holds. By the outside-disk Neumann argument, $\lambda \in \rho(T)$.
Therefore every $\lambda \in \sigma(T)$ satisfies $|\lambda| \leq \|T\|_{\mathrm{op}}$.

Structural Commentary: By Neumann, $\rho(T)$ is open and $\sigma(T) \subseteq \{\lambda : |\lambda| \leq \|T\|_{\text{op}}\}$. By Liouville, $\sigma(T) \neq \varnothing$.
Key Insight: Complex Banach spectra are nonempty compact obstructions to invertibility. □

Definition 6.3.3. *Spectral Radius*
Let $\mathcal{X}$ be a nonzero complex Banach space and let $T \in \mathcal{L}(\mathcal{X})$. The *spectral radius* of T is $r(T) := \sup_{\lambda \in \sigma(T)} |\lambda|$.

Theorem 6.3.4. *Spectral Radius Formula*
Let $\mathcal{X}$ be a nonzero complex Banach space and let $T \in \mathcal{L}(\mathcal{X})$.
Then the sequence $(\|T^n\|_{op}^{1/n})_{n\geq 1}$ converges in $[0,\infty)$, and $\lim_{n\to\infty} \|T^n\|_{op}^{1/n} = r(T)$.

Proof. Set $a_n := \|T^n\|_{\text{op}}$ for $n \geq 0$, so $a_0 = 1$ and $a_{m+n} \leq a_m a_n$. If $a_m = 0$ for some $m \geq 1$, then T is nilpotent.
Also $\|T^n\|_{\text{op}}^{1/n} \to 0$, $\sigma(T) = \{0\}$ by finite Neumann series and Theorem 6.3.2.
Hence assume $a_n > 0$ for all $n \geq 1$. For fixed $m \geq 1$ and $n = qm + r$ with $0 \leq r < m$, $a_n^{1/n} \leq a_m^{q/n} a_r^{1/n}$.
By $\limsup$ in n, $\limsup_n a_n^{1/n} \leq a_m^{1/m}$, hence $\limsup_n a_n^{1/n} \leq \inf_{m\geq 1} a_m^{1/m} \leq \liminf_n a_n^{1/n}$.
Thus $L := \lim_n a_n^{1/n} = \inf_{m\geq 1} a_m^{1/m}$. If $|\lambda| > L$, choose n with $a_n < |\lambda|^n$.
Then $\|T^n/\lambda^n\|_{\text{op}} < 1$, so Corollary 5.1.7 makes $\lambda^n I - T^n$ invertible.
With $Q_n := \sum_{j=0}^{n-1} \lambda^{n-1-j} T^j$, $\lambda^n I - T^n = (\lambda I - T)Q_n = Q_n(\lambda I - T)$; as these are polynomials in T,
$(\lambda I - T)^{-1} = Q_n(\lambda^n I - T^n)^{-1}$. Thus $\lambda \in \rho(T)$, so $\sigma(T) \subseteq \{z \in \mathbb{C} : |z| \leq L\}$ and $r(T) \leq L$.
Let $R > r(T)$, $R_0 > \max\{R, \|T\|_{\text{op}}\}$. For $|z| = R_0$, by Neumann expansion, $(zI - T)^{-1} = \sum_{k\geq 0} z^{-k-1} T^k$.
By Cauchy's coefficient formula $T^n = \frac{1}{2\pi i} \int_{|z|=R_0} z^n (zI - T)^{-1}\, dz$.
Since $\{z : R \leq |z| \leq R_0\} \subseteq \rho(T)$, Cauchy's theorem moves the contour to $|z| = R$.
With $M_R := \sup_{|z|=R} \left\|(zI - T)^{-1}\right\|_{\text{op}} < +\infty$, $a_n \leq M_R R^{n+1}$, hence $L \leq R$. By letting $R \downarrow r(T)$, $L \leq r(T)$.
Structural Commentary: By submultiplicativity, L exists; Neumann, $r(T) \leq L$; resolvent bounds, $L \leq r(T)$.
Key Insight: The spectral radius is asymptotic operator-power growth. □

Definition 6.3.5. *Quadratic Form and Rayleigh Quotient*
Let $\mathcal{H}$ be a real Hilbert space and let $T \in \mathcal{L}(\mathcal{H})$ be self-adjoint.

(i) *Quadratic form*: $Q_T(h) := \langle Th, h\rangle$ for $h \in \mathcal{H}$.
(ii) *Rayleigh quotient*: $R_T(h) := \frac{\langle Th,h\rangle}{\langle h,h\rangle}$ for $h \in \mathcal{H} \setminus \{0\}$.

A unit-sphere maximizer of Q_T is equivalently a maximizer of R_T on $\mathcal{H} \setminus \{0\}$.

Example 6.3.6. *A Self-Adjoint Operator without Eigenvectors*
Let $a < b$, set $H := L^2([a,b];\mathbb{C})$, and define $(Tf)(x) := xf(x)$.
With $M := \max\{|a|, |b|\}$, $\|Tf\|_2 \leq M \|f\|_2$, so $T \in \mathcal{L}(H)$.
For $u, v \in H$, $\langle Tu, v\rangle = \int_a^b xu(x)\overline{v(x)}\, dx = \int_a^b u(x)\overline{xv(x)}\, dx = \langle u, Tv\rangle$, hence $T = T^*$.
If $Tf = \lambda f$ for $\lambda \in \mathbb{C}$, then $(x - \lambda)f(x) = 0$ a.e. Let $E_\lambda := \{x \in [a,b] : x = \lambda\}$.
Since $m(E_\lambda) = 0$, $f = 0$ a.e. on $[a,b] \setminus E_\lambda$ and on E_λ, hence $f = 0$ in H.
Thus no nonzero $f \in H$ satisfies $Tf = \lambda f$, so T has no eigenvectors.

Lemma 6.3.7. *Hilbert–Schmidt Lemma*
Let $0 \neq \mathcal{H}$ be real Hilbert space, $T = T^* \in \mathcal{L}(\mathcal{H})$ compact, $Q_T(h) := \langle Th, h\rangle$. Then $\exists \lambda \in \mathbb{R}$, $h_* \in \mathcal{H}$ such that:

(i) $\|h_*\| = 1$;
(ii) $Th_* = \lambda h_*$;
(iii) $|\lambda| = \|T\|_{op} = \sup_{\|h\|=1} |Q_T(h)|$.

Proof. If $T = 0$, choose $\|h_*\| = 1$ and set $\lambda = 0$; then (i)–(iii) hold. Assume $T \neq 0$ and put $\eta := \|T\|_{\text{op}}$.
By Theorem 5.2.38, $\eta = \sup_{\|h\|=1} |Q_T(h)| > 0$. Choose $\|x_n\| = 1$ and $s_n \in \{-1, 1\}$ with $Q_{s_n T}(x_n) \to \eta$.
Passing to a subsequence, $s_n = s$; write $h_n := x_n$ and $A := sT$.
By Theorems 6.1.17 and 6.2.7, after passing to a further subsequence, $h_n \rightharpoonup h_*$ and $Ah_n \to Ah_*$ in norm.
Since $Q_A(h_n) - Q_A(h_*) = \langle Ah_n - Ah_*, h_n\rangle + \langle Ah_*, h_n - h_*\rangle \to 0$, $Q_A(h_*) = \eta$. Set $\lambda := s\eta$.

(i) By weak lower semicontinuity, $\|h_*\| \leq 1$.
Since $|Q_A(g)| \leq \eta \|g\|^2$ $\forall g \in \mathcal{H}$, $\eta = Q_A(h_*) \leq \eta \|h_*\|^2$. As $\eta > 0$, $\|h_*\| = 1$.
(ii) By (i), $R_A(h_*) = \eta$. For $\|h\| = 1$, $R_A(h) = Q_A(h) \leq |Q_T(h)| \leq \eta$, so h_* maximizes R_A.
For $h_0 \in \mathcal{H}$, $\phi(t) := R_A(h_* + th_0)$ has $\phi'(0) = 0$, hence $0 = 2\langle Ah_* - \eta h_*, h_0\rangle$.
Since h_0 is arbitrary, $Ah_* = \eta h_*$. Thus $Th_* = s\eta h_* = \lambda h_*$.
(iii) By the definition of λ and by Theorem 5.2.38, $|\lambda| = \eta = \|T\|_{\text{op}} = \sup_{\|h\|=1} |Q_T(h)|$.

Structural Commentary: By compactness, signed Q_T attains $\|T\|_{\text{op}}$; by stationarity, $Th_* = \lambda h_*$.
Key Insight: A compact self-adjoint norm maximizer is an eigenvector. □

Corollary 6.3.8. *Extremal Rayleigh Values Are Eigenvalues*
Let $\mathcal{H}$ be a nonzero real Hilbert space, let $T \in \mathcal{L}(\mathcal{H})$ be compact and self-adjoint, and set $Q_T(h) := \langle Th, h\rangle$, $\alpha := \inf_{\|h\|=1} Q_T(h)$, $\beta := \sup_{\|h\|=1} Q_T(h)$.

(i) If $\beta > 0$, then $\exists h_\beta \in \mathcal{H}$ such that $\|h_\beta\| = 1$ and $Th_\beta = \beta h_\beta$.
(ii) If $\alpha < 0$, then $\exists h_\alpha \in \mathcal{H}$ such that $\|h_\alpha\| = 1$ and $Th_\alpha = \alpha h_\alpha$.
(iii) If $\beta > 0$ and $(h_n) \subset \mathcal{H}$ satisfies $\|h_n\| = 1$, $Q_T(h_n) \to \beta$, then $\exists n_j \uparrow \infty$ and $h_\beta \in \mathcal{H}$ with $h_{n_j} \to h_\beta$ in norm, $\|h_\beta\| = 1$, and $Th_\beta = \beta h_\beta$.

Proof.

(i) Assume $\beta > 0$. Choose $\|u_n\| = 1$ with $Q_T(u_n) \to \beta$.
By Theorems 6.1.17 and 6.2.7, after passing to a subsequence, $u_n \rightharpoonup u_*$ and $Tu_n \to Tu_*$ in norm.
Since $Q_T(u_n) - Q_T(u_*) = \langle Tu_n - Tu_*, u_n\rangle + \langle Tu_*, u_n - u_*\rangle \to 0$, $Q_T(u_*) = \beta$.
By weak lower semicontinuity, $\|u_*\| \le 1$. As $Q_T(g) \le \beta\|g\|^2\ \forall g \in \mathcal{H}$, $\beta = Q_T(u_*) \le \beta\|u_*\|^2$; $\|u_*\| = 1$.
Thus u_* maximizes R_T. For $h \in \mathcal{H}$, $\phi(t) := R_T(u_* + th)$ has $\phi'(0) = 0$, so $0 = 2\langle Tu_* - \beta u_*, h\rangle$.
Hence $Tu_* = \beta u_*$; take $h_\beta := u_*$.

(ii) Assume $\alpha < 0$. Apply (i) to $-T$. Its upper Rayleigh value is $\beta_{-T} = \sup_{\|h\|=1}\langle -Th, h\rangle = -\alpha > 0$, so $\exists h_\alpha$ with $\|h_\alpha\| = 1$ and $(-T)h_\alpha = (-\alpha)h_\alpha$. Hence $Th_\alpha = \alpha h_\alpha$.

(iii) Assume $\beta > 0$, $\|h_n\| = 1$, $Q_T(h_n) \to \beta$. By compactness step in (i), $h_{n_j} \rightharpoonup h_\beta$, $Th_{n_j} \to Th_\beta$ in norm.
As in (i), $Q_T(h_\beta) = \beta$, $\|h_\beta\| = 1$, and $Th_\beta = \beta h_\beta$.
By Theorem 6.1.20, since $\|h_{n_j}\| = \|h_\beta\| = 1$, $h_{n_j} \to h_\beta$ in norm.

Structural Commentary: By compactness, attain β; by $-T$, attain α; by Radon–Riesz, $\rightharpoonup + \|\cdot\| \to 1 \Rightarrow \to$.
Key Insight: Compact self-adjoint Rayleigh extrema are eigenvalues. □

Theorem 6.3.9. *Hilbert–Schmidt Theorem for Compact Self-Adjoint Operators*
Let $\mathcal{H}$ be a real Hilbert space and let $K \in \mathcal{L}(\mathcal{H})$ be compact and self-adjoint.
If $\operatorname{rank} K = +\infty$, then $\exists$ orthonormal sequence $(\psi_k)_{k\ge1} \subset \mathcal{H}$ and nonzero scalars $(\lambda_k)_{k\ge1} \subset \mathbb{R}$ such that:

(i) $K\psi_k = \lambda_k\psi_k$ *for all* $k \ge 1$, $|\lambda_{k+1}| \le |\lambda_k|$, *and* $\lambda_k \to 0$;
(ii) $\operatorname{cspan}\{\psi_k : k \ge 1\} = (\ker K)^\perp$;
(iii) $Kh = \sum_{k\ge1} \lambda_k \langle h, \psi_k\rangle \psi_k$ *for every* $h \in \mathcal{H}$, *with norm convergence.*

If $\operatorname{rank} K < +\infty$, then:

(iv) $\exists m \ge 0$, *nonzero* $\lambda_1, \dots, \lambda_m \in \mathbb{R}$, *and an orthonormal basis* $(\psi_k)_{k=1}^m$ *of* $\operatorname{range} K = (\ker K)^\perp$ *such that* $K\psi_k = \lambda_k\psi_k$ *and* $Kh = \sum_{k=1}^m \lambda_k \langle h, \psi_k\rangle \psi_k$ *for every* $h \in \mathcal{H}$.

Proof.

(i) Put $M_0 := \{0\}$ and $H_0 := \mathcal{H}$. If $K|_{H_j} \ne 0$, then H_j is K-invariant and $K|_{H_j}$ is compact self-adjoint.
By Lemma 6.3.7, $\psi_{j+1} \in H_j$, $\lambda_{j+1} \ne 0$ with $\|\psi_{j+1}\| = 1$, $K\psi_{j+1} = \lambda_{j+1}\psi_{j+1}$, and $|\lambda_{j+1}| = \left\|K|_{H_j}\right\|_{\mathrm{op}}$.
Set $M_{j+1} := M_j \oplus \operatorname{span}\{\psi_{j+1}\}$, $H_{j+1} := M_{j+1}^\perp$. Since $K(M_{j+1}) \subseteq M_{j+1}$, $K = K^*$, $K(H_{j+1}) \subseteq H_{j+1}$.
Thus the construction continues while $K|_{H_j} \ne 0$, and $|\lambda_{j+1}| \le |\lambda_j|$.
If $\operatorname{rank} K = +\infty$, it cannot stop, since $K|_{H_m} = 0$ implies $\operatorname{range} K \subseteq M_m$.
If $\lambda_k \not\to 0$, then for some $\varepsilon > 0$, $\|K\psi_j - K\psi_k\|^2 = \lambda_j^2 + \lambda_k^2 \ge 2\varepsilon^2$ for infinitely many $j \ne k$, contradiction.

(ii) Set $M := \operatorname{cspan}\{\psi_k : k \ge 1\}$. Since $K(M) \subseteq M$ and $K = K^*$, $K(M^\perp) \subseteq M^\perp$.
If $K|_{M^\perp} \ne 0$, by Lemma 6.3.7 choose $\phi \in M^\perp$, $\mu \ne 0$ with $\|\phi\| = 1$ and $K\phi = \mu\phi$.
Then $\phi \in H_{k-1}\ \forall k$, so $|\mu| \le \left\|K|_{H_{k-1}}\right\|_{\mathrm{op}} = |\lambda_k| \to 0$, contradiction. Hence $M^\perp \subseteq \ker K$.
Conversely, $x \in \ker K$ implies $\langle x, \psi_k\rangle = \lambda_k^{-1}\langle Kx, \psi_k\rangle = 0\ \forall k$, so $\ker K \subseteq M^\perp$.
Thus $M^\perp = \ker K$ and $M = (\ker K)^\perp$ by Theorem 5.2.12.

(iii) For $h \in \mathcal{H}$, write $h = m + z$ with $m \in M = (\ker K)^\perp$ and $z \in \ker K$. By Theorem 5.2.22,
$m = \sum_{k\ge1} \langle h, \psi_k\rangle \psi_k$ in norm. By continuity of K, $Kh = Km = \sum_{k\ge1} \lambda_k \langle h, \psi_k\rangle \psi_k$ in norm.

(iv) If $\operatorname{rank} K < +\infty$, the construction stops at some $m \ge 0$; otherwise $\{\psi_k\} \subset \operatorname{range} K$ is an infinite orthonormal set in finite-dimensional $\operatorname{range} K$. Let $M_m := \operatorname{span}\{\psi_1, \dots, \psi_m\}$.
Since $K|_{M_m^\perp} = 0$, $\operatorname{range} K \subseteq M_m$; since $\psi_k = \lambda_k^{-1}K\psi_k$, $M_m \subseteq \operatorname{range} K$. Hence $M_m = \operatorname{range} K$.
Also $M_m^\perp = \ker K$ by argument in (ii), so $\operatorname{range} K = (\ker K)^\perp$. For $h = m_0 + z$ with $m_0 \in M_m$, $z \in \ker K$,
by the finite orthonormal expansion of m_0, $Kh = Km_0 = \sum_{k=1}^m \lambda_k \langle h, \psi_k\rangle \psi_k$.

Structural Commentary: Iterated extremal eigenvectors exhaust $(\ker K)^\perp$; Fourier expansion diagonalizes K.
Key Insight: Nonzero compact self-adjoint eigendirections are finite or countable, accumulating only at 0. □

Perspective 6.3.10. *Hilbert Operator Spectral Theory*
On a complex Hilbert space $\mathcal{H}$, normal $T \in \mathcal{L}(\mathcal{H})$ is diagonalized by spectral functional calculus.
By Theorem 6.3.9, compact self-adjoint $K \in \mathcal{L}(\mathcal{H})$ has nonzero eigenvalues (λ_k) and an orthonormal eigenfamily (ψ_k) spanning $(\ker K)^\perp$, so $\mathcal{H} = \ker K \oplus \operatorname{cspan}\{\psi_k\}$ and $Kh = \sum_k \lambda_k \langle h, \psi_k\rangle \psi_k\ \forall h \in \mathcal{H}$.
The sum is finite iff $\operatorname{rank} K < +\infty$; otherwise $\lambda_k \to 0$.

6.4 Measure Duality and Riesz Representation

On a compact Hausdorff space, Riesz–Markov turns positive functionals on $C(K)$ into Radon measures. The remaining step is order-theoretic: every bounded functional is the difference of two positive functionals, exactly as a signed measure is the difference of its Jordan variations.

Proposition 6.4.1. *Positive Functionals on $C(K)$ Are Continuous*
Let K be compact Hausdorff, $C(K) = C(K;\mathbb{R})$, $\|\cdot\|_\infty$, $L : C(K) \to \mathbb{R}$ linear with $L(C(K)_+) \subseteq [0, +\infty)$. Then:

(i) $L \in C(K)^*$.
(ii) $\|L\|_{op} = L(\mathbf{1}_K)$.

Proof.

(i) For $f \in C(K)$, $-\|f\|_\infty \mathbf{1}_K \le f \le \|f\|_\infty \mathbf{1}_K$; $-L(\mathbf{1}_K)\|f\|_\infty \le L(f) \le L(\mathbf{1}_K)\|f\|_\infty$; $|L(f)| \le L(\mathbf{1}_K)\|f\|_\infty$.
(ii) By (i), $\|L\|_{\mathrm{op}} \le L(\mathbf{1}_K)$. If $K = \varnothing$, both sides are 0; if $K \ne \varnothing$, then $\|\mathbf{1}_K\|_\infty = 1$, so $\|L\|_{\mathrm{op}} \ge L(\mathbf{1}_K)$.

Structural Commentary: $-\|f\|_\infty \mathbf{1}_K \le f \le \|f\|_\infty \mathbf{1}_K$ yields $|L(f)| \le L(\mathbf{1}_K)\,\|f\|_\infty$.
Key Insight: Positivity plus $\mathbf{1}_K$ controls $\|L\|_{\mathrm{op}}$. □

Proposition 6.4.2. *Positive Decomposition of Functionals on $C(K)$*
Let K be compact Hausdorff and let $L \in C(K)^*$. Then $\exists L_+, L_- \in C(K)^*$ positive such that:
(i) $L = L_+ - L_-$.
(ii) $\|L\|_{op} = L_+(\mathbf{1}_K) + L_-(\mathbf{1}_K)$.

Proof.
(i) For $f \in C(K)_+$, set $P(f) := \sup_{0\le g\le f} L(g)$; boundedness of L implies $P(f) < +\infty$.
If $0 \le h \le f_1 + f_2$, then $h = (h \wedge f_1) + (h - h \wedge f_1)$, terms in $[0, f_1]$ and $[0, f_2]$; $P(f_1 + f_2) \le P(f_1) + P(f_2)$.
The reverse inequality follows from $0 \le g_i \le f_i \Rightarrow 0 \le g_1 + g_2 \le f_1 + f_2$; homogeneity is immediate.
Define $L_+(u) := P(u^+) - P(u^-)$ and $L_- := L_+ - L$. Then L_+ is positive linear, $L_-(f) = P(f) - L(f) \ge 0$ for $f \in C(K)_+$, and by Proposition 6.4.1(i), $L_\pm \in C(K)^*$.
(ii) Set $A := L_+(\mathbf{1}_K) + L_-(\mathbf{1}_K)$. By (i) and Proposition 6.4.1(ii), $\|L\|_{\mathrm{op}} \le A$.
For $\varepsilon > 0$, choose $0 \le \varphi \le \mathbf{1}_K$ with $L(\varphi) > P(\mathbf{1}_K) - \varepsilon = L_+(\mathbf{1}_K) - \varepsilon$.
Since $\|2\varphi - \mathbf{1}_K\|_\infty \le 1$ and $L_-(\mathbf{1}_K) = L_+(\mathbf{1}_K) - L(\mathbf{1}_K)$, $\|L\|_{\mathrm{op}} \ge L(2\varphi - \mathbf{1}_K) > A - 2\varepsilon$. Let $\varepsilon \downarrow 0$.
Structural Commentary: $P(f) = \sup_{0\le g\le f} L(g)$ is the positive part on $C(K)_+$; $2\varphi - \mathbf{1}_K$ tests $\|L\|_{\mathrm{op}}$.
Key Insight: $L = L_+ - L_-$ and $\|L\|_{\mathrm{op}} = L_+(\mathbf{1}_K) + L_-(\mathbf{1}_K)$. □

Theorem 6.4.3. *Riesz Representation for $C(K)^*$*
Let K be compact Hausdorff. Let $\mathcal{M}_{\mathrm{Rad}}(K)$ be the finite signed measures ν on K with $\nu^\pm$ Radon.
Let $\|\nu\|_{\mathrm{var}} := |\nu|(K)$, and define $(T\nu)(f) := \int_K f\,d\nu$ for $f \in C(K)$. Then:
(i) T is linear and well defined.
(ii) $\|T(\nu)\|_{op} = \|\nu\|_{\mathrm{var}}$ for all $\nu \in \mathcal{M}_{\mathrm{Rad}}(K)$.
(iii) T is bijective.

Proof.
(i) For $\nu \in \mathcal{M}_{\mathrm{Rad}}(K)$ and $f \in C(K)$, $|T(\nu)(f)| \le \int_K |f|\,d\,|\nu| \le \|f\|_\infty \|\nu\|_{\mathrm{var}}$.
Hence $T(\nu) \in C(K)^*$ and $\|T(\nu)\|_{\mathrm{op}} \le \|\nu\|_{\mathrm{var}}$. Linearity is signed-integral linearity.
(ii) Set $L := T(\nu)$. By Proposition 6.4.2(i), Theorem 5.2.14, $L = L_+ - L_-$, $L_\pm = T(\mu_\pm)$ for finite Radon $\mu_\pm$.
Since $T(\nu^+ + \mu_-) = T(\nu^- + \mu_+)$, by uniqueness in Theorem 5.2.14, $\nu^+ + \mu_- = \nu^- + \mu_+$.
By Theorem 3.1.6(ii),(iii), $\nu^\pm \le \mu_\pm$. Therefore $\|\nu\|_{\mathrm{var}} \le \mu_+(K) + \mu_-(K) = L_+(\mathbf{1}_K) + L_-(\mathbf{1}_K) = \|L\|_{\mathrm{op}}$ by Proposition 6.4.2(ii).
Combine with (i).
(iii) Let $L \in C(K)^*$. Proposition 6.4.2(i), Theorem 5.2.14: $L = L_+ - L_-$, $L_\pm = T(\mu_\pm)$ for finite Radon $\mu_\pm$.
Set $\nu := \mu_+ - \mu_-$. By Theorem 3.1.6(ii),(iii), $\nu^\pm \le \mu_\pm$.
If $0 \le \theta \le \mu$ and μ is finite Radon, then θ is Radon since the same open and compact approximants work with no larger error.
Hence $\nu \in \mathcal{M}_{\mathrm{Rad}}(K)$, $T(\nu) = L$. Thus T is surjective; injectivity follows from (ii).
Structural Commentary: Positive Riesz–Markov: $L_\pm = T(\mu_\pm)$; Jordan minimality: $\|T(\nu)\|_{\mathrm{op}} = \|\nu\|_{\mathrm{var}}$.
Key Insight: $C(K)^* \cong \mathcal{M}_{\mathrm{Rad}}(K)$ isometrically via $L(f) = \int_K f\,d\nu$. □

Example 6.4.4. *Point Evaluation Is a Dirac Measure*
Let $K \neq \emptyset$ be compact Hausdorff and fix $x_0 \in K$. Define $L_{x_0} \in C(K)^*$ by $L_{x_0}(f) := f(x_0)$.
Then $L_{x_0} = T(\delta_{x_0})$, since $\forall f \in C(K)$, $T(\delta_{x_0})(f) = \int_K f\,d\delta_{x_0} = f(x_0)$. Hence $\|L_{x_0}\|_{\mathrm{op}} = \|\delta_{x_0}\|_{\mathrm{var}} = 1$.

Remark 6.4.5. *Interval Form and Stieltjes Integrators*
Let $a < b$ and let ν be a finite signed Radon measure on $[a, b]$, extended by 0 to $\mathbb{R}$. Set $g(x) := \nu((-\infty, x])$.
By Proposition 4.1.5 applied to $\nu^\pm$, $g \in BV(\mathbb{R})$ is right-continuous and $g(-\infty) = 0$.
For $a \le c \le d \le b$, $\nu((c, d]) = g(d) - g(c)$ and $\nu(\{a\}) = g(a) - g(a-)$ with $g(a-) = 0$.
Thus, in the Lebesgue–Stieltjes convention, $\forall f \in C([a, b])$, $T(\nu)(f) = \int_{[a,b]} f\,d\nu = \int_{[a,b]} f\,dg$.

Corollary 6.4.6. *Weak-* Compactness for Radon Measures*
Let K be compact Hausdorff and set $\mathcal{M} := \mathcal{M}_{\mathrm{Rad}}(K)$, the finite signed measures ν on K with $\nu^\pm$ Radon.
Let $\|\nu\|_{\mathrm{var}} := |\nu|(K)$ and let $\tau := \sigma(\mathcal{M}, C(K))$ be induced by $\langle \nu, f\rangle := \int_K f\,d\nu$.
If $A \subseteq \mathcal{M}$ is τ-closed and $\sup_{\nu\in A} \|\nu\|_{\mathrm{var}} < +\infty$, then A is τ-compact.

Proof. Let $(T\nu)(f) := \int_K f\,d\nu$. By Theorem 6.4.3, $T : \mathcal{M} \to C(K)^*$ is an isometric bijection identifying τ with $\sigma(C(K)^*, C(K))$.
Choose $R < +\infty$ with $A \subseteq R\overline{B}_{\mathcal{M}}$. Then $T(A)$ is weak-* closed and $T(A) \subseteq R\overline{B}_{C(K)^*}$.
By Theorem 6.1.6, $R\overline{B}_{C(K)^*}$ is weak-* compact; hence $T(A)$ and $A = T^{-1}(T(A))$ are weak-* compact.
Structural Commentary: Riesz isometry: reduce to weak-* closed $T(A) \subseteq R\overline{B}_{C(K)^*}$; Banach–Alaoglu: compact.
Key Insight: $T : \mathcal{M}_{\mathrm{Rad}}(K) \cong C(K)^*$ transfers Banach–Alaoglu compactness to Radon measures. □

Corollary 6.4.7. *Bounded Measures on Compact Metric Spaces Have Weak-* Subsequences*
Let K be compact metric and let $\mu_n \ge 0$ be Borel measures on K with $M := \sup_n \mu_n(K) < +\infty$.
Then $\exists n_k \uparrow \infty$ and a Radon measure $\mu \ge 0$ on K such that $\int_K f\,d\mu_{n_k} \to \int_K f\,d\mu$ for all $f \in C(K)$.

Proof. Set $T_n(f) := \int_K f\,d\mu_n$. By Proposition 6.4.1(ii), $T_n \in C(K)^*$, $T_n \ge 0$, and $\|T_n\|_{\mathrm{op}} = \mu_n(K) \le M$.
Since $C(K)$ is separable by Theorem 9.2.10, by Theorem 6.1.8, $\exists n_k \uparrow \infty$ and $T \in C(K)^*$ with $T_{n_k}(f) \to T(f)$ for all $f \in C(K)$.
Positivity passes to T, so by Theorem 5.2.14, $T(f) = \int_K f\,d\mu$ for some Radon $\mu \ge 0$.
Structural Commentary: Bound (T_n) in $C(K)^*$; use separability and Helly; represent the positive limit.
Key Insight: Bounded positive measures on compact metric K are weak-* sequentially compact on $C(K)$. □

Part XV
Probability Foundations and Distributions

1 Probability Spaces and Random Variables

1.1 Probability Spaces and Event Algebra

Probability assigns numbers to experimental outcomes; measure theory specifies which subsets are events.

Definition 1.1.1. *Sample Spaces, Events, and Probability Spaces*

(i) A *sample space* is a set Ω of possible outcomes.
(ii) An *outcome* or *realization* is a point $\omega \in \Omega$.
(iii) An *event* is a subset $A \subseteq \Omega$; the admissible events form a *σ-algebra* $\mathcal{F} \subseteq \mathcal{P}(\Omega)$.
(iv) A *probability measure* on $(\Omega, \mathcal{F})$ is a measure $\mathbb{P} : \mathcal{F} \to [0,1]$ with $\mathbb{P}(\Omega) = 1$.
(v) The triple $(\Omega, \mathcal{F}, \mathbb{P})$ is a *probability space*.

Key Insight: Probability is countably additive size normalized so that the whole sample space has mass 1.

Method 1.1.2. *Sample Space Construction Method*
Choose Ω as the set of complete outcomes and encode the target condition as an event $A \subseteq \Omega$:

(i) *Finite product method*: for m discrete trials with state set S, use $\Omega = S^m$ and coordinate constraints.
For two coin tosses, $S = \{H, T\}$, $\Omega = S^2$, and first toss heads gives $A = \{\omega \in \Omega : \omega_1 = H\} = \{HH, HT\}$.
(ii) *Interval method*: for real-valued measurements, use $\Omega = \mathbb{R}$ and translate inequalities into intervals.
$10 < \omega \leq 23$ gives $A = (10, 23]$.
(iii) *Cylinder method*: for infinite sequences with state set S, use $\Omega = S^{\mathbb{N}}$ and constrain finitely many coordinates; for coin tosses, $S = \{H, T\}$ and first head on toss 3 gives $A = \{\omega \in \Omega : \omega_1 = T, \omega_2 = T, \omega_3 = H\}$.

Example 1.1.3. *Introductory Sample Spaces and Events*

(i) If a commute passes three traffic lights, each with outcome stop s or continue c, then $\Omega = \{c, s\}^3$. The event that the first light is a stop is $\{sss, ssc, scc, scs\}$.
(ii) If a print queue length is modeled as random, one possible sample space is $\Omega = \{0, 1, 2, \ldots\}$; with a known capacity N, one may instead use $\Omega = \{0, 1, \ldots, N\}$.
(iii) If the measured waiting time between events is nonnegative, a natural sample space is $\Omega = [0, \infty)$.

Key Insight: Choose Ω at the event resolution needed.

Definition 1.1.4. *Event Algebra, Indicators, and Monotone Events*

(i) For $A \in \mathcal{F}$, the *complement* is $A^c := \Omega \setminus A$.
(ii) For $A, B \in \mathcal{F}$, the *union* and *intersection* are $A \cup B$ and $A \cap B$.
(iii) For $A, B \in \mathcal{F}$, the *difference* is $A \setminus B := A \cap B^c$.
(iv) *Commutativity*: $A \cup B = B \cup A$ and $A \cap B = B \cap A$.
(v) *Associativity*: $(A \cup B) \cup C = A \cup (B \cup C)$ and $(A \cap B) \cap C = A \cap (B \cap C)$.
(vi) *Distributivity*: $A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$ and $A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$.
(vii) *De Morgan laws*: $(A \cup B)^c = A^c \cap B^c$ and $(A \cap B)^c = A^c \cup B^c$.
(viii) Events $(A_i)_{i \in I}$ are *disjoint* or *mutually exclusive* if $A_i \cap A_j = \emptyset$ for $i \neq j$.
(ix) Events $(A_i)_{i \in I}$ form a *partition* of Ω if $A_i \cap A_j = \emptyset$ for $i \neq j$ and $\bigcup_{i \in I} A_i = \Omega$.
(x) The *indicator* of $A \in \mathcal{F}$ is $\mathbf{1}_A : \Omega \to \{0, 1\}$, where $\mathbf{1}_A(\omega) = 1$ for $\omega \in A$ and $\mathbf{1}_A(\omega) = 0$ for $\omega \notin A$.
(xi) A sequence (A_n) is *increasing* to A, written $A_n \uparrow A$, if $A_1 \subseteq A_2 \subseteq \cdots$ and $A = \bigcup_{n \geq 1} A_n$.
(xii) A sequence (A_n) is *decreasing* to A, written $A_n \downarrow A$, if $A_1 \supseteq A_2 \supseteq \cdots$ and $A = \bigcap_{n \geq 1} A_n$.

Proposition 1.1.5. *Indicator Algebra for Unions and Intersections*
For events $A, B \in \mathcal{F}$: $\mathbf{1}_{A \cap B} = \mathbf{1}_A \mathbf{1}_B = \min\{\mathbf{1}_A, \mathbf{1}_B\}$, and $\mathbf{1}_{A \cup B} = \max\{\mathbf{1}_A, \mathbf{1}_B\}$.

Proof. Fix $\omega \in \Omega$ and set $a := \mathbf{1}_A(\omega)$, $b := \mathbf{1}_B(\omega)$. Then $a, b \in \{0, 1\}$, $\mathbf{1}_{A \cap B}(\omega) = ab = \min\{a, b\}$, and $\mathbf{1}_{A \cup B}(\omega) = \max\{a, b\}$. Since ω was arbitrary, the identities hold pointwise.
Structural Commentary: Boolean operations on events become arithmetic operations on 0-1 variables.
Key Insight: Indicators let event algebra be manipulated inside sums and expectations. □

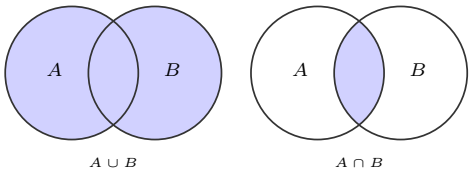

Figure 224: Set operations become event operations in a probability space.

Example 1.1.6. *Endpoint Sensitivity in Monotone Limits*
Let $\Omega = \mathbb{R}$.

(i) If $A_i = [0, \frac{1}{i}]$, then $\bigcup_{i=1}^{\infty} A_i = [0, 1]$ and $\bigcap_{i=1}^{\infty} A_i = \{0\}$.
(ii) If $A_i = (0, \frac{1}{i})$, then $\bigcup_{i=1}^{\infty} A_i = (0, 1)$ and $\bigcap_{i=1}^{\infty} A_i = \emptyset$.

Key Insight: Monotone set limits remember whether boundary points are included.

Proposition 1.1.7. *First Consequences of the Probability Axioms*
For events $A, B \in \mathcal{F}$:

(i) Null event: $\mathbb{P}(\emptyset) = 0$.
(ii) Monotonicity: $A \subseteq B \Rightarrow \mathbb{P}(A) \leq \mathbb{P}(B)$.
(iii) Bounds: $0 \leq \mathbb{P}(A) \leq 1$.
(iv) Complement: $\mathbb{P}(A^c) = 1 - \mathbb{P}(A)$.
(v) Disjoint additivity: $A \cap B = \emptyset \Rightarrow \mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B)$.
(vi) Two-set inclusion-exclusion: $\mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cap B)$.

Proof.

(i) Countable additivity on $\Omega = \Omega \sqcup \emptyset \sqcup \emptyset \sqcup \cdots$ gives $1 = 1 + \sum_{n \geq 1} \mathbb{P}(\emptyset)$, hence $\mathbb{P}(\emptyset) = 0$.
(ii) If $A \subseteq B$, then $B = A \sqcup (B \setminus A)$, so $\mathbb{P}(B) = \mathbb{P}(A) + \mathbb{P}(B \setminus A) \geq \mathbb{P}(A)$.
(iii) Since $\emptyset \subseteq A \subseteq \Omega$, (i) and (ii) give $0 = \mathbb{P}(\emptyset) \leq \mathbb{P}(A) \leq \mathbb{P}(\Omega) = 1$.
(iv) Since $\Omega = A \sqcup A^c$, $1 = \mathbb{P}(\Omega) = \mathbb{P}(A) + \mathbb{P}(A^c)$, so $\mathbb{P}(A^c) = 1 - \mathbb{P}(A)$.
(v) If $A \cap B = \emptyset$, then $A \cup B = A \sqcup B$, so $\mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B)$.
(vi) Decompose $A \cup B = (A \setminus B) \sqcup (A \cap B) \sqcup (B \setminus A)$, $A = (A \setminus B) \sqcup (A \cap B)$, and $B = (A \cap B) \sqcup (B \setminus A)$. Hence $\mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cap B)$.

Structural Commentary: The algebraic identities are set partitions in disguise.
Key Insight: Split overlapping sets into disjoint pieces before adding probabilities. □

Example 1.1.8. *Two Coin Tosses and Inclusion-Exclusion*
Let $\Omega = \{HH, HT, TH, TT\}$ with $\mathbb{P}(\{\omega\}) = \frac{1}{4}$ for all $\omega \in \Omega$. Set $H_1 = \{HH, HT\}$ and $H_2 = \{HH, TH\}$.
Since $H_1 \cap H_2 = \{HH\}$, $\mathbb{P}(H_1 \cup H_2) = \mathbb{P}(H_1) + \mathbb{P}(H_2) - \mathbb{P}(H_1 \cap H_2) = \frac{1}{2} + \frac{1}{2} - \frac{1}{4} = \frac{3}{4}$.

Proposition 1.1.9. *Three-Set Inclusion-Exclusion and Bonferroni*
For events $A, B, C \in \mathcal{F}$:

(i) $\mathbb{P}(A \cup B \cup C) = \mathbb{P}(A) + \mathbb{P}(B) + \mathbb{P}(C) - \mathbb{P}(A \cap B) - \mathbb{P}(A \cap C) - \mathbb{P}(B \cap C) + \mathbb{P}(A \cap B \cap C)$.
(ii) $\mathbb{P}(A \cap B) \geq \mathbb{P}(A) + \mathbb{P}(B) - 1$.

Proof.

(i) Let $U = A \cup B$. Then $A \cup B \cup C = U \cup C$ and $U \cap C = (A \cap C) \cup (B \cap C)$.
By two-set inclusion-exclusion, $\mathbb{P}(U \cup C) = \mathbb{P}(U) + \mathbb{P}(C) - \mathbb{P}(U \cap C)$, $\mathbb{P}(U) = \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cap B)$, and $\mathbb{P}(U \cap C) = \mathbb{P}(A \cap C) + \mathbb{P}(B \cap C) - \mathbb{P}(A \cap B \cap C)$. Substitution gives (i).
(ii) Since $\mathbb{P}(A \cup B) \leq 1$ and $\mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cap B)$, rearrange.

Structural Commentary: Inclusion-exclusion alternates between overcounting and correcting overlaps.
Key Insight: Bonferroni inequalities are one-sided forms of inclusion-exclusion. □

Theorem 1.1.10. *Continuity of Probabilities*

(i) Continuity from below: if $A_n \uparrow A$, then $\lim_{n \to \infty} \mathbb{P}(A_n) = \mathbb{P}(A)$.
(ii) Continuity from above: if $A_n \downarrow A$, then $\lim_{n \to \infty} \mathbb{P}(A_n) = \mathbb{P}(A)$.

Proof.

(i) Set $B_1 = A_1$ and $B_n = A_n \setminus A_{n-1}$ for $n \geq 2$. Then (B_n) is disjoint, $A_n = \bigcup_{j=1}^{n} B_j$, and $A = \bigcup_{j=1}^{\infty} B_j$, so countable additivity gives $\mathbb{P}(A_n) = \sum_{j=1}^{n} \mathbb{P}(B_j) \to \sum_{j=1}^{\infty} \mathbb{P}(B_j) = \mathbb{P}(A)$.
(ii) Set $C_n = A_1 \setminus A_n$. Then $C_n \uparrow A_1 \setminus A$, so (i) gives $\mathbb{P}(C_n) \to \mathbb{P}(A_1 \setminus A)$; since $A_1 = A_n \sqcup C_n$ and $A_1 = A \sqcup (A_1 \setminus A)$, finite additivity gives $\mathbb{P}(A_n) = \mathbb{P}(A_1) - \mathbb{P}(C_n) \to \mathbb{P}(A_1) - \mathbb{P}(A_1 \setminus A) = \mathbb{P}(A)$.

Structural Commentary: Monotone limits convert countable additivity into limit rules.
Key Insight: Increasing uses increments; decreasing uses complements. □

Definition 1.1.11. *Events Occurring Infinitely Often and Eventually Always*
For events $(A_n)_{n \geq 1}$:

(i) *Tail union*: $B_n := \bigcup_{i=n}^{\infty} A_i$.
(ii) *Tail intersection*: $C_n := \bigcap_{i=n}^{\infty} A_i$.
(iii) *Limsup*: $\limsup_{n \to \infty} A_n := \bigcap_{n=1}^{\infty} B_n = \bigcap_{n=1}^{\infty} \bigcup_{i=n}^{\infty} A_i$.
(iv) *Liminf*: $\liminf_{n \to \infty} A_n := \bigcup_{n=1}^{\infty} C_n = \bigcup_{n=1}^{\infty} \bigcap_{i=n}^{\infty} A_i$.
(v) *Infinitely often*: $\omega \in \limsup_n A_n$ iff $\omega \in A_n$ for infinitely many n.
(vi) *Eventually always*: $\omega \in \liminf_n A_n$ iff $\omega \in A_n$ for all but finitely many n.

Proposition 1.1.12. *Tail Monotonicity*
For events $(A_n)_{n \geq 1}$ with tail union B_n and tail intersection C_n:

(i) Tail unions: $B_{n+1} \subseteq B_n$ for all n, hence $B_n \downarrow \bigcap_{n \geq 1} B_n$.
(ii) Tail intersections: $C_n \subseteq C_{n+1}$ for all n, hence $C_n \uparrow \bigcup_{n \geq 1} C_n$.

Proof.

(i) Since $\{i : i \geq n+1\} \subseteq \{i : i \geq n\}$, $B_{n+1} = \bigcup_{i=n+1}^{\infty} A_i \subseteq \bigcup_{i=n}^{\infty} A_i = B_n$.

(ii) Since $\{i : i \geq n+1\} \subseteq \{i : i \geq n\}$, $C_n = \bigcap_{i=n}^{\infty} A_i \subseteq \bigcap_{i=n+1}^{\infty} A_i = C_{n+1}$.

Structural Commentary: Tail shifts turn recurrence and permanence into monotone limits.
Key Insight: Tail unions track recurrence; tail intersections track permanence. □

Proposition 1.1.13. *Union Bound and Countable Intersections of Almost-Sure Events*
For events $(A_n)_{n\geq 1}$:

(i) Union bound: $\mathbb{P}(\bigcup_{n=1}^{\infty} A_n) \leq \sum_{n=1}^{\infty} \mathbb{P}(A_n)$.

(ii) Countable almost-sure intersection: if $\mathbb{P}(A_n) = 1$ for all n, then $\mathbb{P}(\bigcap_{n=1}^{\infty} A_n) = 1$.

Proof.

(i) Set $B_n := A_n \setminus \bigcup_{j<n} A_j$. Then (B_n) is disjoint, $\bigcup_n B_n = \bigcup_n A_n$, and $B_n \subseteq A_n$.
Hence $\mathbb{P}(\bigcup_n A_n) = \sum_n \mathbb{P}(B_n) \leq \sum_n \mathbb{P}(A_n)$.

(ii) If $\mathbb{P}(A_n) = 1$ for all n, then $\mathbb{P}(A_n^c) = 0$ for all n.
By (i), $\mathbb{P}((\bigcap_n A_n)^c) = \mathbb{P}(\bigcup_n A_n^c) \leq \sum_n \mathbb{P}(A_n^c) = 0$, so $\mathbb{P}(\bigcap_n A_n) = 1$.

Structural Commentary: Countable subadditivity is countable additivity after disjointization.
Key Insight: Almost sure statements survive countable intersections. □

1.2 Finite Probability, Counting, and Independence

Definition 1.2.1. *Uniform Probability on a Countable Space*
Let Ω be countable.

(i) A probability measure $\mathbb{P}$ on $(\Omega, \mathcal{P}(\Omega))$ is *uniform* if $\exists c \in [0,1]$ such that $\mathbb{P}(\{\omega\}) = c$ for all $\omega \in \Omega$.
(ii) The constant c is the *common atom mass*.

Proposition 1.2.2. *No Uniform Probability on a Countably Infinite Set*
Let $\Omega = \{0, 1, 2, \ldots\}$. No uniform probability measure exists on $(\Omega, \mathcal{P}(\Omega))$.

Proof. Assume uniform $\mathbb{P}$ exists, and let c be its common atom mass.
Since $\Omega = \bigsqcup_{n=0}^{\infty} \{n\}$, countable additivity gives $1 = \mathbb{P}(\Omega) = \sum_{n=0}^{\infty} \mathbb{P}(\{n\}) = \sum_{n=0}^{\infty} c$.
If $c = 0$, the sum is 0; if $c > 0$, the sum diverges. Both contradict $1 = \mathbb{P}(\Omega)$.
Structural Commentary: Countable additivity forces total mass to equal the sum of the atom masses.
Key Insight: Equal mass on countably many atoms is incompatible with total mass 1. □

Method 1.2.3. *Finite Uniform Probability by Counting*
Let $0 < |\Omega| < \infty$ and assume the *uniform model* $\mathbb{P}(\{\omega\}) = |\Omega|^{-1}$ for all $\omega \in \Omega$.
For $A \subseteq \Omega$, $\mathbb{P}(A) = \sum_{\omega \in A} \mathbb{P}(\{\omega\}) = \frac{|A|}{|\Omega|}$, so probability reduces to counting.

Method 1.2.4. *Counting Workflow for Uniform Finite Probability*
For a finite uniform sample space Ω and an event $A \subseteq \Omega$:

(i) choose complete outcomes so that each $\omega \in \Omega$ is equally likely;
(ii) count $|\Omega|$; and count $|A|$, usually by products, complements, or disjoint cases;
(iii) conclude $\mathbb{P}(A) = |A| \,/\, |\Omega|$.

Key Insight: The hard step is often choosing equally likely outcomes, not applying the ratio.

Example 1.2.5. *Simpson's Paradox in Two Urn Games*
Let $p(U)$ be the red probability in urn U, and let B_i, W_i be the black and white urns in game i.
Within games, $p(B_1) = 5/11 > 3/7 = p(W_1)$ and $p(B_2) = 6/9 > 9/14 = p(W_2)$.
After pooling by color into B and W, $p(B) = 11/20 < 12/21 = p(W)$, so the aggregate winner is white.
Key Insight: A within-group advantage can reverse after aggregation when the group sizes change.

Example 1.2.6. *Complement Counting in Uniform Models*

(i) For plates $\Omega = L^3 \times D^3$ with $|L| = 26$ and $|D| = 10$, $|\Omega| = 26^3 \cdot 10^3$. If E is the event of no repeated letters and no repeated digits, then $|E| = (26)_3(10)_3$, so $\mathbb{P}(E) = \frac{(26)_3(10)_3}{26^3 \cdot 10^3}$.
(ii) For $1 \leq n \leq 365$ iid uniform birthdays, take $\Omega = \{1, \ldots, 365\}^n$. If C is the event of a shared birthday, then $C^c = D_n(\{1, \ldots, 365\})$, so $\mathbb{P}(C) = 1 - \frac{(365)_n}{365^n}$; for $n = 23$, $\mathbb{P}(C) > 1/2$.

Key Insight: "At least one collision" is often easier to count by subtracting the no-collision event.

Definition 1.2.7. *Independent Events*

(i) Events $A, B \in \mathcal{F}$ are *independent*, written $A \perp\!\!\!\perp B$, if $\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B)$.
(ii) A family $(A_i)_{i \in I} \subseteq \mathcal{F}$ is *pairwise independent* if A_i and A_j are independent whenever $i \neq j$.
(iii) A family $(A_i)_{i \in I} \subseteq \mathcal{F}$ is *mutually independent* if $\mathbb{P}(\bigcap_{i \in J} A_i) = \prod_{i \in J} \mathbb{P}(A_i)$ for every finite $J \subseteq I$.

Key Insight: Mutual independence means multiplicativity for every finite subfamily, not just pairs.

Example 1.2.8. *Pairwise Independence Need Not Be Mutual*
Let $\Omega = \{HH, HT, TH, TT\}$ with $\mathbb{P}(\{\omega\}) = \frac{1}{4}\ \forall \omega \in \Omega$.
Set $A = \{HH, HT\}$, $B = \{HH, TH\}$, $C = \{HT, TH\}$.
Then $\mathbb{P}(A) = \mathbb{P}(B) = \mathbb{P}(C) = \frac{1}{2}$, $\mathbb{P}(A \cap B) = \mathbb{P}(A \cap C) = \mathbb{P}(B \cap C) = \frac{1}{4}$, so A, B, C pairwise independent.
But $A \cap B \cap C = \emptyset$, so $\mathbb{P}(A \cap B \cap C) = 0 \neq \frac{1}{8} = \mathbb{P}(A)\mathbb{P}(B)\mathbb{P}(C)$.
Key Insight: Pairwise checks do not control higher-order intersections.

Proposition 1.2.9. *Basic Independence Tests*
Let $A, B \in \mathcal{F}$.

(i) If $A \cap B = \emptyset$ and $\mathbb{P}(A)\mathbb{P}(B) > 0$, then $A \not\perp\!\!\!\perp B$.
(ii) If $A \perp\!\!\!\perp B$, then $A^c \perp\!\!\!\perp B$, $A \perp\!\!\!\perp B^c$, and $A^c \perp\!\!\!\perp B^c$.
(iii) If $\mathbb{P}(A) \in \{0, 1\}$, then $A \perp\!\!\!\perp C$ for every $C \in \mathcal{F}$.
(iv) If $A \perp\!\!\!\perp A$, then $\mathbb{P}(A) \in \{0, 1\}$.

Proof.

(i) Since $A \cap B = \emptyset$, $\mathbb{P}(A \cap B) = 0 \neq \mathbb{P}(A)\mathbb{P}(B)$.
(ii) If $A \perp\!\!\!\perp B$, then $\mathbb{P}(A^c \cap B) = \mathbb{P}(B) - \mathbb{P}(A \cap B) = (1 - \mathbb{P}(A))\mathbb{P}(B) = \mathbb{P}(A^c)\mathbb{P}(B)$
and $\mathbb{P}(A \cap B^c) = \mathbb{P}(A) - \mathbb{P}(A \cap B) = \mathbb{P}(A)(1 - \mathbb{P}(B)) = \mathbb{P}(A)\mathbb{P}(B^c)$.
Applying the first identity to $A \perp\!\!\!\perp B^c$ gives $A^c \perp\!\!\!\perp B^c$.
(iii) Let $C \in \mathcal{F}$. If $\mathbb{P}(A) = 0$, then $0 \leq \mathbb{P}(A \cap C) \leq \mathbb{P}(A) = 0$, so $\mathbb{P}(A \cap C) = 0 = \mathbb{P}(A)\mathbb{P}(C)$.
If $\mathbb{P}(A) = 1$, then $\mathbb{P}(A^c) = 0$, hence $A^c \perp\!\!\!\perp C$ by the previous case and $A \perp\!\!\!\perp C$ by (ii).
(iv) Let $p = \mathbb{P}(A)$. From $A \perp\!\!\!\perp A$, $p = \mathbb{P}(A \cap A) = p^2$, hence $p \in \{0, 1\}$.

Structural Commentary: Independence is probabilistic, not visual; disjointness usually means strong dependence.
Key Insight: Complements preserve independence because B splits into $A \cap B$ and $A^c \cap B$. □

Method 1.2.10. *Independence, Complement, and Decomposition Methods*

(i) *Verify independence*: compute $\mathbb{P}(A)$, $\mathbb{P}(B)$, and $\mathbb{P}(A \cap B)$; conclude $A \perp\!\!\!\perp B$ iff $\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B)$.
(ii) *Use complements*: if A^c is simpler, compute $\mathbb{P}(A) = 1 - \mathbb{P}(A^c)$.
If $A^c = \bigcap_{j=1}^{n} C_j$ with independent C_j, then $\mathbb{P}(A) = 1 - \prod_{j=1}^{n} \mathbb{P}(C_j)$.
(iii) *Disjoint decomposition*: write $E = \bigsqcup_j A_j$ with disjoint A_j, then $\mathbb{P}(E) = \sum_j \mathbb{P}(A_j)$.
(iv) *Geometric summation*: if $\mathbb{P}(A_j) = ar^{j-1}$ for $j \geq 1$ and $|r| < 1$, then $\mathbb{P}(E) = \sum_{j \geq 1} ar^{j-1} = \frac{a}{1-r}$.

Example 1.2.11. *Independence, Complements, and First Success*

(i) *Independence by counting*: for a fair die, $\Omega = \{1, \ldots, 6\}$, $A = \{2, 4, 6\}$, and $B = \{1, 2, 3, 4\}$.
Then $\mathbb{P}(A \cap B) = \frac{2}{6} = (\frac{3}{6})(\frac{4}{6}) = \mathbb{P}(A)\mathbb{P}(B)$, hence $A \perp\!\!\!\perp B$.
(ii) *Complement method*: for independent fair tosses $X_1, \ldots, X_{10}$, let $A = \{\exists j \leq 10 : X_j = H\}$
and $T_j = \{X_j = T\}$. Then $A^c = \bigcap_{j=1}^{10} T_j$ and $\mathbb{P}(A) = 1 - \mathbb{P}(A^c) = 1 - \prod_{j=1}^{10} \mathbb{P}(T_j) = 1 - (\frac{1}{2})^{10}$.
(iii) *First-success decomposition*: let $p_1 = \frac{1}{3}$, $p_2 = \frac{1}{4}$.
Let A_j be player 1's first success on turn j before player 2 succeeds.
Then $E = \bigsqcup_{j \geq 1} A_j$, $\mathbb{P}(A_j) = ((1 - p_1)(1 - p_2))^{j-1} p_1 = (\frac{1}{2})^{j-1}/3$, and $\mathbb{P}(E) = \sum_{j \geq 1} \mathbb{P}(A_j) = \frac{2}{3}$.

Example 1.2.12. *Reliability and Match Probabilities*
Let A_i be the event that component i works, and assume all relevant events are mutually independent.

(i) Series: if $\mathbb{P}(A_i^c) = p$ for $1 \leq i \leq n$ and $W_s = \bigcap_{i=1}^{n} A_i$, then $\mathbb{P}(W_s) = (1 - p)^n$ and $\mathbb{P}(W_s^c) = 1 - (1 - p)^n$.
(ii) Parallel: if $W_p = \bigcup_{i=1}^{n} A_i$, then $\mathbb{P}(W_p^c) = \mathbb{P}(\bigcap_{i=1}^{n} A_i^c) = p^n$.
(iii) DNA match: let $N_j \in \{A, C, G, T\}$ with $\mathbb{P}(N_j = x) = p_{xj}$ for $j = 1, 2$.
If $N_1 \perp\!\!\!\perp N_2$, then $\mathbb{P}(N_1 = N_2) = \sum_{x \in \{A,C,G,T\}} p_{x1} p_{x2}$.

Key Insight: Independence multiplies intersections; complements handle failures; matches sum disjoint cases.

1.3 Random Variables, Laws, and Distribution Functions

Definition 1.3.1. *Random Variables, Laws, and Distribution Functions*

(i) A *real-valued random variable* on $(\Omega, \mathcal{F}, \mathbb{P})$ is map $X : \Omega \to \mathbb{R}$ s.t. $\{\omega \in \Omega : X(\omega) \in B\} \in \mathcal{F}\ \forall B \in \mathcal{B}(\mathbb{R})$.
(ii) Its *law* or *distribution* is $\mathcal{L}(X) : \mathcal{B}(\mathbb{R}) \to [0, 1]$ given by $\mathcal{L}(X)(B) := \mathbb{P}(X^{-1}(B)) = \mathbb{P}(X \in B)$.
(iii) Its *cumulative distribution function* is $F_X : \mathbb{R} \to [0, 1]$ given by $F_X(x) := \mathbb{P}(X \leq x) = \mathcal{L}(X)((-\infty, x])$.

Definition 1.3.2. *Distribution Functions and Densities*

(i) A *distribution function* is $F : \mathbb{R} \to [0, 1]$ such that $x \leq y \Rightarrow F(x) \leq F(y)$, $F(x) = \lim_{t \downarrow x} F(t)$ for all $x \in \mathbb{R}$, $\lim_{x \to -\infty} F(x) = 0$, and $\lim_{x \to \infty} F(x) = 1$.
(ii) A *density* for F is an integrable $g : \mathbb{R} \to [0, \infty)$ with $\int_{-\infty}^{\infty} g(x)\,dx = 1$ and $F(t) = \int_{-\infty}^{t} g(x)\,dx\ \forall t \in \mathbb{R}$.
If g is continuous, then $F'(t) = g(t)$.

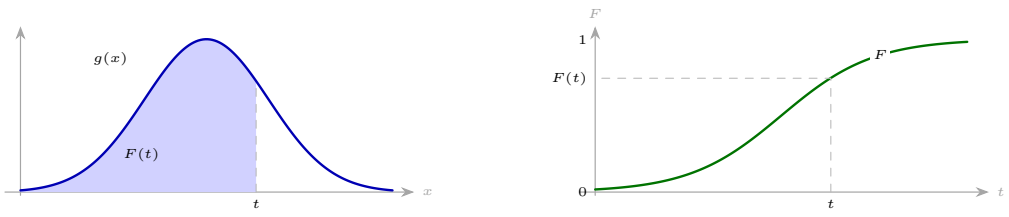

Figure 225: A normal density accumulates area into the distribution function $\Phi(t) = \int_{-\infty}^{t} g(x)\,dx$.

Definition 1.3.3. *Discrete and Continuous Random Variables*

(i) X is *discrete* if $X(\Omega) \subseteq S$ for some finite or countable $S = \{x_1, x_2, \ldots\} \subseteq \mathbb{R}$.
(ii) The *probability mass function* of discrete X is $f_X : S \to [0,1]$, $f_X(x) := \mathbb{P}(X = x)$, $\sum_{x \in S} f_X(x) = 1$.
(iii) The *discrete CDF* is $F_X(x) = \mathbb{P}(X \le x) = \sum_{x_i \le x} f_X(x_i)$.
(iv) X is *continuous* if its law has a density $f_X : \mathbb{R} \to [0, \infty)$.
(v) The *continuous probabilities* satisfy $\mathbb{P}(a < X < b) = \int_a^b f_X(t)\,dt$ and $F_X(x) = \int_{-\infty}^{x} f_X(t)\,dt$.
(vi) The *point-mass distinction*: for continuous X, $\mathbb{P}(X = x) = 0$ for every fixed x, so $f_X(x) \neq \mathbb{P}(X = x)$.

A law may be mixed. It can have atoms and a continuous density on the remaining part.

Remark 1.3.4. *Mixed Laws Are Natural*
For a component lifetime X, one may have $\mathbb{P}(X = 0) = p > 0$ and, conditional on $X > 0$, a density g on $(0, \infty)$.
Then $\mathcal{L}(X)$ has an atom plus a continuous part, so it is mixed.

Example 1.3.5. *Counting Heads in Two Tosses*
Let $\Omega = \{H, T\}^2$ with $\mathbb{P}(\{\omega\}) = \frac{1}{4}$, and set $X(\omega) = |\{j \in \{1,2\} : \omega_j = H\}|$.
Then $f_X(k) = \mathbb{P}(X = k) = \binom{2}{k} 2^{-2}$ for $k \in \{0,1,2\}$, so $(f_X(0), f_X(1), f_X(2)) = (\frac{1}{4}, \frac{1}{2}, \frac{1}{4})$.
Hence $F_X(x) = 0$ for $x < 0$, $F_X(x) = \frac{1}{4}$ for $0 \le x < 1$, $F_X(x) = \frac{3}{4}$ for $1 \le x < 2$, $F_X(x) = 1$ for $x \ge 2$.
Key Insight: A CDF is defined for every real x, even when a discrete random variable takes only a few values.

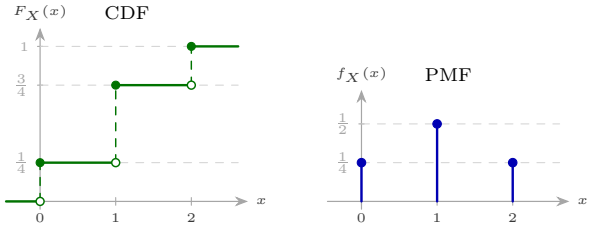

Figure 226: CDF and PMF for the number of heads in two independent fair coin tosses.

Proposition 1.3.6. *CDF Probability Calculus*
Let X have CDF F and define $F(x^-) := \lim_{y \uparrow x} F(y)$.

(i) Point mass: $\mathbb{P}(X = x) = F(x) - F(x^-)$.
(ii) Half-open interval: if $x < y$, then $\mathbb{P}(x < X \le y) = F(y) - F(x)$.
(iii) Right tail: $\mathbb{P}(X > x) = 1 - F(x)$.
(iv) Continuous endpoints: if X is continuous and $a < b$, then $\mathbb{P}(a < X < b) = \mathbb{P}(a \le X < b) = \mathbb{P}(a < X \le b) = \mathbb{P}(a \le X \le b)$.

Proof.

(i) Let $E_n = \{x - \frac{1}{n} < X \le x\}$. Then $E_n \downarrow \{X = x\}$ and $\mathbb{P}(E_n) = F(x) - F(x - \frac{1}{n})$.
Hence $\mathbb{P}(X = x) = \lim_n \mathbb{P}(E_n) = F(x) - F(x^-)$.
(ii) Since $\{X \le y\} = \{X \le x\} \sqcup \{x < X \le y\}$, $F(y) = F(x) + \mathbb{P}(x < X \le y)$.
(iii) Since $\{X > x\} = \{X \le x\}^c$, $\mathbb{P}(X > x) = 1 - \mathbb{P}(X \le x) = 1 - F(x)$.
(iv) If X is continuous, then $\mathbb{P}(X = t) = 0$ for all $t \in \mathbb{R}$. For $I_1 = (a,b)$, $I_2 = [a,b)$, $I_3 = (a,b]$, and $I_4 = [a,b]$, each $X^{-1}(I_j) \backslash X^{-1}(I_1) \subseteq \{X = a\} \cup \{X = b\}$, hence all four probabilities are equal.

Structural Commentary: CDF calculus subtracts nested lower-level events.
Key Insight: CDF jumps are point masses; continuous laws have none. □

Definition 1.3.7. *Survival and Hazard Functions*
Let $T \ge 0$ have CDF F and density f, and set $D := \{t \ge 0 : 1 - F(t) > 0\}$.

(i) *Survival Function*: $S : [0, \infty) \to [0,1]$, $S(t) := \mathbb{P}(T > t) = 1 - F(t)$.
(ii) *Hazard Function*: $h : D \to [0, \infty)$, $h(t) := \frac{f(t)}{1 - F(t)} = \frac{f(t)}{S(t)}$.

Structural Commentary: On intervals where S is differentiable and positive, $h(t) = -\frac{d}{dt} \log S(t)$.

Proposition 1.3.8. *Hazard Determines the Density*
Let $T \ge 0$ have survival $S(t) := \mathbb{P}(T > t)$ with $S \in C^1([0, \infty))$, $S(t) > 0$, $S(0) = 1$, density $f(t) := -S'(t)$, and hazard $h(t) := \frac{f(t)}{S(t)}$.
Put $H(t) := \int_0^t h(s)\,ds$. Then, for $t \ge 0$:

(i) Survival: $S(t) = e^{-H(t)}$.

(ii) *Density*: $f(t) = h(t)e^{-H(t)}$.

Proof. Fix $t \geq 0$.

(i) *Survival*: Since $(\log S)' = S'/S = -h$, $\log S(t) - \log S(0) = -H(t)$. Since $S(0) = 1$, $S(t) = e^{-H(t)}$.
(ii) *Density*: Since $h = f/S$, $f(t) = h(t)S(t) = h(t)e^{-H(t)}$.

Structural Commentary: $h = -S'/S = -(\log S)'$, so H is the cumulative log-decay of survival.
Key Insight: The hazard determines the law through $S = e^{-H}$ and $f = hS$. □

Example 1.3.9. *Constant and Power Hazards*
For $t \geq 0$:

(i) *Exponential*: If $F(t) = 1 - e^{-\lambda t}$ with $\lambda > 0$, then $S(t) = e^{-\lambda t}$, $f(t) = \lambda e^{-\lambda t}$, and $h(t) = \lambda$.
(ii) *Weibull-Type*: If $F(t) = 1 - e^{-\alpha t^\beta}$ with $\alpha, \beta > 0$, then $S(t) = e^{-\alpha t^\beta}$, $f(t) = \alpha\beta t^{\beta-1} e^{-\alpha t^\beta}$, $h(t) = \alpha\beta t^{\beta-1}$.

Key Insight: Power hazards increase for $\beta > 1$, decrease for $0 < \beta < 1$, and are constant for $\beta = 1$.

Definition 1.3.10. *Quantiles and Equality in Distribution*

(i) For a CDF F, the *quantile function* is $F^{-1}(q) := \inf\{x \in \mathbb{R} : F(x) \geq q\}$, $q \in (0, 1)$.
(ii) If F is continuous and strictly increasing, then F^{-1} is the ordinary inverse: $F(F^{-1}(q)) = q$ for $q \in (0, 1)$ and $F^{-1}(F(x)) = x$ for $x \in \mathbb{R}$.
(iii) The *pth quantile* is $x_p = F^{-1}(p)$; under (ii), $F(x_p) = p$ uniquely. Here $x_{\frac{1}{2}}$ is the median and $x_{\frac{1}{4}}, x_{\frac{3}{4}}$ are the lower and upper quartiles.
(iv) Random variables X, Y are *equal in distribution*, written $X \overset{\text{dist}}{=} Y$, iff $F_X = F_Y$ on $\mathbb{R}$.

Example 1.3.11. *Value at Risk as a Quantile*
Let $V_0 > 0$, $R = \frac{V_1 - V_0}{V_0}$, and $F_R(x) = \mathbb{P}(R \leq x)$.
The loss is $L = V_0 - V_1 = -V_0 R$, so $\{L \geq v\} = \{R \leq -\frac{v}{V_0}\}$ and $\mathbb{P}(L \geq v) = F_R(-\frac{v}{V_0})$.
If F_R is invertible and $\mathbb{P}(L \geq v_\alpha) = \alpha$, then $v_\alpha = -V_0 F_R^{-1}(\alpha)$.
Key Insight: VaR is a lower-tail return quantile converted back into a dollar loss.

1.4 Standard Distribution Families and Approximations

Definition 1.4.1. *Core Discrete Distributions*
Common discrete laws include:

(i) *Point mass*: $X \sim \delta_a$ for $a \in \mathbb{R}$ if $\mathbb{P}(X = a) = 1$.
(ii) *Discrete uniform*: $X \sim \text{Unif}\{1, \dots, k\}$ for $k \in \mathbb{N}$ if $\mathbb{P}(X = x) = \frac{1}{k}$ for $x = 1, \dots, k$.
(iii) *Bernoulli*: $X \sim \text{Bernoulli}(p)$ for $p \in [0, 1]$ if $\mathbb{P}(X = 1) = p$ and $\mathbb{P}(X = 0) = 1 - p$. Equivalently $\mathbb{P}(X = x) = p^x(1 - p)^{1-x}$ for $x \in \{0, 1\}$.
(iv) *Binomial*: $X \sim \text{Binomial}(n, p)$ for $n \in \mathbb{N}$ and $p \in [0, 1]$ if $\mathbb{P}(X = x) = \binom{n}{x} p^x (1 - p)^{n-x}$ for $x = 0, \dots, n$.
(v) *Geometric*: $X \sim \text{Geom}(p)$, $p \in (0, 1]$, if $\mathbb{P}(X = k) = p(1 - p)^{k-1}$ for $k \geq 1$; X counts trials to first success.
(vi) *Negative binomial*: $X \sim \text{NegBin}(r, p)$, $r \in \mathbb{N}$, $p \in (0, 1]$, if $\mathbb{P}(X = k) = \binom{k-1}{r-1} p^r (1 - p)^{k-r}$ for $k \geq r$; X counts trials to the rth success.
(vii) *Hypergeometric*: $X \sim \text{Hypergeom}(n, r, m)$ if $\mathbb{P}(X = k) = \dfrac{\binom{r}{k}\binom{n-r}{m-k}}{\binom{n}{m}}$ for $\max\{0, m - n + r\} \leq k \leq \min\{r, m\}$.
(viii) *Poisson*: $X \sim \text{Poisson}(\lambda)$ for $\lambda \geq 0$ if $\mathbb{P}(X = x) = \frac{e^{-\lambda}\lambda^x}{x!}$ for $x = 0, 1, 2, \dots$.

Definition 1.4.2. *Core Continuous Distributions*
Common continuous laws include:

(i) *Uniform*: $X \sim \text{Uniform}(a, b)$ for $a < b$ if $f_X(x) = (b - a)^{-1} \mathbf{1}_{[a,b]}(x)$.
(ii) *Normal*: $X \sim N(\mu, \sigma^2)$ for $\mu \in \mathbb{R}$, $\sigma > 0$, if $f_X(x) = (\sigma\sqrt{2\pi})^{-1} \exp(-\frac{(x-\mu)^2}{2\sigma^2})$ for $x \in \mathbb{R}$. $N(0, 1)$ has density ϕ and CDF Φ.
(iii) *Exponential*: $X \sim \text{Exp}(\lambda)$ for $\lambda > 0$ if $f_X(x) = \lambda e^{-\lambda x} \mathbf{1}_{[0,\infty)}(x)$.
(iv) *Gamma*: $X \sim \text{Gamma}(\alpha, \lambda)$ for $\alpha, \lambda > 0$ if $f_X(x) = \lambda^\alpha \Gamma(\alpha)^{-1} x^{\alpha-1} e^{-\lambda x} \mathbf{1}_{[0,\infty)}(x)$; $\text{Exp}(\lambda) = \text{Gamma}(1, \lambda)$.
(v) *Beta*: $X \sim \text{Beta}(\alpha, \beta)$ for $\alpha, \beta > 0$ if $f_X(x) = \Gamma(\alpha + \beta)(\Gamma(\alpha)\Gamma(\beta))^{-1} x^{\alpha-1}(1 - x)^{\beta-1} \mathbf{1}_{(0,1)}(x)$.
(vi) *Cauchy*: $X \sim \text{Cauchy}(0, 1)$ if $f_X(x) = (\pi(1 + x^2))^{-1}$ for $x \in \mathbb{R}$.
(vii) χ^2: $X \sim \chi^2_p$ for $p > 0$ if $f_X(x) = (\Gamma(\frac{p}{2}) 2^{\frac{p}{2}})^{-1} x^{\frac{p}{2}-1} e^{-\frac{x}{2}} \mathbf{1}_{(0,\infty)}(x)$.

Definition 1.4.3. *Normal Right-Tail Quantile*
For $0 < \alpha < 1$ and $Z \sim N(0, 1)$, $z(\alpha) := \Phi^{-1}(1 - \alpha)$, so $\mathbb{P}(Z > z(\alpha)) = \alpha$.

Method 1.4.4. *Discrete Distribution Model Recipes*

(i) *Indicators*: for $A \in \mathcal{F}$, $\mathbf{1}_A \sim \text{Bernoulli}(\mathbb{P}(A))$.
(ii) *Binomial counts*: if $B_1, \dots, B_n$ are independent $\text{Bernoulli}(p)$ variables, then $\sum_{i=1}^{n} B_i \sim \text{Binomial}(n, p)$.
(iii) *Geometric waiting*: the probability of first success on trial k is $(1 - p)^{k-1} p$.
(iv) *Negative-binomial waiting*: for iid $B_i \sim \text{Bernoulli}(p)$ and $T_r = \min\{k : \sum_{i=1}^{k} B_i = r\}$, $\{T_r = k\} = \{B_k = 1, \sum_{i=1}^{k-1} B_i = r - 1\}$, so $\mathbb{P}(T_r = k) = \binom{k-1}{r-1} p^r (1 - p)^{k-r}$.
(v) *Hypergeometric sampling*: if $M \subseteq [n]$, $|M| = r$, and S is a uniform m-subset, then $X = |S \cap M|$ and $\mathbb{P}(X = k) = \dfrac{\binom{r}{k}\binom{n-r}{m-k}}{\binom{n}{m}}$ for $\max\{0, m - n + r\} \leq k \leq \min\{r, m\}$.

Key Insight: Name the event; PMFs come from independence or subset counts.

Proposition 1.4.5. *Poisson Limit of Rare Binomial Counts*
Let $\lambda > 0$, $k \in \mathbb{N}_0$, and $X_n \sim \text{Binomial}(n, \frac{\lambda}{n})$ for all sufficiently large n. Then $\lim_{n\to\infty} \mathbb{P}(X_n = k) = \frac{e^{-\lambda}\lambda^k}{k!}$.

Proof. For large n, $\mathbb{P}(X_n = k) = \binom{n}{k}(\frac{\lambda}{n})^k(1-\frac{\lambda}{n})^{n-k} = \frac{\lambda^k}{k!}\prod_{j=0}^{k-1}(1-\frac{j}{n})(1-\frac{\lambda}{n})^n(1-\frac{\lambda}{n})^{-k}$.
Since $\prod_{j=0}^{k-1}(1-\frac{j}{n}) \to 1$, $(1-\frac{\lambda}{n})^n \to e^{-\lambda}$, and $(1-\frac{\lambda}{n})^{-k} \to 1$, the limit is $\frac{e^{-\lambda}\lambda^k}{k!}$.
Structural Commentary: Rare binomial masses split into fixed-k choices and an exponential no-event factor.
Key Insight: Large n, small p, fixed np turns binomial masses into Poisson masses. □

Method 1.4.6. *Recursive Binomial and Poisson Mass Computation*
Let $q := 1 - p$.

(i) If $X \sim \text{Binomial}(n, p)$, $p_k := \mathbb{P}(X = k)$, and $q > 0$, then $p_0 = q^n$ and $\frac{p_k}{p_{k-1}} = \frac{(n-k+1)p}{kq}$ for $1 \le k \le n$.

(ii) If $X \sim \text{Poisson}(\lambda)$ and $p_k := \mathbb{P}(X = k)$, then $p_0 = e^{-\lambda}$ and $\frac{p_k}{p_{k-1}} = \frac{\lambda}{k}$ for $k \ge 1$.

Key Insight: Successive mass ratios avoid repeatedly evaluating large factorials.

Example 1.4.7. *Majority Decoding as a Binomial Tail*
Let $n = 2m + 1$ and let $C_i \sim \text{Bernoulli}(p)$ be independent corruption indicators.
Then $X = \sum_{i=1}^{n} C_i \sim \text{Binomial}(n, p)$ and the majority decoder is correct iff $X \le m$.
For $n = 5$, $p = 0.1$, $\mathbb{P}(X \le 2) = 0.9^5 + 5(0.1)(0.9)^4 + 10(0.1)^2(0.9)^3 \approx 0.9914$.
Key Insight: Repetition coding converts reliability into a lower binomial tail.

Example 1.4.8. *Poisson Approximation for Rare Repeated Events*
Let $I_j = \mathbf{1}_{\{\text{double six on roll } j\}}$ for $1 \le j \le 100$.
Then $I_j \sim \text{Bernoulli}(\frac{1}{36})$ iid, $X = \sum_{j=1}^{100} I_j \sim \text{Binomial}(100, \frac{1}{36})$, and with $\lambda = \frac{100}{36} = \frac{25}{9}$, $\mathbb{P}(X = k) \approx \frac{e^{-\frac{25}{9}}(\frac{25}{9})^k}{k!}$.
Key Insight: Rare repeated event counts are often well approximated by a Poisson law with $\lambda = np$.

Proposition 1.4.9. *Exponential Memorylessness*
If $T \sim \text{Exp}(\lambda)$ with $\lambda > 0$, then $\mathbb{P}(T > s + t \mid T > s) = \mathbb{P}(T > t)$ for all $s, t \ge 0$.

Proof. For $u \ge 0$, $\mathbb{P}(T > u) = e^{-\lambda u}$. Hence $\mathbb{P}(T > s + t \mid T > s) = \frac{\mathbb{P}(T>s+t)}{\mathbb{P}(T>s)} = \frac{e^{-\lambda(s+t)}}{e^{-\lambda s}} = e^{-\lambda t} = \mathbb{P}(T > t)$.
Structural Commentary: Conditioning on survival to time s leaves the residual tail unchanged.
Key Insight: Exponential tails convert elapsed time into a cancellable factor. □

Remark 1.4.10. *Poisson Counts and Exponential Gaps*
In homogeneous Poisson process, counts satisfy $N(t) \sim \text{Poisson}(\lambda t)$; interarrival gaps satisfy $S_i \sim \text{Exp}(\lambda)$ iid.

Proposition 1.4.11. *Standardizing Normal Variables*
For $\sigma, \sigma_i > 0$:

(i) Standardization: if $X \sim N(\mu, \sigma^2)$, then $\frac{X-\mu}{\sigma} \sim N(0, 1)$.

(ii) Affine reconstruction: if $Z \sim N(0, 1)$, then $\mu + \sigma Z \sim N(\mu, \sigma^2)$.

(iii) Independent sums: if $X_i \sim N(\mu_i, \sigma_i^2)$ are independent, then $\sum_{i=1}^{n} X_i \sim N(\sum_{i=1}^{n} \mu_i, \sum_{i=1}^{n} \sigma_i^2)$.

(iv) Interval probabilities: if $X \sim N(\mu, \sigma^2)$ and $a < b$, then $\mathbb{P}(a < X < b) = \Phi(\frac{b-\mu}{\sigma}) - \Phi(\frac{a-\mu}{\sigma})$.

Proof.

(i) Let $Y = \frac{X-\mu}{\sigma}$. By change of variables, $f_Y(z) = \sigma f_X(\mu + \sigma z) = (2\pi)^{-\frac{1}{2}} e^{-\frac{z^2}{2}}$, so $Y \sim N(0, 1)$.

(ii) Let $Y = \mu + \sigma Z$. Then $f_Y(y) = \sigma^{-1}\phi(\frac{y-\mu}{\sigma}) = (\sigma\sqrt{2\pi})^{-1}\exp(-\frac{(y-\mu)^2}{2\sigma^2})$, hence $Y \sim N(\mu, \sigma^2)$.

(iii) It suffices by induction to treat $n = 2$.
Let $X_i \sim N(\mu_i, v_i)$ be independent, $S = X_1 + X_2$, $v = v_1 + v_2$, $w = \frac{v_1 v_2}{v}$, and $a_s = \frac{v_2\mu_1 + v_1(s-\mu_2)}{v}$.
Then $f_S(s) = \int_{\mathbb{R}} f_1(u) f_2(s-u)\, du$, and completing the square gives
$f_1(u)f_2(s-u) = (2\pi v)^{-\frac{1}{2}} e^{-\frac{(s-\mu_1-\mu_2)^2}{2v}} (2\pi w)^{-\frac{1}{2}} e^{-\frac{(u-a_s)^2}{2w}}$.
The second factor integrates to 1, so $S \sim N(\mu_1 + \mu_2, v_1 + v_2)$; induction gives (iii).

(iv) Let $Z = \frac{X-\mu}{\sigma}$. Since $\sigma > 0$, $\{a < X < b\} = \{\frac{a-\mu}{\sigma} < Z < \frac{b-\mu}{\sigma}\}$.
Hence $\mathbb{P}(a < X < b) = \Phi(\frac{b-\mu}{\sigma}) - \Phi(\frac{a-\mu}{\sigma})$.

Structural Commentary: Normal laws are stable under affine maps and independent addition.
Key Insight: Standardize to $N(0, 1)$, compute with Φ, then transform back. □

Example 1.4.12. *Normal Tail and Quantile Standardization*
Let $X \sim N(3, 5)$ and $Z = \frac{X-3}{\sqrt{5}} \sim N(0, 1)$. Then $\mathbb{P}(X > 1) = \mathbb{P}(Z > -\frac{2}{\sqrt{5}}) = 1 - \Phi(-\frac{2}{\sqrt{5}}) \approx 0.81$.
If $\mathbb{P}(X < q) = 0.2$, then $\Phi(\frac{q-3}{\sqrt{5}}) = 0.2$, so $q = 3 + \sqrt{5}\,\Phi^{-1}(0.2) \approx 3 - 0.8416\sqrt{5} \approx 1.1181$.

2 Joint Distributions, Multivariate Laws, and Transformations

2.1 Joint Distributions and Independence

Definition 2.1.1. *Joint and Marginal Distributions*

(i) The *joint mass function* of discrete X, Y is $f_{X,Y}(x,y) := \mathbb{P}(X = x, Y = y)$.
(ii) The *discrete marginals* are $f_X(x) = \sum_y f_{X,Y}(x,y)$ and $f_Y(y) = \sum_x f_{X,Y}(x,y)$.
(iii) The *continuous marginals* are $f_X(x) = \int_{-\infty}^{\infty} f_{X,Y}(x,y)\,dy$, and $f_Y(y) = \int_{-\infty}^{\infty} f_{X,Y}(x,y)\,dx$.
(iv) The *joint CDF* is $F_{X,Y}(x,y) := \mathbb{P}(X \le x, Y \le y)$. (X,Y) has joint density $f_{X,Y}$.

Example 2.1.2. *A Three-Toss Joint Mass Table*

Let $\Omega = \{H,T\}^3$ with $\mathbb{P}(\{\omega\}) = 2^{-3}$, set $X = \mathbf{1}_{\{\omega_1 = H\}}$, $Y = \sum_{i=1}^{3} \mathbf{1}_{\{\omega_i = H\}}$, and write $p_{xy} := \mathbb{P}(X = x, Y = y)$.

	$Y=0$	$Y=1$	$Y=2$	$Y=3$
$X=0$	$\frac{1}{8}$	$\frac{2}{8}$	$\frac{1}{8}$	0
$X=1$	0	$\frac{1}{8}$	$\frac{2}{8}$	$\frac{1}{8}$

Thus $p_{0,2} = \frac{1}{8}$, $\sum_y p_{0y} = \sum_y p_{1y} = \frac{1}{2}$, and $\sum_x p_{xj} = \binom{3}{j} 2^{-3}$ for $j = 0, \dots, 3$.

Proposition 2.1.3. *Rectangular Increments of a Joint CDF*
Let $F(x,y) := \mathbb{P}(X \le x, Y \le y)$.

(i) If $x_1 < x_2$ and $y_1 < y_2$, then $\mathbb{P}(x_1 < X \le x_2,\ y_1 < Y \le y_2) = F(x_2,y_2) - F(x_1,y_2) - F(x_2,y_1) + F(x_1,y_1)$.
(ii) If (X,Y) has density $f_{X,Y}$, $F \in C^2$, then $F(x,y) = \int_{-\infty}^{x}\int_{-\infty}^{y} f_{X,Y}(u,v)\,dv\,du$; $f_{X,Y}(x,y) = \partial_x \partial_y F(x,y)$.

Proof.

(i) Set $A_{ij} := \{X \le x_i,\ Y \le y_j\}$ and $R := \{x_1 < X \le x_2,\ y_1 < Y \le y_2\}$.
Pointwise, $\mathbf{1}_R = \mathbf{1}_{A_{22}} - \mathbf{1}_{A_{12}} - \mathbf{1}_{A_{21}} + \mathbf{1}_{A_{11}}$; applying $\mathbb{E}$ gives the identity.
(ii) The density assumption gives $F(x,y) = \mathbb{P}(X \le x, Y \le y) = \int_{-\infty}^{x}\int_{-\infty}^{y} f_{X,Y}(u,v)\,dv\,du$.
Since $F \in C^2$, the two-variable FTC gives $\partial_x \partial_y F = f_{X,Y}$.

Structural Commentary: Joint CDFs encode southwest rectangles; finite rectangles are four-corner increments.
Key Insight: Mixed derivatives are infinitesimal rectangular increments. □

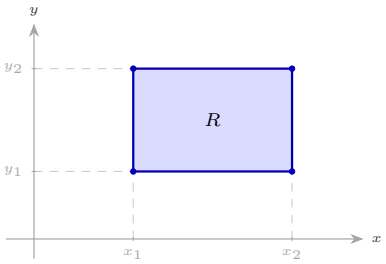

Figure 227: The rectangular probability is a four-term increment of the joint CDF.

Example 2.1.4. *A Non-Rectangular Bivariate Density*
Let $S = \{(x,y) : x^2 \le y \le 1\}$ and $f_{X,Y}(x,y) = cx^2 y \mathbf{1}_S(x,y)$.
Since $S = \{(x,y) : -1 \le x \le 1,\ x^2 \le y \le 1\}$, $1 = c\int_{-1}^{1}\int_{x^2}^{1} x^2 y\,dy\,dx = \frac{4c}{21}$, so $c = \frac{21}{4}$.
For $E = \{X \ge Y\}$, $S \cap E = \{(x,y) : 0 \le x \le 1,\ x^2 \le y \le x\}$, hence $\mathbb{P}(E) = (\frac{21}{4})\int_0^1\int_{x^2}^{x} x^2 y\,dy\,dx = \frac{3}{20}$.
Key Insight: In bivariate integration, pick one variable first and let the other range over the corresponding slice.

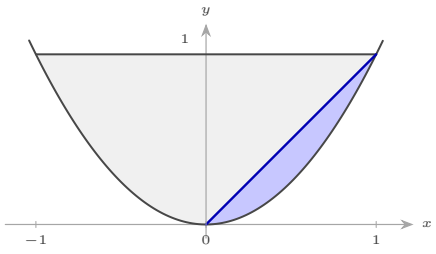

Figure 228: Gray: support $x^2 \le y \le 1$; blue: event $X \ge Y$ $(x^2 \le y \le x)$.

Definition 2.1.5. *Independent Random Variables and IID Samples*

(i) Random variables $X_1, \dots, X_n$ are *independent* if $\mathbb{P}(X_1 \in B_1, \dots, X_n \in B_n) = \prod_{i=1}^{n} \mathbb{P}(X_i \in B_i)\ \forall B_i \in \mathcal{B}(\mathbb{R})$.
(ii) They are *identically distributed* if $\mathcal{L}(X_1) = \cdots = \mathcal{L}(X_n)$.
(iii) They are *iid* if they are independent and identically distributed.
(iv) The *random vector* $X = (X_1, \dots, X_n)$ is a *random sample* when $X_1, \dots, X_n$ are iid from a common law.

Proposition 2.1.6. *Factorization Tests for Independence*

(i) Discrete factorization: discrete X, Y are independent iff $f_{X,Y}(x,y) = f_X(x)f_Y(y)$ for all x, y.
(ii) Density factorization: if (X, Y) has joint density $f_{X,Y}$ and marginals f_X, f_Y, then X, Y are independent iff $f_{X,Y}(x,y) = f_X(x)f_Y(y)$ a.e.
(iii) Rectangular support test: if $f_{X,Y}(x,y) = g(x)h(y)\mathbf{1}_{A\times B}(x,y)$ for measurable A, B, then X, Y are independent after normalization.

Proof.

(i) ($\Rightarrow$) If $X \perp\!\!\!\perp Y$, then $f_{X,Y}(x,y) = \mathbb{P}(X = x, Y = y) = \mathbb{P}(X = x)\mathbb{P}(Y = y) = f_X(x)f_Y(y)$.
(i) ($\Leftarrow$) If $f_{X,Y} = f_X f_Y$, then for A, B, $\mathbb{P}(X \in A, Y \in B) = \sum_{x\in A}\sum_{y\in B} f_X(x)f_Y(y) = \mathbb{P}(X \in A)\mathbb{P}(Y \in B)$.
(ii) ($\Rightarrow$) If $X \perp\!\!\!\perp Y$, the product law has density $f_X f_Y$, so uniqueness of densities gives $f_{X,Y} = f_X f_Y$ a.e.
(ii) ($\Leftarrow$) If $f_{X,Y} = f_X f_Y$ a.e., then for Borel A, B, $\mathbb{P}(X \in A, Y \in B) = \int_A \int_B f_X(x)f_Y(y)\,dy\,dx = \mathbb{P}(X \in A)\mathbb{P}(Y \in B)$.
(iii) Let $G = \int_A g$ and $H = \int_B h$. Normalization gives $GH = 1$, while $f_X(x) = g(x)H\mathbf{1}_A(x)$ and $f_Y(y) = h(y)G\mathbf{1}_B(y)$, hence $f_X(x)f_Y(y) = f_{X,Y}(x,y)$ a.e.; apply (ii).

Structural Commentary: Independence is product structure of the joint law.
Key Insight: Independence means the joint law factors. □

2.2 Multivariate Models and Copulas

Definition 2.2.1. *Two Multivariate Families*

(i) *Multinomial*: for $n \in \mathbb{N}$ and $p \in [0,1]^k$ with $\sum_{j=1}^k p_j = 1$, $X \sim \text{Multinomial}(n,p)$ if $\mathbb{P}(X = x) = n!(x_1!\cdots x_k!)^{-1}\prod_{j=1}^k p_j^{x_j}$ for $x \in \mathbb{N}_0^k$ with $\sum_{j=1}^k x_j = n$; then $X_j \sim \text{Binomial}(n, p_j)$.
(ii) *Multivariate normal*: for $\mu \in \mathbb{R}^k$ and symmetric positive definite $\Sigma \in \mathbb{R}^{k\times k}$, $X \sim N(\mu,\Sigma)$ if $f_X(x) = ((2\pi)^k \det\Sigma)^{-\frac{1}{2}}\exp(-\frac{(x-\mu)^t\Sigma^{-1}(x-\mu)}{2})$ for $x \in \mathbb{R}^k$. $N(0, I_k)$ has independent $N(0,1)$ coordinates.

Proposition 2.2.2. *Multivariate Normal Affine Standardization*

Let $k \in \mathbb{N}$, $\mu \in \mathbb{R}^k$, $\Sigma \in \mathbb{R}^{k\times k}$ with $\Sigma \succ 0$, and $A = \Sigma^{\frac{1}{2}}$.

(i) For $X \in \mathbb{R}^k$, $X \sim N(\mu,\Sigma) \iff A^{-1}(X-\mu) \sim N(0, I_k)$.
(ii) For $Z \in \mathbb{R}^k$, $Z \sim N(0, I_k) \iff \mu + AZ \sim N(\mu,\Sigma)$.

Proof.

(i) ($\Rightarrow$) Put $Z = A^{-1}(X-\mu)$. With $x = \mu + Az$, $|\det A| = (\det\Sigma)^{\frac{1}{2}}$ and $(Az)^t\Sigma^{-1}(Az) = z^t z$. By change of variables, $f_Z(z) = f_X(\mu+Az)|\det A| = (2\pi)^{-\frac{k}{2}}\exp(-\frac{z^t z}{2})$.
(i) ($\Leftarrow$) Put $Z = A^{-1}(X-\mu) \sim N(0, I_k)$, so $X = \mu + AZ$. With $z = A^{-1}(x-\mu)$ and $|\det A^{-1}| = (\det\Sigma)^{-\frac{1}{2}}$, $f_X(x) = f_Z(A^{-1}(x-\mu))|\det A^{-1}| = ((2\pi)^k\det\Sigma)^{-\frac{1}{2}}\exp(-\frac{(x-\mu)^t\Sigma^{-1}(x-\mu)}{2})$.
(ii) ($\Rightarrow$) If $Z \sim N(0, I_k)$ and $X := \mu + AZ$, then $A^{-1}(X-\mu) = Z$; by (i) ($\Leftarrow$), $X \sim N(\mu,\Sigma)$.
(ii) ($\Leftarrow$) If $X := \mu + AZ \sim N(\mu,\Sigma)$, then $Z = A^{-1}(X-\mu)$; by (i) ($\Rightarrow$), $Z \sim N(0, I_k)$.

Structural Commentary: Positive definite covariance is an affine deformation of the standard normal.
Key Insight: Standardize by $\Sigma^{-\frac{1}{2}}$; reconstruct by $\Sigma^{\frac{1}{2}}$. □

Proposition 2.2.3. *Basic Multivariate Normal Calculus*

Let $X = (X_a, X_b) \sim N(\mu,\Sigma)$ with $X_a \in \mathbb{R}^r$, $X_b \in \mathbb{R}^s$, $\mu = (\mu_a,\mu_b)$, and $\Sigma = \begin{pmatrix}\Sigma_{aa} & \Sigma_{ab}\\ \Sigma_{ba} & \Sigma_{bb}\end{pmatrix} \succ 0$.

(i) Marginal: $X_a \sim N(\mu_a, \Sigma_{aa})$.
(ii) Conditional: $X_b \mid X_a = x_a \sim N(\mu_b + \Sigma_{ba}\Sigma_{aa}^{-1}(x_a-\mu_a), \Sigma_{bb} - \Sigma_{ba}\Sigma_{aa}^{-1}\Sigma_{ab})$.
(iii) Linear form: for any vector a, $a^tX \sim N(a^t\mu, a^t\Sigma a)$.

Proof.

(i) Let $P_a X = X_a$. By Proposition 2.2.2, $X = \mu + \Sigma^{\frac{1}{2}}Z$ with $Z \sim N(0, I)$. Hence $X_a = P_a\mu + P_a\Sigma^{\frac{1}{2}}Z \sim N(\mu_a, P_a\Sigma P_a^t) = N(\mu_a,\Sigma_{aa})$.
(ii) Set $S := \Sigma_{bb} - \Sigma_{ba}\Sigma_{aa}^{-1}\Sigma_{ab}$ and $m(x_a) := \mu_b + \Sigma_{ba}\Sigma_{aa}^{-1}(x_a-\mu_a)$. The block determinant and inverse identities give $\det\Sigma = \det\Sigma_{aa}\det S$ and $(x-\mu)^t\Sigma^{-1}(x-\mu) = (x_a-\mu_a)^t\Sigma_{aa}^{-1}(x_a-\mu_a) + (x_b-m(x_a))^tS^{-1}(x_b-m(x_a))$. Thus $f_{b|a}(x_b \mid x_a) = \frac{f_{a,b}(x_a,x_b)}{f_a(x_a)}$ is the $N(m(x_a), S)$ density.
(iii) With $X = \mu + \Sigma^{\frac{1}{2}}Z$, $a^tX = a^t\mu + (\Sigma^{\frac{1}{2}}a)^tZ$. Since Z has independent $N(0,1)$ coordinates, $(\Sigma^{\frac{1}{2}}a)^tZ \sim N(0, a^t\Sigma a)$, hence $a^tX \sim N(a^t\mu, a^t\Sigma a)$.

Structural Commentary: Marginals, conditionals, and linear projections of Gaussian vectors remain Gaussian.
Key Insight: Gaussian calculus is affine calculus plus Schur complements. □

Definition 2.2.4. *Copulas*

(i) A *copula* is a joint CDF $C : [0,1]^2 \to [0,1]$.
(ii) *Uniform marginals*: $C(u,1) = u$ and $C(1,v) = v$ for $u, v \in [0,1]$.
(iii) If $C \in C^2$, its *copula density* is $c(u,v) := \partial_u\partial_v C(u,v)$.

Proposition 2.2.5. *Constructing a Joint Law from Marginals and a Copula*
Let F_X, F_Y be continuous CDFs with densities f_X, f_Y, and let C be a copula.
Define $F_{X,Y}(x,y) := C(F_X(x), F_Y(y))$. Then $F_{X,Y}$ has marginals F_X, F_Y.
If $C \in C^2$ with density $c = \partial_u \partial_v C$, then $f_{X,Y}(x,y) = c(F_X(x), F_Y(y)) f_X(x) f_Y(y)$.

Proof. $F_{X,Y}(x,\infty) = C(F_X(x), 1) = F_X(x)$ and $F_{X,Y}(\infty, y) = C(1, F_Y(y)) = F_Y(y)$.
If densities exist, $\partial_x \partial_y C(F_X(x), F_Y(y)) = (\partial_u \partial_v C)(F_X(x), F_Y(y)) f_X(x) f_Y(y)$ by the chain rule.
Structural Commentary: Marginals and dependence are separated into F_X, F_Y and C.
Key Insight: Marginals alone do not determine a joint law; the copula supplies the dependence. □

Example 2.2.6. *Farlie–Morgenstern Copulas*
For $|\alpha| \le 1$, $C_\alpha(u,v) = uv\{1 + \alpha(1-u)(1-v)\}$ is a copula with density $c_\alpha(u,v) = 1 + \alpha(1-2u)(1-2v)$.
Here $\alpha = 0$ gives the independence copula uv, while $\alpha = -1$ and $\alpha = 1$ give densities $2u + 2v - 4uv$ and $2 - 2u - 2v + 4uv$ on $[0,1]^2$, respectively; all have uniform marginals.

2.3 Transformations of Random Variables

Method 2.3.1. *One-Variable Transformations*
Let $Y = r(X)$.
(i) *Discrete pushforward*: if X is discrete, then $f_Y(y) = \mathbb{P}(Y = y) = \mathbb{P}(X \in r^{-1}(\{y\})) = \sum_{x : r(x) = y} f_X(x)$.
(ii) *CDF method*: for $Y = r(X)$, compute $F_Y(y) = \int_{\{x : r(x) \le y\}} f_X(x)\,dx$; $f_Y(y) = F_Y'(y)$ where differentiable.
(iii) *Monotone change*: if r is strictly monotone on $\operatorname{supp} X$ with inverse s, then $f_Y(y) = f_X(s(y))\,|s'(y)|\,\mathbf{1}_{r(\operatorname{supp} X)}(y)$.
Key Insight: The CDF method works because it translates the transformed event back into an event about X.

Example 2.3.2. *Log Transform of an Exponential Variable*
Let $X \sim \mathrm{Exp}(1)$ and $Y = \log X$. Since $r(x) = \log x$ has inverse $s(y) = e^y$ with $s'(y) = e^y$, the change-of-variables formula gives $f_Y(y) = f_X(e^y) e^y = e^y e^{-e^y}$ for $y \in \mathbb{R}$.

Example 2.3.3. *A Nonmonotone Square Transform*
Let $X \sim \mathrm{Uniform}(-1, 3)$ and $Y = X^2$. Since $f_X = \frac{1}{4}$ on $[-1,3]$, $r^{-1}(\{y\}) \cap [-1,3] = \{-\sqrt{y}, \sqrt{y}\}$ for $0 < y < 1$ and $\{\sqrt{y}\}$ for $1 < y < 9$.
Hence $f_Y(y) = \frac{1}{4\sqrt{y}} \mathbf{1}_{(0,1)}(y) + \frac{1}{8\sqrt{y}} \mathbf{1}_{(1,9)}(y)$.
Key Insight: Non-one-to-one transformations require splitting the range into cases.

Example 2.3.4. *Squaring a Standard Normal*
Let $Z \sim N(0,1)$ and $X = Z^2$. For $x > 0$, $F_X(x) = \mathbb{P}(|Z| \le \sqrt{x}) = \Phi(\sqrt{x}) - \Phi(-\sqrt{x})$,
so $f_X(x) = x^{-\frac{1}{2}} \phi(\sqrt{x}) = (2\pi)^{-\frac{1}{2}} x^{-\frac{1}{2}} e^{-\frac{x}{2}}$. Hence $X \sim \chi^2_1 = \mathrm{Gamma}(\frac{1}{2}, \frac{1}{2})$ in the rate convention.

Example 2.3.5. *Reciprocal of a Uniform Variable*
Let $U \sim \mathrm{Uniform}(0,1)$ and $V = \frac{1}{U}$. Then $F_V(v) = 0$ for $v < 1$, while for $v \ge 1$, $F_V(v) = \mathbb{P}(U \ge \frac{1}{v}) = 1 - \frac{1}{v}$.
Hence $f_V(v) = v^{-2} \mathbf{1}_{[1,\infty)}(v)$.

Proposition 2.3.6. *Probability Integral Transform and Inverse Transform*
Let $F : I \to (0,1)$ be a continuous strictly increasing CDF with inverse $F^{-1} : (0,1) \to I$.
(i) If $X \sim F$, then $F(X) \sim \mathrm{Uniform}(0,1)$.
(ii) If $U \sim \mathrm{Uniform}(0,1)$ and $Y = F^{-1}(U)$, then $F_Y = F$.

Proof.
(i) For $0 < u < 1$, $\mathbb{P}(F(X) \le u) = \mathbb{P}(X \le F^{-1}(u)) = F(F^{-1}(u)) = u$, with endpoint values $0, 1$.
(ii) For $x \in I$, $\mathbb{P}(Y \le x) = \mathbb{P}(F^{-1}(U) \le x) = \mathbb{P}(U \le F(x)) = F(x)$.
Structural Commentary: F maps its law to uniform scale; F^{-1} maps uniform scale back.
Key Insight: Uniform random numbers become target laws by applying inverse CDFs. □

Method 2.3.7. *Several-Variable Transformations*
For $Z = r(X, Y)$ with joint density $f_{X,Y}$:
(i) *Sublevel set*: define $A_z := \{(x,y) : r(x,y) \le z\}$.
(ii) *CDF integral*: compute $F_Z(z) = \mathbb{P}(Z \le z) = \iint_{A_z} f_{X,Y}(x,y)\,dx\,dy$.
(iii) *Density*: differentiate where possible, $f_Z(z) = F_Z'(z)$.

Example 2.3.8. *Sum of Two Independent Uniforms*
Let $X_1, X_2 \sim \mathrm{Uniform}(0,1)$ be independent and $Y = X_1 + X_2$.
Since $f_{X_1,X_2} = \mathbf{1}_{[0,1]^2}$, $F_Y(y)$ is the area of $A_y = \{(x_1, x_2) \in [0,1]^2 : x_1 + x_2 \le y\}$,
so $F_Y(y) = \frac{y^2}{2} \mathbf{1}_{[0,1]}(y) + (1 - \frac{(2-y)^2}{2}) \mathbf{1}_{(1,2]}(y) + \mathbf{1}_{(2,\infty)}(y)$. Hence $f_Y(y) = y \mathbf{1}_{(0,1)}(y) + (2-y) \mathbf{1}_{(1,2)}(y)$.

Proposition 2.3.9. *Two-Dimensional Density Change of Variables*
Let (X,Y) have density $f_{X,Y}$ on $D \subseteq \mathbb{R}^2$, and let $T : D \xrightarrow{C^1} E$ be one-to-one with inverse h and $\det DT \ne 0$ on D. For $(U,V) = T(X,Y)$, $f_{U,V}(u,v) = f_{X,Y}(h(u,v))\,|\det Dh(u,v)|\,\mathbf{1}_E(u,v)$.

Proof. For Borel $B \subseteq E$, $\mathbb{P}((U,V) \in B) = \mathbb{P}((X,Y) \in h(B))$
$= \int_{h(B)} f_{X,Y}(x,y)\,dx\,dy = \int_B f_{X,Y}(h(u,v))\,|\det Dh(u,v)|\,du\,dv$ (by Theorem 5.1.11)
Structural Commentary: Transforming a density means preserving probability mass while rescaling area.
Key Insight: The absolute Jacobian accounts for local volume distortion. □

Example 2.3.10. *Sums and Quotients*
Let (X,Y) have joint density $f_{X,Y}$.
(i) Sum: for $S = X + Y$, $f_S(s) = \int_{\mathbb{R}} f_{X,Y}(x, s-x)\,dx$; if $X \perp\!\!\!\perp Y$, then $f_S(s) = \int_{\mathbb{R}} f_X(x) f_Y(s-x)\,dx$.

(ii) Quotient: for $Z = \frac{Y}{X}$, $f_Z(z) = \int_{\mathbb{R}} |x|\, f_{X,Y}(x, xz)\, dx$; if $X \perp\!\!\!\perp Y$, then $f_Z(z) = \int_{\mathbb{R}} |x|\, f_X(x) f_Y(xz)\, dx$.

Key Insight: Add one auxiliary coordinate, change variables, integrate it out.

Example 2.3.11. *Polar Transform of Two Standard Normals*

Let $X, Y \overset{\text{iid}}{\sim} N(0,1)$, $R = (X^2+Y^2)^{\frac{1}{2}}$, and $\Theta = \operatorname{atan2}(Y, X)$.

Polar change of variables gives $f_{R,\Theta}(r,\theta) = (2\pi)^{-1} r e^{-\frac{r^2}{2}} \mathbf{1}_{[0,\infty)}(r) \mathbf{1}_{[0,2\pi)}(\theta)$,
so $R \perp\!\!\!\perp \Theta$, $\Theta \sim \text{Uniform}(0, 2\pi)$, and $R^2 \sim \text{Exp}(\frac{1}{2})$.
Hence for iid $U_1, U_2 \sim \text{Uniform}(0,1)$, $(\sqrt{-2\log U_1}\cos(2\pi U_2), \sqrt{-2\log U_1}\sin(2\pi U_2)) \sim N(0, I_2)$.

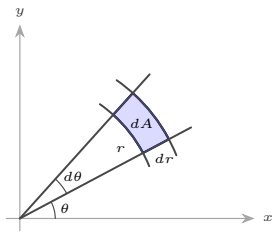

Figure 229: In polar coordinates, a small patch has area approximately $r\, dr\, d\theta$.

3 Expectation and Integration in Probability

3.1 Expectation, Variance, and LOTUS

Expectation is the averaging operation attached to a probability law. In the notation of Section 1.1.1, if X has law F_X, then integration against F_X is the common notation that covers both sums for discrete variables and ordinary integrals for variables with densities.

Definition 3.1.1. *Expectation Through the Law*

Let X be real-valued with distribution function F_X.

(i) *Expectation*: if $\int_{\mathbb{R}} |x|\, dF_X(x) < \infty$, then $\mathbb{E}(X) := \int_{\mathbb{R}} x\, dF_X(x)$.
(ii) *Discrete form*: if X has support S, mass function f_X, $\mathbb{E}(X) = \sum_{x \in S} x f_X(x)$ when $\sum_{x \in S} |x| f_X(x) < \infty$.
(iii) *Density form*: if X has density f_X, then $\mathbb{E}(X) = \int_{\mathbb{R}} x f_X(x)\, dx$ when $\int_{\mathbb{R}} |x| f_X(x)\, dx < \infty$.
(iv) *Function form*: for measurable $r : \mathbb{R} \to \mathbb{R}$, if $\int_{\mathbb{R}} |r(x)|\, dF_X(x) < \infty$, then $\mathbb{E}(r(X)) := \int_{\mathbb{R}} r(x)\, dF_X(x)$.

Proposition 3.1.2. *Indicators Turn Probabilities into Expectations*

For $A \in \mathcal{F}$, let $\mathbf{1}_A : \Omega \to \{0,1\}$ be $\mathbf{1}_A(\omega) = 1$ for $\omega \in A$ and $\mathbf{1}_A(\omega) = 0$ for $\omega \notin A$. Then $\mathbb{E}(\mathbf{1}_A) = \mathbb{P}(A)$.

Proof. Since $\Omega = A \sqcup A^c$ and $\mathbf{1}_A = 1$ on A, 0 on A^c, $\mathbb{E}(\mathbf{1}_A) = 1 \cdot \mathbb{P}(A) + 0 \cdot \mathbb{P}(A^c) = \mathbb{P}(A)$.
Structural Commentary: Indicators encode events as 0-1 random variables.
Key Insight: Probabilities are expectations of indicators. □

Example 3.1.3. *Expectation of the Two-Toss Head Count*

Let $\Omega = \{H,T\}^2$ with $\mathbb{P}(\{\omega\}) = \frac{1}{4}$, and let $X(\omega)$ be the number of heads in ω.

Then $f_X(k) = \binom{2}{k} 2^{-2}$ for $k = 0,1,2$, so $\mathbb{E}(X) = \sum_{k=0}^{2} k f_X(k) = 0 \cdot \frac{1}{4} + 1 \cdot \frac{1}{2} + 2 \cdot \frac{1}{4} = 1$.

Example 3.1.4. *First Expectation Computations*

(i) If $X \sim \text{Bernoulli}(p)$, then $\mathbb{E}X = 0(1-p) + 1p = p$.
(ii) If $X \sim \text{Uniform}(-1, 3)$, then $\mathbb{E}X = (\frac{1}{4}) \int_{-1}^{3} x\, dx = 1$.
(iii) If $X \sim \text{Cauchy}(0,1)$, then $\mathbb{E}|X| = (\frac{2}{\pi}) \int_0^\infty x(1+x^2)^{-1}\, dx = \infty$, so $\mathbb{E}X$ does not exist.

Theorem 3.1.5. *Expectation of a Function*

Let r be measurable and assume the displayed expectations exist.

(i) One variable: for real-valued X, $\mathbb{E}(r(X)) = \int_{\mathbb{R}} r(x)\, dF_X(x)$.
(ii) Several variables: for (X,Y) with joint law $F_{X,Y}$, $\mathbb{E}(r(X,Y)) = \int_{\mathbb{R}^2} r(x,y)\, dF_{X,Y}(x,y)$.

Proof.

(i) Since $\mathcal{L}(X) = X_* \mathbb{P}$, $\mathbb{E}(r(X)) = \int_\Omega r(X(\omega))\, d\mathbb{P}(\omega) = \int_{\mathbb{R}} r(x)\, d\mathcal{L}(X)(x) = \int_{\mathbb{R}} r(x)\, dF_X(x)$.
(ii) Let $W = (X,Y)$. Since $\mathcal{L}(W) = W_* \mathbb{P} = F_{X,Y}$,
$\mathbb{E}(r(X,Y)) = \int_\Omega r(W(\omega))\, d\mathbb{P}(\omega) = \int_{\mathbb{R}^2} r(x,y)\, d\mathcal{L}(W)(x,y) = \int_{\mathbb{R}^2} r(x,y)\, dF_{X,Y}(x,y)$.

Structural Commentary: Expectations of transformations integrate over the transformed law.
Key Insight: Pushforward laws let functions move from random variables to their values. □

Remark 3.1.6. *Law-Based Integration*

For measurable r, $\mathbb{E}(r(X))$ depends only on the law of X: $\mathbb{E}(r(X)) = \int_{\mathbb{R}} r(x)\, dF_X(x)$ whenever integrable.
Discrete laws give $\sum_x r(x) f_X(x)$; density laws give $\int_{\mathbb{R}} r(x) f_X(x)\, dx$.

Example 3.1.7. *Using the Function Rule*

(i) If $X \sim \text{Uniform}(0,1)$ and $Y = e^X$, then $\mathbb{E}Y = \mathbb{E}(e^X) = \int_0^1 e^x\, dx = e - 1$.
(ii) If $X \sim \text{Uniform}(0,1)$ and $Y = \max\{X, 1-X\}$, then $\mathbb{E}Y = \int_0^{\frac{1}{2}} (1-x)\, dx + \int_{\frac{1}{2}}^1 x\, dx = \frac{3}{4}$.
(iii) If $(X,Y) \sim \text{Uniform}([0,1]^2)$ and $Z = X^2 + Y^2$, then $\mathbb{E}Z = \int_0^1 \int_0^1 (x^2+y^2)\, dx\, dy = \frac{2}{3}$.

Definition 3.1.8. *Variance and Covariance*

(i) The *variance* of X is $\mathrm{Var}(X) := \mathbb{E}[(X - \mathbb{E}X)^2]$, assuming $\mathbb{E}(X^2) < \infty$.
(ii) The *standard deviation* of X is $\mathrm{sd}(X) := \sqrt{\mathrm{Var}(X)}$.
(iii) The *covariance* of X, Y is $\mathrm{Cov}(X, Y) := \mathbb{E}[(X - \mathbb{E}X)(Y - \mathbb{E}Y)]$, assuming $\mathbb{E}(X^2), \mathbb{E}(Y^2) < \infty$.

3.2 Moments, Sample Statistics, and Random Vectors

Definition 3.2.1. *Moments, Correlation, and Sample Statistics*

(i) The *kth moment* of X is $\mathbb{E}(X^k)$, assuming $\mathbb{E}|X|^k < \infty$.
(ii) The *correlation* of X, Y is $\mathrm{Corr}(X, Y) := \frac{\mathrm{Cov}(X,Y)}{\sqrt{\mathrm{Var}(X)}\sqrt{\mathrm{Var}(Y)}}$, assuming $\mathrm{Var}(X), \mathrm{Var}(Y) > 0$.
(iii) The *sample mean* of $X_1, \ldots, X_n$ is $\overline{X}_n := n^{-1} \sum_{i=1}^{n} X_i$.
(iv) The *sample variance* of $X_1, \ldots, X_n$ is $S_n^2 := (n-1)^{-1} \sum_{i=1}^{n} (X_i - \overline{X}_n)^2$.

Theorem 3.2.2. *Expectation, Variance, and Covariance Algebra*
Assume all displayed quantities exist and $a_i, a, b \in \mathbb{R}$.

(i) Linearity: $\mathbb{E}(\sum_i a_i X_i) = \sum_i a_i \mathbb{E}X_i$.
(ii) Independent product: if $X_1, \ldots, X_n$ are independent, then $\mathbb{E}(\prod_i X_i) = \prod_i \mathbb{E}X_i$.
(iii) Variance identities: $\mathrm{Var}(X) = \mathbb{E}(X^2) - (\mathbb{E}X)^2$ *and* $\mathrm{Var}(aX + b) = a^2 \mathrm{Var}(X)$.
(iv) Covariance identity: $\mathrm{Cov}(X, Y) = \mathbb{E}(XY) - \mathbb{E}X\,\mathbb{E}Y$.
(v) Variance of a linear combination: $\mathrm{Var}(\sum_i a_i X_i) = \sum_i a_i^2 \mathrm{Var}(X_i) + 2 \sum_{i<j} a_i a_j \mathrm{Cov}(X_i, X_j)$.

Proof.

(i) $\mathbb{E}(\sum_i a_i X_i) = \int_\Omega \sum_i a_i X_i \, d\mathbb{P} = \sum_i a_i \int_\Omega X_i \, d\mathbb{P} = \sum_i a_i \mathbb{E}X_i$.
(ii) By independence, $\mathcal{L}(X_1, \ldots, X_n) = \prod_i F_{X_i}$; $\mathbb{E}(\prod_i X_i) = \int_{\mathbb{R}^n} \prod_i x_i \, d\prod_i F_{X_i}(x_i) = \prod_i \int_{\mathbb{R}} x_i \, dF_{X_i}(x_i) = \prod_i \mathbb{E}X_i$.
(iii) $\mathrm{Var}(X) = \mathbb{E}(X^2 - 2X\mathbb{E}X + (\mathbb{E}X)^2) = \mathbb{E}(X^2) - (\mathbb{E}X)^2$.
Also $\mathrm{Var}(aX + b) = \mathbb{E}[(aX + b - a\mathbb{E}X - b)^2] = a^2 \mathrm{Var}(X)$.
(iv) $\mathrm{Cov}(X, Y) = \mathbb{E}(XY - X\mathbb{E}Y - Y\mathbb{E}X + \mathbb{E}X\mathbb{E}Y) = \mathbb{E}(XY) - \mathbb{E}X\,\mathbb{E}Y$.
(v) With $S = \sum_i a_i X_i$, (iv) gives

$$\mathrm{Var}(S) = \mathrm{Cov}(S, S) = \sum_{i,j} a_i a_j \mathrm{Cov}(X_i, X_j) = \sum_i a_i^2 \mathrm{Var}(X_i) + 2 \sum_{i<j} a_i a_j \mathrm{Cov}(X_i, X_j).$$

Structural Commentary: Expectation is linear; variance and covariance are quadratic and bilinear consequences.
Key Insight: Expand products, then use linearity. □

Example 3.2.3. *Indicator Sums as a Method*

(i) If $X \sim \mathrm{Binomial}(n, p)$, write $X = \sum_{i=1}^{n} I_i$ with independent $I_i \sim \mathrm{Bernoulli}(p)$.
Then $\mathbb{E}X = np$ and $\mathrm{Var}(X) = np(1-p)$.
(ii) Let $\xi_i \in \{-1, 1\}$ with $\mathbb{P}(\xi_i = -1) = p$ and $\mathbb{P}(\xi_i = 1) = 1 - p$, independently, and $X_n = \sum_{i=1}^{n} \xi_i$.
Then $\mathbb{E}X_n = n(1-2p)$ and $\mathrm{Var}(X_n) = 4np(1-p)$.
(iii) Let $F_n = c \prod_{i=1}^{n} M_i$ with independent $M_i \in \{2, \frac{1}{2}\}$ and $\mathbb{P}(M_i = 2) = \mathbb{P}(M_i = \frac{1}{2}) = \frac{1}{2}$.
Then $\mathbb{E}F_n = c \prod_{i=1}^{n} \mathbb{E}M_i = c(\frac{5}{4})^n$.

Proposition 3.2.4. *Zero Variance Means Almost Surely Constant*
For $X \in L^2$ and $m := \mathbb{E}X$, $\mathrm{Var}(X) = 0$ iff $X = m$ a.s.

Proof.

($\Rightarrow$) If $\mathrm{Var}(X) = 0$, then $\mathbb{E}[(X - m)^2] = 0$. Since $(X - m)^2 \geq 0$, $\mathbb{P}((X - m)^2 > 0) = 0$, hence $X = m$ a.s.
($\Leftarrow$) If $X = m$ a.s., then $(X - m)^2 = 0$ a.s., so $\mathrm{Var}(X) = \mathbb{E}[(X - m)^2] = 0$.

Structural Commentary: Variance is the mean squared distance from the mean.
Key Insight: Zero nonnegative expectation forces zero almost surely. □

Proposition 3.2.5. *Tail Integral Formula*
If $X \geq 0$ has density f_X, distribution function F_X, and $\mathbb{E}X < \infty$,
then $\mathbb{E}X = \int_0^\infty \mathbb{P}(X > x)\, dx = \int_0^\infty (1 - F_X(x))\, dx$.

Proof. For $b > 0$, integration by parts gives $\int_0^b x f_X(x)\, dx = -b(1 - F_X(b)) + \int_0^b (1 - F_X(x))\, dx$.
Since $\mathbb{E}X < \infty$, $b(1 - F_X(b)) \leq \int_b^\infty x f_X(x)\, dx \to 0$. Letting $b \to \infty$ yields $\mathbb{E}X = \int_0^\infty (1 - F_X(x))\, dx = \int_0^\infty \mathbb{P}(X > x)\, dx$.
Structural Commentary: A nonnegative variable is integrated by summing its survival probabilities.
Key Insight: Expectation equals area under the tail. □

Example 3.2.6. *Maximum of Uniform Samples*
Let $X_1, \ldots, X_n$ be independent $\mathrm{Uniform}(0, 1)$ variables and $Y_n = \max_i X_i$.
Then $F_{Y_n}(y) = \mathbb{P}(X_1 \leq y, \ldots, X_n \leq y) = y^n$ for $0 \leq y \leq 1$. So $\mathbb{E}Y_n = \int_0^1 (1 - F_{Y_n}(y))\, dy = \int_0^1 (1 - y^n)\, dy = \frac{n}{n+1}$.

Theorem 3.2.7. *Mean and Variance of the Basic Sample Statistics*
Let $X_1, \dots, X_n$ be iid with $\mathbb{E}X_i = \mu$ and $\mathrm{Var}(X_i) = \sigma^2 < \infty$.
(i) Sample-mean expectation: $\mathbb{E}\overline{X}_n = \mu$.
(ii) Sample-mean variance: $\mathrm{Var}(\overline{X}_n) = \frac{\sigma^2}{n}$.
(iii) Unbiased sample variance: $\mathbb{E}S_n^2 = \sigma^2$.

Proof.
(i) $\mathbb{E}\overline{X}_n = n^{-1}\sum_{i=1}^{n}\mathbb{E}X_i = n^{-1}n\mu = \mu$.
(ii) Independence gives $\mathrm{Var}(\overline{X}_n) = n^{-2}\sum_{i=1}^{n}\mathrm{Var}(X_i) = n^{-2}n\sigma^2 = \frac{\sigma^2}{n}$.
(iii) Since $\sum_{i=1}^{n}(X_i - \overline{X}_n)^2 = \sum_{i=1}^{n}(X_i - \mu)^2 - n(\overline{X}_n - \mu)^2$. Thus $\mathbb{E}[(n-1)S_n^2] = n\sigma^2 - n(\frac{\sigma^2}{n}) = (n-1)\sigma^2$.
Structural Commentary: Averaging preserves mean and scales variance.
Key Insight: Center at μ, then subtract the fluctuation of $\overline{X}_n$. □

Lemma 3.2.8. *Expected Squared Deviation from a Sample Mean*
Let $X_1, \dots, X_n$ be independent with $\mathbb{E}X_i = \mu_i$ and $\mathrm{Var}(X_i) = \sigma^2$ for $1 \le i \le n$.
Set $\overline{X} := \frac{1}{n}\sum_{i=1}^{n}X_i$ and $\overline{\mu} := \frac{1}{n}\sum_{i=1}^{n}\mu_i$. Then $\mathbb{E}(X_i - \overline{X})^2 = (\mu_i - \overline{\mu})^2 + \frac{n-1}{n}\sigma^2$ for $1 \le i \le n$.

Proof. Set $U_i := X_i - \overline{X}$. Then $\mathbb{E}U_i = \mu_i - \overline{\mu}$, $\mathrm{Var}(\overline{X}) = \frac{\sigma^2}{n}$, and $\mathrm{Cov}(X_i, \overline{X}) = \frac{\sigma^2}{n}$ by independence.
Hence $\mathrm{Var}(U_i) = \mathrm{Var}(X_i) + \mathrm{Var}(\overline{X}) - 2\,\mathrm{Cov}(X_i, \overline{X}) = \sigma^2 + \frac{\sigma^2}{n} - 2\frac{\sigma^2}{n} = \frac{n-1}{n}\sigma^2$.
Thus $\mathbb{E}U_i^2 = (\mathbb{E}U_i)^2 + \mathrm{Var}(U_i) = (\mu_i - \overline{\mu})^2 + \frac{n-1}{n}\sigma^2$.
Structural Commentary: $X_i - \overline{X}$ has mean $\mu_i - \overline{\mu}$ and variance $\mathrm{Var}(X_i - \overline{X}) = \frac{n-1}{n}\sigma^2$.
Key Insight: $\mathrm{Cov}(X_i, \overline{X}) = \frac{\sigma^2}{n}$ removes exactly one $\frac{\sigma^2}{n}$ from the raw variance σ^2. □

Definition 3.2.9. *Mean Vector and Covariance Matrix*
For a random vector $X = (X_1, \dots, X_k)^t$:
(i) *Mean vector*: $\mathbb{E}X := (\mathbb{E}X_1, \dots, \mathbb{E}X_k)^t$.
(ii) *Covariance matrix*: $\mathrm{Var}(X) := [\mathrm{Cov}(X_i, X_j)]_{i,j=1}^{k}$.

Proposition 3.2.10. *Linear Transformations of Random Vectors*
Let $X \in \mathbb{R}^k$ satisfy $\mathbb{E}X = \mu$ and $\mathrm{Var}(X) = \Sigma$.
i. Linear form: for $a \in \mathbb{R}^k$, $\mathbb{E}(a^tX) = a^t\mu$ and $\mathrm{Var}(a^tX) = a^t\Sigma a$.
ii. Matrix transform: for $A \in \mathbb{R}^{m\times k}$, $\mathbb{E}(AX) = A\mu$ and $\mathrm{Var}(AX) = A\Sigma A^t$.

Proof.
i. $\mathbb{E}(a^tX) = a^t\mathbb{E}X = a^t\mu$, and $\mathrm{Var}(a^tX) = \mathbb{E}[(a^t(X-\mu))^2] = a^t\mathbb{E}[(X-\mu)(X-\mu)^t]a = a^t\Sigma a$.
ii. $\mathbb{E}(AX) = A\mathbb{E}X = A\mu$, and $\mathrm{Var}(AX) = \mathbb{E}[(AX - A\mu)(AX - A\mu)^t] = A\mathbb{E}[(X-\mu)(X-\mu)^t]A^t = A\Sigma A^t$.
Structural Commentary: Linear maps push means forward and conjugate covariance matrices.
Key Insight: Center first; then move constants outside expectations. □

Example 3.2.11. *Multinomial Covariance Structure*
If $X \sim \mathrm{Multinomial}(n, p)$ with $p = (p_1, \dots, p_k)$, then $\mathbb{E}X = np$ and $\mathrm{Var}(X_i) = np_i(1-p_i)$.
For $i \ne j$, $X_i + X_j \sim \mathrm{Binomial}(n, p_i + p_j)$, so $n(p_i+p_j)(1-p_i-p_j) = np_i(1-p_i) + np_j(1-p_j) + 2\,\mathrm{Cov}(X_i, X_j)$.
Hence $\mathrm{Cov}(X_i, X_j) = -np_ip_j$.

3.3 Probability Inequalities

Theorem 3.3.1. *Markov and Chebyshev Inequalities*
i. Markov: if $X \ge 0$ and $\mathbb{E}X < \infty$, then for $t > 0$, $\mathbb{P}(X \ge t) \le \frac{\mathbb{E}X}{t}$.
ii. Chebyshev: if $\mu := \mathbb{E}X$ and $\sigma^2 := \mathrm{Var}(X) < \infty$, then for $t > 0$, $\mathbb{P}(|X - \mu| \ge t) \le \frac{\sigma^2}{t^2}$.

Proof.
i. Since $X \ge t\mathbf{1}_{\{X \ge t\}}$, taking expectations gives $\mathbb{E}X \ge t\mathbb{P}(X \ge t)$.
ii. Apply (i) to $Y := (X-\mu)^2 \ge 0$ with threshold t^2, then $\mathbb{P}(|X-\mu| \ge t) = \mathbb{P}(Y \ge t^2) \le \frac{\mathbb{E}Y}{t^2} = \frac{\sigma^2}{t^2}$.
Structural Commentary: Tail bounds convert moment control into probability control.
Key Insight: Dominate the tail indicator by a scaled nonnegative random variable. □

Example 3.3.2. *A Distribution-Free Error-Rate Bound*
Let $X_1, \dots, X_n$ be independent Bernoulli(p) error indicators and $\overline{X}_n := n^{-1}\sum_{i=1}^{n}X_i$. Since $\mathbb{E}\overline{X}_n = p$ and $\mathrm{Var}(\overline{X}_n) = \frac{p(1-p)}{n}$, Chebyshev gives, for $\varepsilon > 0$, $\mathbb{P}(|\overline{X}_n - p| > \varepsilon) \le \frac{p(1-p)}{n\varepsilon^2} \le \frac{1}{4n\varepsilon^2}$.

Theorem 3.3.3. *Cauchy–Schwarz and Jensen*
If $X, Y \in L^2$, then $\mathbb{E}|XY| \le \sqrt{\mathbb{E}(X^2)\mathbb{E}(Y^2)}$.
If $g : I \to \mathbb{R}$ convex, $X \in I$ a.s., $X, g(X) \in L^1$, then $\mathbb{E}g(X) \ge g(\mathbb{E}X)$; for concave g, inequality reverses.

Proof. For Cauchy–Schwarz, apply the L^2 inner-product inequality to $|X|$ and $|Y|$.
For Jensen, set $m := \mathbb{E}X$ and take an affine support $\ell(x) := g(m) + s(x-m)$ with $\ell \le g$ on I.
Then $\mathbb{E}g(X) \ge \mathbb{E}\ell(X) = g(m) + s(\mathbb{E}X - m) = g(\mathbb{E}X)$. For concave g, apply the convex case to $-g$.
Structural Commentary: Cauchy–Schwarz controls products; Jensen moves convexity through expectation.
Key Insight: Use Hilbert-space geometry for products and supporting lines for convex functions. □

Theorem 3.3.4. *Hoeffding's Bounded-Sum Bound*
Let $Y_1, \dots, Y_n$ be independent, $\mathbb{E}Y_i = 0$, $a_i \le Y_i \le b_i$ a.s., and $V := \sum_{i=1}^{n} (b_i - a_i)^2$. For $S_n := \sum_{i=1}^{n} Y_i$ and $t, \varepsilon > 0$, $\mathbb{P}(S_n \ge \varepsilon) \le \exp(-t\varepsilon + \frac{t^2 V}{8})$; if $V > 0$, then $\mathbb{P}(S_n \ge \varepsilon) \le \exp(-\frac{2\varepsilon^2}{V})$.

Proof. For $t > 0$, Markov gives $\mathbb{P}(S_n \ge \varepsilon) = \mathbb{P}(e^{tS_n} \ge e^{t\varepsilon}) \le e^{-t\varepsilon}\mathbb{E}e^{tS_n}$.
Independence gives $\mathbb{E}e^{tS_n} = \prod_{i=1}^{n} \mathbb{E}e^{tY_i}$, and Hoeffding's lemma gives $\mathbb{E}e^{tY_i} \le \exp(\frac{t^2(b_i-a_i)^2}{8})$.
Hence $\mathbb{P}(S_n \ge \varepsilon) \le \exp(-t\varepsilon + \frac{t^2 V}{8})$. If $V > 0$, minimize the exponent at $t = \frac{4\varepsilon}{V}$ to obtain $\exp(-\frac{2\varepsilon^2}{V})$.
Structural Commentary: Hoeffding turns bounded independent increments into exponential tail decay.
Key Insight: Exponentiate the sum, factor the MGF, then optimize t. □

Corollary 3.3.5. *Hoeffding for Bernoulli Averages*
If $X_1, \dots, X_n$ independent Bernoulli(p) *variables, $\overline{X}_n := n^{-1} \sum_{i=1}^{n} X_i$, then $\mathbb{P}(|\overline{X}_n - p| > \varepsilon) \le 2e^{-2n\varepsilon^2}$.*

Proof. Set $Y_i^+ := \frac{X_i - p}{n}$.
Then $\mathbb{E}Y_i^+ = 0$, $Y_i^+ \in [-\frac{p}{n}, \frac{1-p}{n}]$, and $V = \sum_i (\frac{1}{n})^2 = \frac{1}{n}$, by Theorem 3.3.4, $\mathbb{P}(\overline{X}_n - p \ge \varepsilon) \le e^{-2n\varepsilon^2}$.
Apply same argument to $Y_i^- := \frac{p - X_i}{n}$, $\mathbb{P}(p - \overline{X}_n \ge \varepsilon) \le e^{-2n\varepsilon^2}$; the union bound yields the claim.
Structural Commentary: Bernoulli averages are sums of bounded centered increments.
Key Insight: Control both tails separately, then add them. □

3.4 Moment Generating Functions

Definition 3.4.1. *Moment Generating Function*
The *moment generating function* of X is $\psi_X(t) := \mathbb{E}(e^{tX})$ on $D_X := \{t \in \mathbb{R} : \mathbb{E}e^{tX} < \infty\}$.
If $(-\delta, \delta) \subseteq D_X$ for some $\delta > 0$, then $\psi_X^{(k)}(0) = \mathbb{E}(X^k)$ for all $k \ge 1$.

Proposition 3.4.2. *Basic MGF Properties*
Assume the MGFs below are finite on a common open interval about 0.

(i) Affine transform: if $a, b \in \mathbb{R}$ and $Y = aX + b$, then $\psi_Y(t) = e^{bt}\psi_X(at)$.

(ii) Independent sum: if $X_1, \dots, X_n$ are independent and $Y := \sum_{i=1}^{n} X_i$, then $\psi_Y(t) = \prod_{i=1}^{n} \psi_{X_i}(t)$.

(iii) Uniqueness: if $\psi_X(t) = \psi_Y(t)$ for all t in an open interval containing 0, then $\mathcal{L}(X) = \mathcal{L}(Y)$.

Proof.
(i) $\psi_Y(t) = \mathbb{E}e^{t(aX+b)} = e^{bt}\mathbb{E}e^{(at)X} = e^{bt}\psi_X(at)$.
(ii) For admissible t, $e^{tX_1}, \dots, e^{tX_n}$ are independent and integrable.
Hence $\psi_Y(t) = \mathbb{E}e^{t\sum_{i=1}^{n} X_i} = \mathbb{E}\prod_{i=1}^{n} e^{tX_i} = \prod_{i=1}^{n} \mathbb{E}e^{tX_i} = \prod_{i=1}^{n} \psi_{X_i}(t)$.
(iii) Let $\mu := \mathcal{L}(X)$ and $\nu := \mathcal{L}(Y)$. If $\psi_X = \psi_Y$ on $(-\delta, \delta)$, then $\int_{\mathbb{R}} e^{tx}\, d\mu(x) = \int_{\mathbb{R}} e^{tx}\, d\nu(x)$ for all $|t| < \delta$.
Uniqueness of the two-sided Laplace transform gives $\mu = \nu$.
Structural Commentary: MGFs turn affine maps and independent sums into algebraic operations.
Key Insight: Exponentials convert sums into products, and the MGF near 0 determines the law. □

Example 3.4.3. *MGF Computations*
(i) If $X \sim \text{Exp}(1)$, then $\psi_X(t) = \mathbb{E}e^{tX} = \int_0^\infty e^{(t-1)x}\, dx = (1-t)^{-1}$ for $t < 1$.
Hence $\mathbb{E}X = \psi_X'(0) = 1$ and $\text{Var}(X) = \psi_X''(0) - (\psi_X'(0))^2 = 1$.
(ii) If $X \sim \text{Binomial}(n, p)$, then $X = \sum_{i=1}^{n} B_i$ with independent $B_i \sim \text{Bernoulli}(p)$.
Hence $\psi_X(t) = \prod_{i=1}^{n} \psi_{B_i}(t) = (pe^t + 1 - p)^n$.

Method 3.4.4. *MGF Calculus for Classical Laws*
If $\psi_X(t) = \mathbb{E}e^{tX}$ exists near 0, then $\mathbb{E}X = \psi_X'(0)$ and $\text{Var}(X) = \psi_X''(0) - \psi_X'(0)^2$.
(i) If $X \sim \text{Poisson}(\lambda)$, then $\psi_X(t) = \exp(\lambda(e^t - 1))$, $\mathbb{E}X = \lambda$, and $\text{Var}(X) = \lambda$.
(ii) If $X \sim \text{Gamma}(\alpha, \lambda)$ with rate λ, then $\psi_X(t) = (\frac{\lambda}{\lambda - t})^\alpha$ for $t < \lambda$, $\mathbb{E}X = \frac{\alpha}{\lambda}$, and $\text{Var}(X) = \frac{\alpha}{\lambda^2}$.
(iii) If $Z \sim N(0,1)$, then $\psi_Z(t) = e^{\frac{t^2}{2}}$; for $Y = \mu + \sigma Z$, $\psi_Y(t) = \exp(\mu t + \frac{\sigma^2 t^2}{2})$.

Corollary 3.4.5. *Independent Sums from MGFs*
Let $X \perp\!\!\!\perp Y$, and interpret all MGFs on a common neighborhood of 0.

(i) If $\lambda, \mu > 0$, $X \sim \text{Poisson}(\lambda)$, and $Y \sim \text{Poisson}(\mu)$, then $X + Y \sim \text{Poisson}(\lambda + \mu)$.

(ii) If $X \sim \text{Gamma}(\alpha_1, \lambda)$ and $Y \sim \text{Gamma}(\alpha_2, \lambda)$ with $\alpha_1, \alpha_2, \lambda > 0$, then $X + Y \sim \text{Gamma}(\alpha_1 + \alpha_2, \lambda)$.

(iii) If $\mu, \nu \in \mathbb{R}$, $\sigma, \tau > 0$, $X \sim N(\mu, \sigma^2)$, and $Y \sim N(\nu, \tau^2)$, then $X + Y \sim N(\mu + \nu, \sigma^2 + \tau^2)$.

Proof.

(i) $\psi_{X+Y}(t) = \psi_X(t)\psi_Y(t) = \exp(\lambda(e^t-1))\exp(\mu(e^t-1)) = \exp((\lambda+\mu)(e^t-1))$, QED.

(ii) For $t < \lambda$, $\psi_{X+Y}(t) = \psi_X(t)\psi_Y(t) = (\frac{\lambda}{\lambda-t})^{\alpha_1+\alpha_2}$, QED.

(iii) $\psi_{X+Y}(t) = \psi_X(t)\psi_Y(t) = \exp(\mu t + \frac{\sigma^2t^2}{2})\exp(\nu t + \frac{\tau^2t^2}{2}) = \exp((\mu+\nu)t + \frac{(\sigma^2+\tau^2)t^2}{2})$, QED.

Structural Commentary: Independence turns convolution into multiplication of MGFs.
Key Insight: Closed distribution families are stable when their MGF parameters add. □

Method 3.4.6. *Common Means, Variances, and MGFs*
MGFs are stated on their natural neighborhood of 0; values at $t = 0$ are by continuity.
The geometric and negative-binomial rows use the total-trials convention.

Distribution	$\mathbb{E}X$	$\mathrm{Var}(X)$	$\psi_X(t)$
point mass at a	a	0	e^{at}
Bernoulli(p)	p	$p(1-p)$	$1-p+pe^t$

4 Order Statistics, Extrema, and Moment Methods

4.1 Order Statistics, Extrema, and Moment Methods

Order statistics describe the sorted values of an independent sample. They turn joint density calculations into formulas for minima, maxima, medians, ranges, and distribution-free tolerance intervals.

Definition 4.1.1. *Order Statistics*
For real-valued $X_1, \dots, X_n$,

(i) The *order statistics* are the pointwise rearrangement $X_{(1)} \le X_{(2)} \le \cdots \le X_{(n)}$ of $X_1, \dots, X_n$.

(ii) $X_{(1)} = \min_{1\le i\le n} X_i$, $X_{(n)} = \max_{1\le i\le n} X_i$, and if $n = 2m+1$, then $X_{(m+1)}$ is the sample median.

Proposition 4.1.2. *Minimum and Maximum of an IID Continuous Sample*
Let $n \ge 1$ and $X_1, \dots, X_n \overset{\text{iid}}{\sim} F$, where F is differentiable with density $f = F'$.
Set $V = X_{(1)} = \min_i X_i$ and $U = X_{(n)} = \max_i X_i$; then for $u, v \in \mathbb{R}$, $F_U(u) = F(u)^n$, $f_U(u) = nf(u)F(u)^{n-1}$, $F_V(v) = 1-(1-F(v))^n$, and $f_V(v) = nf(v)(1-F(v))^{n-1}$.

Proof. Since $\{U \le u\} = \bigcap_{i=1}^n \{X_i \le u\}$, independence gives $F_U(u) = \prod_{i=1}^n F(u) = F(u)^n$.
Differentiation gives $f_U(u) = nf(u)F(u)^{n-1}$.
Since $\{V > v\} = \bigcap_{i=1}^n \{X_i > v\}$, independence gives $1 - F_V(v) = \prod_{i=1}^n (1-F(v)) = (1-F(v))^n$.
Differentiation of $F_V(v) = 1-(1-F(v))^n$ gives $f_V(v) = nf(v)(1-F(v))^{n-1}$.
Structural Commentary: Extremes convert order events into products over independent coordinates.
Key Insight: Maxima use all observations to the left; minima use all observations to the right. □

Example 4.1.3. *Series and Parallel Exponential Lifetimes*
Let $T_1, \dots, T_n \overset{\text{ind}}{\sim} \text{Exp}(\lambda)$ be component lifetimes.

(i) For a series system, all components must survive, so system failure occurs at the first component failure: $V = \min_i T_i = T_{(1)}$. Thus $F_V(v) = 1 - e^{-n\lambda v}$ and $f_V(v) = n\lambda e^{-n\lambda v}$ for $v \ge 0$; hence $V \sim \text{Exp}(n\lambda)$.

(ii) For a parallel system, one surviving component suffices, so system failure occurs only after all components fail: $U = \max_i T_i = T_{(n)}$. Thus $F_U(u) = (1-e^{-\lambda u})^n$ and $f_U(u) = n\lambda e^{-\lambda u}(1-e^{-\lambda u})^{n-1}$ for $u \ge 0$.

Theorem 4.1.4. *Density of the kth Order Statistic*
Let $X_1, \dots, X_n$ be iid real-valued random variables with differentiable CDF F and density $f = F'$.
For $1 \le k \le n$ and $x \in \mathbb{R}$, $f_{X_{(k)}}(x) = \frac{n!}{(k-1)!(n-k)!} f(x)F(x)^{k-1}(1-F(x))^{n-k}$.

Proof. $N_x = \sum_{i=1}^n \mathbf{1}_{\{X_i \le x\}}$; $N_x \sim \text{Bin}(n, F(x))$, $\{X_{(k)} \le x\} = \{N_x \ge k\}$; $F_{X_{(k)}}(x) = \sum_{j=k}^n \binom{n}{j} F(x)^j (1-F(x))^{n-j}$.
With $p = F(x)$, $\frac{d}{dp}\sum_{j=k}^n \binom{n}{j} p^j(1-p)^{n-j} = \frac{n!}{(k-1)!(n-k)!}p^{k-1}(1-p)^{n-k}$, and the chain rule gives stated density.
Structural Commentary: The multinomial count of left, middle, and right observations supplies the coefficient.
Key Insight: An order statistic is located by counting how many sample points fall on each side. □

Corollary 4.1.5. *Uniform Order Statistics Are Beta*
If $X_1, \dots, X_n \overset{\text{iid}}{\sim} \text{Uniform}(0,1)$, *then for* $1 \le k \le n$, $X_{(k)} \sim \text{Beta}(k, n-k+1)$ *with density* $f_{X_{(k)}}(x) = \frac{n!}{(k-1)!(n-k)!} x^{k-1}(1-x)^{n-k} \mathbf{1}_{(0,1)}(x)$.

Proof. On $(0,1)$, $F(x) = x$ and $f(x) = 1$, so Theorem 4.1.4 gives $f_{X_{(k)}}(x) = \frac{n!}{(k-1)!(n-k)!} x^{k-1}(1-x)^{n-k}$.
Also $B(k, n-k+1) = \frac{(k-1)!(n-k)!}{n!}$, hence this density is the Beta$(k, n-k+1)$ density.
Structural Commentary: Uniform order statistics reduce the general density to the beta normalizing constant.
Key Insight: Counting positions in a uniform sample produces beta powers of left and right mass. □

Proposition 4.1.6. *Joint Density of Minimum and Maximum*
Let $n \ge 2$, *let* $X_1, \dots, X_n \overset{\text{iid}}{\sim} F$ *with differentiable CDF* F, *density* $f = F'$; $V = X_{(1)}$, $U = X_{(n)}$, $R = U - V$.

(i) For $v < u$, $f_{V,U}(v,u) = n(n-1)f(v)f(u)(F(u) - F(v))^{n-2}$, *and* $f_{V,U}(v,u) = 0$ *for* $v \ge u$.
(ii) If $F(t) = t$ *on* $[0,1]$, *then* $f_{V,U}(v,u) = n(n-1)(u-v)^{n-2}\mathbf{1}_{\{0<v<u<1\}}$.
(iii) In the uniform case, $f_R(r) = n(n-1)r^{n-2}(1-r)\mathbf{1}_{(0,1)}(r)$, *with* $F_R(r) = 0$ *for* $r < 0$, $F_R(r) = nr^{n-1} - (n-1)r^n$ *for* $0 \le r \le 1$, *and* $F_R(r) = 1$ *for* $r \ge 1$.

Proof.
(i) For $v < u$, $G(v,u) = \mathbb{P}(V \ge v, U \le u) = \mathbb{P}(v \le X_i \le u,\ 1 \le i \le n) = (F(u) - F(v))^n$, so $f_{V,U}(v,u) = -\partial_v \partial_u G(v,u) = n(n-1)f(v)f(u)(F(u) - F(v))^{n-2}$.
(ii) If $F(t) = t$ and $f(t) = 1$ on $(0,1)$, by (i), $f_{V,U}(v,u) = n(n-1)(u-v)^{n-2}$ on $0 < v < u < 1$, else 0.
(iii) For $0 < r < 1$, $f_R(r) = \int_0^{1-r} f_{V,U}(v, v+r)\, dv = n(n-1)r^{n-2}(1-r)$. Integration gives $F_R(r) = \int_0^r f_R(s)\, ds = nr^{n-1} - (n-1)r^n$; outside $[0,1]$, the support gives $F_R(r) \in \{0,1\}$.
Structural Commentary: Mixed derivatives select the two boundary observations.
Key Insight: Fixed extremes leave only interior mass. □

Example 4.1.7. *Distribution-Free Tolerance Interval*
Let $X_1, \dots, X_n$ be iid with continuous CDF F, and set $Q = F(X_{(n)}) - F(X_{(1)})$.
By the probability integral transform, $U_i = F(X_i) \overset{\text{iid}}{\sim} \text{Uniform}(0,1)$, so $Q \overset{d}{=} U_{(n)} - U_{(1)}$.
Therefore, for $0 \le \alpha \le 1$, $\mathbb{P}(Q > \alpha) = 1 - F_R(\alpha) = 1 - n\alpha^{n-1} + (n-1)\alpha^n$. For $n = 100$ and $\alpha = .95$, $\mathbb{P}(Q > .95) \approx .96$: $[X_{(1)}, X_{(n)}]$ covers at least .95 of the F-mass with probability about .96.

The expectation calculus developed above also supports a useful collection of moment methods: identifying whether the mean exists, replacing difficult distributions of functions by direct expectation, controlling spread by covariance, and using generating functions or Taylor expansion when direct integration is cumbersome.

Example 4.1.8. *Existence and First Distributional Means*
(i) If $X \sim \text{Geom}(p)$ on $\{1, 2, \dots\}$ and $q = 1 - p$, then $\mathbb{E}X = p \sum_{k \ge 1} k q^{k-1} = p \frac{d}{dq} \frac{q}{1-q} = \frac{1}{p}$.
(ii) If $X \sim \text{Poisson}(\lambda)$, then $\mathbb{E}X = e^{-\lambda} \sum_{k \ge 1} \frac{k\lambda^k}{k!} = \lambda e^{-\lambda} \sum_{j \ge 0} \frac{\lambda^j}{j!} = \lambda$.
(iii) If $X \sim \text{Cauchy}(0,1)$, then $\mathbb{E}|X| = \frac{2}{\pi} \int_0^\infty x(1+x^2)^{-1}\, dx = \infty$, so X is not integrable and $\mathbb{E}X$ is undefined.
(iv) If $\mathbb{P}(Y = 2^k) = 2^{-(k+1)}$ for $k \ge 0$, then $\mathbb{E}Y = \sum_{k \ge 0} 2^{-1} = \infty$; truncation is essential.
Key Insight: Expectation is a finite absolute average, not merely a formal symmetry or a plausible center.

Method 4.1.9. *Indicator Sums Without Independence*
(i) For a finite index set I and events $(A_i)_{i \in I}$, if $W = \sum_{i \in I} \mathbf{1}_{A_i}$, then $\mathbb{E}W = \sum_{i \in I} \mathbb{P}(A_i)$.
(ii) The identity uses only linearity of expectation; the events A_i need not be independent.

Example 4.1.10. *Counting Word Occurrences*
Let $S_1, \dots, S_N \overset{\text{iid}}{\sim} \text{Uniform}\{A, C, G, T\}$ and fix a word $w \in \{A, C, G, T\}^q$.
For $1 \le m \le N - q + 1$, set $I_m = \mathbf{1}_{\{(S_m, \dots, S_{m+q-1}) = w\}}$ and $W = \sum_{m=1}^{N-q+1} I_m$.
Then $\mathbb{P}(I_m = 1) = 4^{-q}$ and $\mathbb{E}W = (N - q + 1)4^{-q}$.
Overlaps may create dependence; linearity does not require independence.

Example 4.1.11. *Coupon Collection by Waiting Times*
Draw uniformly from n coupon types, and let X_r be the waiting time for the rth new type. Then $X_r \sim \text{Geom}(\frac{n-r+1}{n})$ on $\{1, 2, \dots\}$, so $\mathbb{E}X_r = \frac{n}{n-r+1}$.
For $T = \sum_{r=1}^n X_r$, linearity gives $\mathbb{E}T = \sum_{r=1}^n \frac{n}{n-r+1} = nH_n$, where $H_n = \sum_{j=1}^n \frac{1}{j} \sim \log n + \gamma$.

Theorem 4.1.12. *Correlation Bound and Equality Case*
Let $X, Y \in L^2$ *have means* μ_X, μ_Y *and standard deviations* $0 < \sigma_X, \sigma_Y < \infty$, *set* $\rho = \frac{\text{Cov}(X,Y)}{\sigma_X \sigma_Y}$, *and define* $Z_X = \frac{X - \mu_X}{\sigma_X}$, $Z_Y = \frac{Y - \mu_Y}{\sigma_Y}$.

(i) $\mathbb{E}Z_X = \mathbb{E}Z_Y = 0$, $\text{Var}(Z_X) = \text{Var}(Z_Y) = 1$, *and* $\text{Cov}(Z_X, Z_Y) = \rho$.
(ii) $-1 \le \rho \le 1$, *equivalently* $|\rho| \le 1$.
(iii) $\rho = \pm 1$ *iff* $Z_Y = \pm Z_X$ *a.s., equivalently* $Y = \mu_Y \pm (\frac{\sigma_Y}{\sigma_X})(X - \mu_X)$ *a.s., with the same sign.*

Proof.
(i) $\mathbb{E}Z_X = 0$, $\text{Var}(Z_X) = \sigma_X^{-2} \text{Var}(X) = 1$, and similarly for Z_Y. Moreover, $\text{Cov}(Z_X, Z_Y) = \sigma_X^{-1}\sigma_Y^{-1} \text{Cov}(X, Y) = \rho$.

(ii) Since $0 \le \mathrm{Var}(Z_X \pm Z_Y) = 2 \pm 2\rho$, both $1+\rho \ge 0$ and $1-\rho \ge 0$, hence $|\rho| \le 1$.
(*iii*) ($\Rightarrow$) If $\rho = 1$, then $\mathbb{E}(Z_X - Z_Y)^2 = 0$, so $Z_X = Z_Y$ a.s..
If $\rho = -1$, then $\mathbb{E}(Z_X + Z_Y)^2 = 0$, so $Z_X = -Z_Y$ a.s.
(*iii*) ($\Leftarrow$) If $Z_Y = \pm Z_X$, then $\rho = \mathrm{Cov}(Z_X, \pm Z_X) = \pm 1$, and $\frac{Y-\mu_Y}{\sigma_Y} = \pm\frac{X-\mu_X}{\sigma_X}$
iff $Y = \mu_Y \pm (\frac{\sigma_Y}{\sigma_X})(X - \mu_X)$ a.s.

Structural Commentary: Correlation is centred covariance after unit-variance normalization.
Key Insight: Perfect correlation means no residual scatter around an affine line. □

Example 4.1.13. *Bivariate Uniform Association*
For (X, Y) with uniform marginals on $[0,1]$, $\mathbb{E}X = \mathbb{E}Y = \frac{1}{2}$ and $\mathrm{Var}(X) = \mathrm{Var}(Y) = \frac{1}{12}$.
Hence $\mathrm{Cov}(X,Y) = \mathbb{E}(XY) - \frac{1}{4}$ and $\rho = 12\,\mathrm{Cov}(X,Y)$.
If $\mathbb{E}(XY) = \frac{2}{9}$, then $\mathrm{Cov}(X,Y) = -\frac{1}{36}$, $\rho = -\frac{1}{3}$; if $\mathbb{E}(XY) = \frac{5}{18}$, then $\mathrm{Cov}(X,Y) = \frac{1}{36}$, $\rho = \frac{1}{3}$.
The sign of ρ records negative or positive association.

Method 4.1.14. *Moment Propagation by Taylor Expansion*
Let the relevant variables have finite second moments, and let g be C^2 near the relevant mean point.
(i) If $Y = g(X)$, $\mu = \mathbb{E}X$, and $\sigma^2 = \mathrm{Var}(X)$, then $\mathbb{E}Y \approx g(\mu)$ and $\mathrm{Var}(Y) \approx [g'(\mu)]^2\sigma^2$.
(ii) The second-order mean correction is $\mathbb{E}g(X) \approx g(\mu) + \frac{1}{2}g''(\mu)\sigma^2$.
(iii) For $Z = g(\mathbf{X})$, $\mu = \mathbb{E}\mathbf{X}$, and $\Sigma = \mathrm{Cov}(\mathbf{X})$, $\mathrm{Var}(Z) \approx \nabla g(\mu)^\top \Sigma \nabla g(\mu)$ and $\mathbb{E}Z \approx g(\mu) + \frac{1}{2}\,\mathrm{tr}(\Sigma H_g(\mu))$.

Structural Commentary: Taylor expansion propagates moments through local derivatives.
Key Insight: Smooth nonlinear functions are locally linear for variance and locally quadratic for mean correction.

Example 4.1.15. *Approximate Moments of a Ratio*
Let $Z = \frac{Y}{X}$, $\mu_X \neq 0$, $\mu = (\mu_X, \mu_Y)$, and write $\sigma_X^2 = \mathrm{Var}(X)$, $\sigma_Y^2 = \mathrm{Var}(Y)$, $\sigma_{XY} = \mathrm{Cov}(X,Y)$.
For $g(x,y) = \frac{y}{x}$, Taylor propagation gives $\mathbb{E}Z \approx \frac{\mu_Y}{\mu_X} + \frac{\sigma_X^2\mu_Y}{\mu_X^3} - \frac{\sigma_{XY}}{\mu_X^2}$
and $\mathrm{Var}(Z) \approx \frac{\sigma_X^2\mu_Y^2}{\mu_X^4} + \frac{\sigma_Y^2}{\mu_X^2} - \frac{2\sigma_{XY}\mu_Y}{\mu_X^3}$. The approximation is ill-conditioned as $|\mu_X| \downarrow 0$.

5 Normal-Derived Distributions

5.1 Normal-Derived Distribution Families

Independent $N(0,1)$ variables generate the normal-derived inference laws used below: χ^2 sums, Student t ratios, and F ratios.

Proposition 5.1.1. *Chi-Square Sums*
Let $n \ge 1$ and $Z_1, \dots, Z_n \overset{\text{ind}}{\sim} N(0,1)$.

(i) For $V = \sum_{i=1}^n Z_i^2$, $V \sim \chi_n^2 = \mathrm{Gamma}(\frac{n}{2}, \frac{1}{2})$ in the rate convention,
$f_V(v) = 2^{-\frac{n}{2}}\Gamma(\frac{n}{2})^{-1}v^{\frac{n}{2}-1}e^{-\frac{v}{2}}\mathbf{1}_{(0,\infty)}(v)$, $\psi_V(t) = (1-2t)^{-\frac{n}{2}}$ for $t < \frac{1}{2}$, $\mathbb{E}V = n$, and $\mathrm{Var}(V) = 2n$.
(ii) If $U \sim \chi_m^2$, $W \sim \chi_n^2$, and $U \perp\!\!\!\perp W$, then $U + W \sim \chi_{m+n}^2$.

Proof.

(i) For $Z \sim N(0,1)$ and $t < \frac{1}{2}$, $\mathbb{E}e^{tZ^2} = (2\pi)^{-\frac{1}{2}}\int_{\mathbb{R}} e^{-\frac{(1-2t)z^2}{2}}\,dz = (1-2t)^{-\frac{1}{2}}$.
By independence, $\psi_V(t) = \prod_{i=1}^n \mathbb{E}e^{tZ_i^2} = (1-2t)^{-\frac{n}{2}}$. By MGF uniqueness, $V \sim \mathrm{Gamma}(\frac{n}{2}, \frac{1}{2})$.
Differentiating ψ_V at 0 gives $\mathbb{E}V = n$ and $\mathrm{Var}(V) = 2n$.
(ii) If $U \perp\!\!\!\perp W$, then $\psi_{U+W}(t) = (1-2t)^{-\frac{m}{2}}(1-2t)^{-\frac{n}{2}} = (1-2t)^{-\frac{m+n}{2}}$, hence $U + W \sim \chi_{m+n}^2$.

Structural Commentary: Chi-square degrees of freedom add by MGF exponents.
Key Insight: Squared independent standard normals form gamma sums. □

Definition 5.1.2. *Normal Sample Statistics*
(i) *Sample*: $X_1, \dots, X_n$ are independent with $X_i \sim N(\mu, \sigma^2)$, $n \ge 2$, and $\sigma^2 > 0$.
(ii) *Sample mean*: $\overline{X} := n^{-1}\sum_{i=1}^n X_i$ estimates the location μ.
(iii) *Sample variance*: $S^2 := (n-1)^{-1}\sum_{i=1}^n (X_i - \overline{X})^2$ estimates the scale σ^2.

Proposition 5.1.3. *Normal Sample Mean*
Let $X_1, \dots, X_n$ be independent with $X_i \sim N(\mu, \sigma^2)$, and set $\overline{X} := n^{-1}\sum_{i=1}^n X_i$. Then $\overline{X} \sim N(\mu, \frac{\sigma^2}{n})$.

Proof. Since independent normal sums are normal, $\overline{X}$ is normal.
Also $\mathbb{E}\overline{X} = n^{-1}\sum_i \mathbb{E}X_i = \mu$ and $\mathrm{Var}(\overline{X}) = n^{-2}\sum_i \mathrm{Var}(X_i) = \frac{\sigma^2}{n}$. Thus $\overline{X} \sim N(\mu, \frac{\sigma^2}{n})$.

Structural Commentary: Averaging preserves normality and divides variance by n.
Key Insight: The sample mean is an exact normal pivot center, not an asymptotic approximation. □

Theorem 5.1.4. *Mean-Residual Independence*
Let $X_1, \dots, X_n$ be independent with $X_i \sim N(\mu, \sigma^2)$, set $\overline{X} := n^{-1}\sum_i X_i$, $R := (X_1 - \overline{X}, \dots, X_n - \overline{X})$,
and $S^2 := (n-1)^{-1}\sum_i R_i^2$. Then $\overline{X} \perp\!\!\!\perp R$, hence $\overline{X} \perp\!\!\!\perp S^2$.

Proof. Let $Z_i := \frac{X_i-\mu}{\sigma}$, so $Z \sim N_n(0, I_n)$. Choose orthogonal Q with first row $n^{-\frac{1}{2}}\mathbf{1}^\top$, set $Y := QZ$.
Then $Y \sim N_n(0, I_n)$, $Y_1 \perp\!\!\!\perp (Y_2, \ldots, Y_n)$. Since $\overline{X} = \mu + \frac{\sigma Y_1}{\sqrt{n}}$ and $R = \sigma(I - n^{-1}\mathbf{1}\mathbf{1}^\top)Z = \sigma Q^\top(0, Y_2, \ldots, Y_n)^\top$, $\overline{X}$ is function of Y_1, R is function of $(Y_2, \ldots, Y_n)$. Therefore $\overline{X} \perp\!\!\!\perp R$, by $S^2 = (n-1)^{-1}\sum_i R_i^2$, $\overline{X} \perp\!\!\!\perp S^2$.

Structural Commentary: Mean and residuals are orthogonal projections.
Key Insight: For Gaussian vectors, orthogonal components are independent. □

Theorem 5.1.5. *Sample Variance Chi-Square Law*
Given independent $X_1, \ldots, X_n$; $X_i \sim N(\mu, \sigma^2)$; $S^2 := (n-1)^{-1}\sum_{i=1}^n (X_i - \overline{X})^2$. *Then* $\frac{(n-1)S^2}{\sigma^2} \sim \chi^2_{n-1}$.

Proof. Let $Z_i := \frac{X_i-\mu}{\sigma}$, so $Z = (Z_1, \ldots, Z_n) \sim N_n(0, I_n)$.
Choose orthogonal matrix Q with first row $n^{-\frac{1}{2}}(1, \ldots, 1)$, set $Y := QZ$.
Orthogonal invariance gives $Y \sim N_n(0, I_n)$ with independent coordinates.
Then $Y_1 = \frac{\sqrt{n}(\overline{X}-\mu)}{\sigma}$ and $\sum_{j=2}^n Y_j^2 = \sum_{i=1}^n (Z_i - \overline{Z})^2 = \frac{(n-1)S^2}{\sigma^2}$.
Thus $\frac{(n-1)S^2}{\sigma^2}$ is the sum of squares of $n-1$ independent $N(0,1)$ variables, hence χ^2_{n-1}.
Structural Commentary: Cantering leaves $n-1$ residual directions.
Key Insight: The sample variance is the squared Gaussian residual length scaled by σ^2. □

Definition 5.1.6. *Student t Distribution*
If $Z \sim N(0,1)$, $U \sim \chi^2_n$, $Z \perp\!\!\!\perp U$, then $T = Z/\sqrt{\frac{U}{n}}$ has *Student t distribution* with $df = n \geq 1$, $T \sim t_n$.

Proposition 5.1.7. *Student t Density*
Let $n \geq 1$ *and* $T = Z/\sqrt{\frac{U}{n}}$ *with* $Z \sim N(0,1)$, $U \sim \chi^2_n$, *and* $Z \perp\!\!\!\perp U$.

(i) For $t \in \mathbb{R}$, $f_T(t) = \frac{\Gamma(\frac{n+1}{2})}{\sqrt{n\pi}\Gamma(\frac{n}{2})}(1 + \frac{t^2}{n})^{-\frac{n+1}{2}}$.
(ii) For all $t \in \mathbb{R}$, $f_T(-t) = f_T(t)$.
(iii) For each fixed $t \in \mathbb{R}$, $\lim_{n\to\infty} f_T(t) = \phi(t) = (2\pi)^{-\frac{1}{2}}e^{-\frac{t^2}{2}}$.

Proof.

(i) For fixed $u > 0$, $z = t\sqrt{\frac{u}{n}}$ has Jacobian $\sqrt{\frac{u}{n}}$, so $f_T(t) = \int_0^\infty \phi(t\sqrt{\frac{u}{n}})\sqrt{\frac{u}{n}} f_U(u)\, du$.
Substituting $\phi(z) = (2\pi)^{-\frac{1}{2}}e^{-\frac{z^2}{2}}$ and $f_U(u) = 2^{-\frac{n}{2}}\Gamma(\frac{n}{2})^{-1}u^{\frac{n}{2}-1}e^{-\frac{u}{2}}\mathbf{1}_{(0,\infty)}(u)$ gives
$f_T(t) = \frac{1}{\sqrt{n\pi}2^{\frac{n+1}{2}}\Gamma(\frac{n}{2})}\int_0^\infty u^{\frac{n+1}{2}-1}e^{-\frac{(1+\frac{t^2}{n})u}{2}}\, du$. Then $F_T(t) = \Gamma(\frac{n+1}{2})2^{\frac{n+1}{2}}(1 + \frac{t^2}{n})^{-\frac{n+1}{2}}$, yielding density.
(ii) By (i), $f_T(t) = c_n h_n(t^2)$ for $c_n > 0$, so $f_T(-t) = f_T(t)$ for all t.
(iii) For fixed t, $f_T(t) = (2\pi)^{-\frac{1}{2}}\frac{\Gamma(\frac{n+1}{2})}{\sqrt{\frac{n}{2}}\Gamma(\frac{n}{2})}(1 + \frac{t^2}{n})^{-\frac{n+1}{2}}$, gamma ratio tends to 1, last factor tends to $e^{-\frac{t^2}{2}}$.

Structural Commentary: Student t is a normal scale mixture with random chi-square scale.
Key Insight: Random denominator uncertainty thickens the normal tails. □

Example 5.1.8. *t_1 is Cauchy*
If $T \sim t_1$, then $f_T(t) = \Gamma(1)(\sqrt{\pi}\Gamma(\frac{1}{2}))^{-1}(1+t^2)^{-1} = \frac{1}{\pi(1+t^2)}$, so $T \sim \text{Cauchy}(0,1)$.

Definition 5.1.9. *F Distribution*
If $U \sim \chi^2_m$, $V \sim \chi^2_n$, $U \perp\!\!\!\perp V$, then $W = (\frac{U}{m})/(\frac{V}{n})$ has *F distribution*, $df = (m,n)$, $W \sim F_{m,n}$.

Proposition 5.1.10. *F Density*
Let $m, n \geq 1$ *and* $W = (\frac{U}{m})/(\frac{V}{n})$, *where* $U \sim \chi^2_m$, $V \sim \chi^2_n$, *and* $U \perp\!\!\!\perp V$.

(i) $f_W(w) = \frac{\Gamma(\frac{m+n}{2})}{\Gamma(\frac{m}{2})\Gamma(\frac{n}{2})}(\frac{m}{n})^{\frac{m}{2}}w^{\frac{m}{2}-1}(1 + \frac{mw}{n})^{-\frac{m+n}{2}}\mathbf{1}_{(0,\infty)}(w)$.
(ii) If $n > 2$, *then* $\mathbb{E}W = \frac{n}{n-2}$.

Proof.

(i) For $w > 0$, set $u = \frac{mwv}{n}$; the Jacobian is $\frac{mv}{n}$, so $f_W(w) = \int_0^\infty f_U(\frac{mwv}{n})f_V(v)(\frac{mv}{n})\, dv$. By substitution,
$f_W(w) = Cw^{\frac{m}{2}-1}\int_0^\infty v^{\frac{m+n}{2}-1}e^{-\frac{(1+\frac{mw}{n})v}{2}}\, dv$; $C = \frac{(\frac{m}{n})^{\frac{m}{2}}}{2^{\frac{m+n}{2}}\Gamma(\frac{m}{2})\Gamma(\frac{n}{2})}$, by gamma integral, QED.
(ii) Since $U \perp\!\!\!\perp V$, $\mathbb{E}W = (\frac{n}{m})\mathbb{E}U\,\mathbb{E}(V^{-1}) = n\,\mathbb{E}(V^{-1}) = \frac{n}{n-2}$ for $n > 2$.

Structural Commentary: An F variable is a ratio of independent chi-square averages.
Key Insight: Denominator variability controls the right tail and the mean condition $n > 2$. □

Corollary 5.1.11. *Reciprocal F and Squared t*

(i) For $m, n \geq 1$, *if* $W \sim F_{m,n}$, *then* $W^{-1} \sim F_{n,m}$.
(ii) If $T \sim t_n$, *then* $T^2 \sim F_{1,n}$.

Proof.

(i) Write $W = (\frac{U}{m})/(\frac{V}{n})$ with $U \sim \chi^2_m$, $V \sim \chi^2_n$, and $U \perp\!\!\!\perp V$; then $W^{-1} = (\frac{V}{n})/(\frac{U}{m}) \sim F_{n,m}$.
(ii) Write $T = Z/\sqrt{\frac{V}{n}}$ with $Z \sim N(0,1)$, $V \sim \chi^2_n$, and $Z \perp\!\!\!\perp V$; since $Z^2 \sim \chi^2_1$, $T^2 = (\frac{Z^2}{1})/(\frac{V}{n}) \sim F_{1,n}$.

Structural Commentary: Reciprocals swap F degrees of freedom, and squaring t removes the normal sign.
Key Insight: Both identities are immediate from the same chi-square-ratio representation. □

Part XVI
Probability and Stochastic Systems

1 Conditional Probability and Conditional Expectation

1.1 Conditional Probability

Definition 1.1.1. *Conditional Probability*
For $A, B \in \mathcal{F}$ with $\mathbb{P}(B) > 0$, the *conditional probability* of A given B is $\mathbb{P}(A \mid B) := \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(B)}$, i.e. the probability of A under the normalised restriction of $\mathbb{P}$ to B.

Example 1.1.2. *Diagnostic Table*
Let T be the event of a positive test and D the event of disease, with observed counts

	D	D^c	total
T	25	14	39
T^c	18	78	96
total	43	92	135

Let $N(\cdot)$ be counts, $\widehat{\mathbb{P}}(A \mid B) = \frac{N(A \cap B)}{N(B)}$.
Thus $\widehat{\mathbb{P}}(D \mid T) = \frac{25}{39}$, $\widehat{\mathbb{P}}(D^c \mid T^c) = \frac{78}{96}$, $\widehat{\mathbb{P}}(D^c \mid T) = \frac{14}{39}$, and $\widehat{\mathbb{P}}(D \mid T^c) = \frac{18}{96}$.

Proposition 1.1.3. *Conditioning on a Fixed Event Gives a Probability Measure*
For $B \in \mathcal{F}$ with $\mathbb{P}(B) > 0$, define $\mathbb{P}_B : \mathcal{F} \to [0,1]$ by $\mathbb{P}_B(A) := \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(B)}$.
Then $\mathbb{P}_B$ is a probability measure on $(\Omega, \mathcal{F})$.

Proof. For $A \in \mathcal{F}$, $\mathbb{P}_B(A) \geq 0$, and $\mathbb{P}_B(\Omega) = \frac{\mathbb{P}(B)}{\mathbb{P}(B)} = 1$.
If $(A_i)_{i \geq 1}$ are pairwise disjoint, then $(A_i \cap B)_{i \geq 1}$ are pairwise disjoint and $(\bigcup_i A_i) \cap B = \bigcup_i (A_i \cap B)$.
Thus $\mathbb{P}_B(\bigcup_i A_i) = \frac{\mathbb{P}(\bigcup_i (A_i \cap B))}{\mathbb{P}(B)} = \sum_i \frac{\mathbb{P}(A_i \cap B)}{\mathbb{P}(B)} = \sum_i \mathbb{P}_B(A_i)$.
Structural Commentary: Conditioning normalizes the restriction of $\mathbb{P}$ to B.
Key Insight: Once B is fixed, conditional probability is ordinary probability on the restricted world. □

Remark 1.1.4. *Conditional Probability Is Not Symmetric*
In general, $\mathbb{P}(A \mid B) \neq \mathbb{P}(B \mid A)$; conditioning fixes the reference population. For disease event D and positive-test event T, large $\mathbb{P}(T \mid D)$ need not imply large $\mathbb{P}(D \mid T)$ when $\mathbb{P}(D)$ is small.

Proposition 1.1.5. *Multiplication and Chain Rules*
Let $A, B, C \in \mathcal{F}$ with $\mathbb{P}(A) > 0$, $\mathbb{P}(B) > 0$, and $\mathbb{P}(B \cap C) > 0$.
(i) $\mathbb{P}(A \cap B) = \mathbb{P}(A \mid B)\mathbb{P}(B) = \mathbb{P}(B \mid A)\mathbb{P}(A)$.
(ii) $\mathbb{P}(A \cap B \cap C) = \mathbb{P}(A \mid B \cap C)\mathbb{P}(B \mid C)\mathbb{P}(C)$.

Proof.
(i) For $\mathbb{P}(F) > 0$, $\mathbb{P}(E \mid F)\mathbb{P}(F) = \mathbb{P}(E \cap F)$; apply this with $(E, F) = (A, B)$ and (B, A).
(ii) Since $\mathbb{P}(B \cap C) > 0$, $\mathbb{P}(A \mid B \cap C)\mathbb{P}(B \mid C)\mathbb{P}(C) = \frac{\mathbb{P}(A \cap B \cap C)}{\mathbb{P}(B \cap C)} \frac{\mathbb{P}(B \cap C)}{\mathbb{P}(C)} \mathbb{P}(C) = \mathbb{P}(A \cap B \cap C)$.
Structural Commentary: The chain rule orders information as C, then B within C, then A within $B \cap C$.
Key Insight: A joint probability factors into conditional increments along a chosen order. □

Example 1.1.6. *Cards Without Replacement*
Draw two cards from a standard deck without replacement. Let A be the event that the first card is the ace of clubs and B the event that the second card is the queen of diamonds. Since $\mathbb{P}(A) = \frac{1}{52}$ and $\mathbb{P}(B \mid A) = \frac{1}{51}$, $\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B \mid A) = \frac{1}{52 \cdot 51}$. The factor $\mathbb{P}(B \mid A)$ uses the 51-card deck remaining after A occurs.

Proposition 1.1.7. *Independence Through Conditioning*
Let $A, B \in \mathcal{F}$ with $\mathbb{P}(A) > 0$ and $\mathbb{P}(B) > 0$. The following are equivalent:
(i) A and B are independent.
(ii) $\mathbb{P}(A \mid B) = \mathbb{P}(A)$.
(iii) $\mathbb{P}(B \mid A) = \mathbb{P}(B)$.

Proof.
(i) $\Rightarrow$ *(ii)* If A and B are independent, then $\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B)$, so $\mathbb{P}(A \mid B) = \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(B)} = \mathbb{P}(A)$.
(ii) $\Rightarrow$ *(iii)* If $\mathbb{P}(A \mid B) = \mathbb{P}(A)$, then $\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B)$, so $\mathbb{P}(B \mid A) = \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(A)} = \mathbb{P}(B)$.
(iii) $\Rightarrow$ *(i)* If $\mathbb{P}(B \mid A) = \mathbb{P}(B)$, then $\mathbb{P}(A \cap B) = \mathbb{P}(B \mid A)\mathbb{P}(A) = \mathbb{P}(A)\mathbb{P}(B)$, hence A and B are independent.
Structural Commentary: Each condition is $\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B)$ normalized by a positive marginal.
Key Insight: Independence means conditioning on either event preserves the probability of the other. □

Theorem 1.1.8. *Law of Total Probability*
(i) Let $A_1, \ldots, A_k \in \mathcal{F}$ form a finite partition of Ω with $\mathbb{P}(A_i) > 0$ for all i.
(ii) For every $B \in \mathcal{F}$, $\mathbb{P}(B) = \sum_{i=1}^{k} \mathbb{P}(B \mid A_i)\mathbb{P}(A_i)$.

Proof.

(i) The partition assumptions give $B = \bigsqcup_{i=1}^{k} (B \cap A_i)$, hence $\mathbb{P}(B) = \sum_{i=1}^{k} \mathbb{P}(B \cap A_i)$.

(ii) For each i, $\mathbb{P}(B \cap A_i) = \mathbb{P}(B \mid A_i)\mathbb{P}(A_i)$; substituting in (i) gives the formula.

Structural Commentary: The partition $\{A_i\}_{i=1}^{k}$ decomposes B into disjoint cases $B \cap A_i$.
Key Insight: Total probability is weighted averaging over cases. □

Example 1.1.9. *Second Draw by Total Probability*
An urn has 3 red balls, 1 blue ball; draw twice without replacement, let R_i be the event that draw i is red.
By total probability, $\mathbb{P}(R_2) = \mathbb{P}(R_2 \mid R_1)\mathbb{P}(R_1) + \mathbb{P}(R_2 \mid R_1^c)\mathbb{P}(R_1^c) = \frac{2}{3} \cdot \frac{3}{4} + 1 \cdot \frac{1}{4} = \frac{3}{4}$.
Key Insight: The second draw has the same marginal red probability as the first.

Definition 1.1.10. *Prior and Posterior Probabilities*
Let $A_1, \ldots, A_k \in \mathcal{F}$ be a partition with $\mathbb{P}(A_i) > 0$ for all i, and let $B \in \mathcal{F}$ with $\mathbb{P}(B) > 0$.

(i) $\mathbb{P}(A_i)$ is the *prior probability* of A_i.

(ii) $\mathbb{P}(A_i \mid B)$ is the *posterior probability* of A_i after conditioning on B.

Theorem 1.1.11. *Bayes' Theorem*

Let $A_1, \ldots, A_k \in \mathcal{F}$ satisfy $A_i \cap A_j = \varnothing$ for $i \neq j$, $\bigcup_{i=1}^{k} A_i = \Omega$, and $\mathbb{P}(A_i) > 0$ for all i.

If $B \in \mathcal{F}$ with $\mathbb{P}(B) > 0$, then for each i, $\mathbb{P}(A_i \mid B) = \dfrac{\mathbb{P}(B|A_i)\mathbb{P}(A_i)}{\sum_{j=1}^{k} \mathbb{P}(B|A_j)\mathbb{P}(A_j)}$.

Proof. For fixed i, $\mathbb{P}(A_i \mid B) = \frac{\mathbb{P}(A_i \cap B)}{\mathbb{P}(B)} = \frac{\mathbb{P}(B|A_i)\mathbb{P}(A_i)}{\mathbb{P}(B)}$.
Since $B = \bigsqcup_{j=1}^{k} (B \cap A_j)$, $\mathbb{P}(B) = \sum_{j=1}^{k} \mathbb{P}(B \cap A_j) = \sum_{j=1}^{k} \mathbb{P}(B \mid A_j)\mathbb{P}(A_j)$. Substitution gives the formula.
Structural Commentary: Bayes reweights priors by likelihoods, then normalises.
Key Insight: Posterior equals likelihood times prior divided by evidence. □

Corollary 1.1.12. *Posterior Mass Must Balance*
Let $A_1, \ldots, A_k \in \mathcal{F}$ be a partition of Ω with $\mathbb{P}(A_i) > 0$ for all i, and let $B \in \mathcal{F}$ with $\mathbb{P}(B) > 0$.
If $\mathbb{P}(A_1 \mid B) < \mathbb{P}(A_1)$, then there exists $i \in \{2, \ldots, k\}$ such that $\mathbb{P}(A_i \mid B) > \mathbb{P}(A_i)$.

Proof. Suppose $\mathbb{P}(A_i \mid B) \leq \mathbb{P}(A_i)$ for all $i \geq 2$
As $\sum_{i=1}^{k} \mathbb{P}(A_i \mid B) = \sum_{i=1}^{k} \mathbb{P}(A_i) = 1$, hence $1 = \sum_{i=1}^{k} \mathbb{P}(A_i \mid B) < \mathbb{P}(A_1) + \sum_{i=2}^{k} \mathbb{P}(A_i) = 1$, a contradiction.
Structural Commentary: Posterior mass is conserved across the partition.
Key Insight: A decrease in one cell must be offset by an increase in another. □

Example 1.1.13. *Transition Probabilities*
Let states U, M, L denote upper, middle, lower groups, and let $P = (p_{ij})$ with $p_{ij} = \mathbb{P}(j_2 \mid i_1)$:

	U_2	M_2	L_2
U_1	.45	.48	.07
M_1	.05	.70	.25
L_1	.01	.50	.49

For $\pi_1 = (.10, .40, .50)$, total probability gives $\pi_2 = \pi_1 P$ and $\mathbb{P}(U_2) = .45(.10) + .05(.40) + .01(.50) = .07$.
Bayes gives the inverse query $\mathbb{P}(U_1 \mid U_2) = \frac{\mathbb{P}(U_2|U_1)\mathbb{P}(U_1)}{\mathbb{P}(U_2)} = \frac{.45(.10)}{.07} \approx .64$.
Key Insight: Use πP forward and Bayes backward.

Example 1.1.14. *Base Rates in a Medical Test*
Let D be disease and T a positive test, with joint law

	D	D^c
T	0.0081	0.0900
T^c	0.0009	0.9010

Then $\mathbb{P}(T \mid D) = \frac{0.0081}{0.0081+0.0009} = 0.9$, $\mathbb{P}(T^c \mid D^c) = \frac{0.9010}{0.9010+0.0900} \approx 0.91$, $\mathbb{P}(D \mid T) = \frac{0.0081}{0.0081+0.0900} \approx 0.083$.
Key Insight: A rare condition can have small posterior probability after a positive test.

Example 1.1.15. *Rare Classes and Screening Errors*
Let L denote lying and $T = L^c$ truth, with $\mathbb{P}(+ \mid L) = .88$, $\mathbb{P}(+ \mid T) = .14$, $\mathbb{P}(L) = .01$, and $\mathbb{P}(T) = .99$.
Bayes gives $\mathbb{P}(T \mid +) = \frac{\mathbb{P}(+|T)\mathbb{P}(T)}{\mathbb{P}(+|T)\mathbb{P}(T)+\mathbb{P}(+|L)\mathbb{P}(L)} = \frac{(.14)(.99)}{(.14)(.99)+(.88)(.01)} \approx .94$.
Key Insight: Rare-class positives can mostly come from the common class.

Example 1.1.16. *Monty Hall*
The player chooses door 1. Let $\omega = (\omega_1, \omega_2)$, where ω_1 is the prize door and ω_2 is Monty's opened door.
Monty opens neither door 1 nor the prize door, and chooses uniformly from $\{2, 3\}$ when $\omega_1 = 1$.
The induced probabilities are $\mathbb{P}(1, 2) = \mathbb{P}(1, 3) = \frac{1}{6}$ and $\mathbb{P}(2, 3) = \mathbb{P}(3, 2) = \frac{1}{3}$.
Let $S = \{\omega_1 = 1\}$ be the event that staying wins.
Given $\omega_2 = 2$, the staying-win probability is $\mathbb{P}(S \mid \omega_2 = 2) = \frac{\frac{1}{6}}{\frac{1}{6}+\frac{1}{3}} = \frac{1}{3}$.
Thus switching wins with probability $\frac{2}{3}$, and the case $\omega_2 = 3$ is symmetric.
Key Insight: Once Monty's rule is part of the sample space, switching has conditional probability $\frac{2}{3}$.

Example 1.1.17. *Three Cards and Conditional Sampling*
Cards are GG, RR, and GR. Choose a card uniformly and then a side uniformly.
Let V be the event that the visible side is green and H the event that the hidden side is green.
Among the three equally likely green visible sides, two have green hidden side, so $\mathbb{P}(H \mid V) = \frac{2}{3}$.

Example 1.1.18. *Conditioning Changes the Reference Class*
Let $X \sim \text{Binomial}(5, \frac{1}{4})$ be number of blue-eyed children, Y be event that youngest child has blue eyes.

(i) Given $X \geq 1$, $\mathbb{P}(X \geq 3 \mid X \geq 1) = \frac{\binom{5}{3}(\frac{1}{4})^3(\frac{3}{4})^2 + \binom{5}{4}(\frac{1}{4})^4(\frac{3}{4}) + (\frac{1}{4})^5}{1-(\frac{3}{4})^5} = \frac{106}{781}$.

(ii) Given Y, $\mathbb{P}(X \geq 3 \mid Y) = 1 - \left(\frac{3}{4}\right)^4 - 4\left(\frac{1}{4}\right)\left(\frac{3}{4}\right)^3 = \frac{67}{256}$.

Key Insight: Similar information can determine different conditioning events.

Example 1.1.19. *Bayes with Several Categories*
Let $O \in \{M, W, L\}$ denote operating system with probabilities $(0.30, 0.50, 0.20)$.
Let I be infection, with $\mathbb{P}(I \mid O = M) = 0.65$, $\mathbb{P}(I \mid O = W) = 0.82$, and $\mathbb{P}(I \mid O = L) = 0.50$.
Bayes' theorem gives $\mathbb{P}(W \mid I) = \frac{0.82 \cdot 0.50}{0.65 \cdot 0.30 + 0.82 \cdot 0.50 + 0.50 \cdot 0.20} = \frac{82}{141}$.

Example 1.1.20. *Posterior and Predictive Probabilities*
Let C be uniform on $\{C_1, \ldots, C_5\}$, and suppose coin C_i has head probability p_i.
The head-probability vector is $(p_1, p_2, p_3, p_4, p_5) = \left(0, \frac{1}{4}, \frac{1}{2}, \frac{3}{4}, 1\right)$. Let H_n be the event that toss n is heads.
The posterior after one head is $\mathbb{P}(C_i \mid H_1) = \frac{p_i}{p_1+p_2+p_3+p_4+p_5} = \left(0, \frac{1}{10}, \frac{1}{5}, \frac{3}{10}, \frac{2}{5}\right)_i$.
The predictive probability is $\mathbb{P}(H_2 \mid H_1) = \sum_{i=1}^{5} p_i \mathbb{P}(C_i \mid H_1) = \frac{3}{4}$.
If B_4 is the event that the first head occurs on toss 4,
the posterior is $\mathbb{P}(C_i \mid B_4) = \frac{(1-p_i)^3 p_i}{\sum_{j=1}^{5}(1-p_j)^3 p_j}$, and $\left(\mathbb{P}(C_i \mid B_4)\right)_{i=1}^{5} = \left(0, \frac{27}{46}, \frac{16}{46}, \frac{3}{46}, 0\right)$.

Key Insight: Bayes' theorem updates hidden parameters; prediction averages over the posterior.

Definition 1.1.21. *Conditional Mass and Density Functions*

(i) *Discrete*: if X, Y are discrete and $f_Y(y) > 0$, the conditional mass function is
$f_{X|Y}(x \mid y) := \mathbb{P}(X = x \mid Y = y) = \frac{f_{X,Y}(x,y)}{f_Y(y)}$.

(ii) *Continuous*: if X, Y have a joint density and $f_Y(y) > 0$, the conditional density is
$f_{X|Y}(x \mid y) := \frac{f_{X,Y}(x,y)}{f_Y(y)}$, so $\mathbb{P}(X \in A \mid Y = y) = \int_A f_{X|Y}(x \mid y)\, dx$ for measurable A.

Proposition 1.1.22. *Joint Factorizations and Total Probability for Conditional Laws*
Assume the displayed sums or integrals are well defined.

(i) If (X, Y) is discrete, $p_Y(y) > 0$, then $p_{X,Y}(x,y) = p_{X|Y}(x \mid y) p_Y(y)$, $p_X(x) = \sum_y p_{X|Y}(x \mid y) p_Y(y)$.

(ii) If (X, Y) has density, $f_X(x) > 0$, then $f_{X,Y}(x,y) = f_{Y|X}(y \mid x) f_X(x)$, $f_Y(y) = \int_{-\infty}^{\infty} f_{Y|X}(y \mid x) f_X(x)\, dx$.

Proof.

(i) For $p_Y(y) > 0$, $p_{X|Y}(x \mid y) = \frac{p_{X,Y}(x,y)}{p_Y(y)}$.
Hence $p_{X,Y}(x,y) = p_{X|Y}(x \mid y) p_Y(y)$ and $p_X(x) = \sum_y p_{X,Y}(x,y) = \sum_y p_{X|Y}(x \mid y) p_Y(y)$.

(ii) For $f_X(x) > 0$, $f_{Y|X}(y \mid x) = \frac{f_{X,Y}(x,y)}{f_X(x)}$.
Hence $f_{X,Y}(x,y) = f_{Y|X}(y \mid x) f_X(x)$ and $f_Y(y) = \int_{-\infty}^{\infty} f_{X,Y}(x,y)\, dx = \int_{-\infty}^{\infty} f_{Y|X}(y \mid x) f_X(x)\, dx$.

Structural Commentary: Conditional laws disintegrate a joint law into a marginal law and a fiber law.
Key Insight: Total probability is marginalization after conditional factorization. □

Example 1.1.23. *Conditional Masses from the Three-Toss Table*
Let Y be the number of heads in three fair tosses, and let $X = 1$ iff the first toss is heads.
Since $p_Y(1) = \frac{3}{8}$, $p_{X,Y}(0,1) = \frac{2}{8}$, and $p_{X,Y}(1,1) = \frac{1}{8}$, one has $p_{X|Y}(0 \mid 1) = \frac{2}{3}$ and $p_{X|Y}(1 \mid 1) = \frac{1}{3}$.
Thus, given $Y = 1$, the first toss is more likely tails.

Example 1.1.24. *Uniform Square*
If $(X, Y) \sim \text{Uniform}([0,1]^2)$, then for $0 \leq y \leq 1$, $0 \leq x \leq 1$, $f_{X|Y}(x \mid y) = 1$. Hence $X \mid Y = y \sim \text{Uniform}(0, 1)$.

Example 1.1.25. *Conditioning in the Parabolic Region*
Let (X, Y) have density $f(x,y) = \frac{21}{4}x^2 y$, $x^2 \leq y \leq 1$. Then $f_X(x) = \frac{21}{8}x^2(1 - x^4)$, $-1 \leq x \leq 1$.
For $x^2 \leq y \leq 1$, $f_{Y|X}(y \mid x) = \frac{\frac{21}{4}x^2 y}{\frac{21}{8}x^2(1-x^4)} = \frac{2y}{1-x^4}$.
At $x = \frac{1}{2}$, $f_{Y|X}(y \mid \frac{1}{2}) = \frac{32y}{15}$, so $\mathbb{P}(Y \geq \frac{3}{4} \mid X = \frac{1}{2}) = \int_{\frac{3}{4}}^{1} \frac{32y}{15}\, dy = \frac{7}{15}$.

Example 1.1.26. *Poisson Thinning*
Let $\lambda > 0$, $0 \leq p \leq 1$, $N \sim \text{Poisson}(\lambda)$, and $X \mid N = n \sim \text{Binomial}(n, p)$.
For $k \in \mathbb{N}_0$, by total probability, $\mathbb{P}(X = k) = \sum_{n=k}^{\infty} e^{-\lambda} \frac{\lambda^n}{n!} \binom{n}{k} p^k (1-p)^{n-k} = e^{-\lambda p} \frac{(\lambda p)^k}{k!}$, thus $X \sim \text{Poisson}(\lambda p)$.

Example 1.1.27. *A Triangular Exponential Joint Density*
Let $\lambda > 0$ and $f_{X,Y}(x,y) = \lambda^2 e^{-\lambda y} \mathbf{1}_{\{0 \leq x \leq y\}}$.
For $x \geq 0$, $f_X(x) = \int_x^{\infty} \lambda^2 e^{-\lambda y}\, dy = \lambda e^{-\lambda x}$; for $y \geq 0$, $f_Y(y) = \int_0^y \lambda^2 e^{-\lambda y}\, dx = \lambda^2 y e^{-\lambda y}$.
Hence $f_{Y|X}(y \mid x) = \frac{f_{X,Y}(x,y)}{f_X(x)} = \lambda e^{-\lambda(y-x)} \mathbf{1}_{[x,\infty)}(y)$ and $f_{X|Y}(x \mid y) = \frac{f_{X,Y}(x,y)}{f_Y(y)} = y^{-1} \mathbf{1}_{[0,y]}(x)$.
Thus $Y \mid X = x \sim x + \text{Exp}(\lambda)$ and $X \mid Y = y \sim \text{Uniform}(0, y)$.

Example 1.1.28. *Bivariate Normal Conditional Density*
Let (X, Y) be bivariate normal with means μ_X, μ_Y, standard deviations $\sigma_X, \sigma_Y > 0$, and correlation $\rho \in (-1, 1)$.
For fixed x, $f_{Y|X}(y \mid x) = \frac{f_{X,Y}(x,y)}{f_X(x)} = \{\sigma_Y \sqrt{2\pi(1-\rho^2)}\}^{-1} \exp\left[-\frac{(y-\mu_Y-\rho\sigma_Y\sigma_X^{-1}(x-\mu_X))^2}{2\sigma_Y^2(1-\rho^2)}\right]$.
Thus $Y \mid X = x \sim N(\mu_Y + \rho\sigma_Y\sigma_X^{-1}(x-\mu_X), \sigma_Y^2(1-\rho^2))$; if $\rho = 0$, this law is independent of x.

1.2 Conditional Expectation

Definition 1.2.1. *Conditional Expectation Given a Random Variable*
Let X, Y be random variables, and assume the relevant sums or integrals exist.

(i) *Discrete case*: If X, Y are discrete, then $\mathbb{E}(X \mid Y = y) := \sum_x x\, p_{X|Y}(x \mid y)$.

(ii) *Density case*: If X, Y have conditional density $f_{X|Y}$, then $\mathbb{E}(X \mid Y = y) := \int_{\mathbb{R}} x f_{X|Y}(x \mid y)\, dx$

(iii) *Measurable transforms*: For measurable r,

$$\mathbb{E}(r(X,Y) \mid Y = y) = \begin{cases} \sum_x r(x,y) p_{X|Y}(x \mid y), & \text{discrete case,} \\ \int_{\mathbb{R}} r(x,y) f_{X|Y}(x \mid y)\, dx, & \text{density case.} \end{cases}$$

(iv) *Random-variable form*: $\mathbb{E}(X \mid Y)$ is the function $g(Y)$ with $g(y) = \mathbb{E}(X \mid Y = y)$.

Example 1.2.2. *A Conditional Uniform Model*
Let $X \sim \text{Uniform}(0,1)$ and, conditionally on $X = x$, let $Y \sim \text{Uniform}(x, 1)$.
For $0 \le x < 1$ and $x < y < 1$, $f_{Y|X}(y \mid x) = \frac{1}{1-x}$, so $\mathbb{E}(Y \mid X = x) = \frac{1}{1-x}\int_x^1 y\, dy = \frac{1+x}{2}$; $\mathbb{E}(Y \mid X) = \frac{1+X}{2}$.

Theorem 1.2.3. *Tower Property*
Let X, Y be real-valued random variables whose joint law is either discrete or admits a density, and let $r : \mathbb{R}^2 \to \mathbb{R}$ be measurable. If $\mathbb{E}|Y| < \infty$ and $\mathbb{E}|r(X,Y)| < \infty$, then $\mathbb{E}[\mathbb{E}(Y \mid X)] = \mathbb{E}Y$ and $\mathbb{E}[\mathbb{E}(r(X,Y) \mid X)] = \mathbb{E}(r(X,Y))$.

Proof. Let $h(x,y)$ denote either y or $r(x,y)$, and set $g_h(x) := \mathbb{E}(h(X,Y) \mid X = x)$.
In the density case, $g_h(x) = \int h(x,y) f_{Y|X}(y \mid x)\, dy$ and $f(x,y) = f_X(x) f_{Y|X}(y \mid x)$,
so Fubini gives $\mathbb{E}[g_h(X)] = \int\int h(x,y) f(x,y)\, dy\, dx = \mathbb{E}h(X,Y)$.
In the discrete case, $\mathbb{E}[g_h(X)] = \sum_x \sum_y h(x,y) p_{Y|X}(y \mid x) p_X(x) = \sum_x \sum_y h(x,y) p_{X,Y}(x,y) = \mathbb{E}h(X,Y)$.
Taking $h(x,y) = y$ and $h(x,y) = r(x,y)$ gives the two identities.
Structural Commentary: Conditional expectation first averages over fibers $\{X = x\}$, and the outer expectation averages those fiber means over the law of X.
Key Insight: Iterated expectation removes the conditioning variable without changing the total mean. □

Example 1.2.4. *Using the Tower Property*
Let $X \sim \text{Uniform}(0,1)$ and, conditionally on $X = x$, let $Y \sim \text{Uniform}(x, 1)$.
Since $\mathbb{E}(Y \mid X) = \frac{1+X}{2}$ and $\mathbb{E}X = \frac{1}{2}$, the tower property gives $\mathbb{E}Y = \mathbb{E}[\mathbb{E}(Y \mid X)] = \mathbb{E}\left[\frac{1+X}{2}\right] = \frac{3}{4}$.

Proposition 1.2.5. *Pulling Out What Is Known*
Let X, Y be real-valued random variables whose joint law is either discrete or admits a density, and let $r, s : \mathbb{R} \to \mathbb{R}$ be measurable with $\mathbb{E}|s(Y)| < \infty$, $\mathbb{E}|r(X)s(Y)| < \infty$, and $\mathbb{E}|r(X)| < \infty$. Then $\mathbb{E}(r(X)s(Y) \mid X) = r(X)\mathbb{E}(s(Y) \mid X)$ and $\mathbb{E}(r(X) \mid X) = r(X)$.

Proof. Let K_x be the conditional law of Y given $X = x$, so $K_x(\{y\}) = p_{Y|X}(y \mid x)$ in the discrete case and $K_x(dy) = f_{Y|X}(y \mid x)\, dy$ in the density case. Set $m_s(x) := \int s(y) K_x(dy) = \mathbb{E}(s(Y) \mid X = x)$, with the integral read as a sum in the discrete case. For admissible x, $\mathbb{E}(r(X)s(Y) \mid X = x) = \int r(x)s(y) K_x(dy) = r(x) m_s(x)$, and $\mathbb{E}(r(X) \mid X = x) = \int r(x) K_x(dy) = r(x)$. Evaluating at $x = X$ gives the identities.
Structural Commentary: Conditioning on X makes every function of X fixed inside remaining average over Y.
Key Insight: Known factors can be treated as constants under conditional expectation. □

Corollary 1.2.6. *Constant Conditional Mean Implies Uncorrelated*
Let $X, Y \in L^2$ and suppose $\mathbb{E}(X \mid Y) = c$ a.s. for some constant $c \in \mathbb{R}$. Then $c = \mathbb{E}X$ and $\text{Cov}(X,Y) = 0$.

Proof. The tower property gives $\mathbb{E}X = \mathbb{E}[\mathbb{E}(X \mid Y)] = c$.
Since Y is known when conditioning on Y, $\mathbb{E}(XY \mid Y) = Y\mathbb{E}(X \mid Y) = cY$.
Taking expectations gives $\mathbb{E}(XY) = c\mathbb{E}Y = \mathbb{E}X\,\mathbb{E}Y$, hence $\text{Cov}(X,Y) = \mathbb{E}(XY) - \mathbb{E}X\,\mathbb{E}Y = 0$.
Structural Commentary: A constant conditional mean kills covariance with all functions of Y, hence with Y.
Key Insight: Mean independence implies uncorrelatedness, but not conversely. □

Definition 1.2.7. *Conditional Variance*
Let X, Y be real-valued random variables with finite second conditional moment for each x under consideration.

(i) The conditional mean is $\mu(x) := \mathbb{E}(Y \mid X = x)$.

(ii) The conditional variance at x is $v(x) := \text{Var}(Y \mid X = x) := \mathbb{E}((Y - \mu(x))^2 \mid X = x)$.

(iii) The conditional-variance random variable is $\text{Var}(Y \mid X) := v(X)$.

Theorem 1.2.8. *Law of Total Variance*
Let X, Y be real-valued random variables with $\mathbb{E}Y^2 < \infty$. Set $b(x) := \mathbb{E}(Y \mid X = x)$ and $v(x) := \text{Var}(Y \mid X = x)$, and write $b(X)$ and $v(X)$ for the induced random variables. Then $\text{Var}(Y) = \mathbb{E}[v(X)] + \text{Var}(b(X))$.

Proof. Let $m := \mathbb{E}Y$ and $e := Y - b(X)$.
The tower property gives $\mathbb{E}b(X) = m$, and $\mathbb{E}(e \mid X) = \mathbb{E}(Y \mid X) - b(X) = 0$.
Since $Y - m = e + (b(X) - m)$, expansion gives $\text{Var}(Y) = \mathbb{E}e^2 + 2\mathbb{E}[e(b(X) - m)] + \mathbb{E}(b(X) - m)^2$.
The cross term is zero because $\mathbb{E}[e(b(X) - m)] = \mathbb{E}[(b(X) - m)\mathbb{E}(e \mid X)] = 0$.
Also $\mathbb{E}e^2 = \mathbb{E}[\mathbb{E}(e^2 \mid X)] = \mathbb{E}[v(X)]$, $\mathbb{E}(b(X) - m)^2 = \text{Var}(b(X))$. Thus $\text{Var}(Y) = \mathbb{E}[v(X)] + \text{Var}(b(X))$.
Structural Commentary: Variance splits into within-fiber variance and between-fiber mean variation.
Key Insight: Total variance equals average conditional variance plus variance of conditional expectation. □

Example 1.2.9. *Random Binomial Proportion*
Let $Q \sim \text{Uniform}(0,1)$ and, conditionally on $Q = q$, let $X \sim \text{Binomial}(n, q)$.
Then $\mathbb{E}(X \mid Q) = nQ$, so $\mathbb{E}X = \mathbb{E}(nQ) = \frac{n}{2}$. Also $\text{Var}(X \mid Q) = nQ(1-Q)$.
Hence $\mathbb{E}[\text{Var}(X \mid Q)] = n\int_0^1 q(1-q)\,dq = \frac{n}{6}$, $\text{Var}(\mathbb{E}(X \mid Q)) = \text{Var}(nQ) = \frac{n^2}{12}$. Thus $\text{Var}(X) = \frac{n}{6} + \frac{n^2}{12}$.

1.3 Conditional Moment Methods and Prediction

Conditional expectation is not only a way to compute means. It is also the geometric projection rule behind random-sum formulas and least-squares prediction.

Proposition 1.3.1. *Random Sums*
Let $N \in \mathbb{N}_0$ a.s. with $\mathbb{E}N^2 < \infty$, and let $(X_i)_{i\geq 1}$ be iid, independent of N, with $\mathbb{E}X_1 = m$ and $\text{Var}(X_1) = v < \infty$.
Set $T = \sum_{i=1}^{N} X_i$, with $T = 0$ on $\{N = 0\}$.

(i) $\mathbb{E}T = m\mathbb{E}N$.
(ii) $\text{Var}(T) = v\mathbb{E}N + m^2\,\text{Var}(N)$.

Proof.

(i) On $\{N = n\}$, $T = \sum_{i=1}^{n} X_i$, so $\mathbb{E}(T \mid N = n) = nm$ and $\mathbb{E}(T \mid N) = mN$; hence $\mathbb{E}T = \mathbb{E}\mathbb{E}(T \mid N) = m\mathbb{E}N$.

(ii) On $\{N = n\}$, independence gives $\text{Var}(T \mid N = n) = nv$, so $\text{Var}(T \mid N) = vN$.
Total variance gives $\text{Var}(T) = \mathbb{E}(vN) + \text{Var}(mN) = v\mathbb{E}N + m^2\,\text{Var}(N)$.

Structural Commentary: The randomness of the number of summands contributes the second variance term.
Key Insight: First condition on how many summands exist; then average over that count. □

Proposition 1.3.2. *MGF of a Random Sum*
Let $T = \sum_{i=1}^{N} X_i$, where $N \in \mathbb{N}_0$ is independent of iid $(X_i)_{i\geq 1}$.
If ψ_N and ψ_X are finite at the relevant arguments, then $\psi_T(t) = \psi_N(\log \psi_X(t))$.

Proof. On $\{N = n\}$, independence gives $\mathbb{E}(e^{tT} \mid N = n) = \mathbb{E}e^{t\sum_{i=1}^{n} X_i} = \prod_{i=1}^{n} \psi_X(t) = [\psi_X(t)]^n$.
Hence $\psi_T(t) = \mathbb{E}[\psi_X(t)^N] = \mathbb{E}e^{N\log\psi_X(t)} = \psi_N(\log\psi_X(t))$.
Structural Commentary: Conditioning on N turns the random sum into a fixed product of MGFs.
Key Insight: Random counts compose MGFs by substituting $\log\psi_X(t)$ into ψ_N. □

Example 1.3.3. *Compound Poisson Count*
Let $N \sim \text{Poisson}(\mu)$ and, given N, let $T = \sum_{i=1}^{N} X_i$ with iid $X_i \sim \text{Poisson}(\lambda)$ independent of N.
Since $\psi_N(s) = \exp(\mu(e^s - 1))$ and $\psi_X(t) = \exp(\lambda(e^t - 1))$, one has $\psi_T(t) = \psi_N(\log\psi_X(t)) = \exp(\mu(e^{\lambda(e^t-1)} - 1))$.

Proposition 1.3.4. *Best Constant Predictor*
For $Y \in L^2$, $\arg\min_{c\in\mathbb{R}} \mathbb{E}(Y-c)^2 = \mathbb{E}Y$, and $\min_{c\in\mathbb{R}} \mathbb{E}(Y-c)^2 = \text{Var}(Y)$.

Proof. Let $\mu = \mathbb{E}Y$. Since $\mathbb{E}(Y-\mu) = 0$, $\mathbb{E}(Y-c)^2 = \mathbb{E}[(Y-\mu)+(\mu-c)]^2 = \text{Var}(Y) + (\mu-c)^2$.
Since $(\mu-c)^2 \geq 0$ with equality iff $c = \mu$, the unique minimizer is $c = \mu$.
Structural Commentary: The mean is the orthogonal projection of Y onto the constants.
Key Insight: Best constant prediction equals the average. □

Theorem 1.3.5. *Conditional Expectation as Best Predictor*
Let $X, Y \in L^2$ and $\mathcal{G} := \{h(X) : h(X) \in L^2\}$. Let $M := \mathbb{E}(Y \mid X)$, then $M \in \mathcal{G}$, $\mathbb{E}(Y-M)^2 \leq \mathbb{E}(Y-Z)^2 \forall Z \in \mathcal{G}$.

Proof. For $Z \in \mathcal{G}$, both M and Z are $\sigma(X)$-measurable.
Since $\mathbb{E}(Y - M \mid X) = 0$, $\mathbb{E}[(Y-M)(M-Z)] = \mathbb{E}[(M-Z)\mathbb{E}(Y-M \mid X)] = 0$.
Hence $\mathbb{E}(Y-Z)^2 = \mathbb{E}(Y-M)^2 + \mathbb{E}(M-Z)^2 \geq \mathbb{E}(Y-M)^2$.
Structural Commentary: Prediction from X is performed fiber by fiber over the conditional laws of Y.
Key Insight: The optimal nonlinear least-squares predictor is the conditional mean. □

Definition 1.3.6. *Best Linear Predictor*
For $X, Y \in L^2$, set $\mathcal{A}_X := \{\alpha + \beta X : \alpha, \beta \in \mathbb{R}\}$.
A *best linear predictor* of Y from X is any $\widehat{Y}^* \in \arg\min_{Z\in\mathcal{A}_X} \mathbb{E}(Y-Z)^2$.

Theorem 1.3.7. *Best Linear Predictor*
Let $X, Y \in L^2$, $\sigma_X^2 := \text{Var}(X) > 0$, $\mu_X := \mathbb{E}X$, and $\mu_Y := \mathbb{E}Y$.

(i) $\arg\min_{Z\in\mathcal{A}_X} \mathbb{E}(Y-Z)^2 = \{\alpha^* + \beta^* X\}$, *where* $\beta^* = \frac{\text{Cov}(X,Y)}{\sigma_X^2}$ *and* $\alpha^* = \mu_Y - \beta^*\mu_X$.
(ii) $\min_{Z\in\mathcal{A}_X} \mathbb{E}(Y-Z)^2 = \text{Var}(Y) - \frac{\text{Cov}(X,Y)^2}{\sigma_X^2}$.
(iii) If $\text{Var}(Y) > 0$ *and* $\rho = \text{Corr}(X,Y)$, *then the minimum error is* $\text{Var}(Y)(1-\rho^2)$.

Proof.

(i) Let $q(\alpha,\beta) := \mathbb{E}(Y-\alpha-\beta X)^2$. For fixed β, $q(\alpha,\beta) = \text{Var}(Y-\beta X) + (\mu_Y - \alpha - \beta\mu_X)^2$,
so $\alpha(\beta) = \mu_Y - \beta\mu_X$ uniquely minimizes over α.

(ii) Then $q(\alpha(\beta),\beta) = \mathrm{Var}(Y-\beta X) = \mathrm{Var}(Y) + \beta^2\sigma_X^2 - 2\beta\,\mathrm{Cov}(X,Y)$.
Since $\sigma_X^2 > 0$, this quadratic has unique minimizer $\beta^* = \frac{\mathrm{Cov}(X,Y)}{\sigma_X^2}$.

(iii) Substituting β^* gives $\mathrm{Var}(Y) - \frac{\mathrm{Cov}(X,Y)^2}{\sigma_X^2}$. If $\rho = \frac{\mathrm{Cov}(X,Y)}{\sigma_X\sigma_Y}$, then this equals $\mathrm{Var}(Y)(1-\rho^2)$.

Structural Commentary: Linear prediction projects Y onto $\mathcal{A}_X$.
Key Insight: The optimal slope is normalized covariance. □

Example 1.3.8. *Bivariate Normal Prediction*
If (X,Y) is bivariate normal with means μ_X,μ_Y, standard deviations $\sigma_X,\sigma_Y > 0$, and correlation $\rho \in (-1,1)$, then $Y \mid X \sim N(\mu_Y + \rho\sigma_Y\sigma_X^{-1}(X-\mu_X), \sigma_Y^2(1-\rho^2))$.
Thus $\mathbb{E}(Y \mid X) = \mu_Y + \rho\sigma_Y\sigma_X^{-1}(X-\mu_X)$ is linear, with conditional variance $\sigma_Y^2(1-\rho^2)$.

Example 1.3.9. *Regression to the Mean*
Let $\mathbb{E}X = \mathbb{E}Y = \mu$, $\mathrm{Var}(X) = \mathrm{Var}(Y) = \sigma^2 > 0$, and $\mathrm{Corr}(X,Y) = \rho$. Best linear predictor is $\widehat{Y} = \mu + \rho(X-\mu)$.
For $0 < \rho < 1$, $|\widehat{Y}-\mu| = \rho|X-\mu| < |X-\mu|$, so predicted scores regress toward μ.

2 Probabilistic Convergence

2.1 Modes of Probabilistic Convergence

Pointwise convergence is too strict for most random sequences. The useful replacement is to ask whether probabilities, laws, or moments of the errors become small.

Definition 2.1.1. *Modes of Probabilistic Convergence*
Let $(X_n)_{n\ge1}$ and X be real-valued random variables with distribution functions F_n and F.

(i) *Convergence in probability*: $X_n \xrightarrow{\mathbb{P}} X$ iff $\mathbb{P}(|X_n - X| > \varepsilon) \to 0$ for every $\varepsilon > 0$.
(ii) *Convergence in distribution*: $X_n \rightsquigarrow X$ iff $F_n(t) \to F(t)$ at every continuity point t of F.
(iii) *Convergence in L^p*: for $p \ge 1$, $X_n \xrightarrow{L^p} X$ iff $\mathbb{E}\,|X_n - X|^p \to 0$.
(iv) *Convergence in quadratic mean*: $X_n \xrightarrow{qm} X$ iff $X_n \xrightarrow{L^2} X$.
(v) *Almost-sure convergence*: $X_n \xrightarrow{\text{a.s.}} X$ iff $\mathbb{P}(\{\omega \in \Omega : X_n(\omega) \to X(\omega)\}) = 1$.
(vi) *Constant limits*: if $X = c$ almost surely for a constant c, then $X_n \xrightarrow{\mathbb{P}} c$, $X_n \rightsquigarrow c$, $X_n \xrightarrow{L^p} c$, $X_n \xrightarrow{qm} c$, and $X_n \xrightarrow{\text{a.s.}} c$ denote convergence to that constant random variable in the corresponding modes.

Example 2.1.2. *A Shrinking Normal Law*
Let $X_n \sim N(0, \frac{1}{n})$, and let F be the distribution function of δ_0.
Since $\sqrt{n}X_n \sim N(0,1)$, $F_n(t) = \mathbb{P}(X_n \le t) = \Phi(\sqrt{n}t)$, so $F_n(t) \to 0$ for $t < 0$ and $F_n(t) \to 1$ for $t > 0$.
Hence $F_n(t) \to F(t)$ at every continuity point $t \ne 0$ of F, and therefore $X_n \rightsquigarrow 0$.

Theorem 2.1.3. *Basic Implications Between Convergence Modes*
Let X_n and X be real-valued random variables with distribution functions F_n and F, and let $c \in \mathbb{R}$.

(i) $X_n \xrightarrow{qm} X \Rightarrow X_n \xrightarrow{\mathbb{P}} X$.
(ii) $X_n \xrightarrow{\mathbb{P}} X \Rightarrow X_n \rightsquigarrow X$.
(iii) $X_n \rightsquigarrow c \Rightarrow X_n \xrightarrow{\mathbb{P}} c$.
(iv) $X_n \xrightarrow{\text{a.s.}} X \Rightarrow X_n \xrightarrow{\mathbb{P}} X$.
(v) $X_n \xrightarrow{L^1} X \Rightarrow X_n \xrightarrow{\mathbb{P}} X$, *and* $X_n \xrightarrow{qm} X \Rightarrow X_n \xrightarrow{L^1} X$.

Proof.

(i) If $X_n \xrightarrow{qm} X$, then for each $\varepsilon > 0$, Markov gives $\mathbb{P}(|X_n - X| > \varepsilon) \le \varepsilon^{-2}\mathbb{E}\,|X_n - X|^2 \to 0$.
(ii) Let x be a continuity point of F.
For each $\varepsilon > 0$, $F(x-\varepsilon) - \mathbb{P}(|X_n - X| > \varepsilon) \le F_n(x) \le F(x+\varepsilon) + \mathbb{P}(|X_n - X| > \varepsilon)$,
so $F(x-\varepsilon) \le \liminf_n F_n(x) \le \limsup_n F_n(x) \le F(x+\varepsilon)$; letting $\varepsilon \downarrow 0$ gives $F_n(x) \to F(x)$.
(iii) For $\varepsilon > 0$, the distribution function of c is continuous at $c-\varepsilon$ and $c+\varepsilon$.
Hence $\mathbb{P}(|X_n - c| > \varepsilon) \le F_n(c-\varepsilon) + 1 - F_n(c+\varepsilon) \to 0$.
(iv) Fix $\varepsilon > 0$ and set $Y_n = \mathbf{1}_{\{|X_n - X| > \varepsilon\}}$. If $X_n \to X$ a.s., then $Y_n \to 0$ a.s. and $0 \le Y_n \le 1$.
Hence dominated convergence gives $\mathbb{P}(|X_n - X| > \varepsilon) = \mathbb{E}Y_n \to 0$.
(v) If $X_n \xrightarrow{L^1} X$, then $\mathbb{P}(|X_n - X| > \varepsilon) \le \varepsilon^{-1}\mathbb{E}\,|X_n - X| \to 0$ by Markov.
If $X_n \xrightarrow{qm} X$, then $\mathbb{E}\,|X_n - X| \le (\mathbb{E}\,|X_n - X|^2)^{\frac{1}{2}} \to 0$ by Cauchy–Schwarz.

Structural Commentary: Strong modes give tail bounds; distribution convergence gives c.d.f. control.
Key Insight: Convert to tail bounds; use c.d.f. squeezes when laws enter. □

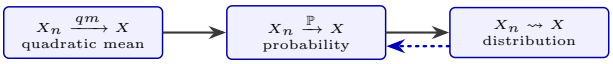

Figure 230: Solid: always; dotted: point-mass limit.

Example 2.1.4. *Why the Reverse Arrows Fail*

(i) Let $U \sim \mathrm{Uniform}(0,1)$ and $X_n = \sqrt{n}\mathbf{1}_{(0,\frac{1}{n})}(U)$. Then for each $\varepsilon > 0$, $\mathbb{P}(|X_n| > \varepsilon) \le \frac{1}{n} \to 0$,
so $X_n \xrightarrow{\mathbb{P}} 0$, but $\mathbb{E}X_n^2 = 1$ for all n; hence $X_n \not\to 0$ in quadratic mean.

(ii) Let $X \sim N(0,1)$ and set $X_n = -X$. Then $X_n \sim X$ for all n, so $X_n \rightsquigarrow X$,
but for every $\varepsilon > 0$, $\mathbb{P}(|X_n - X| > \varepsilon) = \mathbb{P}(2|X| > \varepsilon) > 0$ for all n; hence $X_n \not\to X$ in probability.

Remark 2.1.5. *A Warning About Expectations*
Convergence in probability does not imply convergence of expectations.
If $\mathbb{P}(X_n = n^2) = \frac{1}{n}$, $\mathbb{P}(X_n = 0) = 1 - \frac{1}{n}$, then $\forall \varepsilon > 0$, $\mathbb{P}(|X_n| > \varepsilon) = \frac{1}{n} \to 0$, so $X_n \xrightarrow{\mathbb{P}} 0$, $\mathbb{E}X_n = n \to +\infty$.

Definition 2.1.6. *Asymptotic Uniform Integrability*
A sequence (X_n) is *asymptotically uniformly integrable* if $\lim_{M\to\infty} \limsup_{n\to\infty} \mathbb{E}(|X_n| \mathbf{1}_{\{|X_n|>M\}}) = 0$.

Proposition 2.1.7. *Recovering Expectations from Probability Convergence*
Let $b \in \mathbb{R}$. If $X_n \xrightarrow{\mathbb{P}} b$ and (X_n) is asymptotically uniformly integrable, then $\mathbb{E}X_n \to b$.

Proof. For $M > |b|$, set $\tau_M(x) = (-M) \vee (x \wedge M)$. As τ_M bounded, continuous; $\tau_M(b) = b$, $\tau_M(X_n) \xrightarrow{\mathbb{P}} b$.
For $\eta > 0$, $\mathbb{E}|\tau_M(X_n) - b| \le \eta + 2M\mathbb{P}(|\tau_M(X_n) - b| > \eta)$, so $\mathbb{E}\tau_M(X_n) \to b$ after $n \to \infty$ and $\eta \downarrow 0$.
Moreover, $|X_n - \tau_M(X_n)| \le |X_n| \mathbf{1}_{\{|X_n|>M\}}$, hence $\limsup_n |\mathbb{E}X_n - b| \le \limsup_n \mathbb{E}(|X_n| \mathbf{1}_{\{|X_n|>M\}})$.
Letting $M \to \infty$ and using asymptotic uniform integrability gives $\mathbb{E}X_n \to b$.
Structural Commentary: Truncation makes convergence bounded; asymptotic uniform integrability kills tails.
Key Insight: Probability convergence handles the truncations; tail control restores expectations. □

Theorem 2.1.8. *Continuous Mapping and Slutsky Rules*
Let $g : \mathbb{R} \to \mathbb{R}$ be continuous, and let $c \in \mathbb{R}$.

(i) $X_n \xrightarrow{\mathbb{P}} X \Rightarrow g(X_n) \xrightarrow{\mathbb{P}} g(X)$.
(ii) $X_n \rightsquigarrow X \Rightarrow g(X_n) \rightsquigarrow g(X)$.
(iii) $X_n \rightsquigarrow X$ *and* $Y_n \xrightarrow{\mathbb{P}} c \Rightarrow X_n + Y_n \rightsquigarrow X + c$ *and* $X_n Y_n \rightsquigarrow cX$.
(iv) $X_n \xrightarrow{\mathbb{P}} X$ *and* $Y_n \xrightarrow{\mathbb{P}} Y \Rightarrow X_n + Y_n \xrightarrow{\mathbb{P}} X + Y$ *and* $X_n Y_n \xrightarrow{\mathbb{P}} XY$.

Proof.
(i) Fix $\varepsilon, \eta > 0$. Choose K, $\mathbb{P}(|X| > K) < \eta$, $\delta \le 1$ s.t. $|x - y| < \delta$, $|x|, |y| \le K + 1$; $|g(x) - g(y)| < \varepsilon$.
Then $\mathbb{P}(|g(X_n) - g(X)| > \varepsilon) \le \mathbb{P}(|X| > K) + \mathbb{P}(|X_n - X| > \delta)$, so $\limsup$ at most η.
(ii) Let t be a continuity point of the law of $g(X)$ and set $A_t = \{x : g(x) \le t\}$.
Since $\partial A_t \subseteq \{x : g(x) = t\}$ and $\mathbb{P}(g(X) = t) = 0$, the continuity-set form of weak convergence gives
$\mathbb{P}(g(X_n) \le t) = \mathbb{P}(X_n \in A_t) \to \mathbb{P}(X \in A_t) = \mathbb{P}(g(X) \le t)$.
(iii) If $Z_n \rightsquigarrow Z$ and $R_n \xrightarrow{\mathbb{P}} 0$, then $Z_n + R_n \rightsquigarrow Z$ by the c.d.f. squeeze
$F_{Z_n}(t - \eta) - \mathbb{P}(|R_n| > \eta) \le F_{Z_n + R_n}(t) \le F_{Z_n}(t + \eta) + \mathbb{P}(|R_n| > \eta)$,
followed by $n \to \infty$ and $\eta \downarrow 0$ through continuity points of F_Z.
Since $X_n + c \rightsquigarrow X + c$ by (ii), applying this with $Z_n = X_n + c$ and $R_n = Y_n - c$ gives $X_n + Y_n \rightsquigarrow X + c$.
Also $X_n \rightsquigarrow X$ implies (X_n) is tight, so $\mathbb{P}(|X_n(Y_n - c)| > \varepsilon) \le \mathbb{P}(|X_n| > K) + \mathbb{P}(|Y_n - c| > \frac{\varepsilon}{K})$.
Letting $n \to \infty$, then $K \uparrow \infty$ gives $X_n(Y_n - c) \xrightarrow{\mathbb{P}} 0$.
Since $cX_n \rightsquigarrow cX$ by (ii), the additive perturbation just proved gives $X_n Y_n = cX_n + X_n(Y_n - c) \rightsquigarrow cX$.
(iv) For sums, $\mathbb{P}(|(X_n + Y_n) - (X + Y)| > \varepsilon) \le \mathbb{P}(|X_n - X| > \frac{\varepsilon}{2}) + \mathbb{P}(|Y_n - Y| > \frac{\varepsilon}{2}) \to 0$.
For products, (X_n) and Y are tight, $\mathbb{P}(|X_n(Y_n - Y)| > \frac{\varepsilon}{2}) \le \mathbb{P}(|X_n| > K) + \mathbb{P}(|Y_n - Y| > \frac{\varepsilon}{2K})$,
while $\mathbb{P}(|Y(X_n - X)| > \frac{\varepsilon}{2}) \le \mathbb{P}(|Y| > K) + \mathbb{P}(|X_n - X| > \frac{\varepsilon}{2K})$; let $n \to \infty$ and then $K \uparrow \infty$.
Structural Commentary: Continuity transports convergence; Slutsky absorbs probability-small errors.
Key Insight: Control the bounded high-probability part; let the tails vanish. □

2.2 Probability on Metric Spaces

3 Limit Theorems

3.1 Laws of Large Numbers

The law of large numbers formalizes the idea that a large sample average is close to the mean of the distribution.

Perspective 3.1.1. *Law of the Sample Mean*
If $X_1, \ldots, X_n$ are IID, mean μ, variance σ^2, then $\overline{X}_n := n^{-1} \sum_{i=1}^n X_i$ is a random variable with law $\mathcal{L}(\overline{X}_n)$.
By Theorem 3.2.7, $\mathbb{E}\overline{X}_n = \mu$ and $\mathrm{Var}(\overline{X}_n) = \frac{\sigma^2}{n}$, so $\mathcal{L}(\overline{X}_n)$ concentrates around μ as $n \to \infty$.

Theorem 3.1.2. *Weak Law of Large Numbers*
Let $(X_i)_{i\ge1}$ be IID real-valued random variables with $\mathbb{E}X_1 = \mu$, $\mathrm{Var}(X_1) = \sigma^2 < +\infty$. Set $\overline{X}_n := n^{-1} \sum_{i=1}^n X_i$.
Then $\overline{X}_n \xrightarrow{\mathbb{P}} \mu$, equivalently $\mathbb{P}(|\overline{X}_n - \mu| > \varepsilon) \to 0$ for every $\varepsilon > 0$.

Proof. For $n \ge 1$, $\mathbb{E}\overline{X}_n = n^{-1} \sum_{i=1}^n \mathbb{E}X_i = \mu$ and, by independence, $\mathrm{Var}(\overline{X}_n) = n^{-2} \sum_{i=1}^n \mathrm{Var}(X_i) = \frac{\sigma^2}{n}$.
For every $\varepsilon > 0$, Chebyshev gives $\mathbb{P}(|\overline{X}_n - \mu| > \varepsilon) \le \frac{\mathrm{Var}(\overline{X}_n)}{\varepsilon^2} = \frac{\sigma^2}{n\varepsilon^2} \to 0$, hence $\overline{X}_n \xrightarrow{\mathbb{P}} \mu$.
Structural Commentary: Averaging keeps the mean fixed and divides variance by n.
Key Insight: Chebyshev turns vanishing variance into convergence in probability. □

Proposition 3.1.3. *Weak LLN with Vanishing Average Variance*
Let $(X_i)_{i\ge1}$ be independent, $X_i \in L^2$, with $\mu_i := \mathbb{E}X_i$ and $\sigma_i^2 := \mathrm{Var}(X_i)$.
Set $\overline{X}_n := n^{-1} \sum_{i=1}^n X_i$ and $m_n := n^{-1} \sum_{i=1}^n \mu_i$. If $m_n \to \mu$ and $n^{-2} \sum_{i=1}^n \sigma_i^2 \to 0$, then $\overline{X}_n \xrightarrow{\mathbb{P}} \mu$.

Proof. $\mathbb{E}\overline{X}_n = m_n$. By independence, $\mathrm{Var}(\overline{X}_n) = n^{-2}\sum_{i=1}^{n}\sigma_i^2 \to 0$. Fix $\varepsilon > 0$. $\forall$ large n, $|m_n - \mu| < \frac{\varepsilon}{2}$.

Hence $\{|\overline{X}_n - \mu| > \varepsilon\} \subseteq \{|\overline{X}_n - m_n| > \frac{\varepsilon}{2}\}$. By Chebyshev, $\mathbb{P}(|\overline{X}_n - \mu| > \varepsilon) \le \frac{4\,\mathrm{Var}(\overline{X}_n)}{\varepsilon^2} \to 0$.
Structural Commentary: Identical distribution is not essential for a weak law.
Key Insight: It is enough that the mean target stabilises and the average variance vanishes. □

Example 3.1.4. *Coin Proportions and Chebyshev Scale*

Let $X_i \sim \mathrm{Bernoulli}(p)$ be IID head indicators, $\overline{X}_n := n^{-1}\sum_{i=1}^{n} X_i$. Then $\mathbb{E}\overline{X}_n = p$, $\mathrm{Var}(\overline{X}_n) = \frac{p(1-p)}{n}$, $\overline{X}_n \xrightarrow{\mathbb{P}} p$.

For $p = \frac{1}{2}$, Chebyshev gives $\mathbb{P}(0.4 \le \overline{X}_n \le 0.6) \ge 1 - \frac{1}{4n(0.1)^2} = 1 - \frac{25}{n}$, at least 0.7 for $n \ge 84$.

If $n = 10000$ fair tosses produce 5067 heads, then $\overline{X}_n = 0.5067$, while $\mathrm{Var}(\overline{X}_n) = \frac{1}{4n} = 2.5 \cdot 10^{-5}$ and $\mathrm{sd}(\overline{X}_n) = 0.005$. The observed deviation is about 1.34 standard deviations from $\frac{1}{2}$.

Theorem 3.1.5. *Strong Law of Large Numbers*

Let $(X_i)_{i\ge1}$ be IID real-valued random variables with $X_1 \in L^1$, $\mu := \mathbb{E}X_1$, and $\overline{X}_n := n^{-1}\sum_{i=1}^{n} X_i$.

Then $\overline{X}_n \xrightarrow{\text{a.s.}} \mu$, equivalently $\mathbb{P}(\lim_{n\to\infty} \overline{X}_n = \mu) = 1$.

Proof. After replacing X_i by $X_i - \mu$, assume $\mu = 0$. Set $Y_i := X_i \mathbf{1}_{\{|X_i| \le i\}}$.

Since $\sum_{i=1}^{\infty}\mathbb{P}(X_i \ne Y_i) = \sum_{i=1}^{\infty}\mathbb{P}(|X_1| > i) < +\infty$, Borel–Cantelli gives $X_i = Y_i$ eventually a.s.

Hence $n^{-1}\sum_{i=1}^{n}(X_i - Y_i) \to 0$ a.s. For $Z_i := Y_i - \mathbb{E}Y_i$, independence gives

$\sum_{i=1}^{\infty}\frac{\mathrm{Var}(Z_i)}{i^2} \le \sum_{i=1}^{\infty}\frac{\mathbb{E}(X_1^2\mathbf{1}_{\{|X_1|\le i\}})}{i^2} < +\infty$, by Kolmogorov's variance criterion, $n^{-1}\sum_{i=1}^{n} Z_i \to 0$ a.s.

By dominated convergence, $\mathbb{E}Y_i \to 0$, hence Cesaro averaging gives $n^{-1}\sum_{i=1}^{n}\mathbb{E}Y_i \to 0$.

Combining $X_i - Y_i$, Z_i, and $\mathbb{E}Y_i$ gives $\overline{X}_n \to 0$ a.s.; adding back μ completes the proof.
Structural Commentary: Truncate tails; centered truncations have summable variance.
Key Insight: Replace by an eventually equal truncated sequence, then average the centered part. □

Corollary 3.1.6. *Strong Implies Weak*

Let $(X_i)_{i\ge1}$ be IID real-valued random variables, $X_1 \in L^1$, $\mu := \mathbb{E}X_1$, $\overline{X}_n := n^{-1}\sum_{i=1}^{n} X_i$. Then $\overline{X}_n \xrightarrow{\mathbb{P}} \mu$.

Proof. By Theorem 3.1.5, $\overline{X}_n \to \mu$ a.s. For $\varepsilon > 0$, set $Y_n := \mathbf{1}_{\{|\overline{X}_n - \mu| > \varepsilon\}}$.

Then $Y_n \to 0$ a.s. and $0 \le Y_n \le 1$, so dominated convergence gives $\mathbb{P}(|\overline{X}_n - \mu| > \varepsilon) = \mathbb{E}Y_n \to 0$.
Structural Commentary: Almost-sure convergence gives pointwise tail indicators tending to zero.
Key Insight: Dominate the indicators by 1 and integrate. □

Proposition 3.1.7. *Consistency of Empirical Moments and Variance*
Let $(X_i)_{i\ge1}$ be iid, $X_1 \in L^2$, $\mu := \mathbb{E}X_1$, and $\sigma^2 := \mathrm{Var}(X_1)$.

For $n \ge 2$, set $\overline{X}_n := n^{-1}\sum_{i=1}^{n} X_i$ and $S_n^2 := (n-1)^{-1}\sum_{i=1}^{n}(X_i - \overline{X}_n)^2$. Then $S_n^2 \xrightarrow{\mathbb{P}} \sigma^2$.

More generally, if $X_1 \in L^r$ for an integer $r \ge 1$, then $n^{-1}\sum_{i=1}^{n} X_i^r \xrightarrow{\mathbb{P}} \mathbb{E}X_1^r$.

Proof. Since $(X_i^r)_{i\ge1}$ is iid and integrable, the strong law gives $n^{-1}\sum_{i=1}^{n} X_i^r \to \mathbb{E}X_1^r$ a.s., hence in probability.

Let $m_2 := \mathbb{E}X_1^2 = \sigma^2 + \mu^2$. The cases $r = 1, 2$ give $\overline{X}_n \to \mu$ and $n^{-1}\sum_{i=1}^{n} X_i^2 \to m_2$ a.s.

Since $S_n^2 = \frac{n}{n-1}(n^{-1}\sum_{i=1}^{n} X_i^2 - \overline{X}_n^2)$, continuous mapping gives $S_n^2 \to m_2 - \mu^2 = \sigma^2$ a.s., hence in probability.
Structural Commentary: Sample moments are averages of transformed observations.
Key Insight: Apply the strong law to X_i^r, then pass through the continuous variance formula. □

Remark 3.1.8. *Why Integrability Matters*
If $X_1 \notin L^1$, the mean $\mathbb{E}X_1$ need not exist and sample averages need not converge to any finite deterministic limit; integrability is the condition that makes a law of large numbers meaningful.

3.2 Central Limit Theory

The law of large numbers says that $\overline{X}_n$ is close to μ for large n. The central limit theorem describes the scale and shape of the remaining fluctuation.

Theorem 3.2.1. *Central Limit Theorem*
Let $(X_i)_{i\ge1}$ be IID real-valued random variables, $\mathbb{E}X_1 = \mu$, $\mathrm{Var}(X_1) = \sigma^2 \in (0, +\infty)$.

Let $\overline{X}_n := n^{-1}\sum_{i=1}^{n} X_i$, $Z_n := \sigma^{-1}\sqrt{n}(\overline{X}_n - \mu)$.

Then $Z_n \rightsquigarrow N(0,1)$, equivalently $\mathbb{P}(Z_n \le z) \to \Phi(z) := \int_{-\infty}^{z}(2\pi)^{-\frac{1}{2}}e^{-\frac{x^2}{2}}\,dx$ $\forall z \in \mathbb{R}$.

Proof. Set $Y_i := \frac{X_i-\mu}{\sigma}$, so $\mathbb{E}Y_i = 0$, $\mathrm{Var}(Y_i) = 1$, and $Z_n = n^{-\frac{1}{2}} \sum_{i=1}^{n} Y_i$.

For $\varphi(t) := \mathbb{E}e^{\mathrm{i}tY_1}$, the finite second moment expansion gives $\varphi(u) = 1 - \frac{u^2}{2} + o(u^2)$ as $u \to 0$.

By independence, $\varphi_{Z_n}(t) = [\varphi(\frac{t}{\sqrt{n}})]^n = [1 - \frac{t^2}{2n} + o(\frac{1}{n})]^n \to e^{-\frac{t^2}{2}}$ for every $t \in \mathbb{R}$.

Since $e^{-\frac{t^2}{2}}$ is the characteristic function of $N(0,1)$, Levy's continuity theorem gives $Z_n \rightsquigarrow N(0,1)$; continuity of Φ gives the displayed c.d.f. convergence.

Structural Commentary: Centering and scaling turn the sum into unit-variance IID increments.

Key Insight: Characteristic functions turn normalized sums into powers, whose limit is Gaussian. □

Method 3.2.2. *Equivalent CLT Approximation Forms*

Let $\overline{X}_n := n^{-1} \sum_{i=1}^{n} X_i$ with mean μ and variance $\sigma^2 \in (0, +\infty)$, and set $Z_n := \sigma^{-1}\sqrt{n}(\overline{X}_n - \mu)$.

(i) Standardized form: $Z_n \approx N(0,1)$.
(ii) Centered form: $\sqrt{n}(\overline{X}_n - \mu) \approx N(0, \sigma^2)$.
(iii) Sample-mean form: $\overline{X}_n \approx N(\mu, \frac{\sigma^2}{n})$.

Use any equivalent form to approximate probabilities involving $\overline{X}_n$.

Example 3.2.3. *Measurement Error and Sample Size*

Let $X_1, \ldots, X_n$ be independent measurements with $\mathbb{E}X_i = \mu$ and $\mathrm{Var}(X_i) = \sigma^2$.
For $c > 0$, the CLT gives $\mathbb{P}(|\overline{X}_n - \mu| < c) \approx \Phi(\frac{c\sqrt{n}}{\sigma}) - \Phi(\frac{-c\sqrt{n}}{\sigma})$.
For $(n, \sigma, c) = (16, 1, 0.5)$, this is $\Phi(2) - \Phi(-2) \approx 0.954$.

Lemma 3.2.4. *MGF Continuity Theorem*

Let Z_n, Z be real-valued with MGFs $\psi_n(t) := \mathbb{E}e^{tZ_n}$ and $\psi(t) := \mathbb{E}e^{tZ}$ finite on $(-a, a)$ for some $a > 0$.
If $\psi_n(t) \to \psi(t)$ for all $t \in (-a, a)$, then $Z_n \rightsquigarrow Z$.

Proof. For each $s \in \mathbb{R}$, the characteristic functions satisfy $\varphi_n(s) = \mathbb{E}e^{\mathrm{i}sZ_n} = \psi_n(\mathrm{i}s)$ by analytic continuation on the strip $\{z : |\mathrm{Re}\, z| < a\}$.
Pointwise MGF convergence near 0 gives $\varphi_n(s) \to \varphi(s)$, the characteristic function of Z; Levy's continuity theorem yields $Z_n \rightsquigarrow Z$.

Structural Commentary: Local MGF convergence determines local characteristic-function convergence.

Key Insight: MGFs near 0 identify the weak limit. □

Proposition 3.2.5. *MGF Proof of the IID CLT*

Let $(X_i)_{i\geq 1}$ be iid with $\mathbb{E}X_1 = 0$, $\mathrm{Var}(X_1) = \sigma^2 \in (0, +\infty)$, and MGF $M(t) := \mathbb{E}e^{tX_1}$ finite near 0.
Set $S_n := \sum_{i=1}^{n} X_i$ and $Z_n := \frac{S_n}{\sigma\sqrt{n}}$. Then $Z_n \rightsquigarrow N(0,1)$, equivalently $\mathbb{P}(Z_n \leq x) \to \Phi(x)$ for all $x \in \mathbb{R}$.

Proof. For fixed t near 0, independence gives $M_{Z_n}(t) = \mathbb{E}e^{\frac{tS_n}{\sigma\sqrt{n}}} = \prod_{i=1}^{n} \mathbb{E}e^{\frac{tX_i}{\sigma\sqrt{n}}} = [M(\frac{t}{\sigma\sqrt{n}})]^n$.

Since $M(0) = 1$, $M'(0) = 0$, and $M''(0) = \sigma^2$, Taylor expansion gives $M(s) = 1 + \frac{\sigma^2 s^2}{2} + o(s^2)$ as $s \to 0$.

Hence $M_{Z_n}(t) = (1 + \frac{t^2}{2n} + o(\frac{1}{n}))^n \to e^{\frac{t^2}{2}}$, the MGF of $N(0,1)$.
Lemma 3.2.4 gives $Z_n \rightsquigarrow N(0,1)$, and continuity of Φ gives the c.d.f. convergence.

Structural Commentary: The MGF proof needs the stronger near-zero MGF assumption.

Key Insight: Standardization gives $\frac{t^2}{2n}$; independence exponentiates. □

Example 3.2.6. *A Poisson Error-Count Approximation*

Let $X_1, \ldots, X_{125} \sim \mathrm{Poisson}(5)$ be IID and set $\overline{X}_{125} = 125^{-1} \sum_{i=1}^{125} X_i$.

Since $\mu = 5$ and $\sigma^2 = 5$, the CLT gives $\mathbb{P}(\overline{X}_{125} < 5.5) \approx \Phi(\frac{\sqrt{125}(5.5-5)}{\sqrt{5}}) = \Phi(2.5) \approx 0.9938$.

Example 3.2.7. *Normal Approximation to a Poisson Count*

Let $X_\lambda \sim \mathrm{Poisson}(\lambda)$, $Z_\lambda := \frac{X_\lambda - \lambda}{\sqrt{\lambda}}$. Then $M_{Z_\lambda}(t) = \exp(-t\sqrt{\lambda} + \lambda(e^{\frac{t}{\sqrt{\lambda}}} - 1))$ and $\log M_{Z_\lambda}(t) = \frac{t^2}{2} + o(1)$, so $Z_\lambda \rightsquigarrow N(0,1)$. If $X \sim \mathrm{Poisson}(900)$, then $\mathbb{P}(X > 950) = \mathbb{P}(\frac{X-900}{30} > \frac{5}{3}) \approx 1 - \Phi(\frac{5}{3}) \approx 0.04779$, close to 0.04712.

Example 3.2.8. *Normal Approximation to the Binomial*

If $X \sim \mathrm{Binomial}(n, p)$, $np > 5$, $n(1-p) > 5$, then $X \approx N(np, np(1-p))$; $\frac{X-np}{\sqrt{np(1-p)}} \approx N(0,1)$.

For $X \sim \mathrm{Binomial}(100, \frac{1}{2})$, $\mathbb{P}(X \geq 60) \approx 1 - \Phi(\frac{60-50}{5}) = 1 - \Phi(2) \approx 0.0228$.

Example 3.2.9. *Skewed Summands Need More Averaging*

Let $E_1, \ldots, E_n$ be iid $\mathrm{Exp}(1)$ and $G_n := \sum_{i=1}^{n} E_i \sim \mathrm{Gamma}(n, 1)$. Then $\frac{G_n - n}{\sqrt{n}} \rightsquigarrow N(0,1)$.

Skewness makes the normal approximation slower for small n.

Example 3.2.10. *Products and Lognormal Shape*

Let $Y_n = y_0 \prod_{i=1}^{n} X_i$ with iid $X_i > 0$, and suppose $\mu_\ell := \mathbb{E}\log X_1$ and $\sigma_\ell^2 := \mathrm{Var}(\log X_1) \in (0, +\infty)$.

Since $\log Y_n = \log y_0 + \sum_{i=1}^{n} \log X_i$, the CLT gives $\log Y_n \approx N(\log y_0 + n\mu_\ell, n\sigma_\ell^2)$, so Y_n is approximately lognormal. Likewise $V_n = v_0 \prod_{i=1}^{n} R_i$ when iid log-returns $\log R_i$ have finite positive variance.

Theorem 3.2.11. *Studentized Central Limit Theorem*

Let $(X_i)_{i\geq 1}$ be IID real-valued random variables with $\mathbb{E}X_1 = \mu$ and $\mathrm{Var}(X_1) = \sigma^2 \in (0, +\infty)$.
Set $\overline{X}_n := n^{-1} \sum_{i=1}^{n} X_i$, $S_n^2 := (n-1)^{-1} \sum_{i=1}^{n} (X_i - \overline{X}_n)^2$, and $T_n := S_n^{-1}\sqrt{n}(\overline{X}_n - \mu)$. Then $T_n \rightsquigarrow N(0,1)$.

Proof. The CLT gives $Z_n := \sigma^{-1}\sqrt{n}(\overline{X}_n - \mu) \rightsquigarrow N(0,1)$, and Proposition 3.1.7 gives $S_n^2 \xrightarrow{\mathbb{P}} \sigma^2$, hence $S_n \xrightarrow{\mathbb{P}} \sigma$.
Thus $\frac{\sigma}{S_n} \xrightarrow{\mathbb{P}} 1$, and Slutsky's rule from Theorem 2.1.8 gives $T_n = Z_n(\frac{\sigma}{S_n}) \rightsquigarrow N(0,1)$.
Structural Commentary: Studentization replaces the unknown σ by the consistent estimate S_n.
Key Insight: Slutsky permits multiplying the CLT statistic by $\frac{\sigma}{S_n} \to 1$. □

Theorem 3.2.12. *Berry–Esseen Rate*
Let $(X_i)_{i\geq 1}$ be IID real-valued random variables, $\mathbb{E}X_1 = \mu$, $\mathrm{Var}(X_1) = \sigma^2 \in (0,+\infty)$, $\rho_3 := \mathbb{E}\,|X_1-\mu|^3 < +\infty$.
Let $\overline{X}_n := n^{-1}\sum_{i=1}^n X_i$, $Z_n := \sigma^{-1}\sqrt{n}(\overline{X}_n - \mu)$, $\Phi(z) := \int_{-\infty}^z (2\pi)^{-\frac{1}{2}} e^{-\frac{x^2}{2}}\,dx$; $\sup_{z\in\mathbb{R}} |\mathbb{P}(Z_n \leq z) - \Phi(z)| \leq \frac{33}{4}\frac{\rho_3}{\sigma^3\sqrt{n}}$.

Proof. Set $Y_i := \frac{X_i-\mu}{\sigma}$, $\rho := \mathbb{E}\,|Y_1|^3 = \frac{\rho_3}{\sigma^3}$, and $W_n := n^{-\frac{1}{2}}\sum_{i=1}^n Y_i = Z_n$.
For $\varphi(t) := \mathbb{E}e^{itY_1}$, Taylor's formula with $\mathbb{E}Y_1 = 0$, $\mathbb{E}Y_1^2 = 1$, $\mathbb{E}\,|Y_1|^3 = \rho$ gives $\varphi(t) = 1 - \frac{t^2}{2} + O(\rho\,|t|^3)$ near 0.
Thus $\varphi_{W_n}(t) = [\varphi(\frac{t}{\sqrt{n}})]^n$ differs from $e^{-\frac{t^2}{2}}$ by $O(\rho n^{-\frac{1}{2}})$ in Esseen's smoothing integral.
Standard optimised smoothing bound gives $\sup_z |\mathbb{P}(W_n \leq z) - \Phi(z)| \leq \frac{33}{4}\frac{\rho}{\sqrt{n}}$. Substitute $\rho = \frac{\rho_3}{\sigma^3}$, QED.
Structural Commentary: Berry–Esseen bounds the CLT error by standardised third absolute moment.
Key Insight: Normalise, compare characteristic functions, then apply Esseen smoothing. □

Theorem 3.2.13. *Multivariate Central Limit Theorem*
Let $(X_i)_{i\geq 1}$ be IID random vectors in $\mathbb{R}^k$ with $\mathbb{E}X_1 = \mu \in \mathbb{R}^k$ and $\mathrm{Cov}(X_1) = \Sigma$, and set $\overline{X}_n := n^{-1}\sum_{i=1}^n X_i$.
Then $\sqrt{n}(\overline{X}_n - \mu) \rightsquigarrow N_k(0,\Sigma)$.

Proof. For $a \in \mathbb{R}^k$, set $Y_{i,a} := a^t(X_i - \mu)$ and $s_a^2 := a^t\Sigma a$.
Then $(Y_{i,a})_{i\geq 1}$ are IID, $\mathbb{E}Y_{1,a} = 0$, $\mathrm{Var}(Y_{1,a}) = s_a^2$, and $a^t\sqrt{n}(\overline{X}_n - \mu) = n^{-\frac{1}{2}}\sum_{i=1}^n Y_{i,a}$.
If $s_a^2 > 0$, the scalar CLT gives $a^t\sqrt{n}(\overline{X}_n - \mu) \rightsquigarrow N(0,s_a^2)$; if $s_a^2 = 0$, then $\mathbb{E}Y_{1,a}^2 = 0$, so the same convergence holds with degenerate limit $N(0,0)$. Since $a^tZ \sim N(0,s_a^2)$ for $Z \sim N_k(0,\Sigma)$, by Cramer–Wold, QED.
Structural Commentary: Multivariate convergence is checked through one-dimensional projections.
Key Insight: Project first, apply the scalar CLT, then use Cramer–Wold. □

Theorem 3.2.14. *Delta Method*
Let $(Y_n)_{n\geq 1}$ be real-valued random variables, let $\mu \in \mathbb{R}$ and $\sigma > 0$, and assume $\sigma^{-1}\sqrt{n}(Y_n - \mu) \rightsquigarrow N(0,1)$.
If $g : \mathbb{R} \to \mathbb{R}$ is differentiable at μ and $g'(\mu) \neq 0$, then $(|g'(\mu)|\,\sigma)^{-1}\sqrt{n}(g(Y_n) - g(\mu)) \rightsquigarrow N(0,1)$.
Equivalently $g(Y_n) \approx N(g(\mu), \frac{(g'(\mu))^2\sigma^2}{n})$.

Proof. Set $A_n := \sigma^{-1}\sqrt{n}(Y_n - \mu)$ and define $\rho(\mu) := 0$, $\rho(y) := \frac{g(y)-g(\mu)}{y-\mu} - g'(\mu)$ for $y \neq \mu$.
Then $A_n \rightsquigarrow Z \sim N(0,1)$, $A_n = O_{\mathbb{P}}(1)$, and $Y_n - \mu = \frac{\sigma A_n}{\sqrt{n}} \xrightarrow{\mathbb{P}} 0$.
Differentiability gives $\rho(y) \to 0$ as $y \to \mu$, hence $\rho(Y_n) \xrightarrow{\mathbb{P}} 0$.
For all n, $g(Y_n) - g(\mu) = (g'(\mu) + \rho(Y_n))(Y_n - \mu)$. Thus, with $T_n := (|g'(\mu)|\,\sigma)^{-1}\sqrt{n}(g(Y_n) - g(\mu))$,
$T_n = \mathrm{sgn}(g'(\mu))A_n(1 + \frac{\rho(Y_n)}{g'(\mu)}) \rightsquigarrow \mathrm{sgn}(g'(\mu))Z \sim N(0,1)$ by Theorem 2.1.8.
Structural Commentary: The delta method is first-order Taylor expansion at the limit point.
Key Insight: The derivative rescales the fluctuation; the remainder is negligible in probability. □

Theorem 3.2.15. *Multivariate Delta Method*
Let $(Y_n)_{n\geq 1}$ be random vectors in $\mathbb{R}^k$ with $\sqrt{n}(Y_n - \mu) \rightsquigarrow N_k(0,\Sigma)$, and let $g : \mathbb{R}^k \to \mathbb{R}$ be differentiable at μ with gradient $\nabla g(\mu)$.
Then $\sqrt{n}(g(Y_n) - g(\mu)) \rightsquigarrow N(0, \nabla g(\mu)^t\Sigma\nabla g(\mu))$.

Proof. Set $A_n := \sqrt{n}(Y_n - \mu)$, so $A_n \rightsquigarrow N_k(0,\Sigma)$ and $Y_n \xrightarrow{\mathbb{P}} \mu$.
Differentiability gives $g(Y_n) - g(\mu) = \nabla g(\mu)^t(Y_n - \mu) + r(Y_n)\,\|Y_n - \mu\|$ with $r(Y_n) \xrightarrow{\mathbb{P}} 0$.
Since $A_n = O_{\mathbb{P}}(1)$, $\sqrt{n}r(Y_n)\,\|Y_n - \mu\| = r(Y_n)\,\|A_n\| \xrightarrow{\mathbb{P}} 0$.
Thus $\sqrt{n}(g(Y_n) - g(\mu)) = \nabla g(\mu)^tA_n + o_{\mathbb{P}}(1) \rightsquigarrow N(0, \nabla g(\mu)^t\Sigma\nabla g(\mu))$ by Theorem 2.1.8.
Structural Commentary: Multivariate delta method linearizes g by its gradient.
Key Insight: The gradient projection carries the Gaussian limit; the differentiability remainder vanishes. □

Proposition 3.2.16. *Delta Method*
If $\sqrt{n}(T_n - \theta) \Rightarrow N(0,\Sigma)$ and $g : \mathbb{R}^d \to \mathbb{R}^k$ is differentiable at θ with derivative $Dg(\theta)$,
then $\sqrt{n}(g(T_n) - g(\theta)) \Rightarrow N(0, Dg(\theta)\Sigma Dg(\theta)^\top)$.

Proof. Differentiability gives $g(T_n) - g(\theta) = Dg(\theta)(T_n - \theta) + r_n$ with $\frac{\|r_n\|}{\|T_n-\theta\|} \to 0$ in probability.
Since $\sqrt{n}(T_n - \theta) = O_P(1)$, $\sqrt{n}r_n = o_P(1)$; $\sqrt{n}(g(T_n) - g(\theta)) = Dg(\theta)\sqrt{n}(T_n - \theta) + o_P(1)$, by Slutsky QED.
Structural Commentary: The derivative transports the limiting normal fluctuation through g.
Key Insight: First-order linearisation determines asymptotic variance. □

Example 3.2.17. *Exponentiating a Sample Mean*
Let $(X_i)_{i=1}^n$ be IID with mean μ and variance $\sigma^2 < +\infty$, and set $W_n := e^{\overline{X}_n}$.
For $g(s) = e^s$, $g'(\mu) = e^\mu$, so the delta method gives $W_n \approx N(e^\mu, \frac{e^{2\mu}\sigma^2}{n})$.

Example 3.2.18. *Product and Ratio of Sample Means*

Let $X_i = (X_{1i}, X_{2i})^t$ be IID with mean $\mu = (\mu_1, \mu_2)^t$ and covariance $\Sigma = (\sigma_{ij})$, and set $\overline{X}_{jn} := n^{-1} \sum_{i=1}^{n} X_{ji}$.

For $g(x_1, x_2) = x_1 x_2$, $\nabla g(\mu) = (\mu_2, \mu_1)^t$, so $\sqrt{n}(\overline{X}_{1n}\overline{X}_{2n} - \mu_1\mu_2) \rightsquigarrow N(0, \mu_2^2\sigma_{11} + 2\mu_1\mu_2\sigma_{12} + \mu_1^2\sigma_{22})$.

If $\mu_2 \neq 0$, then for $h(x_1, x_2) = \frac{x_1}{x_2}$ and $a := \nabla h(\mu) = (\frac{1}{\mu_2}, -\frac{\mu_1}{\mu_2^2})^t$, $\sqrt{n}(\frac{\overline{X}_{1n}}{\overline{X}_{2n}} - \frac{\mu_1}{\mu_2}) \rightsquigarrow N(0, a^t\Sigma a)$.

4 Stochastic Processes

4.1 Process-Level Probability

Definition 4.1.1. *Stochastic Process, State Space, and Index Set*

(i) A *stochastic process* is a family $(X_t)_{t\in T}$ of random variables.
(ii) The set T is the *index set*, often representing time.
(iii) Each X_t takes values in a *state space* $\mathcal{X}$.

Typical choices are discrete time $T = \{0, 1, 2, \ldots\}$ and continuous time $T = [0, \infty)$.

Example 4.1.2. *IID Sequences as Processes*
An IID sequence $(X_n)_{n\geq 1}$ is a stochastic process indexed by $T = \{1, 2, \ldots\}$.

Example 4.1.3. *Discrete States and Discrete Time*
If $\mathcal{X} = \{\text{sunny}, \text{cloudy}\}$ and X_n is the weather on day n, then $(X_n)_{n\geq 1}$ is a stochastic process with discrete state space and discrete index set.

Example 4.1.4. *The Empirical CDF as a Process*

Let $X_1, \ldots, X_n$ be IID with CDF F on $[0, 1]$, and define $\widehat{F}_n(t) = n^{-1} \sum_{i=1}^{n} \mathbf{1}\{X_i \leq t\}$.

Then $(\widehat{F}_n(t))_{t\in[0,1]}$ is a stochastic process with continuous index set $[0, 1]$ and state space $[0, 1]$.

Remark 4.1.5. *Sample Paths*
A *sample path* is one realized function $t \mapsto X_t(\omega)$ of a stochastic process.
The state space and index set may each be discrete or continuous.

Proposition 4.1.6. *Finite-Dimensional Chain Rule*
Let $X_{1:n} = (X_1, \ldots, X_n)$ have joint mass function or density $f_{1:n}$.

At points where the needed marginals are positive, $f_{1:n}(x_{1:n}) = f_1(x_1) \prod_{i=2}^{n} f_{i|1:i-1}(x_i \mid x_{1:i-1})$.

Proof. For $i \geq 2$, the definition of conditional density gives $f_{1:i}(x_{1:i}) = f_{i|1:i-1}(x_i \mid x_{1:i-1}) f_{1:i-1}(x_{1:i-1})$.
Iterating this identity from $i = n$ down to 2 yields the product formula.
Structural Commentary: The joint law factors by revealing one coordinate at a time.
Key Insight: Conditional densities convert successive joint marginals into a telescoping product. □

4.2 Filtrations and Adapted Processes

4.3 Martingales in Discrete and Continuous Time

4.4 Markov Chains and Markov Processes

Definition 4.4.1. *Probability Vectors and Markov Matrices*
A vector $\mathbf{x} \in \mathbb{R}^n$ is a *probability vector* if its entries are nonnegative and sum to 1. Let $\mathbf{e} := (1, \ldots, 1)^t$. A matrix $A = [a_{ij}] \in \mathrm{Mat}(n, n, \mathbb{R})$ is a *Markov matrix* if $a_{ij} \geq 0$ for all i, j and $A\mathbf{e} = \mathbf{e}$; equivalently, every row sum is 1.

Lemma 4.4.2. *Basic Properties of Markov Matrices*
If $A \in \mathrm{Mat}(n, n, \mathbb{R})$ is Markov, then $1 \in \mathrm{spec}(A)$, and each A^p is Markov with entries in $[0, 1]$.

Proof. Since $A\mathbf{e} = \mathbf{e}$, 1 is an eigenvalue. Inductively, A^p has nonnegative entries and $A^p\mathbf{e} = \mathbf{e}$, so A^p is Markov. Each nonnegative row sums to 1, so all entries lie in $[0, 1]$.
Structural Commentary: Markov structure is closed under powers.
Key Insight: Nonnegative row sums of 1 bound every entry. □

Theorem 4.4.3. *Unit-Circle Spectrum of Markov Matrices*
If $A \in \mathrm{Mat}(n, n, \mathbb{R})$ is Markov, then $\rho(A) = 1$, and $\dim E_\lambda(A) = m_A(\lambda)$ for every $\lambda \in \mathrm{spec}(A)$ with $|\lambda| = 1$.

Proof. Lemma 4.4.2 makes A power bounded. Theorem 3.3.7 gives $\rho(A) \leq 1$ and $\dim E_\lambda(A) = m_A(\lambda)$ on $|\lambda| = 1$. Since $A\mathbf{e} = \mathbf{e}$, $1 \in \mathrm{spec}(A)$, so $\rho(A) \geq 1$. Thus $\rho(A) = 1$.
Structural Commentary: Bounded Markov powers rule out unit-circle Jordan growth.
Key Insight: $A\mathbf{e} = \mathbf{e}$ forces the eigenvalue 1. □

Theorem 4.4.4. *Positive Markov Matrices Converge to a Stationary Distribution*
Let $n \geq 2$, $\mathbf{e} := (1, \ldots, 1)^t$, and $A = (a_{ij}) \in \mathrm{Mat}(n, n, \mathbb{R})$ satisfy $a_{ij} > 0$ and $A\mathbf{e} = \mathbf{e}$.
Let $\Delta_{n-1} := \{\mathbf{u} \in \mathbb{R}^n : \mathbf{u} \geq 0,\ \mathbf{e}^t\mathbf{u} = 1\}$. Then $\exists!\, \mathbf{x} \in \Delta_{n-1}$ s.t. $A^t\mathbf{x} = \mathbf{x}$, $\mathbf{x} > 0$, $\lim_{p\to\infty} A^p = \mathbf{e}\mathbf{x}^t$.

Proof. Let $A\mathbf{y} = \lambda\mathbf{y}$ with $\mathbf{y} \neq 0$ and $|\lambda| = 1$, and choose k with $|y_k| = \|\mathbf{y}\|_\infty$.

Since $\sum_j a_{kj} = 1$, then $\|\mathbf{y}\|_\infty = |\lambda y_k| = \left|\sum_{j=1}^{n} a_{kj} y_j\right| \leq \sum_{j=1}^{n} a_{kj} |y_j| \leq \|\mathbf{y}\|_\infty$. Thus all inequalities are equalities.
Since $a_{kj} > 0$, $|y_j| = \|\mathbf{y}\|_\infty$ $\forall j$; equality in the triangle inequality gives $\mathbf{y} = c\mathbf{e}$, $c \neq 0$.
Hence $\lambda = 1$, $E_1(A) = \mathrm{span}\{\mathbf{e}\}$, and $\mathrm{spec}(A) \cap \{z \in \mathbb{C} : |z| = 1\} = \{1\}$.
Theorem 4.4.3 makes 1 semisimple, so $A = S([1] \oplus J)S^{-1}$ with $S = [\mathbf{e}\ Y]$ and $\rho(J) < 1$.

First row of S^{-1} is $\mathbf{x}^t$. Then $\mathbf{x}^t A = \mathbf{x}^t$, $\mathbf{x}^t\mathbf{e} = 1$, and $A^p = S([1] \oplus J^p)S^{-1} \longrightarrow S([1] \oplus 0)S^{-1} = \mathbf{e}\mathbf{x}^t$.
Since $A^p \geq 0$, the limit gives $\mathbf{x} \geq 0$; since $A^t\mathbf{x} = \mathbf{x}$, $\mathbf{x}^t\mathbf{e} = 1$, and $A^t > 0$, we get $\mathbf{x} > 0$.
Finally, $\dim E_1(A^t) = n - \operatorname{rank}(A^t - I_n) = n - \operatorname{rank}(A - I_n) = \dim E_1(A) = 1$, so any $\mathbf{u} \in \Delta_{n-1}$ with $A^t\mathbf{u} = \mathbf{u}$ satisfies $\mathbf{u} = c\mathbf{x}$ and $\mathbf{e}^t\mathbf{u} = 1 = \mathbf{e}^t\mathbf{x}$, hence $\mathbf{u} = \mathbf{x}$.
Structural Commentary: Positivity leaves one simple unit-circle block; all other blocks decay.
Key Insight: The limit is the rank-one projection $\mathbf{e}\mathbf{x}^t$. □

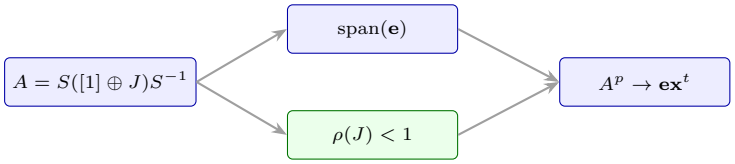

Figure 231: The line span($\mathbf{e}$) remains; all other Jordan directions decay, so $A^p \to \mathbf{e}\mathbf{x}^t$.

The preceding results are matrix facts. In probability language, a row-stochastic matrix becomes a transition matrix for a discrete-time chain.

Definition 4.4.5. *Markov Chain and Transition Matrix*
(i) Let $\mathcal{X}$ be countable and let $(X_n)_{n\geq 0}$ take values in $\mathcal{X}$.
(ii) Process is *Markov chain* if $\mathbb{P}(X_n = x \mid X_0, \ldots, X_{n-1}) = \mathbb{P}(X_n = x \mid X_{n-1})$ $\forall$ admissible n and $x \in \mathcal{X}$.
(iii) It is *homogeneous* if $p_{ij} := \mathbb{P}(X_{n+1} = j \mid X_n = i)$ is independent of n.
(iv) The matrix $P = [p_{ij}]$ is the *transition matrix*; $p_{ij} \geq 0$ and $\sum_{j\in\mathcal{X}} p_{ij} = 1$ for each i.

Figure 232: A Markov chain remembers the current state, not the full past.

Example 4.4.6. *Random Walk with Absorbing Barriers*
Let $\mathcal{X} = \{1, \ldots, N\}$ and $q = 1 - p$. The absorbing random walk has $p_{11} = p_{NN} = 1$, $p_{i,i+1} = p$ and $p_{i,i-1} = q$ for $2 \leq i \leq N - 1$, and all other transition probabilities equal to 0.

Definition 4.4.7. *n-Step Transition Probabilities*
For a homogeneous Markov chain, the *n-step transition probability* from i to j is
$p_{ij}(n) := \mathbb{P}(X_{m+n} = j \mid X_m = i)$; set $P_n = [p_{ij}(n)]$.

Theorem 4.4.8. *Chapman-Kolmogorov Equations*
Let $(X_r)_{r\geq 0}$ be homogeneous Markov chain on countable $\mathcal{X}$. Let $p_{ij}(r) := \mathbb{P}_i(X_r = j)$, $P_r = (p_{ij}(r))_{i,j\in\mathcal{X}}$.
$\forall i, j \in \mathcal{X}$ and $m, n \in \mathbb{N}_0$, $p_{ij}(m+n) = \sum_{k\in\mathcal{X}} p_{ik}(m)p_{kj}(n)$; equivalently, $P_{m+n} = P_m P_n$ and $P_n = P^n$ for $P = P_1$.

Proof. Fix $i, j \in \mathcal{X}$ and $m, n \in \mathbb{N}_0$. By total probability, the Markov property, and homogeneity,
$p_{ij}(m+n) = \mathbb{P}_i(X_{m+n} = j) = \sum_{k\in\mathcal{X}} \mathbb{P}_i(X_{m+n} = j \mid X_m = k)\mathbb{P}_i(X_m = k) = \sum_{k\in\mathcal{X}} p_{kj}(n)p_{ik}(m)$.
Thus $(P_m P_n)_{ij} = \sum_{k\in\mathcal{X}} p_{ik}(m)p_{kj}(n) = p_{ij}(m+n)$ for all i, j, so $P_{m+n} = P_m P_n$.
With $P_0 = I$ and $P = P_1$, induction gives $P_n = P^n$.
Structural Commentary: Transition over $m + n$ steps factors through the intermediate state after m steps.
Key Insight: Conditioning over intermediate states is matrix multiplication. □

Lemma 4.4.9. *Marginal Evolution*
Let $(X_n)_{n\geq 0}$ be a homogeneous Markov chain on countable $\mathcal{X}$ with $P = P_1 = (p_{ij})$, where $p_{ij}(n) := \mathbb{P}_i(X_n = j)$ and $P_n = (p_{ij}(n))$. Define row laws $\mu_n(j) := \mathbb{P}(X_n = j)$. Then $\mu_n = \mu_0 P^n$ for all $n \in \mathbb{N}_0$.

Proof. $\forall j \in \mathcal{X}$, by total probability $\mu_n(j) = \sum_{i\in\mathcal{X}} \mathbb{P}(X_n = j \mid X_0 = i)\mathbb{P}(X_0 = i) = \sum_{i\in\mathcal{X}} \mu_0(i)p_{ij}(n) = (\mu_0 P_n)_j$.
By Theorem 4.4.8, $P_n = P^n$, so $\mu_n(j) = (\mu_0 P^n)_j$ for every $j \in \mathcal{X}$; hence $\mu_n = \mu_0 P^n$.
Structural Commentary: Marginals evolve by multiplying the initial law by the transition semigroup.
Key Insight: Conditioning on X_0 turns distribution evolution into row-vector matrix multiplication. □

Definition 4.4.10. *Communication Classes*
(i) State i *reaches* j, written $i \to j$, if $p_{ij}(n) > 0$ for some $n \geq 0$.
(ii) States i, j *communicate*, written $i \leftrightarrow j$, if $i \to j$ and $j \to i$.
(iii) A *communication class* is an equivalence class under $\leftrightarrow$.
(iv) The chain is *irreducible* if all states lie in one communication class.
(v) A set C is *closed* if $p_{ij} = 0$ for all $i \in C$ and $j \notin C$; a singleton closed class is an *absorbing state*.

Proposition 4.4.11. *Communication Classes Partition the State Space*
Let $(X_n)_{n\geq 0}$ be a homogeneous Markov chain on countable $\mathcal{X}$ with n-step probabilities $p_{ij}(n)$.
Define $i \to j$ iff $\exists n \in \mathbb{N}_0$ such that $p_{ij}(n) > 0$, and $i \leftrightarrow j$ iff $i \to j$ and $j \to i$.
Then $\leftrightarrow$ is equivalence relation, and $\mathcal{X} = \bigsqcup_{C\in\mathcal{C}} C$ where $\mathcal{C} := \{[i]_\leftrightarrow : i \in \mathcal{X}\}$ is set of communication classes.

Proof. Since $p_{ii}(0) = 1$, $i \leftrightarrow i$ for all $i \in \mathcal{X}$; symmetry is immediate from the definition.
If $i \leftrightarrow j$ and $j \leftrightarrow k$, choose $m, n, r, s \in \mathbb{N}_0$ with $p_{ij}(m) > 0$, $p_{jk}(n) > 0$, $p_{kj}(r) > 0$, and $p_{ji}(s) > 0$.
By Theorem 4.4.8, $p_{ik}(m+n) \geq p_{ij}(m)p_{jk}(n) > 0$ and $p_{ki}(r+s) \geq p_{kj}(r)p_{ji}(s) > 0$, hence $i \leftrightarrow k$.
Thus $\leftrightarrow$ is reflexive, symmetric, and transitive.
Its equivalence classes are pairwise disjoint, cover $\mathcal{X}$, and are exactly the communication classes.
Structural Commentary: Communication classes are the equivalence classes generated by mutual reachability.
Key Insight: Positive transition paths concatenate by Chapman-Kolmogorov. □

Definition 4.4.12. *Recurrent and Transient States*

(i) Let $\tau_i^+ := \inf\{n \geq 1 : X_n = i\}$ be the first return time to i.
(ii) State i is *recurrent* or *persistent* if $\mathbb{P}_i(\tau_i^+ < \infty) = 1$.
(iii) State i is *transient* if $\mathbb{P}_i(\tau_i^+ < \infty) < 1$.

Theorem 4.4.13. *Recurrence Criterion*

(i) State i is recurrent iff $S_i := \sum_{n=0}^{\infty} p_{ii}(n) = \infty$.
(ii) State i is transient iff $S_i < \infty$.

Proof. Let $N_i := \sum_{n=0}^{\infty} \mathbf{1}\{X_n = i\}$ and $r_i := \mathbb{P}_i(\tau_i^+ < \infty)$. By Tonelli, $\mathbb{E}_i N_i = \sum_{n=0}^{\infty} p_{ii}(n) = S_i$.

By the Markov property after returns to i, $\mathbb{P}_i(N_i \geq k) = r_i^{k-1}$ for $k \geq 1$, hence $\mathbb{E}_i N_i = \sum_{k=1}^{\infty} r_i^{k-1}$.

(i) (⇒) If i is recurrent, then $r_i = 1$, so $S_i = \mathbb{E}_i N_i = \infty$.
(i) (⇐) If $S_i = \infty$, then $r_i < 1$ would give $\mathbb{E}_i N_i = (1 - r_i)^{-1} < \infty$, a contradiction; hence $r_i = 1$.
(ii) (⇒) If i is transient, then $r_i < 1$, so $S_i = \mathbb{E}_i N_i = (1 - r_i)^{-1} < \infty$.
(ii) (⇐) If $S_i < \infty$, then $r_i = 1$ would give $\mathbb{E}_i N_i = \infty$, a contradiction; hence $r_i < 1$.

Structural Commentary: Recurrence is detected by the expected total number of returns.
Key Insight: Visits to i repeat with geometric return probability r_i. □

Definition 4.4.14. *Period and Ergodicity*

(i) For recurrent i, it is *positive recurrent* if $\mathbb{E}_i \tau_i^+ < \infty$ and *null recurrent* otherwise.
(ii) The *period* of i is $d(i) := \gcd\{n \geq 1 : p_{ii}(n) > 0\}$.
(iii) State i is *aperiodic* if $d(i) = 1$.
(iv) State i is *ergodic* if it is recurrent, positive recurrent, and aperiodic.
(v) The chain is *ergodic* if every state is ergodic.

Definition 4.4.15. *Stationary and Limiting Distributions*

(i) A probability row vector π is *stationary* or *invariant* if $\pi = \pi P$.
(ii) A finite chain has *limiting distribution* π if $p_{ij}(n) \to \pi_j$ for all states i, j.

Equivalently, every row of P^n converges to π.

Remark 4.4.16. *Stationary Need Not Mean Convergent*
For the deterministic three-cycle on $\{1, 2, 3\}$, set $p_{12} = p_{23} = p_{31} = 1$ and all other $p_{ij} = 0$.
Then $\pi = (\frac{1}{3}, \frac{1}{3}, \frac{1}{3})$ satisfies $\pi P = \pi$, but $P^{n+3} = P^n$, so P^n does not converge.

Theorem 4.4.17. *Finite Ergodic Chain Convergence*
Let P be the transition matrix of a finite irreducible aperiodic Markov chain on $\mathcal{X}$.
There is a unique $\pi \in \Delta(\mathcal{X})$ with $\pi P = \pi$, and $P^n \to \mathbf{e}\pi$.

For every bounded $g : \mathcal{X} \to \mathbb{R}$, $N^{-1} \sum_{n=1}^{N} g(X_n) \to \pi(g) := \sum_{j \in \mathcal{X}} g(j)\pi_j$ almost surely.

Proof. Finite irreducibility and aperiodicity imply P is primitive: $P^m > 0$ for some $m \geq 1$.
Row-vector form of Theorem 4.4.4 on $A = P^m$, gives unique $\pi \in \Delta(\mathcal{X})$ with $\pi P^m = \pi$, $(P^m)^k \to \mathbf{e}\pi$.
Since $(\pi P)P^m = \pi P$ and $\pi P \in \Delta(\mathcal{X})$, uniqueness gives $\pi P = \pi$.
For $n = mk + r$ with $0 \leq r < m$, $P^n = (P^m)^k P^r \to \mathbf{e}\pi P^r = \mathbf{e}\pi$.
The finite-state Markov-chain strong law yields $N^{-1} \sum_{n=1}^{N} g(X_n) \to \pi(g)$ almost surely for bounded g.
Structural Commentary: Irreducibility gives one communicating class; aperiodicity removes cyclic obstruction.
Key Insight: Primitivity makes P^n converge to the rank-one projection $\mathbf{e}\pi$. □

Definition 4.4.18. *Detailed Balance*
Let $P = [p_{ij}]$ be a transition matrix on $\mathcal{X}$.
A probability row vector π satisfies *detailed balance* for P if $\pi_i p_{ij} = \pi_j p_{ji}$ for all $i, j \in \mathcal{X}$.

Theorem 4.4.19. *Detailed Balance Implies Stationarity*
Let $P = [p_{ij}]$ be row-stochastic on countable $\mathcal{X}$, and let $\pi \in \Delta(\mathcal{X})$. If $\pi_i p_{ij} = \pi_j p_{ji}$ $\forall i, j \in \mathcal{X}$, then $\pi P = \pi$.

Proof. $\forall j \in \mathcal{X}$, $(\pi P)_j = \sum_{i \in \mathcal{X}} \pi_i p_{ij} = \sum_{i \in \mathcal{X}} \pi_j p_{ji} = \pi_j \sum_{i \in \mathcal{X}} p_{ji} = \pi_j$, since row j of P sums to 1. QED.
Structural Commentary: Detailed balance gives pairwise cancellation of probability fluxes.
Key Insight: Reversibility is stronger than stationarity. □

Proposition 4.4.20. *Detailed Balance Implies Stationarity*
Let $\pi(dx) = f(x)\,dx$ and let P be a Markov kernel on state space X.
If $\pi(dx)P(x, dy) = \pi(dy)P(y, dx)$ as measures on $\mathsf{X} \times \mathsf{X}$, then $\pi P = \pi$.

Proof. For measurable $A \subseteq \mathsf{X}$, $\pi P(A) = \int P(x,A)\,\pi(dx) = \int \mathbf{1}_A(y)\,\pi(dx)P(x,dy)$.
By detailed balance, this equals $\int \mathbf{1}_A(y)\,\pi(dy)P(y,dx) = \int_A P(y,\mathsf{X})\,\pi(dy) = \pi(A)$, proving $\pi P = \pi$.
Structural Commentary: Detailed balance makes the joint law of consecutive states symmetric.
Key Insight: Marginalising the symmetric joint measure gives the same one-step density. □

Proposition 4.4.21. *Two-State Chain Limit*
Let $0 < a, b < 1$, $P = \begin{bmatrix} 1-a & a \\ b & 1-b \end{bmatrix}$. *Set* $\pi = \left(\frac{b}{a+b}, \frac{a}{a+b}\right)$. *Then* $\pi P = \pi$, π *unique,* $P^n \to \mathbf{e}\pi = \begin{bmatrix} \frac{b}{a+b} & \frac{a}{a+b} \\ \frac{b}{a+b} & \frac{a}{a+b} \end{bmatrix}$.

Proof. Solving $\pi P = \pi$ with $\pi\mathbf{e} = 1$ gives $\pi = \left(\frac{b}{a+b}, \frac{a}{a+b}\right)$.
The characteristic polynomial is $(\lambda - 1)(\lambda - (1-a-b))$, so $\operatorname{spec}(P) = \{1, 1-a-b\}$ and $|1-a-b| < 1$.
Thus stationary component is projected onto $\mathbf{e}\pi$, transverse component decays geometrically, giving $P^n \to \mathbf{e}\pi$.
Structural Commentary: The dynamics split into the stationary line and one transverse eigendirection.
Key Insight: The non-unit eigenvalue $1-a-b$ controls convergence. □

4.5 Stationary Processes and Ergodicity

Definition 4.5.1. *Strict and Weak Stationarity*
Let $(X_t)_{t\in\mathbb{Z}}$ be a real-valued stochastic process.

(i) *Strict stationarity*: $\forall k \in \mathbb{N},\ t_1, \ldots, t_k, h \in \mathbb{Z}$, $(X_{t_1}, \ldots, X_{t_k}) \overset{\text{dist}}{=} (X_{t_1+h}, \ldots, X_{t_k+h})$.
(ii) *Weak stationarity*: $\exists \mu \in \mathbb{R}$ and $\gamma : \mathbb{Z} \to \mathbb{R}$ with $\forall t, h \in \mathbb{Z}$, $X_t \in L^2$, $\mathbb{E}X_t = \mu$, and $\operatorname{Cov}(X_t, X_{t-h}) = \gamma(h)$.

Key Insight: (i) plus L^2 implies (ii); (ii) fixes only μ and γ, not finite-dimensional laws.

4.6 Gaussian Processes

4.7 Point Processes and Renewal Structure

Counting processes model random event arrivals over time. The Poisson process is the basic model in which disjoint time intervals contribute independent counts and short intervals usually contain either zero or one event.

Definition 4.7.1. *Counting Process*
A *counting process* is a stochastic process $\{X(t) : t \geq 0\}$ with state space $\{0, 1, 2, \ldots\}$ such that $X(t)$ records the number of events observed up to and including time t.

Definition 4.7.2. *Poisson Process with Intensity Function*
Let $\lambda : [0,\infty) \to [0,\infty)$ be locally integrable.
A counting process $X = \{X(t) : t \geq 0\}$ is a *Poisson process* with *intensity function* λ if:

(i) $X(0) = 0$.
(ii) For $0 = t_0 < t_1 < \cdots < t_n$, the increments $\Delta_k X := X(t_k) - X(t_{k-1})$, $1 \leq k \leq n$, are independent.
(iii) For each $t \geq 0$, as $h \downarrow 0$, $\mathbb{P}(X(t+h) - X(t) = 1) = \lambda(t)h + o(h)$ and $\mathbb{P}(X(t+h) - X(t) \geq 2) = o(h)$.

Theorem 4.7.3. *Increment Distribution*
Let X *be a Poisson process with intensity* λ, *and set* $\Lambda(s,t) := \int_s^t \lambda(u)\,du$ *for* $0 \leq s \leq t$.
Then $X(t) - X(s) \sim \text{Poisson}(\Lambda(s,t))$. *In particular,* $X(t) \sim \text{Poisson}(\Lambda(0,t))$, *so* $\mathbb{E}X(t) = \operatorname{Var}(X(t)) = \Lambda(0,t)$.

Proof. Fix $s \geq 0$ and let $p_k(u) := \mathbb{P}(X(s+u) - X(s) = k)$ with $p_{-1} := 0$. By small-time conditions and independent increments, $p_k(u+h) = p_k(u)(1 - \lambda(s+u)h + o(h)) + p_{k-1}(u)\lambda(s+u)h + o(h)$.
Hence $p_k'(u) = -\lambda(s+u)p_k(u) + \lambda(s+u)p_{k-1}(u)$, with $p_0(0) = 1$ and $p_k(0) = 0$ for $k \geq 1$.
Writing $M(u) := \Lambda(s, s+u)$, the unique solution is $p_k(u) = e^{-M(u)}\frac{M(u)^k}{k!}$ by induction on k.
Taking $u = t - s$ yields $X(t) - X(s) \sim \text{Poisson}(\Lambda(s,t))$. Mean-variance identities follow from Poisson law.
Structural Commentary: The infinitesimal jump rules form a triangular system for the increment probabilities.
Key Insight: Integrating the local rate λ gives the Poisson mean over the interval. □

Definition 4.7.4. *Homogeneous Poisson Process*
If $\lambda(t) \equiv \lambda > 0$, then $X(t)$ is a *homogeneous Poisson process* with *rate* λ. In this case, $X(t) \sim \text{Poisson}(\lambda t)$.

Definition 4.7.5. *Waiting and Interarrival Times*
For a homogeneous Poisson process:

(i) Set $W_0 = 0$ and $W_n := \inf\{t \geq 0 : X(t) \geq n\}$ for $n \geq 1$; $W_1, W_2, \ldots$ are *waiting times*.
(ii) Set $S_n := W_{n+1} - W_n$ for $n \geq 0$; $S_0, S_1, \ldots$ are *sojourn* or *interarrival times*.

Theorem 4.7.6. *Poisson Interarrival Times*
Let X *be a homogeneous Poisson process with rate* $\lambda > 0$.
Then $S_0, S_1, \ldots \overset{\text{iid}}{\sim} \text{Exp}(\lambda)$, *with density* $f(s) = \lambda e^{-\lambda s}$ *for* $s \geq 0$.
For $n \geq 1$, $W_n = \sum_{r=0}^{n-1} S_r \sim \text{Gamma}(n, \lambda)$, *so* $\mathbb{E}W_n = \frac{n}{\lambda}$ *and* $\operatorname{Var}(W_n) = \frac{n}{\lambda^2}$.

Proof. For $t \geq 0$, $\mathbb{P}(S_0 > t) = \mathbb{P}(X(t) = 0) = e^{-\lambda t}$, so $S_0 \sim \text{Exp}(\lambda)$.
By independent stationary increments, $\mathbb{P}(S_n > t \mid \mathcal{F}_{W_n}) = \mathbb{P}(X(W_n + t) - X(W_n) = 0 \mid \mathcal{F}_{W_n}) = e^{-\lambda t}$.
Thus each $S_n \sim \text{Exp}(\lambda)$ and is independent of the past, so the S_n are IID.
Since $W_n = \sum_{r=0}^{n-1} S_r$, the Gamma law and its mean and variance follow.
Structural Commentary: Arrival times are cumulative sums of IID interarrival gaps.
Key Insight: No events in a length-t interval has probability $e^{-\lambda t}$. □

Proposition 4.7.7. *Conditional Binomial Count*
Let X be a homogeneous Poisson process with rate $\lambda > 0$.
For $s, t > 0$ and $n \in \mathbb{N}_0$, $X(t) \mid X(t+s) = n \sim \text{Binomial}\left(n, \frac{t}{t+s}\right)$.

Proof. Let $Y = X(t)$ and $Z = X(t+s) - X(t)$. Then $Y \sim \text{Poisson}(\lambda t)$, $Z \sim \text{Poisson}(\lambda s)$, and $Y \perp Z$.
For $0 \le k \le n$, $\mathbb{P}(Y = k \mid Y + Z = n) = \frac{\frac{(\lambda t)^k}{k!}\frac{(\lambda s)^{n-k}}{(n-k)!}}{\frac{(\lambda(t+s))^n}{n!}} = \binom{n}{k}\left(\frac{t}{t+s}\right)^k\left(\frac{s}{t+s}\right)^{n-k}$; QED.
Structural Commentary: Conditioning on the total allocates independent Poisson counts.
Key Insight: Independent Poisson counts become multinomial after conditioning on their sum. □

Remark 4.7.8. *Uniform Event-Time Diagnostic*
For a homogeneous Poisson process on $[0, T]$, conditional on $X(T) = n$, the event times $(W_1, \ldots, W_n)$ have the law of the order statistics of n IID Uniform$(0, T)$ variables.
Marked nonuniformity in the observed event times is evidence against homogeneity.

Proposition 4.7.9. *Odd Poisson Count*
Let X be a homogeneous Poisson process with rate $\lambda > 0$. For $t \ge 0$, $\mathbb{P}(X(t) \in 2\mathbb{N}_0 + 1) = \frac{1 - e^{-2\lambda t}}{2}$.

Proof. Let $\mu = \lambda t$. Since $X(t) \sim \text{Poisson}(\mu)$, $\mathbb{P}(X(t) \in 2\mathbb{N}_0 + 1) = e^{-\mu}\sum_{k=0}^{\infty}\frac{\mu^{2k+1}}{(2k+1)!} = e^{-\mu}\sinh\mu = \frac{1 - e^{-2\mu}}{2}$.
Structural Commentary: Split the Poisson mass by parity.
Key Insight: The odd terms of e^{μ} sum to $\sinh\mu$. □

Proposition 4.7.10. *Nearest Neighbor in a Planar Poisson Process*
Let Φ be a planar Poisson point process with intensity $\lambda > 0$, fix $x_0 \in \mathbb{R}^2$, and set $R := \inf_{Y \in \Phi}\|Y - x_0\|$.
Then for $t \ge 0$, $\mathbb{P}(R > t) = e^{-\lambda\pi t^2}$, and $\mathbb{E}R = \frac{1}{2\sqrt{\lambda}}$.

Proof. Let $B_t := B(x_0, t)$, $N_t := \#(\Phi \cap B_t)$. Then $N_t \sim \text{Poisson}(\lambda\pi t^2)$, $\{R > t\} = \{N_t = 0\}$,
so $\mathbb{P}(R > t) = e^{-\lambda\pi t^2}$. Since $R \ge 0$, $\mathbb{E}R = \int_0^{\infty}\mathbb{P}(R > t)\,dt = \int_0^{\infty} e^{-\lambda\pi t^2}\,dt = \frac{1}{2\sqrt{\lambda}}$.
Structural Commentary: Nearest-neighbor distance is encoded by empty disks around x_0.
Key Insight: The tail of R is the zero-count probability of a Poisson disk count. □

1 Dynamical Systems and ODEs

1.1 ODE Foundations and Flows

Ordinary differential equations prescribe the evolution of an unknown curve through relations among the curve and its derivatives. Their order, dependence on time, and linearity determine the natural state variables and solution methods.

Definition 1.1.1. *Implicit Scalar ODE and Regular Point*
Let $k \in \mathbb{N}$, $k \geq 1$, $U \subseteq \mathbb{R}^{k+2}$ be open, and $F \in C(U, \mathbb{R})$.
For $I \subseteq \mathbb{R}$, $x \in C^k(I, \mathbb{R})$, set $J_x^k(t) := (t, x(t), x^{(1)}(t), \dots, x^{(k)}(t))$.

(i) $F(t, y_0, \dots, y_k) = 0$ is an *implicit scalar ODE written through order k*; its k-jet form is $F(J_x^k(t)) = 0$.
(ii) x is a *solution* on I iff $J_x^k(t) \in U$ and $F(J_x^k(t)) = 0$ $\forall t \in I$.
(iii) $F \in C^1(U, \mathbb{R})$; $p = (t_*, y_0^*, \dots, y_k^*) \in F^{-1}(0)$ is *regular w.r.t. highest derivative* iff $\partial_{y_k} F(p) \neq 0$.

Key Insight: $\partial_{y_k} F(p) \neq 0$ locally solves the relation for $x^{(k)}$.

Proposition 1.1.2. *Local Explicit Form of a Regular Implicit ODE*
Let $k \in \mathbb{N}$, $k \geq 1$, $U \subseteq \mathbb{R}^{k+2}$ be open, $F \in C^1(U, \mathbb{R})$, $u_* = (t_*, y_0^*, \dots, y_{k-1}^*)$, and $p = (u_*, y_k^*) \in U$ with $F(p) = 0$ and $\partial_{y_k} F(p) \neq 0$. Then $\exists$ open $V \subseteq \mathbb{R}^{k+1}$, $W \subseteq \mathbb{R}$ with $u_* \in V$, $y_k^* \in W$, and a unique $f \in C^1(V, \mathbb{R})$ such that $f(V) \subseteq W$, $f(u_*) = y_k^*$, $V \times W \subseteq U$, and:

(i) $F(u, v) = 0$ iff $v = f(u)$ $\forall (u, v) \in V \times W$.
(ii) If $x \in C^k(I, \mathbb{R})$ and $J_x^k(I) \subseteq V \times W$, then $F(J_x^k(t)) = 0$ $\forall t \in I$ iff $x^{(k)}(t) = f(t, x(t), \dots, x^{(k-1)}(t))$ $\forall t \in I$.

Proof. Let $u = (t, y_0, \dots, y_{k-1})$, $v = y_k$, $\widehat{U} := \{(v, u) : (u, v) \in U\}$, and $\widehat{F}(v, u) := F(u, v)$.
Since $\partial_v \widehat{F}(y_k^*, u_*) = \partial_{y_k} F(p) \neq 0$, by Theorem 4.2.3, there are W, V and a unique $f \in C^1(V, \mathbb{R})$ with $W \times V \subseteq \widehat{U}$, $f(V) \subseteq W$, $f(u_*) = y_k^*$, and $\widehat{F}(v, u) = 0$ iff $v = f(u)$.

(i) For $(u, v) \in V \times W$, $F(u, v) = \widehat{F}(v, u)$, so $F(u, v) = 0$ iff $v = f(u)$.
(ii) Set $u_x(t) := (t, x(t), \dots, x^{(k-1)}(t))$ and $v_x(t) := x^{(k)}(t)$. Since $(u_x(t), v_x(t)) \in V \times W$ $\forall t \in I$, (i) gives $F(J_x^k(t)) = 0$ iff $v_x(t) = f(u_x(t))$ $\forall t \in I$.

Structural Commentary: IFT solves $F(u, y_k) = 0$ for y_k.
Key Insight: $\partial_{y_k} F(p) \neq 0$ turns $F = 0$ into $y_k = f(u)$ locally. □

Definition 1.1.3. *Explicit ODE Systems and Classes*
Let $k, n \in \mathbb{N}$, $k \geq 1$, $U \subseteq \mathbb{R} \times (\mathbb{R}^n)^k$ open, and $f : U \to \mathbb{R}^n$.
Use $X_x(t) := (x(t), x^{(1)}(t), \dots, x^{(k-1)}(t))$, $\xi = (\xi_0, \dots, \xi_{k-1})$, and $\pi(U) := \{\xi \in (\mathbb{R}^n)^k : \exists t \in \mathbb{R},\ (t, \xi) \in U\}$.

(i) $x^{(k)}(t) = f(t, X_x(t))$ is an *explicit ODE system of order k*.
(ii) For an interval $I \subseteq \mathbb{R}$, $x \in C^k(I, \mathbb{R}^n)$ is a *solution* iff $\forall t \in I$, $(t, X_x(t)) \in U$ and $x^{(k)}(t) = f(t, X_x(t))$.
(iii) The system is *autonomous* iff $\exists F : \pi(U) \to \mathbb{R}^n$ with $f(t, \xi) = F(\xi)$ $\forall (t, \xi) \in U$.
(iv) On an interval I, the system is *linear* iff $\exists g \in C(I, \mathbb{R}^n)$ and $A_j \in C(I, \mathbb{R}^{n \times n})$, $0 \leq j < k$,
with $f(t, \xi) = g(t) + \sum_{j=0}^{k-1} A_j(t) \xi_j$ $\forall (t, \xi) \in U \cap (I \times (\mathbb{R}^n)^k)$.
(v) A linear system on I is *homogeneous* iff (iv) holds with $g = 0$.
(vi) A solution $x : I \to \mathbb{R}^n$ is *global* iff $I = \mathbb{R}$.
(vii) A solution $x : I \to \mathbb{R}^n$ is *maximal* iff $\nexists$ solution $\bar{x} : \bar{I} \to \mathbb{R}^n$ with $I \subsetneq \bar{I}$ and $\bar{x}|_I = x$.

Key Insight: The state lift X_x has dimension kn.

Proposition 1.1.4. *Reduction to First Order*
Let $k, n \in \mathbb{N}$, $k \geq 1$, $U \subseteq \mathbb{R} \times (\mathbb{R}^n)^k$ open, and $f : U \to \mathbb{R}^n$.
For $y = (y_1, \dots, y_k)$, define $G(t, y) := (y_2, \dots, y_k, f(t, y))$.
For an interval $I \subseteq \mathbb{R}$ and $x \in C^k(I, \mathbb{R}^n)$, set $y := (x, x^{(1)}, \dots, x^{(k-1)})$ and assume $(t, y(t)) \in U$ $\forall t \in I$.
Then $y \in C^1(I, (\mathbb{R}^n)^k)$, and $x^{(k)}(t) = f(t, y(t))$ $\forall t \in I$ iff $y'(t) = G(t, y(t))$ $\forall t \in I$.

Proof.
($\Rightarrow$) Since $x \in C^k(I, \mathbb{R}^n)$, then $y \in C^1(I, (\mathbb{R}^n)^k)$. The identities $y_j' = x^{(j)} = y_{j+1}$, $1 \leq j < k$, and $y_k' = x^{(k)} = f(t, y(t))$ imply $y' = G(\,\cdot\,, y)$ on I.
($\Leftarrow$) Since $y_k = x^{(k-1)}$, the kth coordinate gives $x^{(k)}(t) = y_k'(t) = G_k(t, y(t)) = f(t, y(t))$ $\forall t \in I$.

Structural Commentary: Coordinates shift; the last coordinate carries f.
Key Insight: Adjoin derivatives to get first order. □

Proposition 1.1.5. *Autonomization by Adjoining Time*
Let $m \in \mathbb{N}$, $U \subseteq \mathbb{R} \times \mathbb{R}^m$ be open, $f : U \to \mathbb{R}^m$, and $\widetilde{f}(s, \xi) := (1, f(s, \xi))$. For an interval $I \subseteq \mathbb{R}$:

(i) If $y \in C^1(I, \mathbb{R}^m)$, $(t, y(t)) \in U$, and $y' = f(t, y)$, then $z(t) := (t, y(t))$ solves $z' = \widetilde{f}(z)$.
(ii) If $z = (s, y) \in C^1(I, \mathbb{R}^{m+1})$, $z(I) \subseteq U$, $z' = \widetilde{f}(z)$, and $s(t_0) = t_0$ for some $t_0 \in I$, then $s = \mathrm{id}_I$ and $y'(t) = f(t, y(t))$ on I.

Proof.
(i) For $z = (t, y)$, $z' = (1, y') = (1, f(t, y)) = \widetilde{f}(t, y) = \widetilde{f}(z)$.
(ii) Since $(s', y') = z' = \widetilde{f}(s, y) = (1, f(s, y))$, $s' = 1$ and $y' = f(s, y)$.
With $s(t_0) = t_0$, $s = \mathrm{id}_I$; hence $y'(t) = f(t, y(t))$.

Structural Commentary: The clock coordinate has $s' = 1$.
Key Insight: $y' = f(t, y)$ becomes $z' = \widetilde{f}(z)$ with $z = (t, y)$. □

Example 1.1.6. *Newtonian Motion as a First-Order System*
Let $q : \mathbb{R} \to \mathbb{R}^3$ be the position of a particle of mass $m > 0$, let $v := q'$, and let $F : \mathbb{R}^3 \to \mathbb{R}^3$ be a position-dependent force. Newton's equation $mq''(t) = F(q(t))$ becomes $(q, v)' = (v, m^{-1}F(q))$ by Proposition 1.1.4. For uniform gravity $F(q) = -mge_3$, where $e_3 := (0, 0, 1)^{\mathsf{T}}$ and $g > 0$, the initial state $(q(0), v(0)) = (q_0, v_0)$ gives $q(t) = q_0 + v_0 t - \frac{g}{2}e_3 t^2$. Thus position and velocity together determine the mechanical state.

Proposition 1.1.7. *Scalar Autonomous Separation*
Let $D \subseteq \mathbb{R}$ be open, $f \in C(D, \mathbb{R})$, $D_f := \{x \in D : f(x) \neq 0\}$, and $x_0 \in D_f$.
Let C be the component of D_f containing x_0, and set $H(x) := \int_{x_0}^{x} \frac{du}{f(u)}$, $K := H(C)$. Then:

(i) K is an open interval and $H : C \to K$ is a differentiable bijection.
(ii) $\phi := H^{-1} : K \to C$ is the unique C-valued solution of $x' = f(x)$ with $x(0) = x_0$.
(iii) K is maximal among intervals of C-valued solutions through x_0, and ϕ is global iff $K = \mathbb{R}$.

Proof.

(i) Since D_f is open, C is an open interval. By Theorem 2.2.1, $H' = 1/f \neq 0$ on C.
Since f has constant sign on C by Theorem 5.1.43, H is strictly monotone.
Hence $H : C \to K = H(C)$ is bijective and K is an open interval.
(ii) By Corollary 1.1.20, $\phi \in C^1(K, C)$ and $\phi' = 1/(H' \circ \phi) = f \circ \phi$. Since $H(x_0) = 0$, $\phi(0) = x_0$.
If $u : L \to C$ solves $u' = f(u)$ with $0 \in L$ and $u(0) = x_0$, then $(H \circ u)' = H'(u)u' = 1$ and $(H \circ u)(0) = 0$.
Hence $H(u(t)) = t$, so $L \subseteq K$ and $u = \phi|_L$.
(iii) If $\bar{\phi} : \bar{K} \to C$ solves $x' = f(x)$, $K \subseteq \bar{K}$, and $\bar{\phi}|_K = \phi$, then (ii) gives $\bar{K} \subseteq K$; hence $\bar{K} = K$.
Thus K is maximal. Since $\operatorname{dom}\phi = K$, ϕ is global iff $K = \mathbb{R}$.

Structural Commentary: Monotone coordinate, inverse trajectory.
Key Insight: Time is accumulated reciprocal speed. □

Method 1.1.8. *Separation of Variables*
Let $D \subseteq \mathbb{R}$ be open, $J \subseteq \mathbb{R}$ open interval, $f \in C(D, \mathbb{R})$, $g \in C(J, \mathbb{R})$, $t_0 \in J$, $x_0 \in D_f := \{x \in D : f(x) \neq 0\}$.
Let $C \ni x_0$ be the component of D_f and $H(x) := \int_{x_0}^{x} \frac{du}{f(u)}$.
Since f has constant sign on C and $H' = 1/f$, $H : C \to H(C)$ is a differentiable bijection.

(i) Set $G(t) := \int_{t_0}^{t} g(s)\,ds$ and let L be the component of $\{t \in J : G(t) \in H(C)\}$ containing t_0.
(ii) Output $x := H^{-1} \circ G$ on L; then $x' = f(x)g$ on L and $x(t_0) = x_0$.

Example 1.1.9. *Global Growth, Finite-Time Blow-Up, and Nonuniqueness*
The separation coordinate distinguishes three basic behaviors.

(i) For $x' = x$ and $x(0) = x_0 > 0$, $H(x) = \log\left(\frac{x}{x_0}\right)$ and $x(t) = x_0 e^t$ on $\mathbb{R}$.
(ii) For $x' = x^2$ and $x(0) = x_0 > 0$, $H(x) = x_0^{-1} - x^{-1}$ and $x(t) = \frac{x_0}{1 - x_0 t}$ on $(-\infty, x_0^{-1})$; $x(t) \to +\infty$ as $t \uparrow x_0^{-1}$.
(iii) For $x' = \sqrt{|x|}$ and $x(0) = 0$, $a \in [0, +\infty)$ determines $x_a(t) := \begin{cases} 0, & t \leq a, \\ \frac{(t-a)^2}{4}, & t \geq a. \end{cases}$ Then $x_a \in C^1(\mathbb{R})$, $x_a' = \sqrt{|x_a|}$, $x_a(0) = 0$, and if $0 \leq a < b$, then $x_a = x_b$ on $(-\infty, a]$ while $x_a > x_b$ on $(a, b]$; hence the IVP is nonunique.

First-order equations can also be rewritten as fixed-point problems on complete function spaces.

Definition 1.1.10. *Scalar Initial-Value Problem*
Let $O \subseteq \mathbb{R}^2$ be open, $(x_0, y_0) \in O$, $g : O \to \mathbb{R}$, and $\mathrm{IVP}(O, g, x_0, y_0) := \{y' = g(x, y),\ y(x_0) = y_0\}$.
For $J \subseteq \mathbb{R}$ with $x_0 \in J$, $f : J \to \mathbb{R}$ solves $\mathrm{IVP}(O, g, x_0, y_0)$ iff

(i) J is open and f is differentiable.
(ii) $\Gamma_f := \{(x, f(x)) : x \in J\} \subseteq O$.
(iii) $f'(x) = g(x, f(x))\ \forall x \in J$, and $f(x_0) = y_0$.

Structural Commentary: $\Gamma_f \subseteq O$ makes $g(\,\cdot\,, f)$ defined; $f(x_0) = y_0$ selects the curve.

Proposition 1.1.11. *Differential and Integral Forms*
Let $O \subseteq \mathbb{R}^2$ be open, $(x_0, y_0) \in O$, $g \in C(O, \mathbb{R})$, $J \subseteq \mathbb{R}$ open with $x_0 \in J$, and $f \in C(J, \mathbb{R})$.
Let $\Gamma_f := \{(x, f(x)) : x \in J\} \subseteq O$. Then f solves $\mathrm{IVP}(O, g, x_0, y_0)$ iff $f(x) = y_0 + \int_{x_0}^{x} g(t, f(t))\,dt\ \forall x \in J$.

Proof.

($\Rightarrow$) If $f'(x) = g(x, f(x))$ on J, $f(x_0) = y_0$, by Theorem 2.2.2, $f(x) - y_0 = \int_{x_0}^{x} f'(t)\,dt = \int_{x_0}^{x} g(t, f(t))\,dt\ \forall x \in J$.
($\Leftarrow$) If $f(x) = y_0 + \int_{x_0}^{x} g(t, f(t))\,dt\ \forall x \in J$, then $g(\,\cdot\,, f(\,\cdot\,))$ is continuous on J.
By Theorem 2.2.1, $f'(x) = g(x, f(x))$ on J. Evaluating at $x = x_0$ gives $f(x_0) = y_0$.

Structural Commentary: Differentiation and integration are inverse along the continuous graph.
Key Insight: The IVP is equivalent to its Volterra integral equation. □

Theorem 1.1.12. *Picard Local Existence Theorem*
Let $O \subseteq \mathbb{R}^2$ be open, $(x_0, y_0) \in O$, and $g \in C(O, \mathbb{R})$.
Assume $|g(x, y_1) - g(x, y_2)| \leq M\,|y_1 - y_2|$ for some $M > 0$ whenever $(x, y_1), (x, y_2) \in O$.
Then $\exists a, b, \ell > 0$ with $Q := [x_0 - a, x_0 + a] \times [y_0 - b, y_0 + b] \subseteq O$ and $J_\ell := (x_0 - \ell, x_0 + \ell)$ such that:

(i) The IVP $y' = g(x, y)$, $y(x_0) = y_0$, has a differentiable solution $f : J_\ell \to \mathbb{R}$ with $\Gamma_f \subseteq Q$.
(ii) If $h : J_\ell \to \mathbb{R}$ is a differentiable solution with $\Gamma_h \subseteq Q$, then $h = f$.

Proof.

(i) Choose $a, b > 0$ with $Q := [x_0 - a, x_0 + a] \times [y_0 - b, y_0 + b] \subseteq O$.
Let $K := \sup_Q |g| < +\infty$, and choose $0 < \ell \le a$ with $\ell K \le b$ and $\ell M < 1$.
Put $I_\ell := [x_0 - \ell, x_0 + \ell]$, $\mathcal{X}_\ell := \{u \in C(I_\ell, \mathbb{R}) : \|u - y_0\|_\infty \le b\}$, and $(Tu)(x) := y_0 + \int_{x_0}^{x} g(t, u(t))\, dt$.
The space $\mathcal{X}_\ell$ is complete, and for $u, v \in \mathcal{X}_\ell$, $\|Tu - y_0\|_\infty \le \ell K \le b$ and $\|Tu - Tv\|_\infty \le \ell M \|u - v\|_\infty$.
Thus $T : \mathcal{X}_\ell \to \mathcal{X}_\ell$ is a contraction; by Theorem 4.5.3, $\exists! u_* \in \mathcal{X}_\ell$ with $Tu_* = u_*$.
For $f := u_*|_{J_\ell}$, $\Gamma_f \subseteq Q$; by Proposition 1.1.11, $f' = g(\cdot, f)$ and $f(x_0) = y_0$.

(ii) Let $h : J_\ell \to \mathbb{R}$ solve the IVP with $\Gamma_h \subseteq Q$. For $0 < r < \ell$, put $I_r := [x_0 - r, x_0 + r]$,
$\mathcal{X}_r := \{u \in C(I_r, \mathbb{R}) : \|u - y_0\|_\infty \le b\}$, and $(T_r u)(x) := y_0 + \int_{x_0}^{x} g(t, u(t))\, dt$.
Since $rM < 1$, T_r is a contraction. By Proposition 1.1.11, $T_r(h|_{I_r}) = h|_{I_r}$ and $T_r(u_*|_{I_r}) = u_*|_{I_r}$.
Uniqueness gives $h = f$ on I_r. Hence $h = f$ on $\bigcup_{0<r<\ell} I_r = J_\ell$.

Structural Commentary: Box control plus short-time contraction.
Key Insight: Picard iteration is Banach iteration. □

Method 1.1.13. *Picard Iteration*
Let $Q := [x_0 - a, x_0 + a] \times [y_0 - b, y_0 + b] \subseteq O$, assume $|g(x, y)| \le K$ for $(x, y) \in Q$,
$|g(x, y_1) - g(x, y_2)| \le M |y_1 - y_2|$ whenever $(x, y_1), (x, y_2) \in Q$. Let $\ell > 0$ with $\ell \le a$, $\ell K \le b$, and $\ell M < 1$.
Set $I_\ell := [x_0 - \ell, x_0 + \ell]$, $J_\ell := (x_0 - \ell, x_0 + \ell)$, $\mathcal{X}_\ell := \{u \in C(I_\ell, \mathbb{R}) : \|u - y_0\|_\infty \le b\}$,
$(Tu)(x) := y_0 + \int_{x_0}^{x} g(t, u(t))\, dt$. Then

(i) Initialize $f_0(x) \equiv y_0$ on I_ℓ.
(ii) Iterate $f_{n+1} := Tf_n$, i.e. $f_{n+1}(x) = y_0 + \int_{x_0}^{x} g(t, f_n(t))\, dt$ for $x \in I_\ell$.
(iii) Let $f_\infty := \lim_{n\to\infty} f_n$ uniformly on I_ℓ, and output $f := f_\infty|_{J_\ell}$.

By Theorem 4.5.3, the limit exists and is the unique fixed point of T; Proposition 1.1.11 identifies its restriction as the unique local solution with graph in Q.

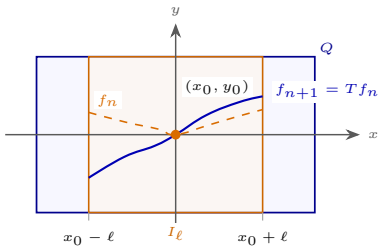

Figure 233: Picard setup: choose ℓ with $\ell K \le b$ so $T(\mathcal{X}_\ell) \subseteq \mathcal{X}_\ell$ and graphs stay in Q.

The same fixed-point formulation applies to vector fields and supports quantitative iteration estimates.

Definition 1.1.14. *Vector IVP and Local State Lipschitz Condition*
Let $n \in \mathbb{N}$, $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, $f : U \to \mathbb{R}^n$, and $(t_0, x_0) \in U$.

(i) The *initial-value problem* is $x' = f(t, x)$, $x(t_0) = x_0$; a solution on an interval $I \ni t_0$ is $x \in C^1(I, \mathbb{R}^n)$ with $(t, x(t)) \in U$ and $x'(t) = f(t, x(t))$ $\forall t \in I$.
(ii) f is *locally Lipschitz in the state, uniformly in time* iff $\forall$ compact $V \subseteq U$, $\exists L_V < +\infty$ such that $\|f(t, x) - f(t, y)\| \le L_V \|x - y\|$ whenever $(t, x), (t, y) \in V$.

Key Insight: State-Lipschitz control makes the integral operator asymptotically contractive under iteration.

Lemma 1.1.15. *C^1 Vector Fields Are Locally State-Lipschitz*
Let $n \in \mathbb{N}$, $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, and $f \in C^1(U, \mathbb{R}^n)$.
$\forall$ compact $K \subseteq U$, $\exists L_K < +\infty$ such that $\|f(t, x) - f(t, y)\| \le L_K \|x - y\|$ whenever $(t, x), (t, y) \in K$.

Proof. Fix compact $K \subseteq U$. If $K = \emptyset$, take $L_K = 0$. Otherwise choose $r > 0$, $K_r := \{z : \operatorname{dist}(z, K) \le r\} \subseteq U$.
Set $A := \max_{K_r} \|D_x f\|$, $M := \max_K \|f\|$, and $L_K := \max\{A, \frac{2M}{r}\}$. For $(t, x), (t, y) \in K$, put $\rho := \|x - y\|$.
If $\rho < r$, then $\sigma(s) := (t, x + s(y - x)) \in K_r$ for $s \in [0, 1]$; by Theorem 3.2.1, $\|f(t, x) - f(t, y)\| \le A\rho$.
If $\rho \ge r$, then $\|f(t, x) - f(t, y)\| \le 2M \le \frac{2M}{r}\rho$. Thus $\|f(t, x) - f(t, y)\| \le L_K \rho$.
Structural Commentary: Nearby pairs use $D_x f$; separated pairs use boundedness.
Key Insight: Compactness yields one state-Lipschitz constant. □

Theorem 1.1.16. *Quantitative Vector Picard–Lindelöf Theorem*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, $f \in C(U, \mathbb{R}^n)$, and $(t_0, x_0) \in U$. Choose $T, \delta > 0$ and set $V := [t_0, t_0 + T] \times \overline{B}_\delta(x_0) \subseteq U$.
Assume $L \ge 0$ and $\|f(t, x) - f(t, y)\| \le L \|x - y\|$ $\forall (t, x), (t, y) \in V$.
Set $M := \max_V \|f\|$, $T_0 := \min\{T, \delta/M\}$ with $\delta/0 := +\infty$, and $I := [t_0, t_0 + T_0]$.
Let $X := C(I, \mathbb{R}^n)$, $\|u\|_\infty := \max_{t\in I} \|u(t)\|$, and $\mathcal{C} := \{u \in X : \|u - x_0\|_\infty \le \delta\}$.
Define $Ku := x_0 + \int_{t_0}^{(\cdot)} f(s, u(s))\, ds$, $u_0 \equiv x_0$, and $u_{m+1} := Ku_m$.

(i) $(u_m) \subseteq \mathcal{C}$ and $u_m \to \phi$ uniformly for some $\phi \in \mathcal{C}$ satisfying $K\phi = \phi$; hence $\phi \in C^1(I, \mathbb{R}^n)$ solves the IVP.
(ii) ϕ is the unique solution on I whose graph lies in V.
(iii) If $M_0 := \max_{t\in I} \|f(t, x_0)\|$, then $\|\phi - u_m\|_\infty \le T_0 M_0 e^{LT_0} \frac{(LT_0)^m}{m!}$ $\forall m \ge 1$.

Proof.

(i) For $u \in \mathcal{C}$, $\|Ku - x_0\|_\infty \le MT_0 \le \delta$; hence $K(\mathcal{C}) \subseteq \mathcal{C}$.
For $u, v \in \mathcal{C}$, induction on $m \ge 1$ yields $\|K^m u(t) - K^m v(t)\| \le \frac{L^m (t - t_0)^m}{m!} \|u - v\|_\infty$ for $t \in I$.

Hence $\|u_{m+1}-u_m\|_\infty \le \frac{(LT_0)^m}{m!}\|Ku_0-u_0\|_\infty$, so (u_m) is uniformly Cauchy.
By Theorem 8.1.1, X is complete; since $\mathcal{C}$ is closed, $u_m \to \phi \in \mathcal{C}$.
The case $m=1$ implies K is continuous on $\mathcal{C}$, so $K\phi = \lim_{m\to\infty} Ku_m = \lim_{m\to\infty} u_{m+1} = \phi$.
Thus $\phi(t) = x_0 + \int_{t_0}^t f(s,\phi(s))\,ds$, so $\phi \in C^1(I,\mathbb{R}^n)$, $\phi(t_0)=x_0$, and $\phi' = f(\cdot,\phi)$.

(ii) If $Ku=u$ and $Kv=v$ in $\mathcal{C}$, then $\|u-v\|_\infty = \|K^m u - K^m v\|_\infty \le \frac{(LT_0)^m}{m!}\|u-v\|_\infty \ \forall m \ge 1$.
Choose m with $(LT_0)^m/m! < 1$; hence $u=v$.
If y solves the IVP on I with graph in V, then $y \in \mathcal{C}$ and integration implies $Ky = y$; hence $y=\phi$.

(iii) Since $\|Ku_0-u_0\|_\infty \le T_0M_0$, (i) implies $\|\phi-u_m\|_\infty \le \sum_{j=m}^{\infty}\|u_{j+1}-u_j\|_\infty \le T_0M_0\sum_{j=m}^{\infty}\frac{(LT_0)^j}{j!}$.

For $a \ge 0$, $(m+k)! \ge m!k!$ implies $\sum_{j=m}^{\infty}\frac{a^j}{j!} \le \frac{a^m}{m!}e^a$; set $a = LT_0$.

Structural Commentary: Factorial iterate bounds replace the short-time contraction restriction.
Key Insight: Iterates contract after sufficiently many integrations. □

Theorem 1.1.17. *Picard–Lindelöf with an Integrable Lipschitz Bound*
Let $U \subseteq \mathbb{R}\times\mathbb{R}^n$ be open, $f \in C(U,\mathbb{R}^n)$, $(t_0,x_0)\in U$, and choose $T,\delta>0$ with $V := [t_0,t_0+T]\times\overline{B}_\delta(x_0) \subseteq U$.
Set $b(t) := \max_{x\in\overline{B}_\delta(x_0)}\|f(t,x)\|$. Let $L:[t_0,t_0+T]\to[0,+\infty)$ be integrable,
satisfy $\|f(t,x)-f(t,y)\| \le L(t)\|x-y\|$ for $(t,x),(t,y)\in V$. Choose $0<T_0\le T$ with $\int_{t_0}^{t_0+T_0} b(s)\,ds \le \delta$.
Put $I := [t_0,t_0+T_0]$, $A(t) := \int_{t_0}^t L(s)\,ds$, $A := A(t_0+T_0)$, and $B_0 := \int_{t_0}^{t_0+T_0}\|f(s,x_0)\|\,ds$.
Let $\mathcal{C} := \{u\in C(I,\mathbb{R}^n) : \|u-x_0\|_\infty \le \delta\}$, $(Ku)(t) := x_0 + \int_{t_0}^t f(s,u(s))\,ds$, $u_0 \equiv x_0$, and $u_{m+1} := Ku_m$. Then:
(i) $K(\mathcal{C}) \subseteq \mathcal{C}$ and $u_m \to \phi \in \mathcal{C}$ uniformly, where $K\phi=\phi$.
(ii) $\phi \in C^1(I,\mathbb{R}^n)$ is the unique solution of $x' = f(t,x)$, $x(t_0)=x_0$, whose graph lies in V.
(iii) $\|\phi-u_m\|_\infty \le B_0 e^A \frac{A^m}{m!}$ for $m \ge 0$.

Proof. For $u\in\mathcal{C}$ and $t\in I$, $\|Ku(t)-x_0\| \le \int_{t_0}^t b(s)\,ds \le \delta$; hence $K(\mathcal{C})\subseteq\mathcal{C}$.
Induction and $dA = L\,ds$ give $\|K^m u(t) - K^m v(t)\| \le \frac{A(t)^m}{m!}\|u-v\|_\infty$ for $u,v\in\mathcal{C}$ and $m\ge 1$.
With $u=Ku_0$ and $v=u_0$, $\|u_{j+1}-u_j\|_\infty \le B_0\frac{A^j}{j!}$ for $j\ge 0$. Thus (u_m) is uniformly Cauchy.

(i) By Theorem 8.1.1, $C(I,\mathbb{R}^n)$ is complete; closedness of $\mathcal{C}$ gives $u_m\to\phi\in\mathcal{C}$.
The case $m=1$ makes K continuous, so $K\phi = \lim_{m\to\infty}Ku_m = \lim_{m\to\infty}u_{m+1} = \phi$.

(ii) By Theorem 2.2.1, the fixed-point identity implies $\phi\in C^1(I,\mathbb{R}^n)$, $\phi(t_0)=x_0$, and $\phi' = f(\cdot,\phi)$.
If y is a solution with graph in V, then $y\in\mathcal{C}$ and $Ky=y$.
If $Ku=u$ and $Kv=v$, then $\|u-v\|_\infty \le \frac{A^m}{m!}\|u-v\|_\infty$ for $m\ge 1$; choose m with $\frac{A^m}{m!}<1$, hence $u=v$.

(iii) By telescoping, $\|\phi-u_m\|_\infty \le B_0\sum_{j=m}^{\infty}\frac{A^j}{j!}$. Since $(m+r)! \ge m!r!$, $\sum_{j=m}^{\infty}\frac{A^j}{j!} \le e^A\frac{A^m}{m!}$.

Structural Commentary: Integrated Lipschitz mass gives factorial iterate bounds.
Key Insight: Repeated integration contracts eventually. □

Remark 1.1.18. *Carathéodory Solutions*
Let $I\subseteq\mathbb{R}$, $t_0\in I$, $x_0\in\mathbb{R}^n$, $\delta>0$, $V := I\times\overline{B}_\delta(x_0)$, and $f: V\to\mathbb{R}^n$.
Suppose $f(\cdot,x)$ is measurable, $f(t,\cdot)$ is continuous for a.e. t, and $\exists b, L\in L^1(I,[0,+\infty))$ with $\|f(t,x)\|\le b(t)$ and $\|f(t,x)-f(t,y)\| \le L(t)\|x-y\|$ for a.e. t and $x,y\in\overline{B}_\delta(x_0)$.
Then a fixed point of $(Kx)(t) := x_0 + \int_{t_0}^t f(s,x(s))\,ds$ lies in $AC(I,\mathbb{R}^n)$ and satisfies $x' = f(\cdot,x)$ a.e.
Generally AC cannot be replaced by C^1. For $f(t,x)=\operatorname{sign}(t)x$, $x(t) := e^{|t|}$ satisfies $x(0)=1$,
$x(t) = 1+\int_0^t \operatorname{sign}(s)x(s)\,ds$, and $x' = \operatorname{sign}(t)x$ for $t\ne 0$, but $x\notin C^1((-1,1))$.

Lemma 1.1.19. *Time Regularity of ODE Solutions*
Let $I\subseteq\mathbb{R}$ be an interval, $k,n\in\mathbb{N}$, $k\ge 1$, $U\subseteq\mathbb{R}\times\mathbb{R}^n$ open, and $f\in C^k(U,\mathbb{R}^n)$.
Let $x\in C^1(I,\mathbb{R}^n)$ and $\gamma := (\mathrm{id}_I, x)$. If $\gamma(I)\subseteq U$ and $x' = f\circ\gamma$, then $x\in C^{k+1}(I,\mathbb{R}^n)$.

Proof. Let P_j mean $x\in C^j(I,\mathbb{R}^n)$. Since $x\in C^1$, P_1 holds.
If P_j holds and $1\le j\le k$, then $\gamma\in C^j(I,U)$, so $x' = f\circ\gamma\in C^j(I,\mathbb{R}^n)$; hence P_{j+1}. Thus P_{k+1}.
Structural Commentary: Bootstrap $x' = f\circ\gamma$.
Key Insight: Vector-field regularity lifts the trajectory by one derivative. □

Lemma 1.1.20. *Generalized Gronwall Inequality*
Let $\alpha,\beta,\psi\in C([0,T],\mathbb{R})$ with $\beta\ge 0$ and $\psi(t) \le \alpha(t) + \int_0^t \beta(s)\psi(s)\,ds \ \forall t\in[0,T]$.

(i) $\psi(t) \le \alpha(t) + \int_0^t \alpha(s)\beta(s)\exp\left(\int_s^t \beta(r)\,dr\right)ds \ \forall t\in[0,T]$.

(ii) If $\alpha(s)\le\alpha(t)$ whenever $0\le s\le t\le T$, then $\psi(t)\le\alpha(t)\exp\left(\int_0^t\beta(s)\,ds\right) \ \forall t\in[0,T]$.

Proof.

(i) Put $q(t) := \int_0^t\beta(s)\psi(s)\,ds$ and $w(t) := \exp\left(-\int_0^t\beta(s)\,ds\right)$. Then $(wq)' = w\beta(\psi-q) \le w\beta\alpha$.
Since $q(0)=0$, integration gives $q(t)\le\int_0^t\alpha(s)\beta(s)\exp\left(\int_s^t\beta(r)\,dr\right)ds$; combine this with $\psi\le\alpha+q$.

(ii) Under the monotonicity hypothesis, (i) gives $\psi(t)\le\alpha(t)\left(1+\int_0^t\beta(s)\exp\left(\int_s^t\beta(r)\,dr\right)ds\right)$.
For $q(s) := \exp\left(\int_s^t\beta(r)\,dr\right)$, $q' = -\beta q$, so the parenthesis equals $1+q(0)-q(t) = \exp\left(\int_0^t\beta(s)\,ds\right)$.

Structural Commentary: An integrating factor controls the accumulated integral term.
Key Insight: Exponential growth is the exact cost of repeated feedback. □

Theorem 1.1.21. *Continuous Dependence on Initial Data and Vector Fields*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, $f, g \in C(U, \mathbb{R}^n)$, $I := [t_0, T]$, and $x, y \in C^1(I, \mathbb{R}^n)$ satisfy $x' = f(\cdot, x)$, $y' = g(\cdot, y)$.
For $w : I \to \mathbb{R}^n$, set $\Gamma_w := \{(t, w(t)) : t \in I\}$. Assume $\Gamma_x \cup \Gamma_y \subseteq V \subseteq U$ with V compact.
Assume $\exists L \geq 0$ such that $\|f(t,p) - f(t,q)\| \leq L \|p - q\|$ whenever $(t,p), (t,q) \in V$.
Set $a := \|x(t_0) - y(t_0)\|$, $E := f - g$, $M := \max_V \|E\|$, $\rho_0(h) := h$, and $\rho_L(h) := L^{-1}(e^{Lh} - 1)$ for $L > 0$.
Then $\|x(t) - y(t)\| \leq e^{L(t-t_0)}a + M\rho_L(t - t_0)\ \forall t \in I$.

Proof. Put $\Delta := x - y$, $\psi := \|\Delta\|$, and $R(s) := f(s, x(s)) - f(s, y(s)) + E(s, y(s))$.
Then $\Delta(t) = \Delta(t_0) + \int_{t_0}^t R(s)\, ds$ and $\|R(s)\| \leq L\psi(s) + M$. Hence $\psi(t) \leq a + \int_{t_0}^t (L\psi(s) + M)\, ds$.
If $L = 0$, then $\psi(t) \leq a + M(t - t_0) = a + M\rho_0(t - t_0)$.
If $L > 0$, set $\chi := \psi + M/L$. Then $\chi(t) \leq a + M/L + \int_{t_0}^t L\chi(s)\, ds$.
By Lemma 1.1.20(ii), $\chi(t) \leq (a + M/L)e^{L(t-t_0)}$, hence $\psi(t) \leq e^{L(t-t_0)}a + M\rho_L(t - t_0)$.
Structural Commentary: Split state error from field error; apply Gronwall.
Key Insight: Initial and model errors propagate exponentially. □

Theorem 1.1.22. *Local Lipschitz Dependence on the Initial Pair*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, $f \in C(U, \mathbb{R}^n)$, and $(t_*, x_*) \in U$. Assume f is locally state-Lipschitz:
$\forall$ compact $K \subseteq U$, $\exists L_K < +\infty$ such that $\|f(t,p) - f(t,q)\| \leq L_K \|p - q\|$ whenever $(t,p), (t,q) \in K$.
Then $\exists I, B, V, \Phi$ with $I \ni t_*$ compact, $B \ni x_*$ an open ball, $V \subseteq U$ compact, and $\Phi : I \times I \times B \to \mathbb{R}^n$.
Set $H := \sup I - \inf I$, $M := \max_V \|f\|$, choose a state-Lipschitz constant L for f on V.
Let $D((r,x),(q,y)) := \|x - y\| + M\,|r - q|$. Then:
(i) $\Phi(r, r, x) = x$, $(t, \Phi(t, r, x)) \in V$, and $\partial_t \Phi(t, r, x) = f(t, \Phi(t, r, x))$ for $(t, r, x) \in I \times I \times B$.
(ii) $\|\Phi(t, r, x) - \Phi(s, q, y)\| \leq e^{LH} D((r,x),(q,y)) + M\,|t - s|$ for $(t, r, x), (s, q, y) \in I \times I \times B$.

Proof. Choose $a, \delta > 0$ with $Q := [t_* - a, t_* + a] \times \overline{B}_\delta(x_*) \subseteq U$, and set $M_Q := \max_Q \|f\|$.
Choose $0 < h < a/2$ with $2hM_Q < \delta/2$, set $I := [t_* - h, t_* + h]$, $B := B_{\delta/2}(x_*)$, and $V := I \times \overline{B}_\delta(x_*)$.
Set $H := 2h$, $M := \max_V \|f\|$, and choose a state-Lipschitz constant L for f on V.

(i) Fix $(r, x) \in I \times B$, set $I_r^+ := [r, t_* + h]$ and $I_r^- := [t_* - h, r]$.
Since $I_r^\pm \times \overline{B}_{\delta/2}(x) \subseteq Q$ and $\left|I_r^\pm\right| \leq 2h$, Theorem 1.1.16, applied forward on I_r^+ and backward on I_r^-, gives a unique $u_{r,x} \in C^1(I, \mathbb{R}^n)$ with $u_{r,x}(r) = x$ and $u'_{r,x} = f(\cdot, u_{r,x})$.
For $t \in I$, $\|u_{r,x}(t) - x\| \leq M_Q\,|t - r| < \delta/2$, hence $\|u_{r,x}(t) - x_*\| < \delta$ and $(t, u_{r,x}(t)) \in V$.
Set $\Phi(t, r, x) := u_{r,x}(t)$; then $\Phi(r, r, x) = x$, $(t, \Phi(t, r, x)) \in V$, and $\partial_t \Phi(t, r, x) = f(t, \Phi(t, r, x))$.
(ii) Let $(t, r, x), (s, q, y) \in I \times I \times B$, $p := \max\{r, q\}$, and $D_0 := D((r,x),(q,y))$.
By (i) and $\|\partial_t \Phi\| \leq M$, $\|\Phi(p, r, x) - \Phi(p, q, y)\| \leq D_0$.
By Lemma 1.1.20(ii), after reversing parameter when $t < p$, $\|\Phi(t, r, x) - \Phi(t, q, y)\| \leq e^{L|t-p|} D_0 \leq e^{LH} D_0$.
The bound $\|\Phi(t, q, y) - \Phi(s, q, y)\| \leq M\,|t - s|$ and the triangle inequality give (ii).
Structural Commentary: Compare at the later start time, then apply Gronwall.
Key Insight: Initial-time error first becomes state error. □

Theorem 1.1.23. *Smooth Dependence and First Variational Equations*
Let $n, p \in \mathbb{N}$, $\Omega \subseteq \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^p$ be open, $f \in C^1(\Omega, \mathbb{R}^n)$, and $(t_0, x_0, \lambda_0) \in \Omega$.
Then $\exists I, B, \Lambda_0, \phi$ with $I \ni t_0$ compact, $B \ni x_0$ and $\Lambda_0 \ni \lambda_0$ open, and $\phi : I \times B \times \Lambda_0 \to \mathbb{R}^n$.
For $(x, \lambda) \in B \times \Lambda_0$, set $\gamma_{x,\lambda}(t) := (t, \phi(t, x, \lambda), \lambda)$.
Write $A_{x,\lambda} := D_x f \circ \gamma_{x,\lambda}$ and $G_{x,\lambda} := D_\lambda f \circ \gamma_{x,\lambda}$. The following hold:
(i) $\phi \in C^1(I \times B \times \Lambda_0, \mathbb{R}^n)$, $\phi(t_0, x, \lambda) = x$, and $\partial_t \phi(t, x, \lambda) = f(t, \phi(t, x, \lambda), \lambda)\ \forall (t, x, \lambda) \in I \times B \times \Lambda_0$.
(ii) $D_x\phi(\cdot, x, \lambda)$ is the unique solution of $Y' = A_{x,\lambda}Y$, $Y(t_0) = I_n$, in $C^1(I, \mathbb{R}^{n\times n})\ \forall (x, \lambda) \in B \times \Lambda_0$.
(iii) $D_\lambda\phi(\cdot, x, \lambda)$ is the unique solution of $Z' = A_{x,\lambda}Z + G_{x,\lambda}$, $Z(t_0) = 0_{n\times p}$, in $C^1(I, \mathbb{R}^{n\times p})\ \forall (x, \lambda) \in B \times \Lambda_0$.

Proof. Put $z := (x, \lambda)$, $z_0 := (x_0, \lambda_0)$, $F : \Omega \to \mathbb{R}^{n+p}$ by $F(t, z) := (f(t, x, \lambda), 0)$; then $F \in C^1(\Omega, \mathbb{R}^{n+p})$.
Choose $a, r > 0$ with $W := [t_0 - a, t_0 + a] \times \overline{B}_{2r}(z_0) \subseteq \Omega$. Set $H := \max_W \|F\|$.
Let $\tau := a$ if $H = 0$, and $\tau := \min\{a, \frac{r}{H}\}$ if $H > 0$. For $z \in B_r(z_0)$, $[t_0 - \tau, t_0 + \tau] \times \overline{B}_r(z) \subseteq W$.
By Lemma 1.1.15, choose a state-Lipschitz constant L_W for F on W, and set $I := [t_0 - \tau, t_0 + \tau]$.
By Theorem 1.1.16, applied forward and backward, $\forall z \in B_r(z_0)$, $\exists! \Phi_z \in C^1(I, \mathbb{R}^{n+p})$ with $\Phi_z(t_0) = z$ and $\Phi'_z = F(\cdot, \Phi_z)$. Define $\Phi(t, z) := \Phi_z(t)$. Choose open B, Λ_0 with $x_0 \in B$, $\lambda_0 \in \Lambda_0$, and $B \times \Lambda_0 \subseteq B_r(z_0)$.

(i) Since the last p components of F vanish, $\Phi(t, x, \lambda) = (\phi(t, x, \lambda), \lambda)$.
Hence $\phi(t_0, x, \lambda) = x$ and $\partial_t \phi(t, x, \lambda) = f(t, \phi(t, x, \lambda), \lambda)$.
By Theorem 1.1.21, applied forward and backward, $\|\Phi_z - \Phi_w\|_\infty \leq e^{\tau L_W} \|z - w\|$ for $z, w \in B_r(z_0)$.
Hence Φ and $\partial_t \Phi = F(t, \Phi)$ are continuous.
Fix $z \in B_r(z_0)$ and set $\mathcal{L}_z(t) := D_z F(t, \Phi_z(t))$. Since $\mathcal{L}_z$ is bounded on I, apply Theorem 1.1.16 finitely many times forward and backward to obtain $P_z \in C^1(I, \mathbb{R}^{(n+p)\times(n+p)})$ with $P'_z = \mathcal{L}_z P_z$ and $P_z(t_0) = I_{n+p}$. Set $C_0 := \max_W \|D_z F\|$; By Lemma 1.1.20(ii) $\|P_z\|_\infty \leq e^{2\tau C_0}$.
For $h \to 0$ with $z + h \in B_r(z_0)$, put $\Delta_h := \Phi_{z+h} - \Phi_z$ and $e_h := \Delta_h - P_z h$.
Set $\eta_{h,s} := \Phi_z + s\Delta_h$, $\mathcal{R}_h(t, s) := D_z F(t, \eta_{h,s}(t)) - \mathcal{L}_z(t)$.
Then $R_h(t) := \int_0^1 \mathcal{R}_h(t, s)\, ds$, $\varepsilon_h := \|R_h\|_\infty$; $\varepsilon_h \to 0$; $e'_h = \mathcal{L}_z e_h + R_h \Delta_h$, $e_h(t_0) = 0$, $\|\Delta_h\|_\infty \leq e^{\tau L_W} \|h\|$.
By Lemma 1.1.20(ii), $\|e_h\|_\infty = O(\varepsilon_h \|h\|) = o(\|h\|)$; thus $D_z\Phi = P_z$.
For $z, w \in B_r(z_0)$, $P_z - P_w$ satisfies $(P_z - P_w)' = \mathcal{L}_z(P_z - P_w) + (\mathcal{L}_z - \mathcal{L}_w)P_w$ and $(P_z - P_w)(t_0) = 0$.
By Lemma 1.1.20(ii), $\|P_z - P_w\|_\infty \leq 2\tau e^{4\tau C_0} \|\mathcal{L}_z - \mathcal{L}_w\|_\infty \to 0$ as $z \to w$. Thus Φ, hence ϕ, is C^1.
(ii) Fix (x, λ) and set $z = (x, \lambda)$. Put $Y := D_x\phi(\cdot, x, \lambda)$, $A := A_{x,\lambda}$, and $G := G_{x,\lambda}$.
Here $\mathcal{L}_z(\xi, \mu) = (A\xi + G\mu, 0)$ and $D_x\Phi = (Y, 0)$. The x-columns of $P'_z = \mathcal{L}_z P_z$ give $Y' = AY$, $Y(t_0) = I_n$.
If $\widetilde{Y}$ also solves this IVP, $W := Y - \widetilde{Y}$ satisfies $W' = AW$, $W(t_0) = 0$; By Lemma 1.1.20(ii) $W = 0$.
(iii) Fix (x, λ) and set $z = (x, \lambda)$. Put $Z := D_\lambda\phi(\cdot, x, \lambda)$, $A := A_{x,\lambda}$, and $G := G_{x,\lambda}$.
Here $\mathcal{L}_z(\xi, \mu) = (A\xi + G\mu, 0)$. Since $D_\lambda\Phi = (Z, I_p)$, the λ-columns give $Z' = AZ + G$, $Z(t_0) = 0_{n\times p}$.
If $\widetilde{Z}$ also solves this IVP, $W := Z - \widetilde{Z}$ satisfies $W' = AW$, $W(t_0) = 0$; By Lemma 1.1.20(ii) $W = 0$.

Structural Commentary: Lift parameters; differentiate the extended flow.
Key Insight: Flow derivatives satisfy variational equations. □

Theorem 1.1.24. *Higher-Order Smooth Dependence*
Let $k, n, p \in \mathbb{N}$, $k \geq 1$, $\Omega \subseteq \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^p$ open, $f \in C^k(\Omega, \mathbb{R}^n)$, and $q_0 = (t_0, x_0, \lambda_0) \in \Omega$.
Then $\exists I \ni t_0$ compact, $B \ni x_0$ open in $\mathbb{R}^n$, $\Lambda_0 \ni \lambda_0$ open in $\mathbb{R}^p$, and $\phi : D \to \mathbb{R}^n$, with $D := I \times B \times \Lambda_0$.
For $\Gamma_\phi(t, x, \lambda) := (t, \phi(t, x, \lambda), \lambda)$:
(i) $\Gamma_\phi(D) \subseteq \Omega$, $\phi(t_0, x, \lambda) = x$, and $\partial_t \phi = f \circ \Gamma_\phi$ on D.
(ii) $\phi \in C^k(D, \mathbb{R}^n)$.

Proof. Let $\mathsf{H}_{r,d}$ mean: every $F \in C^r(\Omega_d, \mathbb{R}^d)$, $\Omega_d \subseteq \mathbb{R} \times \mathbb{R}^d$ open, has a local C^r flow near each $(\tau, z_*) \in \Omega_d$.
By Theorem 1.1.23(i) with a dummy parameter, $\mathsf{H}_{1,d}$ holds $\forall d$. Assume $\mathsf{H}_{j,d}$ for all d. Let $F \in C^{j+1}(\Omega_d, \mathbb{R}^d)$, $(\tau, z_*) \in \Omega_d$, and let Ψ be its local flow. By $\mathsf{H}_{j,d}$, $\Psi \in C^j$. Set $Q := D_z \Psi$ and $E_d := \mathrm{Mat}(d, d, \mathbb{R})$.
By Theorem 1.1.23(ii), $\partial_t Q = D_z F(t, \Psi) Q$ and $Q(\tau, z) = I_d$.
Set $\mathcal{H}(t, \zeta, P) := (F(t, \zeta), D_z F(t, \zeta) P)$ on $\Omega_d \times E_d$, and set $Y := (\Psi, Q)$. Then $\mathcal{H} \in C^j$ and $Y_t = \mathcal{H}(t, Y)$, $Y(\tau, z) = (z, I_d)$.
By $\mathsf{H}_{j,d+d^2}$, the flow Θ of $\mathcal{H}$ is C^j. By uniqueness, $Y(t, z) = \Theta(t, z, I_d)$, so $Q \in C^j$.
By $D_z \Psi = Q \in C^j$ and $\partial_t \Psi = F(t, \Psi) \in C^j$, $\Psi \in C^{j+1}$. By induction, $\mathsf{H}_{r,d}$ holds for all $r, d \in \mathbb{N}$.
Set $m := n + p$, $z := (x, \lambda)$, $z_0 := (x_0, \lambda_0)$, $\widetilde{\Omega} := \{(t, z) : (t, x, \lambda) \in \Omega\}$, and $\widetilde{F}(t, z) := (f(t, x, \lambda), 0_p)$.
By $\mathsf{H}_{k,m}$, after shrinking, choose compact $I \ni t_0$, open $U_0 \ni z_0$, and $\Phi \in C^k(I \times U_0, \mathbb{R}^m)$ with $\partial_t \Phi = \widetilde{F}(t, \Phi)$ and $\Phi(t_0, z) = z$.
Choose $B \ni x_0$ and $\Lambda_0 \ni \lambda_0$ with $B \times \Lambda_0 \subseteq U_0$. Set $D := I \times B \times \Lambda_0$, $\pi_x := \pi_{\mathbb{R}^n}$, $\pi_\lambda := \pi_{\mathbb{R}^p}$, and $\phi := \pi_x \circ \Phi$.
(i) By $\partial_t(\pi_\lambda \circ \Phi) = 0$ and $(\pi_\lambda \circ \Phi)(t_0, x, \lambda) = \lambda$, $\Phi = (\phi, \lambda)$ on D.
By this identity and $(t, \Phi) \in \widetilde{\Omega}$, $\Gamma_\phi(D) \subseteq \Omega$; by $\Phi(t_0, x, \lambda) = (x, \lambda)$, $\phi(t_0, x, \lambda) = x$.
By $\partial_t \Phi = \widetilde{F}(t, \Phi)$ and $\phi = \pi_x \circ \Phi$, $\partial_t \phi = f \circ \Gamma_\phi$ on D.
(ii) By $\Phi \in C^k(I \times U_0, \mathbb{R}^m)$ and linearity of π_x, $\phi \in C^k(D, \mathbb{R}^n)$.
Structural Commentary: Bootstrap through the variational flow.
Key Insight: Parameters are frozen coordinates. □

Proposition 1.1.25. *Regular Perturbation Expansion*
Let $k, n \in \mathbb{N}$, $k \geq 1$, $\Omega \subseteq \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}$ open, $f \in C^k(\Omega, \mathbb{R}^n)$, and $q_0 = (t_0, x_0, \varepsilon_0) \in \Omega$.
Let $D := I \times \Lambda_0$, where $I \ni t_0$ is compact and $\Lambda_0 \ni \varepsilon_0$ is open, and let $\phi \in C^k(D, \mathbb{R}^n)$.
Set $\Gamma_\phi(t, \varepsilon) := (t, \phi(t, \varepsilon), \varepsilon)$ and $h_\varepsilon := \varepsilon - \varepsilon_0$.
Assume $\Gamma_\phi(D) \subseteq \Omega$, $\phi(t_0, \varepsilon) = x_0$, and $\partial_t \phi = f \circ \Gamma_\phi$.
For $0 \leq j \leq k$, set $Z_j := (z_0, \ldots, z_j)$.
For $g = g(t, Z_j, \varepsilon)$ and $0 \leq j < k$, set $\mathcal{D}_j g := \partial_\varepsilon g + \sum_{r=0}^{j} D_{z_r} g \, z_{r+1}$.
Set $f_0(t, z_0, \varepsilon) := f(t, z_0, \varepsilon)$ and $f_{j+1} := \mathcal{D}_j f_j$ for $0 \leq j < k$.
For $0 \leq j \leq k$, set $\phi_j(t) := \partial_\varepsilon^j \phi(t, \varepsilon_0)$ and $\Phi_j(t) := (\phi_0(t), \ldots, \phi_j(t))$.
Set $T_k(t, \varepsilon) := \sum_{j=0}^{k} \frac{\phi_j(t)}{j!} h_\varepsilon^j$.
Set $r_k(t, \varepsilon) := \phi(t, \varepsilon) - T_k(t, \varepsilon)$ and $\rho_k(\varepsilon) := \sup_{t \in I} \|r_k(t, \varepsilon)\|$.
Then:
(i) For $0 \leq j \leq k$, $\phi_j' = f_j(t, \Phi_j, \varepsilon_0)$ and $\phi_j(t_0) = \delta_{j0} x_0$.
(ii) $\rho_k(\varepsilon) = o(|h_\varepsilon|^k)$.
(iii) If $f \in C^{k+1}(\Omega, \mathbb{R}^n)$, then, after shrinking I and Λ_0, $\rho_k(\varepsilon) = O(|h_\varepsilon|^{k+1})$.

Proof. For $0 \leq j \leq k$, set $z_j := \partial_\varepsilon^j \phi$, $\widehat{Z}_j := (z_0, \ldots, z_j)$, and $R_j := f_j(t, \widehat{Z}_j, \varepsilon)$.
For $g = g(t, \varepsilon)$, set $(\mathcal{I} g)(t, \varepsilon) := \int_{t_0}^{t} g(s, \varepsilon) \, ds$.
(i) Since $R_0 = f(t, \phi, \varepsilon)$, the IVP is $z_0 = x_0 + \mathcal{I} R_0$. By the chain rule, $\partial_\varepsilon R_j = R_{j+1}$ for $0 \leq j < k$.
Base $j = 0$ is the IVP. If $z_j = \delta_{j0} x_0 + \mathcal{I} R_j$, then by differentiation under $\mathcal{I}$, $z_{j+1} = \mathcal{I} R_{j+1}$.
By induction, $z_j = \delta_{j0} x_0 + \mathcal{I} R_j$ for $0 \leq j \leq k$.
At $\varepsilon = \varepsilon_0$, $z_j = \phi_j$ and $R_j = f_j(t, \Phi_j, \varepsilon_0)$.
By the preceding identity, $\phi_j = \delta_{j0} x_0 + \mathcal{I}(f_j(\,\cdot\,, \Phi_j, \varepsilon_0))$. Differentiating in t proves (i).
(ii) Put $h := h_\varepsilon$ and $G_t(\eta) := \partial_\varepsilon^k \phi(t, \eta) - \phi_k(t)$.
By integral Taylor, $r_k(t, \varepsilon) = \frac{h^k}{(k-1)!} \int_0^1 (1 - s)^{k-1} G_t(\varepsilon_0 + sh) \, ds$.
Set $\omega(h) := \sup_{(t,s) \in I \times [0,1]} \|G_t(\varepsilon_0 + sh)\|$. By uniform continuity, $\omega(h) \to 0$.
By the formula above, $\rho_k(\varepsilon) \leq \frac{|h|^k}{k!} \omega(h) = o(|h|^k)$.
(iii) If $f \in C^{k+1}$, by Theorem 1.1.24, choose $\widetilde{I} \ni t_0$ and $\widetilde{\Lambda} \ni \varepsilon_0$.
Let $\widetilde{\phi} \in C^{k+1}(\widetilde{I} \times \widetilde{\Lambda}, \mathbb{R}^n)$ satisfy the same IVP.
By local uniqueness from Theorem 1.1.16, after shrinking $I \times \Lambda_0$, $\widetilde{\phi} = \phi$, so $\phi \in C^{k+1}(I \times \Lambda_0, \mathbb{R}^n)$.
Choose compact $J \Subset \Lambda_0$ with $\varepsilon_0 \in J^\circ$.
Set $C_J := \max_{(t,\eta) \in I \times J} \left\| \partial_\varepsilon^{k+1} \phi(t, \eta) \right\|$.
For $\varepsilon \in J$, by the integral remainder, $\rho_k(\varepsilon) \leq \frac{C_J |h_\varepsilon|^{k+1}}{(k+1)!}$.
Structural Commentary: Differentiate, then Taylor expand.
Key Insight: Coefficients satisfy forced IVPs. □

Example 1.1.26. *Linear Drag as a Regular Perturbation*
Let $g > 0$, $\varepsilon \geq 0$, and $v' = -\varepsilon v - g$, $v(0) = 0$. Then $v(t, \varepsilon) = \frac{g(e^{-\varepsilon t} - 1)}{\varepsilon}$ if $\varepsilon > 0$, and $v_0(t) := v(t, 0) = -gt$.

At $\varepsilon_0 = 0$, $v_1' = -v_0 = gt$, $v_1(0) = 0$, hence $v_1(t) = \frac{gt^2}{2}$ and $v(t,\varepsilon) = v_0(t) + \varepsilon v_1(t) + o(\varepsilon)$ on compact t-intervals.
For fixed $\varepsilon > 0$, $t \to +\infty$ gives $v(t,\varepsilon) \to -\frac{g}{\varepsilon}$ but $v_0(t) + \varepsilon v_1(t) \to +\infty$; the expansion is local for bounded t.

Theorem 1.1.27. *Unique Maximal Solution*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, $f \in C(U, \mathbb{R}^n)$, and $(t_0, x_0) \in U$.
Assume $\forall$ compact $V \subseteq U$, $\exists L_V < +\infty$ such that $\|f(t,p) - f(t,q)\| \le L_V \|p - q\|$ whenever $(t,p),(t,q) \in V$.
For an open interval $J \ni t_0$, write $u \in \mathcal{A}(J)$ iff $u \in C^1(J, \mathbb{R}^n)$, $u(t_0) = x_0$, $(t, u(t)) \in U$, and $u' = f(\cdot, u)$.
Let $\mathcal{S}$ be all such pairs (J,u). For $(J,u),(K,v) \in \mathcal{S}$, write $(J,u) \preceq (K,v)$ iff $J \subseteq K$ and $v|_J = u$. Then:

(i) $\exists$ a maximal $(I_*, \phi_*) \in \mathcal{S}$ with $I_* = (T_-, T_+)$.
(ii) $(J,u) \preceq (I_*, \phi_*)$ $\forall (J,u) \in \mathcal{S}$; hence the maximal solution is unique.

Proof. By Theorem 1.1.16, applied forward and backward, $\mathcal{S} \neq \emptyset$. For $(J,u),(K,v) \in \mathcal{S}$, set $E := \{t \in J \cap K : u(t) = v(t)\}$.
Then $t_0 \in E$, E is closed, and local uniqueness at each $s \in E$ makes E open in $J \cap K$.
Since $J \cap K$ is an interval, $E = J \cap K$; thus $u = v$ on $J \cap K$ $\forall (J,u),(K,v) \in \mathcal{S}$.

(i) Set $I_* := \bigcup_{(J,u)\in\mathcal{S}} J$ and let $\phi_*(t) := u(t)$ for any $(J,u) \in \mathcal{S}$ with $t \in J$. Agreement on overlaps makes ϕ_* well defined.
Since all J are open intervals containing t_0, $I_* = (T_-, T_+)$. Locally $\phi_* = u$, so $(I_*, \phi_*) \in \mathcal{S}$.
If $(I_*, \phi_*) \preceq (\widehat{I}, \widehat{\phi}) \in \mathcal{S}$, then $I_* \subseteq \widehat{I} \subseteq I_*$; hence $\widehat{I} = I_*$.
(ii) If $(J,u) \in \mathcal{S}$, then $J \subseteq I_*$ and overlap agreement gives $u = \phi_*|_J$; hence $(J,u) \preceq (I_*, \phi_*)$.
If (K,ψ) is maximal, then $(K,\psi) \preceq (I_*, \phi_*)$; maximality gives $K = I_*$ and $\psi = \phi_*$.

Structural Commentary: Local uniqueness makes solution germs compatible.
Key Insight: The maximal solution is their union. □

Lemma 1.1.28. *Extension Criterion at a Finite Endpoint*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, $f \in C(U, \mathbb{R}^n)$, and assume f is locally Lipschitz in x on compact subsets of U.
Let $\phi \in C^1((T_-, T_+), \mathbb{R}^n)$ satisfy $\phi' = f(\cdot, \phi)$, $(t, \phi(t)) \in U$, and $T_+ < +\infty$.
Then $\exists \varepsilon > 0$ and a solution $\widehat{\phi} : (T_-, T_+ + \varepsilon) \to \mathbb{R}^n$ with $\widehat{\phi}|_{(T_-,T_+)} = \phi$ iff $\exists t_m \uparrow T_+$ and $y \in \mathbb{R}^n$ such that $\phi(t_m) \to y$ and $(T_+, y) \in U$.

Proof.
($\Rightarrow$) Let $\widehat{\phi}$ be such an extension, choose $t_m \uparrow T_+$, and put $y := \widehat{\phi}(T_+)$. Then $\phi(t_m) = \widehat{\phi}(t_m) \to y$ and $(T_+, y) \in U$.
($\Leftarrow$) Choose $r, \eta > 0$ with $W := [T_+ - \eta, T_+ + \eta] \times \overline{B}_r(y) \subseteq U$ and set $M := \max_W \|f\|$.
Choose m large enough that $t_m > T_+ - \eta$, $a := \|\phi(t_m) - y\| < \frac{r}{2}$, and $Mh < \frac{r}{2}$ for $h := T_+ - t_m$; put $J := [t_m, T_+)$ and $B := B_r(y)$.
If $\tau \in J$ is the first exit from B, then $r \le a + M(\tau - t_m) \le a + Mh < r$, impossible. Hence $\phi(J) \subseteq B$.
For $s,t \in J$, $\|\phi(t) - \phi(s)\| \le M|t - s|$, so $\phi(t)$ is Cauchy as $t \uparrow T_+$. Since $\phi(t_m) \to y$, $\lim_{t\uparrow T_+} \phi(t) = y$.
By Theorem 1.1.16, $\exists \varepsilon > 0$ and a solution $\widetilde{\phi}$ on $[T_+, T_+ + \varepsilon)$ with $\widetilde{\phi}(T_+) = y$. Define $\widehat{\phi} = \phi$ on (T_-, T_+) and $\widehat{\phi} = \widetilde{\phi}$ on $[T_+, T_+ + \varepsilon)$.
Continuity of f gives $\phi'(t) \to f(T_+, y) = \widetilde{\phi}'(T_+)$; hence $\widehat{\phi} \in C^1((T_-, T_+ + \varepsilon), \mathbb{R}^n)$ and is the required extension.

Structural Commentary: A convergent endpoint subsequence traps the tail for gluing.
Key Insight: Finite endpoint limits are exactly extendible states. □

Corollary 1.1.29. *Compact Escape at a Finite Maximal Endpoint*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open and $f \in C(U, \mathbb{R}^n)$.
Assume $\forall C \Subset U$, $\exists L_C < +\infty$ such that $(t,p),(t,q) \in C \Rightarrow \|f(t,p) - f(t,q)\| \le L_C \|p - q\|$.
Let $J := (T_-, T_+)$ and let $\phi : J \to \mathbb{R}^n$ be maximal for $x' = f(t,x)$, with $\gamma(t) := (t, \phi(t)) \in U$. Then:

(i) $T_+ < +\infty \Rightarrow \forall K \Subset U$, $\exists \tau < T_+ : \gamma((\tau, T_+)) \cap K = \emptyset$.
(ii) $T_- > -\infty \Rightarrow \forall K \Subset U$, $\exists \tau > T_- : \gamma((T_-, \tau)) \cap K = \emptyset$.
(iii) If $U = \mathbb{R} \times \mathbb{R}^n$, then $T_+ < +\infty \Rightarrow \|\phi(t)\| \to +\infty$ as $t \uparrow T_+$ and $T_- > -\infty \Rightarrow \|\phi(t)\| \to +\infty$ as $t \downarrow T_-$.

Proof.
(i) If (i) fails for some $K \Subset U$, then $\exists t_m \uparrow T_+$ with $\gamma(t_m) \in K$. By compactness, after passing to a subsequence, $\gamma(t_m) \to (T_+, y) \in K \subseteq U$. By Lemma 1.1.28, ϕ admits a proper extension past T_+, contradiction.
(ii) Set $\widetilde{U} := \{(s,x) : (-s,x) \in U\}$, $\widetilde{f}(s,x) := -f(-s,x)$, $\widetilde{J} := (-T_+, -T_-)$, and $u(s) := \phi(-s)$.
Then $u : \widetilde{J} \to \mathbb{R}^n$ is maximal for $u' = \widetilde{f}(\cdot, u)$. For $K \Subset U$, put $\widetilde{K} := \{(-t,x) : (t,x) \in K\} \Subset \widetilde{U}$.
By (i) applied to u at $-T_-$, $\exists a < -T_-$ such that $(s, u(s)) \notin \widetilde{K}$ for $a < s < -T_-$.
With $\tau := -a$, $\gamma((T_-, \tau)) \cap K = \emptyset$.
(iii) Assume $U = \mathbb{R} \times \mathbb{R}^n$ and $T_+ < +\infty$. For $R > 0$, set $K_R := [T_+ - 1, T_+] \times \overline{B}_R(0)$.
By (i), $\exists \tau < T_+$ such that $\gamma((\tau, T_+)) \cap K_R = \emptyset$, hence $\|\phi(t)\| > R$ for $\max\{\tau, T_+ - 1\} < t < T_+$.
Since R is arbitrary, $\|\phi(t)\| \to +\infty$ as $t \uparrow T_+$. If $T_- > -\infty$, apply (ii) to $K_R^- := [T_-, T_- + 1] \times \overline{B}_R(0)$ to obtain $\|\phi(t)\| > R$ near T_-; hence $\|\phi(t)\| \to +\infty$ as $t \downarrow T_-$.

Structural Commentary: Compact recurrence creates an endpoint extension.
Key Insight: Finite maximal time forces compact escape. □

Corollary 1.1.30. *Global Existence under Linear Growth*
Let $f : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$ be continuous.
Assume (LL): $\forall$ compact $V \subseteq \mathbb{R} \times \mathbb{R}^n$, $\exists L_V < +\infty$ such that $\|f(t,p) - f(t,q)\| \le L_V \|p - q\|$ $\forall (t,p),(t,q) \in V$.
Assume (LG): $\forall T > 0$, $\exists M_T, L_T \ge 0$ such that $\|f(t,x)\| \le M_T + L_T \|x\|$ $\forall (t,x) \in [-T, T] \times \mathbb{R}^n$.
If $\phi : (T_-, T_+) \to \mathbb{R}^n$ is maximal and $\phi' = f(\cdot, \phi)$, then $(T_-, T_+) = \mathbb{R}$.

Proof. Fix $t_0 \in (T_-, T_+)$, $x_0 := \phi(t_0)$. If $T_+ < +\infty$, choose $T > \max\{|t_0|, |T_+|\}$ and M_T, L_T from (LG), and set $C_T := (\|x_0\| + M_T(T_+ - t_0))e^{L_T(T_+ - t_0)}$.
With $q(t) := \|\phi(t)\|$, $q(t) \le \|x_0\| + \int_{t_0}^t (M_T + L_T q(s))\, ds$ on $[t_0, T_+)$. Lemma 1.1.20(ii) gives $q(t) \le (\|x_0\| + M_T(t - t_0))e^{L_T(t - t_0)} \le C_T < +\infty$.
Thus $\Gamma_+ := \{(t, \phi(t)) : t \in [t_0, T_+)\} \subseteq K_T := [-T, T] \times \overline{B}_{C_T}(0)$. For $t_m \uparrow T_+$, compactness gives $\phi(t_{m_j}) \to y$ and $(T_+, y) \in K_T$. By (LL) and Lemma 1.1.28, ϕ extends past T_+, contradiction. Hence $T_+ = +\infty$.
Set $g(s,x) := -f(t_0 - s, x)$ and $u(s) := \phi(t_0 - s)$ on $(t_0 - T_+, t_0 - T_-)$. Then $u' = g(\cdot, u)$, u is maximal, and g satisfies (LL),(LG) on

bounded s-intervals. Apply right-endpoint result to u, then $t_0 - T_- = +\infty$, $T_- = -\infty$.
Structural Commentary: Gronwall bounds; compactness forces extension.
Key Insight: Linear growth rules out finite escape. □

Theorem 1.1.31. *Peano Local Existence Theorem*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, $f \in C(U, \mathbb{R}^n)$, and $(t_0, x_0) \in U$. Choose $T, \delta > 0$ with $V := [t_0, t_0 + T] \times \overline{B}_\delta(x_0) \subseteq U$.
Set $M := \max_V \|f\|$, $T_0 := \min\{T, \delta/M\}$ with $\delta/0 := +\infty$, and $I := [t_0, t_0 + T_0]$.
For $y : I \to \mathbb{R}^n$, write $\Gamma_y := \{(t, y(t)) : t \in I\}$. Then:

(i) $\exists \phi \in C(I, \mathbb{R}^n)$ with $\Gamma_\phi \subseteq V$ and $\phi = x_0 + \int_{t_0}^{(\cdot)} f(s, \phi(s))\, ds$ on I.
(ii) This ϕ lies in $C^1(I, \mathbb{R}^n)$ and satisfies $\phi(t_0) = x_0$, $\phi' = f(\cdot\,, \phi)$.

Proof. For $N \geq 1$, set $h_N := T_0/N$, $t_j := t_0 + j h_N$, $\tau_N(t) := t_j$ on $[t_j, t_{j+1})$ for $0 \leq j < N$, and $\tau_N(t_N) := t_{N-1}$.
Construct x_N recursively by $x_N(t_0) := x_0$ and $x_N(t) := x_N(t_j) + (t - t_j) f(t_j, x_N(t_j))$ for $t \in [t_j, t_{j+1}]$, $0 \leq j < N$.
Write $(\mathcal{I}G)(t) := \int_{t_0}^t G(s)\, ds$, $Y_N := (\tau_N, x_N \circ \tau_N)$, and $F_N := f \circ Y_N$; then $x_N = x_0 + \mathcal{I} F_N$.
By induction, $\|x_N(t) - x_0\| \leq M(t - t_0) \leq \delta$ and $\|x_N(t) - x_N(s)\| \leq M\,|t - s|$.
Hence $\Gamma_{x_N} \subseteq V$ and (x_N) is uniformly bounded/equicontinuous.

(i) By Theorem 8.2.1, applied coordinatewise, $x_{N_k} \to \phi \in C(I, \mathbb{R}^n)$ uniformly.
Then $\Gamma_\phi \subseteq V$. Set $Y_\phi := (\mathrm{id}_I, \phi)$ and $f_\phi := f \circ Y_\phi$.
Since $\|\mathrm{id}_I - \tau_N\|_\infty \leq h_N$ and $\|x_N - x_N \circ \tau_N\|_\infty \leq M h_N$, $Y_{N_k}(I), Y_\phi(I) \subseteq V$ and $Y_{N_k} \to Y_\phi$ uniformly.
By uniform continuity of $f|_V$, $F_{N_k} \to f_\phi$ uniformly.
Passing to the limit in $x_{N_k} = x_0 + \mathcal{I} F_{N_k}$ gives $\phi = x_0 + \mathcal{I} f_\phi$.
(ii) Since $f_\phi \in C(I, \mathbb{R}^n)$, by Theorem 2.2.1 applied to (i), $\phi \in C^1(I, \mathbb{R}^n)$, $\phi(t_0) = x_0$, and $\phi' = f_\phi$.

Structural Commentary: Euler polygons plus Arzelà–Ascoli produce a convergent approximate trajectory.
Key Insight: Continuity yields existence through compactness, without uniqueness. □

Definition 1.1.32. *Osgood Modulus of Continuity*
Let $\rho \in C([0, +\infty), [0, +\infty))$.

(i) ρ is a *modulus of continuity* iff $\rho(0) = 0$ and ρ is nondecreasing.
(ii) A modulus ρ satisfies the *Osgood condition* iff $\int_0^1 \frac{dr}{\rho(r)} = +\infty$, interpreted as an improper extended integral; equivalently, $\int_0^a \frac{dr}{\rho(r)} = +\infty\ \forall a > 0$.

Key Insight: Osgood divergence prevents a zero separation from becoming positive in finite time.

Example 1.1.33. *Lipschitz, Hölder, and Almost-Lipschitz Moduli*
For $0 < \alpha < 1$, set $\rho_1(r) := r$, $\rho_\alpha(r) := r^\alpha$, $\rho_{\log}(0) := 0$, and $\rho_{\log}(r) := r(1 + |\log r|)$ for $r > 0$.
These functions are continuous, nondecreasing, and vanish at 0.
Since $\int_0^1 \frac{dr}{r} = +\infty$ and $\int_0^1 r^{-\alpha}\, dr = \frac{1}{1-\alpha} < +\infty$, ρ_1 is Osgood while the Hölder modulus ρ_α is not.
For the almost-Lipschitz modulus, $s = -\log r$ gives $\int_0^1 \frac{dr}{r(1+|\log r|)} = \int_0^{+\infty} \frac{ds}{1+s} = +\infty$, so $\rho_{\log}$ is Osgood.

Theorem 1.1.34. *Osgood Uniqueness Criterion*
Let $n \in \mathbb{N}$, $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, $f \in C(U, \mathbb{R}^n)$, $(t_0, x_0) \in U$, $T > t_0$, and $\delta > 0$.
Put $J := [t_0, T]$, $V := J \times \overline{B}_\delta(x_0)$, and assume $V \subseteq U$.
Let $\rho \in C([0, +\infty), [0, +\infty))$ be nondecreasing, $\rho(0) = 0$, and $\int_0^a \frac{dr}{\rho(r)} = +\infty\ \forall a > 0$.
For $(t, p), (t, q) \in V$, set $A_t(p, q) := |\langle p - q, f(t, p) - f(t, q)\rangle|$.
Assume $\exists C \geq 0$ such that $A_t(p, q) \leq C\,\|p - q\|\,\rho(\|p - q\|)\ \forall (t, p), (t, q) \in V$.
For $w \in C(J, \mathbb{R}^n)$, set $\Gamma_w := \{(t, w(t)) : t \in J\}$.
If $u, v \in C^1(J, \mathbb{R}^n)$ satisfy $\Gamma_u \cup \Gamma_v \subseteq V$, $u(t_0) = v(t_0) = x_0$, $u' = f(\cdot\,, u)$, and $v' = f(\cdot\,, v)$, then $u = v$ on J.

Proof. Assume $S := \{t \in (t_0, T] : u(t) \neq v(t)\} \neq \emptyset$ and fix $t \in S$. Put $\Delta := u - v$ and $d := \|\Delta\|$.
For $s \in J$, set $E(s) := f(s, u(s)) - f(s, v(s))$. The set $Z_t := \{s \in [t_0, t] : d(s) = 0\}$ is nonempty and compact; set $a := \max Z_t$.
Then $a < t$, $d(a) = 0$, and $d > 0$ on $(a, t]$. On $(a, t]$, $d \in C^1$ and $d'(s) = \frac{\langle \Delta(s), E(s)\rangle}{d(s)}$. Hence $d'(s) \leq \frac{A_s(u(s), v(s))}{d(s)} \leq C\rho(d(s))$.
For $m \geq 1$, set $H_m(r) := \int_0^r \frac{dq}{\rho(q) + \frac{1}{m}}$. For $s \in (a, t]$, set $b_m(s) := \frac{\rho(d(s))}{\rho(d(s)) + \frac{1}{m}} \leq 1$.
If $a < r < t$, then on $[r, t]$, $(H_m \circ d)'(s) = \frac{d'(s)}{\rho(d(s)) + \frac{1}{m}} \leq C b_m(s) \leq C$.
Thus $H_m(d(t)) - H_m(d(r)) \leq C(t - r)$. Letting $r \downarrow a$ gives $H_m(d(t)) \leq C(t - a)$.
By Theorem 1.3.1, $H_m(d(t)) \uparrow \int_0^{d(t)} \frac{dq}{\rho(q)} = +\infty$, contradiction. Hence $S = \emptyset$ and $u = v$.
Structural Commentary: Regularize $1/\rho$; separate variables.
Key Insight: Divergence forbids first separation. □

Proposition 1.1.35. *Time Translation and the Local Flow Law*
Let $D \subseteq \mathbb{R}^n$ be open and $f : D \to \mathbb{R}^n$. For $(a, y) \in \mathbb{R} \times D$, let $\mathcal{S}(a, y)$ contain the pairs (I, u) such that $I \ni a$ is an open interval, $u \in C^1(I, D)$, $u(a) = y$, and $u' = f(u)$.
Assume $\mathcal{S}(a, y) \neq \emptyset\ \forall (a, y) \in \mathbb{R} \times D$, and $u = v$ on $I \cap J\ \forall (a, y) \in \mathbb{R} \times D$, $\forall (I, u), (J, v) \in \mathcal{S}(a, y)$.
For $x \in D$, let $\phi_x : I_x \to D$ be the maximal solution with $0 \in I_x$, $\phi_x(0) = x$, and $\phi_x' = f(\phi_x)$.
Define $\mathcal{D}_\Phi := \{(t, x) \in \mathbb{R} \times D : t \in I_x\}$ and $\Phi_t(x) := \phi_x(t)$ for $(t, x) \in \mathcal{D}_\Phi$.

(i) If $\phi : I \to D$, $0 \in I$, and $\phi' = f(\phi)$, then $\psi_\tau(t) := \phi(t - \tau)$ on $\tau + I$ satisfies $\psi_\tau' = f(\psi_\tau)\ \forall \tau \in \mathbb{R}$.
Its initial value is $\psi_\tau(\tau) = \phi(0)$.
(ii) $(0, x) \in \mathcal{D}_\Phi$ and $\Phi_0(x) = x\ \forall x \in D$; hence $\Phi_0 = \mathrm{id}_D$.
(iii) If $(s, x), (t, \Phi_s(x)), (t + s, x) \in \mathcal{D}_\Phi$, then $\Phi_{t+s}(x) = \Phi_t(\Phi_s(x))$.

Proof.

(i) For $t \in \tau + I$, $\psi_\tau'(t) = \phi'(t - \tau) = f(\phi(t - \tau)) = f(\psi_\tau(t))$ and $\psi_\tau(\tau) = \phi(0)$.
(ii) Since $0 \in I_x$, $(0, x) \in \mathcal{D}_\Phi$ and $\Phi_0(x) = \phi_x(0) = x\ \forall x \in D$.

(iii) Set $R := (I_x - s) \cap I_{\Phi_s(x)}$. Then $0, t \in R$ and $(r+s, x), (r, \Phi_s(x)) \in \mathcal{D}_\Phi$ for $r \in R$.
Define $u, v : R \to D$ by $u(r) := \Phi_{r+s}(x)$, $v(r) := \Phi_r(\Phi_s(x))$.
Then $u' = f(u)$ by (i), $v' = f(v)$, $u(0) = v(0) = \Phi_s(x)$.
Uniqueness gives $u = v$ on R, so $\Phi_{t+s}(x) = \Phi_t(\Phi_s(x))$.

Structural Commentary: Shift time; use uniqueness.
Key Insight: Autonomy makes elapsed time compose. □

1.2 Linear Systems and Stability

Scalar first-order linear equations admit an explicit evolution factor and a variation-of-constants representation.

Proposition 1.2.1. *Scalar Variation of Constants*
Let $I \subseteq \mathbb{R}$ be open, $a, g \in C(I, \mathbb{R})$, and $(t_0, x_0) \in I \times \mathbb{R}$.
Put $E(t,s) := \exp\left(\int_s^t a(r)\,dr\right)$ and $\phi(t) := E(t,t_0)x_0 + \int_{t_0}^t E(t,s)g(s)\,ds$. Then:

(i) $\phi \in C^1(I, \mathbb{R})$ and $(\phi' - a\phi, \phi(t_0)) = (g, x_0)$.
(ii) If $x \in C^1(I, \mathbb{R})$ and $(x' - ax, x(t_0)) = (g, x_0)$, then $x = \phi$.

Proof.
(i) Let $B(t) := x_0 + \int_{t_0}^t E(t_0, s)g(s)\,ds$. By additivity, $E(t,s) = E(t,t_0)E(t_0,s)$, so $\phi(t) = E(t,t_0)B(t)$.
By Theorem 2.2.1, $B \in C^1$, $\partial_t E(t,t_0) = a(t)E(t,t_0)$, and $B'(t) = E(t_0,t)g(t)$.
Hence $\phi \in C^1$, $\phi'(t) = a(t)\phi(t) + E(t,t_0)E(t_0,t)g(t) = a(t)\phi(t) + g(t)$, and $\phi(t_0) = x_0$.
(ii) If $(x' - ax, x(t_0)) = (g, x_0)$, then $\frac{d}{dt}(E(t_0,t)x(t)) = E(t_0,t)(x'(t) - a(t)x(t)) = E(t_0,t)g(t)$.
By Theorem 2.2.2, $E(t_0,t)x(t) = x_0 + \int_{t_0}^t E(t_0,s)g(s)\,ds$.
Multiplying by $E(t,t_0)$ and using $E(t,t_0)E(t_0,s) = E(t,s)$ gives $x(t) = \phi(t)$.

Structural Commentary: $E(t_0,t)$ removes $a(t)x$; integration accumulates g.
Key Insight: $(E(t_0,t)x)' = E(t_0,t)g$. □

Proposition 1.2.2. *Fiber-Preserving Change of Variables*
Let $\Omega, \widetilde{\Omega} \subseteq \mathbb{R}^2$ be open, $f : \Omega \to \mathbb{R}$, and $T : \Omega \to \widetilde{\Omega}$ be a C^1 diffeomorphism.
Assume $T(t,x) = (\sigma(t), \eta(t,x))$ and $T^{-1}(s,y) = (\tau(s), \xi(s,y))$. Put $G := \partial_t\eta + \partial_x\eta\, f$.
Define $\widetilde{f} : \widetilde{\Omega} \to \mathbb{R}$ by $\widetilde{f}(s,y) := \tau'(s)G(\tau(s), \xi(s,y))$.
Let $I \subseteq \mathbb{R}$ be an interval, $x \in C^1(I, \mathbb{R})$, $\Gamma_x := \{(t, x(t)) : t \in I\} \subseteq \Omega$, and $J := \sigma(I)$.
Set $y : J \to \mathbb{R}$ by $y(s) := \eta(\tau(s), x(\tau(s)))$. Then $y \in C^1(J, \mathbb{R})$, and $x' = f(\cdot\,, x)$ on I iff $y' = \widetilde{f}(\cdot\,, y)$ on J.

Proof. Since $\det DT(t,x) = \sigma'(t)\partial_x\eta(t,x) \neq 0$, $\sigma' \neq 0$, $\partial_x\eta \neq 0$, and $\tau'(\sigma(t))\sigma'(t) = 1$.

($\Rightarrow$) If $x' = f(\cdot\,, x)$ and $s \in J$, then $y'(s) = \tau'(s)G(\tau(s), x(\tau(s)))$. Since $\xi(s, y(s)) = x(\tau(s))$, $y'(s) = \widetilde{f}(s, y(s))$.
($\Leftarrow$) Let $t \in I$. Differentiating $y(\sigma(t)) = \eta(t, x(t))$ gives $\sigma'(t)y'(\sigma(t)) = \partial_t\eta(t,x(t)) + \partial_x\eta(t,x(t))x'(t)$.
Since $y' = \widetilde{f}(\cdot\,, y)$, $\sigma'(t)y'(\sigma(t)) = G(t, x(t))$. Hence $\partial_x\eta(t,x(t))[x'(t) - f(t,x(t))] = 0$, so $x' = f(\cdot\,, x)$.

Structural Commentary: Transform graphs; apply the chain rule.
Key Insight: $\widetilde{f}$ is the pushed-forward vector field. □

Method 1.2.3. *Homogeneous First-Order Reduction*
Let $D \subseteq \mathbb{R}$ be open, let $f \in C(D, \mathbb{R})$, and let $I \subseteq \mathbb{R} \setminus \{0\}$ be an interval. To solve $x' = f(x/t)$ on a branch for which $x(t)/t \in D$:

(i) Set $y := x/t$, so $x = ty$.
(ii) Differentiate to obtain $y' = (tx' - x)/t^2 = [f(y) - y]/t$.
(iii) Each $c \in D$ satisfying $f(c) = c$ gives the constant-ratio solution $x(t) = ct$.
(iv) On every subinterval where $f(y) \neq y$, separate $dy/(f(y) - y) = dt/t$, solve for y, and recover $x = ty$.

Method 1.2.4. *Affine-Fractional First-Order Reduction*
Let $D \subseteq \mathbb{R}$ be open, let $f \in C(D, \mathbb{R})$, put $A(t,x) := ax + bt + c$ and $B(t,x) := \alpha x + \beta t + \gamma$, and set $\Delta := a\beta - \alpha b$.
Work on a solution interval on which $B(t, x(t)) \neq 0$ and $A(t, x(t))/B(t, x(t)) \in D$.

(i) If $\Delta \neq 0$, there is a unique (t_*, x_*) with $A(t_*, x_*) = B(t_*, x_*) = 0$. Set $s := t - t_*$ and $y := x - x_*$.
Then $\frac{dy}{ds} = f(\frac{ay+bs}{\alpha y+\beta s})$; for $s \neq 0$, $z := y/s$ satisfies $s\frac{dz}{ds} = f(\frac{az+b}{\alpha z+\beta}) - z$.
(ii) If $\Delta = 0$ and $(a,b) \neq (0,0)$, choose the unique $\lambda \in \mathbb{R}$ with $(\alpha, \beta) = \lambda(a,b)$ and set $\widehat{f}(u) := f(\frac{u+c}{\lambda u+\gamma})$ wherever the quotient lies in D.
If $a \neq 0$, use $u := ax + bt$: $u' = a\widehat{f}(u) + b$, with $x = \frac{u-bt}{a}$. If $a = 0$, then $x' = \widehat{f}(bt)$.

Example 1.2.5. *Euler Equation Under Logarithmic Time*
For $t > 0$, set $s := \log t$ and $y(s) := x(e^s)$. Then $x'(t) = t^{-1}y'(s)$ and $x''(t) = t^{-2}(y''(s) - y'(s))$.
Hence Euler equation $t^2x'' + 3tx' + x = 2/t$ becomes constant-coefficient equation $y'' + 2y' + y = 2e^{-s}$.

Proposition 1.2.6. *Exact First-Order Equations*
Let $R := I \times J$ be an open rectangle, let $p, q \in C^1(R, \mathbb{R})$, and fix $(x_0, y_0) \in R$. Then:

(i) If $F \in C^2(R, \mathbb{R})$ satisfies $\partial_y F = p$ and $\partial_x F = q$, then $\partial_x p = \partial_y q$ on R.
(ii) If $\partial_x p = \partial_y q$ on R, then $F_0(x,y) := \int_{x_0}^x q(s, y_0)\,ds + \int_{y_0}^y p(x,r)\,dr$ belongs to $C^2(R, \mathbb{R})$ and satisfies $\partial_y F_0 = p$, $\partial_x F_0 = q$.
(iii) Under the hypothesis of (ii), every $F_1 \in C^2(R, \mathbb{R})$ satisfying $\partial_y F_1 = p$, $\partial_x F_1 = q$ has the form $F_1 = F_0 + c$ for a unique $c \in \mathbb{R}$.
(iv) Under the hypothesis of (ii), for every interval $L \subseteq I$ and every $y \in C^1(L, J)$, $p(\cdot\,, y)y' + q(\cdot\,, y) = 0$ iff $F_0(\cdot\,, y)$ is constant on L.

Proof.
(i) By Corollary 3.2.8, $\partial_x p = \partial_x\partial_y F = \partial_y\partial_x F = \partial_y q$.
(ii) The one-variable fundamental theorem gives $\partial_y F_0 = p$ and $\partial_x F_0 = q(x, y_0) + \int_{y_0}^y \partial_x p(x,r)\,dr$. By the hypothesis and the same theorem, $\partial_x F_0 = q(x,y_0) + \int_{y_0}^y \partial_y q(x,r)\,dr = q(x,y)$. Since these first partials are C^1, $F_0 \in C^2(R, \mathbb{R})$.

(iii) Set $H := F_1 - F_0$. Then $\partial_x H = \partial_y H = 0$. Applying the one-variable fundamental theorem first along the horizontal segment and then along the vertical segment gives $H(x,y) = H(x_0,y_0)$ for every $(x,y) \in R$. Thus $F_1 = F_0 + c$, and evaluation at (x_0,y_0) makes c unique.

(iv) The chain rule gives $(F_0(\,\cdot\,,y))' = q(\,\cdot\,,y) + p(\,\cdot\,,y)y'$. Therefore the differential equation holds exactly when this derivative vanishes, which on an interval is equivalent to constancy.

Structural Commentary: Build a potential; differentiate along graphs.
Key Insight: Mixed partials are the compatibility condition. □

Method 1.2.7. *Integrating Factor Depending Only on x*
Let $R := I \times J \subseteq \mathbb{R}^2$ be an open rectangle, let $p, q \in C^1(R,\mathbb{R})$, assume $p \neq 0$ on R, and fix $x_* \in I$. For $p(x,y)y' + q(x,y) = 0$:

(i) Set $r(x,y) := (\partial_y q - \partial_x p)/p$.
(ii) If $r(x,y) = r_0(x)$ on R, set $\mu(x) := \exp(\int_{x_*}^{x} r_0(s)\,ds)$.
(iii) Multiply by μ: $\partial_x(\mu p) = \mu(r_0 p + \partial_x p) = \mu \partial_y q = \partial_y(\mu q)$, so $\mu p\, y' + \mu q = 0$ is exact by Proposition 1.2.6.

For example, on either half-plane $x > 0$ or $x < 0$, $xy' + 3x - 2y = 0$ has $r_0(x) = -3/x$, so one may take the nonvanishing factor $\mu(x) = x^{-3}$.
A potential is $F(x,y) = y/x^2 - 3/x$, and the solutions are $y = 3x + Cx^2$.

Method 1.2.8. *Bernoulli Linearization*
Let $I \subseteq \mathbb{R}$ be open, let $a, b \in C(I,\mathbb{R})$, and let $n \in \mathbb{R} \setminus \{0,1\}$. On an interval $J \subseteq I$, consider a positive solution $x \in C^1(J,(0,+\infty))$ of $x' = a(t)x + b(t)x^n$.

(i) Set $y := x^{1-n}$.
(ii) Linearize: $y' = (1-n)x^{-n}x' = (1-n)a(t)y + (1-n)b(t)$ on J.
(iii) Solve $y' = \alpha y + \beta$ with $\alpha := (1-n)a$, $\beta := (1-n)b$ (Proposition 1.2.1); recover $x = y^{1/(1-n)}$ on $\{y > 0\}$.

Method 1.2.9. *Riccati Linearization from a Particular Solution*
Let $I \subseteq \mathbb{R}$ be open, $a, b, c \in C(I,\mathbb{R})$, and let $x_p \in C^1(I,\mathbb{R})$ solve $x_p' = ax_p + bx_p^2 + c$.
Let $x \in C^1(J,\mathbb{R})$ solve $x' = ax + bx^2 + c$ on an interval $J \subseteq I$ on which $x \neq x_p$.

(i) Set $u := x - x_p$ and $y := u^{-1}$ on J.
(ii) Subtract and invert: $u' = (a + 2bx_p)u + bu^2$, so $y' = -(a + 2bx_p)y - b$.
(iii) Solve $y' = \alpha y + \beta$ with $\alpha := -(a + 2bx_p)$, $\beta := -b$ (Proposition 1.2.1); recover $x = x_p + y^{-1}$ on $\{y \neq 0\}$.

Theorem 1.2.10. *Autonomous Matrix Evolution and Variation of Constants*
Let $A \in \mathbb{C}^{n\times n}$, $t_0 \in \mathbb{R}$, $x_0 \in \mathbb{C}^n$, and $g \in C(\mathbb{R},\mathbb{C}^n)$. For the matrix exponential from Definition 6.5.1, the following statements hold:

(i) $e^{0A} = I_n$, *and* $\forall s,t \in \mathbb{R}$, $e^{(t+s)A} = e^{tA}e^{sA}$, $(e^{tA})^{-1} = e^{-tA}$, *and* $\frac{d}{dt}e^{tA} = Ae^{tA} = e^{tA}A$.
(ii) $\exists!\, x \in C^1(\mathbb{R},\mathbb{C}^n)$ *with* $(x' - Ax, x(t_0)) = (0, x_0)$, *namely* $x(t) = e^{(t-t_0)A}x_0$.
(iii) $\exists!\, x \in C^1(\mathbb{R},\mathbb{C}^n)$ *with* $(x' - Ax, x(t_0)) = (g, x_0)$, *namely* $x(t) = e^{(t-t_0)A}x_0 + \int_{t_0}^{t} e^{(t-s)A}g(s)\,ds$.

Proof. Fix a submultiplicative matrix norm. Since $\|t^k A^k/k!\| \le |t|^k \|A\|^k/k!$, the defining series converges absolutely for every $t \in \mathbb{C}$. On bounded real t-intervals, it and its termwise derivative converge uniformly.

(i) The identities at $t = 0$ and for the derivative follow from the series. Absolute convergence permits the Cauchy product, and the binomial theorem gives $e^{tA}e^{sA} = \sum_{m=0}^{\infty} \frac{(t+s)^m A^m}{m!} = e^{(t+s)A}$. Taking $s = -t$ gives $e^{tA}e^{-tA} = I_n$.

(ii) Differentiation gives $x' = Ae^{(t-t_0)A}x_0 = Ax$ and $x(t_0) = x_0$.
If y is another solution, then $(e^{-(t-t_0)A}y(t))' = 0$, so $y(t) = e^{(t-t_0)A}x_0$.

(iii) Put $u(t) := e^{-(t-t_0)A}x(t)$. Then $u'(t) = e^{-(t-t_0)A}g(t)$, hence $u(t) = x_0 + \int_{t_0}^{t} e^{-(s-t_0)A}g(s)\,ds$. Multiplication by $e^{(t-t_0)A}$ and (i) give the formula. Conversely, differentiation verifies the equation and initial value; the difference of two solutions is zero by (ii).

Structural Commentary: The inverse exponential removes the homogeneous drift.
Key Insight: Matrix evolution transports forcing impulses from s to t. □

Proposition 1.2.11. *Pure Modes for Powers and Exponentials*
Let $A \in \mathrm{Mat}(n,n,\mathbb{C})$ be diagonalizable with $A = S\Lambda S^{-1}$, where $\Lambda = \mathrm{diag}(\lambda_1,\dots,\lambda_n)$ and the columns of S are $\mathbf{v}_1,\dots,\mathbf{v}_n$. If $\mathbf{x}_0 = \sum_{j=1}^{n} c_j\mathbf{v}_j$, then $A^k\mathbf{x}_0 = \sum_{j=1}^{n} c_j\lambda_j^k\mathbf{v}_j$ for $k \ge 0$; and $e^{tA}\mathbf{x}_0 = \sum_{j=1}^{n} c_j e^{\lambda_j t}\mathbf{v}_j$ for $t \in \mathbb{C}$.

Proof. Let $c = (c_1,\dots,c_n)^t$, so $\mathbf{x}_0 = Sc$.
Then $A^k = S\Lambda^k S^{-1}$, and Definition 6.5.1 gives $e^{tA} = S\left(\sum_{r=0}^{\infty} \frac{t^r\Lambda^r}{r!}\right)S^{-1} = S\,\mathrm{diag}(e^{\lambda_1 t},\dots,e^{\lambda_n t})S^{-1}$.
Applying these two formulas to Sc gives the stated identities.
Structural Commentary: Eigenbasis coordinates decouple powers and exponentials.
Key Insight: Diagonalization turns coupled evolution into independent scalar modes. □

Theorem 1.2.12. *Principal Matrix, Liouville Formula, and Variation of Constants*
Let $A \in C(\mathbb{R},\mathbb{C}^{n\times n})$. Then $\exists!\,\Pi : \mathbb{R}^2 \to \mathbb{C}^{n\times n}$ such that $\forall s,t \in \mathbb{R}$, $\partial_t\Pi(t,s) = A(t)\Pi(t,s)$ and $\Pi(s,s) = I_n$. The following statements hold:

(i) $\forall r,s,t \in \mathbb{R}$, $\Pi(t,r)\Pi(r,s) = \Pi(t,s)$ *and* $\Pi(t,s)^{-1} = \Pi(s,t)$.
(ii) $\forall s,t \in \mathbb{R}$, $\det\Pi(t,s) = \exp\left(\int_s^t \mathrm{tr}\,A(r)\,dr\right)$.
(iii) If $g \in C(\mathbb{R},\mathbb{C}^n)$ and $x_s \in \mathbb{C}^n$, then $\exists!\, x \in C^1(\mathbb{R},\mathbb{C}^n)$ with $(x' - Ax, x(s)) = (g, x_s)$, namely $x(t) = \Pi(t,s)x_s + \int_s^t \Pi(t,r)g(r)\,dr$ for $t \in \mathbb{R}$.

The matrix $\Pi(t,s)$ is the principal matrix solution from s; any matrix solution $X' = AX$ with $\det X(s) \neq 0$ is a fundamental matrix solution.

Proof. Identify $\mathbb{C}^n$ with $\mathbb{R}^{2n}$. For the canonical basis $e_1, \dots, e_n$, Theorem 1.1.27 and Corollary 1.1.30 give a unique global solution of $x' = A(t)x$, $x(s) = e_j$; use these solutions as the columns of $\Pi(t,s)$. Existence and uniqueness of Π hold columnwise.

(i) For fixed r, s, both $t \mapsto \Pi(t,r)\Pi(r,s)$ and $t \mapsto \Pi(t,s)$ solve $X' = A(t)X$ and agree at $t = r$; hence they coincide. Applying the cocycle law to the triples (s,t,s) and (t,s,t) gives $I_n = \Pi(s,t)\Pi(t,s) = \Pi(t,s)\Pi(s,t)$, so $\Pi(t,s)^{-1} = \Pi(s,t)$. If $X(t) := \Pi(t,0)$, then $\Pi(t,s) = X(t)X(s)^{-1}$; hence Π is jointly continuous.

(ii) Let $X(t) := \Pi(t,s)$ and write its columns as $x_1(t), \dots, x_n(t)$. The Leibniz formula and $x_j' = Ax_j$ give $\frac{d}{dt} \det X(t) = \sum_{j=1}^{n} \det(x_1, \dots, Ax_j, \dots, x_n)$ $\operatorname{tr}(A(t)) \det X(t)$. Multiplying by $\exp(-\int_s^t \operatorname{tr} A(r)\, dr)$ and using $\det X(s) = 1$ gives the claimed formula.

(iii) Differentiating the asserted formula gives $x' = A(t)x + g(t)$ and $x(s) = x_s$. If x, y have the same data, then $z := x - y$ solves $z' = A(t)z$, $z(s) = 0$, so the defining property of Π gives $z(t) = \Pi(t,s)z(s) = 0$.

Structural Commentary: Columnwise existence builds Π; uniqueness forces its cocycle law.
Key Insight: $\Pi(t,s)$ transports states and forcing between arbitrary times. □

Method 1.2.13. *Solving $\mathbf{x}'(t) = A\mathbf{x}(t)$ by Jordan Form*
Let $A \in \mathbb{C}^{n\times n}$ and $\mathbf{x}_0 \in \mathbb{C}^n$. To solve $\mathbf{x}'(t) = A\mathbf{x}(t)$ with $\mathbf{x}(0) = \mathbf{x}_0$:

(i) By Theorem 6.2.1, choose $S \in GL_n(\mathbb{C})$ with $A = SJS^{-1}$, where $J = \bigoplus_{i=1}^{r} J_{k_i}(\lambda_i)$.
(ii) Set $\mathbf{y}(t) = S^{-1}\mathbf{x}(t)$ and $\mathbf{y}_0 = S^{-1}\mathbf{x}_0$. Then $\mathbf{y}'(t) = J\mathbf{y}(t)$ and $\mathbf{x}(t) = S\mathbf{y}(t)$.
(iii) Split $\mathbf{y} = (\mathbf{y}_1, \dots, \mathbf{y}_r)$ according to the Jordan blocks. Then $\mathbf{y}_i'(t) = J_{k_i}(\lambda_i)\mathbf{y}_i(t)$.
(iv) By Proposition 6.5.3, $\mathbf{y}_i(t) = e^{tJ_{k_i}(\lambda_i)}\mathbf{y}_i(0) = e^{\lambda_i t} \sum_{q=0}^{k_i-1} \frac{t^q}{q!} J_{k_i}(0)^q \mathbf{y}_i(0)$ for $1 \le i \le r$.
Differentiating verifies the block equation.
(v) Reassemble $\mathbf{y}(t)$ and transform back: $\mathbf{x}(t) = S\mathbf{y}(t)$.

Thus a size-k block with eigenvalue λ contributes entries of the form $e^{\lambda t}p(t)$, where $\deg p < k$.

Perspective 1.2.14. *Jordan Functions and Polynomial Factors*

For a Jordan block $J_k(\lambda) = \lambda I_k + N$ with $N^k = 0$, any polynomial f satisfies $f(J_k(\lambda)) = \sum_{r=0}^{k-1} \frac{f^{(r)}(\lambda)}{r!} N^r$.

The nilpotent part contributes derivative terms; for the exponential these become polynomial factors in t by Proposition 6.5.3. As $t \to +\infty$, $\operatorname{Re}\lambda < 0$ gives blockwise decay and $\operatorname{Re}\lambda > 0$ gives growth.
If $\operatorname{Re}\lambda = 0$, the block evolution is bounded iff $N = 0$.

Example 1.2.15. *Nilpotent Jordan Block Evolution*

Let $N := J_3(0) = \left(\begin{smallmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{smallmatrix}\right)$, so $N^3 = 0$. By Proposition 6.5.3, $e^{tN} = I_3 + tN + \frac{t^2}{2}N^2 = \left(\begin{smallmatrix} 1 & t & \frac{t^2}{2} \\ 0 & 1 & t \\ 0 & 0 & 1 \end{smallmatrix}\right)$. Nilpotent Jordan blocks create polynomial, rather than exponential, growth along generalized-eigenvector chains.

Theorem 1.2.16. *Spectral Criteria for Autonomous Linear Stability*
Let $A \in \mathbb{C}^{n\times n}$ and set $\alpha(A) := \max\{\operatorname{Re}\lambda : \lambda \in \operatorname{spec}(A)\}$. Then:

(i) $e^{tA} \to 0$ *as* $t \to +\infty$ *iff* $\alpha(A) < 0$.
(ii) $\sup_{t\ge 0} \|e^{tA}\| < +\infty$ *iff* $\alpha(A) \le 0$ *and* $\forall \lambda \in \operatorname{spec}(A)$, $\operatorname{Re}\lambda = 0 \implies \dim\ker(A - \lambda I_n) = m_A(\lambda)$.
(iii) If $\alpha(A) < 0$, *then* $\forall \gamma \in (0, -\alpha(A))$, $\exists C_\gamma > 0$ *such that* $\|e^{tA}\| \le C_\gamma e^{-\gamma t}$ $\forall t \ge 0$.

Proof. Choose $S \in GL_n(\mathbb{C})$ with $A = SJS^{-1}$ and use Proposition 6.5.3 on every block $J_k(\lambda)$. Fixed similarity changes all norms by at most the factor $\|S\|\,\|S^{-1}\|$.

(i) Each block exponential is $e^{\lambda t}\sum_{r=0}^{k-1} \frac{t^r N^r}{r!}$. It tends to zero exactly when $\operatorname{Re}\lambda < 0$; if $\operatorname{Re}\lambda \ge 0$, its diagonal entry $e^{\lambda t}$ does not tend to zero.
(ii) If $\operatorname{Re}\lambda < 0$, every polynomial factor is dominated by $e^{\operatorname{Re}\lambda\, t}$ and the block is bounded. If $\operatorname{Re}\lambda = 0$, the block is bounded exactly when $N = 0$, equivalently $k = 1$. If $\operatorname{Re}\lambda > 0$, its diagonal is unbounded.
(iii) Fix $0 < \gamma < -\alpha(A)$. For a block of size k, $e^{\gamma t}\|e^{tJ_k(\lambda)}\|$ is bounded because every $t^r e^{(\operatorname{Re}\lambda + \gamma)t}$ tends to zero. Take the maximum block bound and include the fixed similarity factor.

Structural Commentary: Jordan blocks separate exponential rates from nilpotent polynomial factors.
Key Insight: Boundary-spectrum nilpotence is the sole obstruction to boundedness. □

Definition 1.2.17. *Hurwitz Matrix*
A matrix $A \in \mathbb{C}^{n\times n}$ is *Hurwitz* iff $\max\{\operatorname{Re}\lambda : \lambda \in \operatorname{spec}(A)\} < 0$.

Perspective 1.2.18. *Planar Linear Phase Classification*
For $x' = Ax$ with $A \in \mathbb{R}^{2\times 2}$, two real eigenvalues of negative sign give a sink, two of positive sign give a source, and opposite signs give a saddle.
A nonreal pair $\alpha \pm i\beta$, $\beta \ne 0$, gives a spiral sink when $\alpha < 0$, a spiral source when $\alpha > 0$, and a center when $\alpha = 0$. A defective repeated real eigenvalue λ adds a polynomial shear along its generalized eigenvector; it still gives decay for $\lambda < 0$ and growth for $\lambda > 0$. For $\lambda = 0$, $e^{tA} = I_2 + tA$ in the defective case, so generalized-eigenvector directions grow linearly while the eigenspace consists of equilibria. These labels describe the origin; similarity changes the coordinates of the phase portrait without changing its spectral type.

Theorem 1.2.19. *Basis for Constant-Coefficient Linear ODEs*
Let $p(z) := z^n + c_{n-1}z^{n-1} + \cdots + c_1 z + c_0 = \prod_{j=1}^{m} (z - \lambda_j)^{a_j}$ over $\mathbb{C}$, where the λ_j are distinct and $\sum_{j=1}^{m} a_j = n$. Then:

(i) The functions $x_{j,k}(t) := t^k e^{\lambda_j t}$, $1 \le j \le m$, $0 \le k < a_j$, form a basis of the complex solutions of $p(D)x = 0$, where $D = d/dt$.
(ii) If $c_0, \dots, c_{n-1} \in \mathbb{R}$, write $\lambda_j = \alpha_j + i\beta_j$. The functions $t^k e^{\lambda_j t}$ for the real roots $\beta_j = 0$, together with $t^k e^{\alpha_j t}\cos(\beta_j t)$ and $t^k e^{\alpha_j t}\sin(\beta_j t)$ for one root from each conjugate pair with $\beta_j > 0$, form a real basis, where always $0 \le k < a_j$.

Proof. For $q \in \mathbb{C}[t]$, $(D-\lambda)(e^{\lambda t}q) = e^{\lambda t}q'$. Thus $(D-\lambda_j)^{a_j} x_{j,k} = 0$ for $k < a_j$, so every listed function solves $p(D)x = 0$.

(i) Suppose $\sum_{j=1}^{m} e^{\lambda_j t} q_j(t) = 0$ with $\deg q_j < a_j$. Fix j and apply $\prod_{i \neq j} (D-\lambda_i)^{a_i}$. All terms except the jth vanish, while the remaining term is $e^{\lambda_j t} R_j(D) q_j$, where $R_j(z) := \prod_{i \neq j} (z + \lambda_j - \lambda_i)^{a_i}$ and $R_j(0) \neq 0$.
On polynomials of degree below a_j, $R_j(D) - R_j(0)I$ is nilpotent because it is divisible by D. Thus $R_j(D)$ is invertible, so $q_j = 0$. The n listed functions are linearly independent.
Writing $y := (x, x', \dots, x^{(n-1)})$ converts $p(D)x = 0$ into a first-order companion system. Theorem 1.2.12(iii), with zero forcing, makes $y(0) \mapsto y$ a complex-linear bijection from $\mathbb{C}^n$ onto the global solution space. Thus that space has complex dimension n and the list is a basis.

(ii) Real coefficients pair nonreal roots by conjugation. Taking real and imaginary parts of the paired complex basis functions gives the stated real solutions; the change from each conjugate pair to its real and imaginary parts is invertible over $\mathbb{R}$.

Structural Commentary: Factor $p(D)$; isolate each exponential-polynomial root space.
Key Insight: Root multiplicity becomes polynomial degree. □

Method 1.2.20. *Exponential-Polynomial Forcing*
Let $p \in \mathbb{C}[z] \setminus \{0\}$, $q \in \mathbb{C}[t] \setminus \{0\}$, and $\beta \in \mathbb{C}$, and consider $p(D)x = q(t)e^{\beta t}$. Write $p(z) = (z-\beta)^a h(z)$ with $a \in \mathbb{N}_0$ and $h(\beta) \neq 0$. Set $d := \deg q$ and $\mathbb{C}_{\le d}[t] := \{u \in \mathbb{C}[t] : \deg u \le d\}$.

(i) Solve $h(D+\beta)u = q$ in $\mathbb{C}_{\le d}[t]$; the operator is triangular with nonzero diagonal $h(\beta)$ and hence invertible.
(ii) Choose the polynomial r with $r^{(a)} = u$ and vanishing coefficients in degrees $0, \dots, a-1$.
(iii) Set $x_p(t) := e^{\beta t} r(t)$. Then $p(D)x_p = e^{\beta t} h(D+\beta) D^a r = q(t)e^{\beta t}$ and $\deg r \le \deg q + a$.

The factor t^a in r is the resonance correction when β is a root of p.

Example 1.2.21. *Damping and Resonance*
For $x'' + 2\eta x' + \omega_0^2 x = 0$, with $\eta, \omega_0 > 0$, the roots are $-\eta \pm \sqrt{\eta^2 - \omega_0^2}$. Thus $\eta > \omega_0$, $\eta = \omega_0$, and $\eta < \omega_0$ give over-damping, critical damping, and under-damping, respectively; homogeneous solutions decay.
For the forced equation $x'' + 2\eta x' + \omega_0^2 x = \cos(\omega t)$, a complex particular solution is $z_p(t) = e^{i\omega t}/(\omega_0^2 - \omega^2 + 2i\eta\omega)$, and $x_p = \operatorname{Re} z_p$. If $\eta = 0$ and $\omega = \omega_0$, Method 1.2.20 instead gives $x_p(t) = t\sin(\omega_0 t)/(2\omega_0)$, whose amplitude grows linearly.
For a series RLC circuit, $\eta = R/(2L)$ and $\omega_0 = 1/\sqrt{LC}$; the same three regimes and resonance mechanism govern the current.

Method 1.2.22. *Reduction of Order for a Second Solution*
Let $I \subseteq \mathbb{R}$ be open, let $q_0, q_1 \in C(I, \mathbb{C})$, let $\phi_1 \in C^2(I, \mathbb{C})$ solve $x'' + q_1 x' + q_0 x = 0$, and restrict to an interval $J \subseteq I$ on which $\phi_1 \neq 0$. Fix $t_* \in J$.

(i) Set $x = c\phi_1$. Cancellation of the equation for ϕ_1 gives $\phi_1 c'' + (2\phi_1' + q_1\phi_1)c' = 0$.
(ii) With $d := c'$, solve $d' + (2\phi_1'/\phi_1 + q_1)d = 0$ to obtain $d(t) = C\phi_1(t)^{-2}\exp(-\int_{t_*}^{t} q_1(r)\,dr)$.
(iii) Taking $C = 1$ gives $\phi_2(t) := \phi_1(t)\int_{t_*}^{t} \phi_1(s)^{-2}\exp(-\int_{t_*}^{s} q_1(r)\,dr)\,ds$. Then $W(\phi_1, \phi_2)(t) = \phi_1\phi_2' - \phi_1'\phi_2 = \exp(-\int_{t_*}^{t} q_1(r)\,dr) \neq 0$. Thus ϕ_1, ϕ_2 are linearly independent; uniqueness for the associated two-dimensional first-order system makes them a basis of the solution space on J.

Theorem 1.2.23. *Floquet Normal Form*
Let $A \in C(\mathbb{R}, \mathbb{C}^{n\times n})$ satisfy $A(t+T) = A(t)$ for some $T > 0$, let Π be its principal matrix solution, and set $M(t_0) := \Pi(t_0 + T, t_0)$. Then:

(i) $\forall s, t \in \mathbb{R}$, $\Pi(t+T, s+T) = \Pi(t, s)$.
(ii) $M(t_0)$ *is invertible.*
(iii) $\exists Q(t_0) \in \mathbb{C}^{n\times n}$ *and a T-periodic* $P(\,\cdot\,, t_0) \in C^1(\mathbb{R}, GL_n(\mathbb{C}))$ *such that* $\Pi(t, t_0) = P(t, t_0)e^{(t-t_0)Q(t_0)}$ *and* $P(t_0, t_0) = I_n$.
(iv) $\forall t_0, t_1 \in \mathbb{R}$, $M(t_1) = \Pi(t_1, t_0)M(t_0)\Pi(t_1, t_0)^{-1}$*; consequently, the spectrum and Jordan block sizes of $M(t_0)$ are independent of t_0.*

Proof.

(i) Both $t \mapsto \Pi(t+T, s+T)$ and $t \mapsto \Pi(t, s)$ solve $X' = A(t)X$ and equal I_n at $t = s$, so uniqueness gives the identity.
(ii) Theorem 1.2.12(i) gives $M(t_0)^{-1} = \Pi(t_0, t_0 + T)$.
(iii) By (ii), every Jordan block of $M(t_0)$ has the form $J = \rho I + N$ with $\rho \neq 0$ and $N^k = 0$. Choose $\ell \in \mathbb{C}$ with $e^{\ell} = \rho$ and set $L := \ell I + \sum_{q=1}^{k-1} \frac{(-1)^{q+1}}{q}(\rho^{-1}N)^q$. In the quotient algebra $\mathbb{C}[z]/(z^k)$, the finite logarithm and exponential series satisfy $\exp(\log(1+z)) = 1+z$; substituting $z = \rho^{-1}N$ gives $e^L = J$. Reassembling and conjugating these block logarithms produces $R \in \mathbb{C}^{n\times n}$ with $e^R = M(t_0)$.
Set $Q(t_0) := T^{-1}R$ and $P(t, t_0) := \Pi(t, t_0)e^{-(t-t_0)Q(t_0)}$. Then $P(t_0, t_0) = I_n$. By (i) and the cocycle law, $\Pi(t+T, t_0) = \Pi(t, t_0)M(t_0)$; because $M(t_0) = e^{TQ(t_0)}$, this identity gives $P(t+T, t_0) = P(t, t_0)$. Both factors defining P are C^1 and invertible.
(iv) Periodicity from (i) and the cocycle law give $\Pi(t_1 + T, t_0) = \Pi(t_1, t_0)M(t_0)$ and also $\Pi(t_1 + T, t_0) = M(t_1)\Pi(t_1, t_0)$. Right multiplication by $\Pi(t_1, t_0)^{-1}$ proves the similarity identity, and similarity preserves the spectrum and Jordan block sizes.

Structural Commentary: Take a logarithm of one-period transport; factor the remainder.
Key Insight: Periodic evolution is constant exponential growth in periodic coordinates. □

Definition 1.2.24. *Floquet Multipliers and Exponents*
Let $A \in C(\mathbb{R}, \mathbb{C}^{n\times n})$ be T-periodic, let Π be its principal matrix solution, set $M(t_0) := \Pi(t_0 + T, t_0)$, and choose $Q(t_0)$ with $e^{TQ(t_0)} = M(t_0)$.

(i) The eigenvalues ρ of $M(t_0)$ are the *Floquet multipliers*.
(ii) The eigenvalues γ of a Floquet matrix $Q(t_0)$ are *Floquet exponents*. Spectral mapping gives $\operatorname{spec}(M(t_0)) = \{e^{T\gamma} : \gamma \in \operatorname{spec}(Q(t_0))\}$ and $m_{M(t_0)}(\rho) = \sum_{\substack{\gamma \in \operatorname{spec}(Q(t_0)) \\ e^{T\gamma} = \rho}} m_{Q(t_0)}(\gamma)$. Thus every exponent determines a multiplier by $\rho = e^{T\gamma}$, and the scalar logarithm determines γ only modulo $2\pi i/T$.

Corollary 1.2.25. *Floquet Multiplier Stability Criterion*
Let $A \in C(\mathbb{R}, \mathbb{C}^{n\times n})$ be T-periodic, let Π be its principal matrix solution, and set $M(t_0) := \Pi(t_0+T, t_0)$. Then:

(i) $\sup_{t\ge t_0} \|\Pi(t,t_0)\| < +\infty$ *iff* $|\rho| \le 1$ *for* $\rho \in \operatorname{spec}(M(t_0))$ *and* $\dim\ker(M(t_0) - \rho I_n) = m_{M(t_0)}(\rho)$ *whenever* $|\rho| = 1$.
(ii) $\Pi(t,t_0) \to 0$ *as* $t \to +\infty$ *iff* $\max\{|\rho| : \rho \in \operatorname{spec}(M(t_0))\} < 1$.

Proof. Write $t = t_0 + kT + \tau$, $k \in \mathbb{N}_0$, $0 \le \tau < T$. Periodicity and the cocycle law give by induction $\Pi(t,t_0) = \Pi(t_0+\tau, t_0)M(t_0)^k$. The first factor and its inverse are uniformly bounded for $0 \le \tau \le T$.

(i) Hence $\Pi(\,\cdot\,, t_0)$ is bounded iff $(M(t_0)^k)$ is bounded. By Theorem 3.3.7, this is equivalent to the stated multiplier and multiplicity conditions.
(ii) Likewise, $\Pi(t,t_0) \to 0$ iff $M(t_0)^k \to 0$. By Theorem 3.3.5, this is equivalent to $\rho(M(t_0)) < 1$.

Structural Commentary: Sample at integer periods; reduce continuous evolution to powers of M.
Key Insight: Floquet stability is matrix-power stability of one-period transport. □

Example 1.2.26. *Hill Equation and Its Floquet Discriminant*
Let $q \in C(\mathbb{R}, \mathbb{R})$ be T-periodic and consider $x'' + q(t)x = 0$. Its first-order matrix is $A(t) = \left(\begin{smallmatrix} 0 & 1 \\ -q(t) & 0 \end{smallmatrix}\right)$. Let Π be the principal matrix solution and $M(t_0) := \Pi(t_0+T, t_0)$. Since $\operatorname{tr} A(t) = 0$, by Theorem 1.2.12(ii), $\det M(t_0) = 1$.
With $\Delta := \frac{1}{2}\operatorname{tr} M(t_0)$, the multiplier equation is $\rho^2 - 2\Delta\rho + 1 = 0$. If $|\Delta| < 1$, the multipliers are distinct conjugates on the unit circle and all solutions are bounded. If $|\Delta| > 1$, one real multiplier has modulus above 1 and an unbounded solution exists. At $|\Delta| = 1$, boundedness holds exactly when $M(t_0) = \Delta I_2$; otherwise its nontrivial Jordan block produces linear growth in the period count.
The Mathieu equation $x'' + \omega^2(1 + \varepsilon\cos t)x = 0$ is the standard periodic-coefficient example; its stability regions are determined by $\Delta(\omega, \varepsilon)$.

Theorem 1.2.27. *Perturbation Bounds for Linear Evolution*
Let $A, B \in C(\mathbb{R}, \mathbb{C}^{n\times n})$, let Π_A, Π_{A+B} be the corresponding principal matrix solutions, and fix $t_0 \in \mathbb{R}$. Then:

(i) If $\|\Pi_A(t,s)\| \le Ce^{-\alpha(t-s)}$ *for all* $t \ge s \ge t_0$ *and* $\|B(t)\| \le b$ *for all* $t \ge t_0$, *where* $C, \alpha > 0$, $b \ge 0$, *and* $Cb < \alpha$, *then* $\|\Pi_{A+B}(t,s)\| \le Ce^{-(\alpha - Cb)(t-s)}$ *for all* $t \ge s \ge t_0$.
(ii) If $\|\Pi_A(t,s)\| \le C$ $\forall t \ge s \ge t_0$ *and* $B_1 := \int_{t_0}^{\infty} \|B(r)\|\,dr < +\infty$, *then* $\|\Pi_{A+B}(t,s)\| \le Ce^{CB_1}$ $\forall t \ge s \ge t_0$.

Proof. For fixed $s \ge t_0$, by Theorem 1.2.12(iii), applied columnwise with forcing $B(t)x(t)$, $\Pi_{A+B}(t,s) = \Pi_A(t,s) + \int_s^t \Pi_A(t,r)B(r)\Pi_{A+B}(r,s)\,dr$.

(i) Put $y(t) := e^{\alpha(t-s)}\|\Pi_{A+B}(t,s)\|$. The hypotheses give $y(t) \le C + Cb\int_s^t y(r)\,dr$. By Lemma 1.1.20(ii), after translating s to 0, $y(t) \le Ce^{Cb(t-s)}$, which is the asserted estimate.
(ii) Put $y(t) := \|\Pi_{A+B}(t,s)\|$. Then $y(t) \le C + C\int_s^t \|B(r)\|\,y(r)\,dr$. The same Gronwall estimate gives $y(t) \le C\exp(C\int_s^t \|B(r)\|\,dr) \le Ce^{CB_1}$.

Structural Commentary: Variation of constants converts perturbation into Gronwall feedback.
Key Insight: Perturbation mass subtracts from decay or multiplies boundedness. □

Corollary 1.2.28. *Vanishing Perturbations of a Hurwitz Matrix*
Let $A \in \mathbb{C}^{n\times n}$ be Hurwitz, let $B \in C(\mathbb{R}, \mathbb{C}^{n\times n})$, and suppose $\|B(t)\| \to 0$ as $t \to +\infty$. Set $\delta_A := \min\{-\operatorname{Re}\lambda : \lambda \in \operatorname{spec}(A)\}$. Then $\forall \gamma \in (0, \delta_A)$, $\exists K_\gamma > 0$ such that $\|\Pi_{A+B}(t,0)\| \le K_\gamma e^{-\gamma t}$ $\forall t \ge 0$.

Proof. Fix $0 < \gamma < \eta < \delta_A$. By Theorem 1.2.16(iii), $\exists C_\eta > 0$ with $\left\|e^{(t-s)A}\right\| \le C_\eta e^{-\eta(t-s)}$ for $t \ge s$.
Choose $t_0 \ge 0$ such that $\|B(t)\| \le (\eta - \gamma)/C_\eta$ for $t \ge t_0$. By Theorem 1.2.27(i), $\|\Pi_{A+B}(t,t_0)\| \le C_\eta e^{-\gamma(t-t_0)}$ for $t \ge t_0$.
The cocycle law yields $\Pi_{A+B}(t,0) = \Pi_{A+B}(t,t_0)\Pi_{A+B}(t_0,0)$.
Set $K_1 := C_\eta e^{\gamma t_0}\|\Pi_{A+B}(t_0,0)\|$; then $\|\Pi_{A+B}(t,0)\| \le K_1 e^{-\gamma t}$ for $t \ge t_0$.
Continuity gives $K_0 := \max_{0\le t\le t_0} e^{\gamma t}\|\Pi_{A+B}(t,0)\| < +\infty$. Taking $K_\gamma := \max\{K_0, K_1\}$ proves the claim.
Structural Commentary: Wait until B is smaller than the spectral decay margin.
Key Insight: A vanishing perturbation eventually preserves any smaller decay rate. □

1.3 Nonlinear Stability Theory

Exact formulas are often unnecessary for proving that scalar trajectories remain ordered or trapped. Differential inequalities provide comparison curves for this purpose.

Definition 1.3.1. *Upper and Lower Solutions*
Let $U \subseteq \mathbb{R}^2$ be open, $f : U \to \mathbb{R}$, and $J \subseteq \mathbb{R}$ an open interval. For $u \in C^1(J, \mathbb{R})$ with $\Gamma_u := \{(t, u(t)) : t \in J\} \subseteq U$:

(i) *Upper solution*: $u'(t) \ge f(t, u(t))$ $\forall t \in J$; it is *strict* iff $u'(t) > f(t, u(t))$ $\forall t \in J$.
(ii) *Lower solution*: $u'(t) \le f(t, u(t))$ $\forall t \in J$; it is *strict* iff $u'(t) < f(t, u(t))$ $\forall t \in J$.

Key Insight: Differential inequalities encode one-sided barriers without solving the ODE.

Definition 1.3.2. *Scalar Isocline*
Let $U \subseteq \mathbb{R}^2$ be open, $f : U \to \mathbb{R}$, and $c \in \mathbb{R}$.
For $x' = f(t,x)$, the set $\mathcal{I}_c := \{(t,x) \in U : f(t,x) = c\}$ is the *isocline of slope c*.
Let $J \subseteq \mathbb{R}$ be open and $w \in C^1(J, \mathbb{R})$ satisfy $\Gamma_w := \{(t, w(t)) : t \in J\} \subseteq \mathcal{I}_c$.

(i) If $w'(t) > c$ $\forall t \in J$, then w is a strict upper solution.
(ii) If $w'(t) < c$ $\forall t \in J$, then w is a strict lower solution.

Key Insight: An isocline fixes the ODE slope, so only the graph slope remains to be compared.

Lemma 1.3.3. *Strict Scalar Comparison*
Let $U \subseteq \mathbb{R}^2$ be open, $f \in C(U, \mathbb{R})$, $J \subseteq \mathbb{R}$ open, and $[t_0, T] \subseteq J$ with $t_0 < T$.
For $z \in C^1(J, \mathbb{R})$, set $\Gamma_z := \{(t, z(t)) : t \in J\}$, and let $I_+ := (t_0, T]$. Suppose $x \in C^1(J, \mathbb{R})$, $\Gamma_x \subseteq U$, and $x' = f(\,\cdot\,, x)$.

(i) If $u \in C^1(J, \mathbb{R})$, $\Gamma_u \subseteq U$, $u'(t) > f(t, u(t))$ $\forall t \in J$, *and* $x(t_0) \le u(t_0)$, *then* $x(t) < u(t)$ $\forall t \in I_+$.
(ii) If $v \in C^1(J, \mathbb{R})$, $\Gamma_v \subseteq U$, $v'(t) < f(t, v(t))$ $\forall t \in J$, *and* $v(t_0) \le x(t_0)$, *then* $v(t) < x(t)$ $\forall t \in I_+$.

Proof.

(i) Set $\Delta := u - x$. At every $t \in [t_0, T]$ with $\Delta(t) = 0$, one has $x(t) = u(t)$ and $\Delta'(t) = u'(t) - f(t, u(t)) > 0$. Thus $\Delta(t_0) \geq 0$ implies $\Delta > 0$ on $(t_0, t_0 + \varepsilon]$ for some $\varepsilon > 0$.
If $Z := \{t \in (t_0, T] : \Delta(t) = 0\} \neq \emptyset$, let $t_1 := \inf Z$. Continuity gives $\Delta(t_1) = 0$ and $\Delta > 0$ on (t_0, t_1), so the left derivative satisfies $\Delta'(t_1) \leq 0$. This contradicts $\Delta'(t_1) > 0$. Hence $Z = \emptyset$ and $\Delta > 0$ on I_+.

(ii) Set $\Delta := x - v$. At every zero of Δ, $\Delta' = f(\cdot\,, v) - v' > 0$. The argument from (i), with $x - v$ in place of $u - x$, gives $\Delta > 0$ on I_+.

Structural Commentary: A first contact forces $\Delta' \leq 0$, contradicting the strict residual sign.
Key Insight: Strict differential inequalities forbid barrier crossing. □

Definition 1.3.4. *Local State Lipschitz Condition*
Let $U \subseteq \mathbb{R}^2$ be open and $f : U \to \mathbb{R}$. Then f is *locally Lipschitz in the state, uniformly in time* iff, for every compact $K \subseteq U$, there exists $L_K < +\infty$ such that $|f(t, x) - f(t, y)| \leq L_K |x - y|$ whenever $(t, x), (t, y) \in K$.

Theorem 1.3.5. *Scalar Lipschitz Comparison*
Let $U \subseteq \mathbb{R}^2$ be open and $f \in C(U, \mathbb{R})$. Assume that for every compact $K \subseteq U$, there exists $L_K < +\infty$ such that $|f(t, p) - f(t, q)| \leq L_K |p - q|$ whenever $(t, p), (t, q) \in K$.
Let $I := [t_0, T] \subseteq J$, $J \subseteq \mathbb{R}$ open, $t_0 < T$. For $z : J \to \mathbb{R}$, set $\Gamma_z(A) := \{(t, z(t)) : t \in A\}$, $R_z := z' - f(\cdot\,, z)$.
Suppose $x, y \in C^1(J, \mathbb{R})$, $\Gamma_x(J) \cup \Gamma_y(J) \subseteq U$, and $R_x \leq R_y$ on I. Then:

(i) If $x(t_0) \leq y(t_0)$, then $x \leq y$ on I.
(ii) If $t_1 \in I$ and $x(t_1) < y(t_1)$, then $x < y$ on $[t_1, T]$.

Proof.

(i) Set $\Delta := x - y$ and suppose $S := \{t \in I : \Delta(t) > 0\} \neq \emptyset$. Since $\Delta(t_0) \leq 0$, every component C of S has a left endpoint $\alpha \in I$ with $\Delta(\alpha) = 0$. Choose $t_2 \in C$, so $\Delta > 0$ on $(\alpha, t_2]$.
With $K := \Gamma_x([\alpha, t_2]) \cup \Gamma_y([\alpha, t_2])$ and $L = L_K$, $R_x \leq R_y$ gives $\Delta' \leq f(\cdot\,, x) - f(\cdot\,, y) \leq L\Delta$ on $(\alpha, t_2]$.
Thus $(e^{-L(t-\alpha)}\Delta)' \leq 0$, so $\Delta(t_2) \leq e^{L(t_2-\alpha)}\Delta(\alpha) = 0$, contradicting $t_2 \in S$.

(ii) Set $\delta := y - x$. If $Z := \{t \in (t_1, T] : \delta(t) = 0\} \neq \emptyset$, let $t_2 := \inf Z$. Then $\delta > 0$ on $[t_1, t_2)$ and $\delta(t_2) = 0$.
With $K := \Gamma_x([t_1, t_2]) \cup \Gamma_y([t_1, t_2])$ and $L = L_K$, by $R_x \leq R_y$, $\delta' \geq f(\cdot\,, y) - f(\cdot\,, x) \geq -L\delta$ on $[t_1, t_2)$.
Hence $(e^{L(t-t_1)}\delta)' \geq 0$ and $0 = e^{L(t_2-t_1)}\delta(t_2) \geq \delta(t_1) > 0$, contradiction.

Structural Commentary: On a positive component, the integrating factor makes the order defect nonincreasing.
Key Insight: A nonpositive order defect cannot become positive. □

Lemma 1.3.6. *A Convergent Autonomous State Is an Equilibrium*
Let $f \in C(\mathbb{R}, \mathbb{R})$ and let $x \in C^1([t_0, +\infty), \mathbb{R})$ satisfy $x' = f(x)$. If $x(t) \to x_* \in \mathbb{R}$ as $t \to +\infty$, then:

(i) $x'(t) \to 0$.
(ii) $f(x_*) = 0$.

Proof.

(i) By continuity, $x'(t) = f(x(t)) \to f(x_*) := L$. If $L > 0$, then $x'(t) \geq L/2$ eventually, so integration forces $x(t) \to +\infty$. If $L < 0$, the analogous estimate forces $x(t) \to -\infty$. Both conclusions contradict $x(t) \to x_*$, so $L = 0$ and $x'(t) \to 0$.

(ii) The identity $L = f(x_*)$ from (i) now gives $f(x_*) = 0$.

Structural Commentary: The differential equation converts state convergence into derivative convergence.
Key Insight: A nonzero limiting velocity is incompatible with a finite limiting state. □

Example 1.3.7. *A Trapping Wedge for $x' = x^2 - t^2$*
For $f(t, x) := x^2 - t^2$ on $(0, +\infty) \times \mathbb{R}$, set $u(t) := t$ and $v(t) := -t$.
Then $u' = 1 > 0 = f(t, u)$ and $v' = -1 < 0 = f(t, v)$.
If $t_0 > 0$, $x_0 \in [-t_0, t_0]$, and $x \in C^1([t_0, T_+), \mathbb{R})$ satisfies $x' = x^2 - t^2$ and $x(t_0) = x_0$, then Lemma 1.3.3 gives $-t < x(t) < t$ $\forall t \in (t_0, T_+)$.

Proposition 1.3.8. *Central-Wedge Convergence for $x' = x^2 - t^2$*
Let $t_0 > 0$, $-t_0 < x_0 < t_0$, and let $x : [t_0, T_+) \to \mathbb{R}$ be the maximal forward solution of $x' = x^2 - t^2$, $x(t_0) = x_0$.

(i) $-t < x(t) < t$ for $t \in (t_0, T_+)$.
(ii) $T_+ = +\infty$.
(iii) $x(t) + t \to 0$ as $t \to +\infty$.

Proof.

(i) Let $u(t) := t$ and $v(t) := -t$. Since $u' - (u^2 - t^2) = 1 > 0$, $v' - (v^2 - t^2) = -1 < 0$, and $v(t_0) < x_0 < u(t_0)$, Lemma 1.3.3 implies $v(t) < x(t) < u(t)$ on every compact subinterval of $[t_0, T_+)$.

(ii) By (i), $x' = (x - t)(x + t) < 0$, so x is decreasing.
If $T_+ < +\infty$, then $-T_+ < x(t) \leq x_0$ for $t < T_+$, hence $\ell := \lim_{t \uparrow T_+} x(t) \in [-T_+, x_0]$.
Lemma 1.1.28 extends x through (T_+, ℓ), contradicting maximality. Hence $T_+ = +\infty$.

(iii) Fix $T \geq \max\{t_0, 2\}$, and set $r(t) := \sqrt{t^2 - 2}$, $w(t) := -r(t)$ for $t \geq T$. Since $r^2 - t^2 = w^2 - t^2 = -2$, $r' = t/r > 0 > -2$, and $w' = -t/r \geq -\sqrt{2} > -2$, both r, w are strict upper solutions.
Let $d(t) := t - x(t)$. By (i), $d > 0$ and $t + x > 0$, so $d' = 1 + t^2 - x^2 = 1 + d(t + x) > 1$.
Since $d(t) \to +\infty$ and $t - r(t) \to 0$, choose $T_1 \geq T$ with $d(T_1) > T_1 - r(T_1)$, i.e. $x(T_1) < r(T_1)$.
By strict comparison, $x < r$ for $t > T_1$. If $x(T_1) \leq w(T_1)$, then by strict comparison $x < w$ for $t > T_1$.
If $w(T_1) < x(T_1) < r(T_1)$, then while $w < x < r$, one has $x' < -2$ and $w' \geq -\sqrt{2}$, hence $(x - w)' < -(2 - \sqrt{2})$. Global existence forces a first contact $x(\tau) = w(\tau)$ in finite time, and strict comparison from τ gives $x < w$ thereafter.
Therefore eventually $0 < x(t) + t < t - r(t) = \frac{2}{t + \sqrt{t^2 - 2}} \to 0$.

Structural Commentary: Two nested isocline barriers squeeze the trajectory against $x = -t$.
Key Insight: Every trajectory entering the central wedge is asymptotic to its lower edge. □

Proposition 1.3.9. *Finite-Time Blow-Up Above the Upper Isocline*
Let $t_0 \geq 0$, $x_0 \geq \sqrt{t_0^2+2}$, and let $x : [t_0, T_+) \to \mathbb{R}$ be the maximal forward solution of $x' = x^2 - t^2$, $x(t_0) = x_0$.

(i) $x(t) > \sqrt{t^2+2}$ and $x'(t) > 2$ for $t \in (t_0, T_+)$.
(ii) $T_+ < +\infty$ and $x(t) \to +\infty$ as $t \uparrow T_+$.

Proof.

(i) Set $b(t) := \sqrt{t^2+2}$. Then $b^2 - t^2 = 2$ and $b' = \frac{t}{b} < 1 < 2$, so $b' < b^2 - t^2$.
Since $x_0 \geq b(t_0)$, Lemma 1.3.3 implies $b(t) < x(t)$ for $t > t_0$; hence $x' = x^2 - t^2 > b^2 - t^2 = 2$.

(ii) Suppose $T_+ = +\infty$. By (i), $x(t) > x_0 + 2(t - t_0)$; choose $t_1 \geq t_0$ with $x(t) > \sqrt{2}t > 0$ for $t \geq t_1$.
Then $x' = x^2 - t^2 > \frac{1}{2}x^2$ and $(\frac{1}{x})' = -\frac{x'}{x^2} < -\frac{1}{2}$ on $[t_1, +\infty)$, so $\frac{1}{x(t)} < \frac{1}{x(t_1)} - \frac{1}{2}(t - t_1)$.
This contradicts $x > 0$ for $t > t_1 + \frac{2}{x(t_1)}$. Thus $T_+ < +\infty$. Also $x' > 2$, so $\ell := \lim_{t \uparrow T_+} x(t) \in (x_0, +\infty]$.
If $\ell < +\infty$, Lemma 1.1.28 extends x through (T_+, ℓ), contradicting maximality. Hence $\ell = +\infty$.

Structural Commentary: Above $b(t) = \sqrt{t^2+2}$, linear escape enters the Riccati regime.
Key Insight: Once $x' \geq \frac{1}{2}x^2$, reciprocal decay forces finite-time escape. □

Theorem 1.3.10. *Separatrix Classification for $x' = x^2 - t^2$*
For $a \in \mathbb{R}$, let $x_a : [0, T_a) \to \mathbb{R}$ be the maximal forward solution of $x' = x^2 - t^2$, $x_a(0) = a$.

(i) $\exists!\, a_* \in [0, \sqrt{2}]$ such that $T_{a_*} = +\infty$, $t \leq x_{a_*}(t) \leq \sqrt{t^2+2}$ for $t \geq 0$, and $x_{a_*}(t) - t \to 0$ as $t \to +\infty$.
(ii) If $a > a_*$, then $T_a < +\infty$ and $x_a(t) \to +\infty$ as $t \uparrow T_a$.
(iii) If $a < a_*$, then $T_a = +\infty$ and $x_a(t) + t \to 0$ as $t \to +\infty$.

Proof. Set $\ell(t) := t$ and $b(t) := \sqrt{t^2+2}$. For $T > 0$, let p_T, q_T solve $x' = x^2 - t^2$ backward from $p_T(T) = \ell(T)$ and $q_T(T) = b(T)$. Under $s = T - t$, the reversed equation is $y' = (T-s)^2 - y^2$, while $\widehat{\ell}(s) := T - s$ and $\widehat{b}(s) := \sqrt{(T-s)^2+2}$ satisfy $\widehat{\ell}' < (T-s)^2 - \widehat{\ell}^2$ and $\widehat{b}' > (T-s)^2 - \widehat{b}^2$.
Lemma 1.3.3 and Theorem 1.3.5 trap and order the reversed solutions while they exist. Corollary 1.1.29 then gives existence on $[0, T]$, with $\ell \leq p_T < q_T \leq b$ on $[0, T]$ and strict outer inequalities on $[0, T)$.
Set $\alpha_T := p_T(0)$, $\beta_T := q_T(0)$, and $K_T := [\alpha_T, \beta_T]$. Order preservation gives $a \in K_T$ iff x_a exists on $[0, T]$ and $\ell \leq x_a \leq b$ there. Thus $S \geq T$ implies $K_S \subseteq K_T$, and $(K_n)_{n \geq 1}$ is a nested family of nonempty compact subintervals of $[0, \sqrt{2}]$.

(i) Choose $a_* \in \bigcap_{n \geq 1} K_n \subseteq [0, \sqrt{2}]$. Then x_{a_*} is global, $\ell \leq x_{a_*} \leq b$, and $0 \leq x_{a_*}(t) - t \leq b(t) - t = \frac{2}{b(t)+t} \to 0$.
If $a_1 < a_2$ lie in $\bigcap_{n \geq 1} K_n$, then $\delta := x_{a_2} - x_{a_1}$ satisfies $\delta(0) > 0$ and $\delta' = (x_{a_1} + x_{a_2})\delta \geq 0$.
Thus $0 < a_2 - a_1 \leq \delta(t) \leq b(t) - t \to 0$, impossible, so $\bigcap_{n \geq 1} K_n = \{a_*\}$.

(ii) Let $a > a_*$. Choose n with $a > \beta_n$. By comparison, $x_a > q_n > t$, so $x_a > 0$ and $x_a' > 0$ while both exist.
If $T_a \leq n$, then $\ell_a := \lim_{t \uparrow T_a} x_a(t) \in (a, +\infty]$. Lemma 1.1.28 excludes $\ell_a < +\infty$, so $x_a(t) \to +\infty$.
If $T_a > n$, then $x_a(n) > q_n(n) = \sqrt{n^2+2}$; Proposition 1.3.9 implies $T_a < +\infty$ and $x_a(t) \to +\infty$ as $t \uparrow T_a$.

(iii) Let $a < a_*$. Choose n with $a < \alpha_n$. By comparison, $x_a < p_n < t$.
On $[0, T_a \wedge n)$, whenever $x_a < -t$ one has $x_a' > 0$; after a contact with $-t$, strict comparison prevents a later downward crossing.
Hence $\min\{a, -n\} \leq x_a(t) < n$ on this interval. Corollary 1.1.29 therefore gives $T_a > n$.
Now $x_a(n) < n$. If $-n < x_a(n) < n$, Proposition 1.3.8 gives $T_a = +\infty$ and $x_a(t) + t \to 0$.
If $x_a(n) \leq -n$, set $h := x_a + t$. While $h < 0$, one has $h' = x_a^2 - t^2 + 1 > 1$ and $x_a(n) \leq x_a(t) < -t$. Compact escape gives existence through the finite time $n - h(n)$, so h has a first zero $\tau \in [n, n - h(n)]$. Strict comparison from τ gives $-t < x_a(t)$ for $t > \tau$, and continuity gives $x_a(t_2) < t_2$ for some $t_2 > \tau$.
Proposition 1.3.8 implies $T_a = +\infty$ and $x_a(t) + t \to 0$.

Structural Commentary: Nested corridors isolate the threshold separating blow-up from lower-edge attraction.
Key Insight: The orbit $x_{a_*} \sim t$ separates blow-up from attraction to $-t$. □

Theorem 1.3.11. *Asymptotic Stability by Linearization*
Let $U \subseteq \mathbb{R}^n$ be open with $0 \in U$, let $f \in C^1(U, \mathbb{R}^n)$ satisfy $f(0) = 0$, and set $A := Df(0)$. Assume $\operatorname{Re}\lambda < 0$ for every $\lambda \in \operatorname{spec}(A)$. Then $\exists r, K, \gamma > 0$ such that, for every $x_0 \in \overline{B}_r(0)$:

(i) The IVP $x' = f(x)$, $x(0) = x_0$, has a unique solution $x \in C^1([0, +\infty), U)$.
(ii) The solution satisfies $\|x(t)\| \leq Ke^{-\gamma t}\|x_0\|$ $\forall t \geq 0$.

Proof. Choose $\alpha \in (0, \min\{-\operatorname{Re}\lambda : \lambda \in \operatorname{spec}(A)\})$. By Theorem 1.2.16(iii), $\exists C \geq 1$ with $\|e^{tA}\| \leq Ce^{-\alpha t}$ for $t \geq 0$. Set $g(x) := f(x) - Ax$. Since $Dg(0) = 0$, choose $b \in (0, \alpha/C)$ and $R > 0$ such that $\overline{B}_R(0) \subseteq U$ and $\|g(x)\| \leq b\|x\|$ for $\|x\| \leq R$.
Set $r := R/(2C)$, $K := C$, and $\gamma := \alpha - Cb > 0$. Fix $x_0 \in \overline{B}_r(0)$. By Lemma 1.1.15 and Theorem 1.1.27, the autonomous field $(t, x) \mapsto f(x)$ has a unique maximal solution $x : [0, T_+) \to U$ with $x(0) = x_0$.

(i) Work before the first exit from $B_R(0)$. By Theorem 1.2.10(iii), $x(t) = e^{tA}x_0 + \int_0^t e^{(t-s)A}g(x(s))\,ds$. For $y(t) := e^{\alpha t}\|x(t)\|$, this gives $y(t) \leq C\|x_0\| + Cb\int_0^t y(s)\,ds$.
Lemma 1.1.20(ii) yields $\|x(t)\| \leq Ce^{-\gamma t}\|x_0\| \leq R/2$, so no exit occurs. If $T_+ < +\infty$, the graph remains in $[0, T_+] \times \overline{B}_{R/2}(0) \Subset \mathbb{R} \times U$, contradicting Corollary 1.1.29. Hence $T_+ = +\infty$; uniqueness is part of Theorem 1.1.27.

(ii) The estimate obtained in (i) is valid for every $t \geq 0$ and is exactly $\|x(t)\| \leq Ke^{-\gamma t}\|x_0\|$.

Structural Commentary: Split off Ax; absorb the differentiable remainder by Gronwall.
Key Insight: A Hurwitz linear part dominates its $o(\|x\|)$ remainder. □

1.4 Bifurcation Theory

A parameter can change both the position of equilibria and their number and stability. The harvested logistic equation is a complete scalar model of such a transition.

Definition 1.4.1. *Scalar Saddle-Node Pattern*
Let $\Lambda \subseteq \mathbb{R}$ be an interval, let $F : \mathbb{R} \times \Lambda \to \mathbb{R}$, and set $F_h(x) := F(x,h)$.
For $(x_c, h_c) \in \mathbb{R} \times \Lambda$, the family $(F_h)_{h\in\Lambda}$ has a *saddle-node pattern* at (x_c, h_c) iff $\exists \varepsilon > 0$, a neighborhood $X \subseteq \mathbb{R}$ of x_c, and $\sigma \in \{-1, 1\}$ such that the sets $H_\pm := \{h \in \Lambda : 0 < \pm\sigma(h - h_c) < \varepsilon\}$ are nonempty and:

(i) *Critical section*: $F_{h_c}^{-1}(0) \cap X = \{x_c\}$.
(ii) *Two-equilibrium side*: $\exists x_-, x_+ : H_+ \to X$ such that $F_h^{-1}(0) \cap X = \{x_-(h), x_+(h)\}$ and $x_-(h) < x_+(h)\ \forall h \in H_+$, with $x_\pm(h) \to x_c$ as $h \to h_c$ through H_+.
(iii) *Zero-equilibrium side*: $F_h^{-1}(0) \cap X = \emptyset\ \forall h \in H_-$.

Key Insight: A saddle-node is local creation or annihilation of two equilibria.

Proposition 1.4.2. *Equilibrium Branches of the Harvested Logistic Equation*
For $h \in [0, +\infty)$, let $F_h : \mathbb{R} \to \mathbb{R}$ be given by $F_h(x) := (1-x)x - h$. Set $h_c := \frac{1}{4}$, $x_c := \frac{1}{2}$, and $x_\pm(h) := \frac{1}{2}(1 \pm \sqrt{1-4h})$ for $h \in [0, h_c]$.

(i) $F_h^{-1}(0) = \{x_-(h), x_+(h)\}$ *and* $x_-(h) < x_+(h)\ \forall h \in [0, h_c)$.
(ii) $F_{h_c}^{-1}(0) = \{x_c\}$ *and* $F_{h_c}(x) = -(x - x_c)^2\ \forall x \in \mathbb{R}$.
(iii) $F_h^{-1}(0) = \emptyset\ \forall h \in (h_c, +\infty)$.
(iv) $x_\pm(h) \to x_c$ *as* $h \uparrow h_c$.
(v) The family $(F_h)_{h\in[0,+\infty)}$ has a saddle-node pattern at (x_c, h_c).

Proof. The identity $F_h(x) = h_c - h - (x - x_c)^2$ holds $\forall (x,h) \in \mathbb{R} \times [0, +\infty)$; hence $F_h(x) = 0$ iff $(x - x_c)^2 = h_c - h$.

(i) For $h \in [0, h_c)$, $h_c - h > 0$ and $x_c \pm \sqrt{h_c - h} = x_\pm(h)$, which gives the two distinct zeros.
(ii) Substitution of $h = h_c$ gives $F_{h_c}(x) = -(x - x_c)^2$ and therefore $F_{h_c}^{-1}(0) = \{x_c\}$.
(iii) For $h > h_c$, the relation $(x - x_c)^2 = h_c - h < 0$ has no solution in $\mathbb{R}$.
(iv) The identity $x_\pm(h) = x_c \pm \sqrt{h_c - h}$ and the limit $h_c - h \downarrow 0$ give $x_\pm(h) \to x_c$.
(v) Take $X = \mathbb{R}$, $\sigma = -1$, and $\varepsilon = \frac{1}{8}$. Then $H_+ = (\frac{1}{8}, \frac{1}{4})$ and $H_- = (\frac{1}{4}, \frac{3}{8})$; items (i)–(iv) establish the critical zero, the two coalescing branches on H_+, and the absence of zeros on H_-.

Structural Commentary: Completing the square controls the zero count on both parameter sides.
Key Insight: At h_c, two simple roots merge into one double root. □

Lemma 1.4.3. *Scalar Phase-Line Barriers and Limits*
Let $F \in C^1(\mathbb{R}, \mathbb{R})$, and let $x : [t_0, T_+) \to \mathbb{R}$, $T_+ \in (t_0, +\infty]$, be a maximal forward solution of $x' = F(x)$.

(i) If $e \in F^{-1}(0)$ and $\exists \tau \in [t_0, T_+)$ such that $x(\tau) = e$, then $x(t) = e\ \forall t \in [t_0, T_+)$.
(ii) If x is monotone and $x([t_0, T_+))$ is bounded, then $T_+ = +\infty$ and $\exists \ell \in F^{-1}(0)$ such that $x(t) \to \ell$ as $t \to +\infty$.

Proof.

(i) The constant function $u \equiv e$ satisfies $u' = F(u)$ and $u(\tau) = x(\tau)$. Set $S := \{t \in [t_0, T_+) : x(t) = e\}$. Continuity makes S relatively closed, while local uniqueness makes S relatively open. Since $\tau \in S$ and $[t_0, T_+)$ is connected, $S = [t_0, T_+)$.
(ii) Monotone boundedness gives $\ell := \lim_{t\uparrow T_+} x(t) \in \mathbb{R}$. If $T_+ < +\infty$, by Lemma 1.1.28, x extends through (T_+, ℓ), contradicting maximality. Thus $T_+ = +\infty$.
Suppose $F(\ell) \neq 0$. By continuity and $x(t) \to \ell$, $\exists c > 0$ and $t_1 \geq t_0$ such that $F(x(t))$ has constant sign and $|F(x(t))| \geq c\ \forall t \geq t_1$. Hence $|x(t) - x(s)| = \left|\int_s^t F(x(r))\, dr\right| \geq c(t - s)\ \forall t > s \geq t_1$, contradicting $x(t) \to \ell$. Therefore $F(\ell) = 0$.

Structural Commentary: Uniqueness makes equilibria barriers; maximal extension identifies bounded monotone limits.
Key Insight: A finite phase-line limit must be a zero of F. □

Theorem 1.4.4. *Autonomous Scalar Phase-Line Classification*
Let $F \in C^1(\mathbb{R}, \mathbb{R})$ and let $x : [t_0, T_+) \to \mathbb{R}$ be the maximal forward solution of $x' = F(x)$ with $x(t_0) = x_0$.
Set $E := F^{-1}(0)$. If $x_0 \notin E$, set $\sigma := \operatorname{sgn}(F(x_0))$ and $Z_\sigma := \{e \in E : \sigma(e - x_0) > 0\}$.

(i) If $x_0 \in E$, then $x \equiv x_0$.
(ii) If $x_0 \notin E$, then $(\sigma x)'(t) > 0\ \forall t \in [t_0, T_+)$.
(iii) If $x_0 \notin E$ and $Z_\sigma \neq \emptyset$, then $\exists! e_\sigma \in Z_\sigma$ such that $\sigma e_\sigma = \inf\{\sigma e : e \in Z_\sigma\}$. In this case, $T_+ = +\infty$ and $\sigma(x(t) - e_\sigma) \uparrow 0$ as $t \to +\infty$.
(iv) If $x_0 \notin E$ and $Z_\sigma = \emptyset$, then $\sigma x(t) \uparrow +\infty$ as $t \uparrow T_+$.

Proof.

(i) Since $x_0 \in E$, by Lemma 1.4.3(i), $x(t) = x_0\ \forall t \in [t_0, T_+)$.
(ii) Let C be the component of $\mathbb{R} \setminus E$ containing x_0. Continuity gives $\sigma F > 0$ on C. If x left C, continuity would give $x(\tau) \in E$ for some τ, and Lemma 1.4.3(i) would force $x \equiv x(\tau)$, contradicting $x_0 \notin E$. Thus $x([t_0, T_+)) \subseteq C$ and $(\sigma x)' = \sigma F(x) > 0$.
(iii) Since $F(x_0) \neq 0$, continuity gives $\delta > 0$ such that $E \cap [x_0 - \delta, x_0 + \delta] = \emptyset$. Let $m := \inf\{\sigma e : e \in Z_\sigma\}$ and choose $(e_n) \subseteq Z_\sigma$ with $\sigma e_n \to m$. Then (e_n) converges to $e_\sigma := \sigma m$. Since E is closed, $e_\sigma \in E$; the zero-free neighborhood gives $\sigma(e_\sigma - x_0) > 0$, so $e_\sigma \in Z_\sigma$. Its defining equality makes it unique.
No zero lies strictly between x_0 and e_σ. By (ii) and Lemma 1.4.3(i), σx is increasing and bounded above by σe_σ. Lemma 1.4.3(ii) gives $T_+ = +\infty$ and $x(t) \to \ell \in E$. Since $\sigma x_0 < \sigma\ell \leq \sigma e_\sigma$, one has $\ell \in Z_\sigma$; minimality gives $\sigma e_\sigma \leq \sigma\ell$, hence $\ell = e_\sigma$.
(iv) By (ii), σx is strictly increasing. If it were bounded above, Lemma 1.4.3(ii) would give $x(t) \to \ell \in E$ with $\sigma(\ell - x_0) > 0$, so $\ell \in Z_\sigma$, a contradiction. Therefore $\sigma x(t) \uparrow +\infty$ as $t \uparrow T_+$.

Structural Commentary: Components of $\mathbb{R} \setminus E$ fix the sign; the nearest zero supplies the barrier.
Key Insight: A trajectory approaches its next zero or escapes in the sign direction. □

Theorem 1.4.5. *Subcritical Harvest Phase Line*
Let $h_c := \frac{1}{4}$, $F_h(x) := (1-x)x - h$, $0 \le h < h_c$, and $x_\pm := \frac{1}{2}(1 \pm \sqrt{1-4h})$.
Let $x : [t_0, T_+) \to \mathbb{R}$ be the maximal forward solution of $x' = F_h(x)$ with $x(t_0) = x_0$.

(i) If $x_0 \in \{x_-, x_+\}$, then $T_+ = +\infty$ and $x \equiv x_0$.
(ii) If $x_0 < x_-$, then $x'(t) < 0$ $\forall t \in [t_0, T_+)$ and $x(t) \to -\infty$ as $t \uparrow T_+$.
(iii) If $x_- < x_0 < x_+$, then $T_+ = +\infty$, $x'(t) > 0$ $\forall t \ge t_0$, and $x(t) \to x_+$ as $t \to +\infty$.
(iv) If $x_0 > x_+$, then $T_+ = +\infty$, $x'(t) < 0$ $\forall t \ge t_0$, and $x(t) \to x_+$ as $t \to +\infty$.

Proof. The factorization $F_h = -(\cdot - x_-)(\cdot - x_+)$ gives $F_h < 0$ on $(-\infty, x_-) \cup (x_+, +\infty)$ and $F_h > 0$ on (x_-, x_+).

(i) Since $x_0 \in F_h^{-1}(0)$, by Theorem 1.4.4(i), $x \equiv x_0$. The constant solution is defined on $[t_0, +\infty)$, so maximality gives $T_+ = +\infty$.
(ii) Here $\operatorname{sgn}(F_h(x_0)) = -1$, and no zero lies below x_0. By Theorem 1.4.4(ii),(iv), $x' < 0$ and $-x(t) \uparrow +\infty$ as $t \uparrow T_+$.
(iii) Here $\operatorname{sgn}(F_h(x_0)) = 1$, and x_+ is the nearest zero above x_0. By Theorem 1.4.4(ii),(iii), $T_+ = +\infty$, $x' > 0$, and $x(t) \to x_+$.
(iv) Here $\operatorname{sgn}(F_h(x_0)) = -1$, and x_+ is the nearest zero below x_0. By Theorem 1.4.4(ii),(iii), $T_+ = +\infty$, $x' < 0$, and $x(t) \to x_+$.

Structural Commentary: The factorization fixes three sign intervals; the phase-line theorem handles each.
Key Insight: The upper root attracts every initial state above the lower threshold. □

Theorem 1.4.6. *Critical Harvest Phase Line*
Let $h_c := \frac{1}{4}$, $x_c := \frac{1}{2}$, $F_h(x) := (1-x)x - h$, and $h = h_c$.
Let $x : [t_0, T_+) \to \mathbb{R}$ be the maximal forward solution of $x' = F_{h_c}(x)$ with $x(t_0) = x_0$.

(i) If $x_0 = x_c$, then $T_+ = +\infty$ and $x \equiv x_c$.
(ii) If $x_0 > x_c$, then $T_+ = +\infty$, $x'(t) < 0$ $\forall t \ge t_0$, and $x(t) \to x_c$ as $t \to +\infty$.
(iii) If $x_0 < x_c$, then $x'(t) < 0$ $\forall t \in [t_0, T_+)$ and $x(t) \to -\infty$ as $t \uparrow T_+$.

Proof. The identity $F_{h_c}(x) = -(x - x_c)^2$ gives $F_{h_c}^{-1}(0) = \{x_c\}$ and $F_{h_c} < 0$ on $\mathbb{R} \setminus \{x_c\}$.

(i) Since $x_0 \in F_{h_c}^{-1}(0)$, by Theorem 1.4.4(i), $x \equiv x_c$. The constant solution is defined on $[t_0, +\infty)$, so maximality gives $T_+ = +\infty$.
(ii) Here $\operatorname{sgn}(F_{h_c}(x_0)) = -1$, and x_c is the nearest zero below x_0. By Theorem 1.4.4(ii),(iii), $T_+ = +\infty$, $x' < 0$, and $x(t) \to x_c$.
(iii) Here $\operatorname{sgn}(F_{h_c}(x_0)) = -1$, and no zero lies below x_0. By Theorem 1.4.4(ii),(iv), $x' < 0$ and $-x(t) \uparrow +\infty$ as $t \uparrow T_+$.

Structural Commentary: The double zero is the sole barrier; the sign is negative on both sides.
Key Insight: The critical equilibrium attracts from above and repels toward $-\infty$ below. □

Theorem 1.4.7. *Supercritical Harvest Phase Line*
Let $h_c := \frac{1}{4}$, $x_c := \frac{1}{2}$, $F_h(x) := (1-x)x - h$, and $h > h_c$.
Let $x : [t_0, T_+) \to \mathbb{R}$ be the maximal forward solution of $x' = F_h(x)$ with $x(t_0) = x_0$. Then:

(i) $x'(t) < 0$ $\forall t \in [t_0, T_+)$.
(ii) $x(t) \to -\infty$ as $t \uparrow T_+$.

Proof. For $h > h_c$, $F_h = -(\cdot - x_c)^2 - (h - h_c) < 0$ on $\mathbb{R}$ and $F_h^{-1}(0) = \emptyset$.

(i) By Theorem 1.4.4(ii), with $\sigma = -1$, $x' < 0$.
(ii) Since $F_h^{-1}(0) = \emptyset$, by Theorem 1.4.4(iv), $-x(t) \uparrow +\infty$ as $t \uparrow T_+$.

Structural Commentary: The completed square removes every zero, so the phase-line escape case applies.
Key Insight: Above critical harvest, every trajectory escapes toward $-\infty$. □

Corollary 1.4.8. *Critical Dimensional Harvest Rate*
Let $\kappa, N_{\max} > 0$, let $H \ge 0$, and set $G_H(N) := \kappa(1 - \frac{N}{N_{\max}})N - H$ and $H_c := \frac{\kappa N_{\max}}{4}$.
Let $N : [t_0, T_+) \to \mathbb{R}$ be the maximal forward solution of $N' = G_H(N)$ with $N(t_0) = N_0$.

(i) $G_H^{-1}(0) \cap (0, +\infty) \ne \emptyset$ iff $H \in [0, H_c]$, and $H_c = \max\{\eta \ge 0 : G_\eta^{-1}(0) \cap (0, +\infty) \ne \emptyset\}$.
(ii) For $H \in [0, H_c)$, set $N_\pm(H) := \frac{N_{\max}}{2}(1 \pm \sqrt{1 - \frac{4H}{\kappa N_{\max}}})$. Then $G_H^{-1}(0) = \{N_-(H), N_+(H)\}$ and $G_{H_c}^{-1}(0) = \{\frac{N_{\max}}{2}\}$.
(iii) If $H \in [0, H_c)$ and $N_0 > N_-(H)$, then $T_+ = +\infty$ and $N(t) \to N_+(H)$ as $t \to +\infty$.

Proof. Set $h := \frac{H}{\kappa N_{\max}}$, $h_c := \frac{1}{4}$, $x_c := \frac{1}{2}$, $x_\pm(h) := \frac{1}{2}(1 \pm \sqrt{1-4h})$ for $h \in [0, h_c]$, and $F_h(x) := (1-x)x - h$. Then $G_H(N) = \kappa N_{\max} F_h(\frac{N}{N_{\max}})$.
For the solution, set $x(\tau) := \frac{N(t_0 + \tau/\kappa)}{N_{\max}}$, $x_0 := \frac{N_0}{N_{\max}}$, and $\widehat{T}_+ := \kappa(T_+ - t_0)$. Thus $x : [0, \widehat{T}_+) \to \mathbb{R}$ is the maximal forward solution of $\frac{dx}{d\tau} = F_h(x)$ with $x(0) = x_0$.

(i) By Proposition 1.4.2(i)–(iii), $F_h^{-1}(0) \cap (0, +\infty) \ne \emptyset$ iff $h \in [0, h_c]$. Since $H = \kappa N_{\max} h$ and $H_c = \kappa N_{\max} h_c$, the asserted equivalence and maximum follow.
(ii) By Proposition 1.4.2(i),(ii), $F_h^{-1}(0) = \{x_-(h), x_+(h)\}$ for $h < h_c$ and $F_{h_c}^{-1}(0) = \{x_c\}$. Multiplication by $N_{\max}$ gives $N_\pm(H) = N_{\max} x_\pm(h)$ and $N_{\max} x_c = \frac{N_{\max}}{2}$.
(iii) The inequality $N_0 > N_-(H)$ is equivalent to $x_0 > x_-(h)$. By Theorem 1.4.5(i),(iii),(iv), $\widehat{T}_+ = +\infty$ and $x(\tau) \to x_+(h)$ as $\tau \to +\infty$. Hence $T_+ = +\infty$ and $N(t) \to N_{\max} x_+(h) = N_+(H)$.

Structural Commentary: State and time scaling reduce the dimensional model to the universal quadratic family.
Key Insight: The threshold is one quarter of the unharvested growth scale. □

1.5 Dynamical Systems Structure

For a time-periodic scalar equation, one period of continuous evolution can be compressed into a discrete map. Periodic solutions then become fixed points, and their long-time behavior can be studied through iteration.

Definition 1.5.1. *Scalar Poincaré Map*
Let $f \in C^1(\mathbb{R}^2, \mathbb{R})$ satisfy $f(t+1, x) = f(t, x)\ \forall (t, x) \in \mathbb{R}^2$.

(i) For $x_0 \in \mathbb{R}$, let $\phi_{x_0} : I_{x_0} \to \mathbb{R}$ be the unique maximal solution of $x' = f(t, x)$ with $0 \in I_{x_0}$ and $\phi_{x_0}(0) = x_0$; set $\phi(t, x_0) := \phi_{x_0}(t)$.
(ii) The *one-period domain* is $\mathcal{D} := \{x_0 \in \mathbb{R} : [0, 1] \subseteq I_{x_0}\}$.
(iii) The *Poincaré map* is $P : \mathcal{D} \to \mathbb{R}$, $P(x_0) := \phi(1, x_0)$.

Key Insight: P compresses one period of continuous evolution into one discrete step.

Proposition 1.5.2. *Periodic Orbits and Ordered Returns*
Let $f \in C^1(\mathbb{R}^2, \mathbb{R})$ satisfy $f(t+1, x) = f(t, x)$.
For $x_0 \in \mathbb{R}$, let $\phi_{x_0} : I_{x_0} \to \mathbb{R}$ be the unique maximal solution of $x' = f(t, x)$ with $0 \in I_{x_0}$ and $\phi_{x_0}(0) = x_0$.
Set $\mathcal{D} := \{x_0 \in \mathbb{R} : [0, 1] \subseteq I_{x_0}\}$ and $P : \mathcal{D} \to \mathbb{R}$, $P(x_0) := \phi_{x_0}(1)$.

(i) For $x_0 \in \mathcal{D}$, $P(x_0) = x_0 \iff I_{x_0} = \mathbb{R}$ and $\phi_{x_0}(t+1) = \phi_{x_0}(t)\ \forall t \in \mathbb{R}$.
(ii) For $x_0, y_0 \in \mathcal{D}$, $x_0 < y_0 \implies P(x_0) < P(y_0)$.

Proof.

(i) Suppose first that $P(x_0) = x_0$. For $n \in \mathbb{Z}$, define $u_n : [n, n+1] \to \mathbb{R}$ by $u_n(t) := \phi_{x_0}(t - n)$. Then $u_n' = f(t-n, u_n) = f(t, u_n)$, while $u_n(n+1) = \phi_{x_0}(1) = x_0 = u_{n+1}(n+1)$. The one-periodicity of f makes the one-sided derivatives agree at every integer, so the u_n glue to a one-periodic $u \in C^1(\mathbb{R}, \mathbb{R})$ satisfying $u' = f(t, u)$ and $u(0) = x_0$. Local uniqueness and maximality give $I_{x_0} = \mathbb{R}$ and $\phi_{x_0} = u$.
Conversely, if $I_{x_0} = \mathbb{R}$ and ϕ_{x_0} is one-periodic, then $P(x_0) = \phi_{x_0}(1) = \phi_{x_0}(0) = x_0$.
(ii) Choose an open interval J with $[0, 1] \subseteq J \subseteq I_{x_0} \cap I_{y_0}$. Since $f \in C^1$, it is state-Lipschitz on compact subsets of $\mathbb{R}^2$. By Theorem 1.3.5(ii), $\phi_{x_0}(t) < \phi_{y_0}(t)\ \forall t \in [0, 1]$; evaluation at $t = 1$ gives $P(x_0) < P(y_0)$.

Structural Commentary: Glue one-period segments; compare distinct initial states by scalar order preservation.
Key Insight: Periodic trajectories are fixed points of a strictly increasing return map. □

Proposition 1.5.3. *Periodic Scalar Linear Forcing*
Let $a \in \mathbb{R}$ and $g \in C(\mathbb{R}, \mathbb{R})$ satisfy $g(t+1) = g(t)$ and $g(t) \geq 0\ \forall t \in \mathbb{R}$. Set $I_a := \int_0^1 e^{-as} g(s)\, ds$.
For $x_0 \in \mathbb{R}$, let $x(\cdot\,; x_0)$ be the solution of $x' = ax + g(t)$ with $x(0; x_0) = x_0$, and set $P(x_0) := x(1; x_0)$.
If $a \neq 0$, put $x_{0,*} := -\frac{e^a}{e^a - 1} I_a$ and $x_*(t) := e^{at}\big(x_{0,*} + \int_0^t e^{-as} g(s)\, ds\big)$.

(i) $a \neq 0 \implies x_*$ is the unique one-periodic solution.
(ii) If $a = 0$ and $g \equiv 0$, the one-periodic solutions are $t \mapsto c$, $c \in \mathbb{R}$.
(iii) $a = 0$ and $g \not\equiv 0 \implies$ no one-periodic solution exists.

Proof. By Proposition 1.2.1, $x(t; x_0) = e^{at}\big(x_0 + \int_0^t e^{-as} g(s)\, ds\big)$ and $P(x_0) - x_0 = (e^a - 1)x_0 + e^a I_a$.
If $P(x_0) = x_0$, then $d(t) := x(t+1; x_0) - x(t; x_0)$ satisfies $d' = ad$ and $d(0) = 0$, so $d \equiv 0$. The converse is immediate; hence the one-periodic solutions correspond to $\mathrm{Fix}(P)$.

(i) If $a \neq 0$, then $e^a - 1 \neq 0$ and $\mathrm{Fix}(P) = \{x_{0,*}\}$. Substitution of $x_0 = x_{0,*}$ into the solution formula gives x_*.
(ii) If $a = 0$ and $g \equiv 0$, then $x(t; x_0) = x_0\ \forall (t, x_0) \in \mathbb{R}^2$.
(iii) If $a = 0$ and $g \not\equiv 0$, continuity and nonnegativity give $I_0 = \int_0^1 g(s)\, ds > 0$. Thus $P(x_0) - x_0 = I_0 \neq 0\ \forall x_0 \in \mathbb{R}$.

Structural Commentary: Variation of constants makes the return displacement affine in x_0.
Key Insight: $P(x_0) - x_0 = (e^a - 1)x_0 + e^a I_a$. □

Proposition 1.5.4. *Concave Periodic Return-Map Geometry*
Let $f, g \in C^2(\mathbb{R}, \mathbb{R})$ satisfy $f''(u) < 0\ \forall u \in \mathbb{R}$, $g(t+1) = g(t)$ and $g(t) \geq 0\ \forall t \in \mathbb{R}$, and $g \not\equiv 0$.
Let $W \subseteq \mathbb{R}^2$ be open and $(h, x) \in W$. For $(\eta, y) \in W$, let $\phi_\eta(\cdot\,, y)$ be the unique solution of $z' = f(z) + \eta g(t)$, $z(0) = y$, on $[0, 1]$.
Set $P_\eta(y) := \phi_\eta(1, y)$, $\phi(t) := \phi_h(t, x)$, $A(t) := f'(\phi(t))$, and $\theta(t) := \partial_x \phi_h(t, x)$.

(i) $P_h'(x) = \exp\Big(\int_0^1 A(s)\, ds\Big) > 0$.
(ii) $P_h''(x) = P_h'(x) \int_0^1 f''(\phi(s))\theta(s)\, ds < 0$.
(iii) $\partial_h P_h(x) = \int_0^1 \exp\Big(\int_s^1 A(r)\, dr\Big) g(s)\, ds > 0$.

Proof. Set $\mathcal{F}(t, z, \eta) := f(z) + \eta g(t)$. Since $\mathcal{F} \in C^2(\mathbb{R}^3, \mathbb{R})$, by Theorem 1.1.24, applied successively along the solution arcs over $[0, 1]$, the flow has the required two state derivatives and one parameter derivative.

(i) $\theta' = A\theta$ and $\theta(0) = 1$. Hence $\theta(t) = \exp\Big(\int_0^t A(s)\, ds\Big) > 0$, so $P_h'(x) = \theta(1)$.
(ii) Put $\zeta := \partial_x^2 \phi_h(\cdot\,, x)$. Then $\zeta' = A\zeta + f''(\phi)\theta^2$ and $\zeta(0) = 0$.
By Proposition 1.2.1, $\zeta(1) = \theta(1) \int_0^1 f''(\phi(s))\theta(s)\, ds$. Since $f'' < 0$ and $\theta > 0$, $P_h''(x) = \zeta(1) < 0$.
(iii) Put $\psi := \partial_h \phi_h(\cdot\,, x)$. Then $\psi' = A\psi + g$ and $\psi(0) = 0$.
By Proposition 1.2.1, $\psi(1) = \int_0^1 \exp\Big(\int_s^1 A(r)\, dr\Big) g(s)\, ds$. The integrand is nonnegative and not identically zero, so $\psi(1) > 0$ and $\partial_h P_h(x) = \psi(1)$.

Structural Commentary: Differentiate the flow; solve each scalar variational equation by an integrating factor.
Key Insight: $f'' < 0$ bends the return map; $g \geq 0$ moves it upward. □

Proposition 1.5.5. *Geometry of the Periodically Harvested Return Map*
Let $g(t) := 1 - \sin(2\pi t)$ and $F_\eta(t, z) := (1 - z)z - \eta g(t)$.
Let $W \subseteq \mathbb{R}^2$ be open and $(h, x) \in W$. For $(\eta, y) \in W$, let $\phi_\eta(\cdot\,, y)$ be the unique solution of $z' = F_\eta(t, z)$, $z(0) = y$, on $[0, 1]$.
Set $P_\eta(y) := \phi_\eta(1, y)$ and $\theta_h(t, x) := \partial_x \phi_h(t, x)$.

(i) $P_h'(x) = \exp\Big(\int_0^1 (1 - 2\phi_h(s, x))\, ds\Big) > 0$.

(ii) $P_h''(x) = -2P_h'(x)\int_0^1 \theta_h(s,x)\,ds < 0$.
(iii) $\partial_h P_h(x) = -\int_0^1 \exp\Big(\int_s^1 (1-2\phi_h(r,x))\,dr\Big)\,g(s)\,ds < 0$.

Proof. Put $f(z) := (1-z)z$, $\widetilde{W} := \{(-\eta, y) : (\eta, y) \in W\}$, and $Q_\lambda(y) := P_{-\lambda}(y)$ for $(\lambda, y) \in \widetilde{W}$. Then Q_λ is the return map for $z' = f(z) + \lambda g(t)$, and $f'' = -2$, while $g \geq 0$ and $g \not\equiv 0$. Set $E(s) := \exp\Big(\int_s^1 (1-2\phi_h(r,x))\,dr\Big)$.

(i) By Proposition 1.5.4(i), applied at $(-h, x)$, $P_h'(x) = Q'_{-h}(x) = \exp\Big(\int_0^1 (1-2\phi_h(s,x))\,ds\Big) > 0$.
(ii) By Proposition 1.5.4(ii), $P_h''(x) = Q''_{-h}(x) = -2P_h'(x)\int_0^1 \theta_h(s,x)\,ds < 0$.
(iii) By the chain rule and Proposition 1.5.4(iii), $\partial_h P_h(x) = -\partial_\lambda Q_{-h}(x) = -\int_0^1 E(s)g(s)\,ds < 0$.

Structural Commentary: Reflect the parameter; specialize the general concave return-map identities.
Key Insight: Harvesting shifts the increasing concave return map downward. □

Example 1.5.6. *The Unharvested Return Map*
For $x \in [0, +\infty)$, let $\phi_0(\,\cdot\,, x)$ solve $z' = (1-z)z$ with $z(0) = x$, and set $P_0(x) := \phi_0(1, x)$.
Direct differentiation verifies $\phi_0(t,x) = \frac{e^t x}{1+(e^t-1)x}$ for $t \geq 0$, so $P_0(x) = \frac{ex}{1+(e-1)x}$. Solving $P_0(x) = x$ gives $\mathrm{Fix}(P_0) = \{0, 1\}$. By Proposition 1.5.2(i), these fixed points correspond to the constant one-periodic solutions $z \equiv 0$ and $z \equiv 1$.

Theorem 1.5.7. *Iteration of an Increasing Concave Map*
Let $I \subseteq \mathbb{R}$ be an interval, $P : I \to I$ continuous, strictly increasing, strictly concave, and $\mathrm{Fix}(P) = \{x_1, x_2\}$ with $x_1 < x_2$. For $x \in I$, set $x_0 := x$ and $x_{n+1} := P(x_n)$.
(i) If $x > x_1$, then $x_n \to x_2$.
(ii) If $x = x_1$, then $x_n = x_1$ $\forall n \geq 0$.
(iii) If $x < x_1$, then $x_{n+1} < x_n$ $\forall n \geq 0$ and $x_n \downarrow \inf I$ in $\overline{\mathbb{R}}$; if $\inf I = -\infty$, then $x_n \to -\infty$.

Proof. For $a, b \in I$ with $a < b$, set $m(a,b) := \frac{P(b)-P(a)}{b-a}$. If $a < b < c$, strict concavity at $b = (1-\lambda)a + \lambda c$, $\lambda := \frac{b-a}{c-a} \in (0,1)$, gives $m(a,b) > m(a,c) > m(b,c)$. Since $P(x_j) = x_j$, $m(x_1, x_2) = 1$.

(i) If $x \in (x_1, x_2)$, then $m(x_1, x) > m(x_1, x_2) = 1$ and monotonicity gives $x < P(x) < x_2$. Hence $x_n \uparrow \ell \in (x_1, x_2]$, and continuity gives $P(\ell) = \ell$, so $\ell = x_2$. If $x = x_2$, the sequence is constant.
If $x > x_2$, then $m(x_2, x) < m(x_1, x_2) = 1$ and monotonicity gives $x_2 < P(x) < x$. Hence $x_n \downarrow \ell \in [x_2, x)$, and continuity again gives $\ell = x_2$.
(ii) Since $P(x_1) = x_1$, induction gives $x_n = x_1$ $\forall n \geq 0$.
(iii) If $x < x_1$, then $m(x, x_1) > m(x_1, x_2) = 1$, so $P(x) < x$. Induction gives $x_{n+1} < x_n < x_1$ $\forall n \geq 0$, and $x_n \downarrow \ell \in \overline{\mathbb{R}}$ with $\ell \geq \inf I$. If $\ell > \inf I$, then $\ell \in I$, continuity gives $P(\ell) = \ell < x_1$, and this contradicts $\mathrm{Fix}(P) = \{x_1, x_2\}$. Thus $\ell = \inf I$.

Structural Commentary: Nested secant slopes determine the sign of $P(x) - x$ on three intervals.
Key Insight: The lower fixed point is a threshold; the upper one attracts from above. □

Corollary 1.5.8. *Periodic Logistic Threshold Structure*
Let $g(t) := 1 - \sin(2\pi t)$. For $(\eta, y) \in \mathbb{R}^2$, let $\phi_{\eta,y} : I_{\eta,y} \to \mathbb{R}$ be the unique maximal solution of $z' = (1-z)z - \eta g(t)$ with $0 \in I_{\eta,y}$ and $\phi_{\eta,y}(0) = y$.
Set $\mathcal{D}_\eta := \{y \in \mathbb{R} : [0,1] \subseteq I_{\eta,y}\}$ and $P_\eta : \mathcal{D}_\eta \to \mathbb{R}$, $P_\eta(y) := \phi_{\eta,y}(1)$. Fix $h \geq 0$ and an interval $J \subseteq \mathcal{D}_h$.
(i) $\#\,\mathrm{Fix}(P_h|_J) \leq 2$; hence there are at most two one-periodic solutions with initial values in J.
(ii) If $P_h(J) \subseteq J$, $\mathrm{Fix}(P_h|_J) = \{x_1, x_2\}$ with $x_1 < x_2$, and $x \in J$ satisfies $x > x_1$, then $P_h^n(x) \to x_2$.
(iii) If $P_h(J) \subseteq J$, $\mathrm{Fix}(P_h|_J) = \{x_1, x_2\}$ with $x_1 < x_2$, and $x \in J$ satisfies $x < x_1$, then $P_h^n(x) \downarrow \inf J$ in $\overline{\mathbb{R}}$.
(iv) $\partial_h P_h(x) < 0$ $\forall x \in \mathcal{D}_h$.

Proof. Fix $x \in \mathcal{D}_h$. The solution arc $\{(t, \phi_{h,x}(t), h) : t \in [0,1]\}$ is compact. By Theorem 1.1.24, applied successively along a finite partition of this arc, $\exists$ an open neighborhood $W_x \subseteq \mathbb{R}^2$ of (h, x) on which the time-1 flow is defined and C^2. By Proposition 1.5.5, $P_h'(x) > 0$, $P_h''(x) < 0$, and $\partial_h P_h(x) < 0$. Thus P_h is strictly increasing and strictly concave on J.

(i) If $a < b < c$ were fixed points in J, strict concavity would give $P_h(b) > L_{a,c}(b) = b$, where $L_{a,c}$ is the chord through (a,a) and (c,c), contradicting $P_h(b) = b$. Hence $\#\,\mathrm{Fix}(P_h|_J) \leq 2$. By Proposition 1.5.2(i), these fixed points are exactly the initial values in J of one-periodic solutions.
(ii) Under the stated hypotheses, $P_h|_J : J \to J$ is continuous, strictly increasing, and strictly concave. By Theorem 1.5.7(i), $P_h^n(x) \to x_2$.
(iii) Under the stated hypotheses, by Theorem 1.5.7(iii), $P_h^n(x) \downarrow \inf J$ in $\overline{\mathbb{R}}$.
(iv) The local calculation preceding (i) gives $\partial_h P_h(x) < 0$ $\forall x \in \mathcal{D}_h$.

Structural Commentary: Smooth dependence supplies concavity; graph geometry and iteration classify fixed points.
Key Insight: Two periodic states form a threshold with an attracting upper branch. □

1.6 Semigroups and Evolution Viewpoint

1.7 Measure-Preserving Dynamics and Ergodicity

Measure-preserving dynamics study maps whose pullbacks keep mass fixed. The central question is whether time averages along one orbit recover space averages with respect to an invariant probability measure.

Definition 1.7.1. *Measure-Preserving and Ergodic Transformations*
Let $(X, \mathcal{M}, \mu)$ be a measure space and $T : X \to X$.
For $E, A, B \in \mathcal{M}$, write $T^{-1}E := \{x \in X : T(x) \in E\}$ and $A \triangle B := (A \setminus B) \cup (B \setminus A)$.
(i) T is *measurable* iff $T^{-1}E \in \mathcal{M}$ $\forall E \in \mathcal{M}$.
(ii) If T is measurable, the *pushforward measure* is $(T_*\mu)(E) := \mu(T^{-1}E)$, $E \in \mathcal{M}$.
(iii) A measurable T is *measure preserving* iff $T_*\mu = \mu$.
(iv) For measurable T, $A \in \mathcal{M}$ is *invariant modulo μ* iff $\mu(A \triangle T^{-1}A) = 0$.
(v) If $0 < \mu(X) < +\infty$ and T is measure preserving, then T is *ergodic* iff $\mu(A \triangle T^{-1}A) = 0 \implies \mu(A) \in \{0, \mu(X)\}$ $\forall A \in \mathcal{M}$.

Key Insight: Pullbacks preserve mass; ergodic invariants are trivial.

Proposition 1.7.2. *Integral Test for Measure Preservation*
Let $(X, \mathcal{M}, \mu)$ be a finite measure space and $T : X \to X$ measurable. Then $T_*\mu = \mu$ iff $\forall g \in L^1(X,\mu)$, $g \circ T \in L^1(X,\mu)$ and $\int_X g \circ T \, d\mu = \int_X g \, d\mu$.

Proof.
($\Rightarrow$) If $T_*\mu = \mu$, then $\int_X \mathbf{1}_E \circ T \, d\mu = \mu(T^{-1}E) = \mu(E) = \int_X \mathbf{1}_E \, d\mu$ $\forall E \in \mathcal{M}$. Linearity gives the identity for nonnegative simple functions. For $0 \le g \in L^1(X,\mu)$, choose simple $0 \le s_n \uparrow g$; monotone convergence applied to s_n and $s_n \circ T$ gives the identity and $g \circ T \in L^1(X,\mu)$. Apply this conclusion to $g^{\pm}$ for general $g \in L^1(X,\mu)$.
($\Leftarrow$) Since $\mu(X) < +\infty$, $\mathbf{1}_E \in L^1(X,\mu)$ $\forall E \in \mathcal{M}$. Taking $g = \mathbf{1}_E$ gives $(T_*\mu)(E) = \int_X \mathbf{1}_E \circ T \, d\mu = \int_X \mathbf{1}_E \, d\mu = \mu(E)$.

Structural Commentary: Indicators encode sets; approximation extends the identity to observables.
Key Insight: Measure preservation is equality of integrals after pullback. □

Remark 1.7.3. *Invariant Sets as Invariant Indicators*
If $T_*\mu = \mu$ and $A \in \mathcal{M}$, then $\mu(A \triangle T^{-1}A) = 0 \iff \mathbf{1}_A \circ T = \mathbf{1}_A$ μ-a.e.

Proposition 1.7.4. *Invariant Functions Detect Ergodicity*
Let $(X, \mathcal{M}, \mu)$ satisfy $0 < \mu(X) < +\infty$, and let $T : X \to X$ be measurable with $T_*\mu = \mu$. Then T is ergodic iff $\forall$ measurable $g : X \to \overline{\mathbb{R}}$, $g \circ T = g$ μ-a.e. implies $\exists c \in \overline{\mathbb{R}}$ such that $g = c$ μ-a.e.

Proof.
($\Rightarrow$) Assume T is ergodic and $g \circ T = g$ μ-a.e. For $a \in \mathbb{Q}$, set $A_a := \{g < a\}$. Then $\mu(A_a \triangle T^{-1}A_a) = 0$, so $\mu(A_a) \in \{0, \mu(X)\}$. With $\inf \varnothing := +\infty$, set $c := \inf\{a \in \mathbb{Q} : \mu(A_a) = \mu(X)\} \in \overline{\mathbb{R}}$. If $a < c$, then $\mu(A_a) = 0$; if $b > c$, monotonicity and the definition of c give $\mu(X \setminus A_b) = 0$. Countable unions give $\mu(g < c) = \mu(g > c) = 0$, including $c = \pm\infty$; hence $g = c$ μ-a.e.
($\Leftarrow$) Assume every measurable T-invariant $g : X \to \overline{\mathbb{R}}$ is constant μ-a.e. If $A \in \mathcal{M}$ and $\mu(A \triangle T^{-1}A) = 0$, then $\mathbf{1}_A \circ T = \mathbf{1}_A$ μ-a.e. Thus $\mathbf{1}_A = c$ μ-a.e. for some $c \in \{0,1\}$, so $\mu(A) = c\mu(X) \in \{0, \mu(X)\}$.

Structural Commentary: Level sets convert invariant functions into invariant sets.
Key Insight: Ergodicity collapses invariant observables to constants. □

Method 1.7.5. *Krylov–Bogoliubov Averaging*
Let $X \neq \varnothing$ be compact metric, let $f \in C(X,X)$, and let $\mathcal{P}(X)$ denote the Borel probability measures on X.

(i) Choose $\eta \in \mathcal{P}(X)$ and set $\mu_n := \frac{1}{n}\sum_{k=0}^{n-1} (f^k)_*\eta \in \mathcal{P}(X)$.
(ii) For $g \in C(X)$, record $\int_X g \, d\mu_n = \frac{1}{n}\sum_{k=0}^{n-1} \int_X g \circ f^k \, d\eta$.
(iii) By Corollary 6.4.7, choose $n_j \uparrow \infty$ and a positive Radon measure μ with $\int_X g \, d\mu_{n_j} \to \int_X g \, d\mu$ $\forall g \in C(X)$; testing $g = 1$ gives $\mu \in \mathcal{P}(X)$.
(iv) Use $\int_X g \circ f \, d\mu_n - \int_X g \, d\mu_n = \frac{1}{n}\int_X (g \circ f^n - g)\, d\eta$ and the bound $2\|g\|_\infty / n$. Passing to n_j gives equality of the $C(X)$-integrals of the Radon measures $f_*\mu$ and μ. By Theorem 5.2.13, $f_*\mu = \mu$.

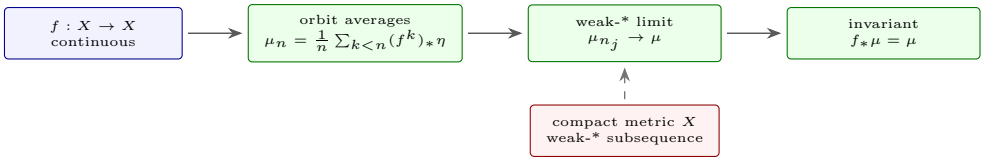

Figure 234: Krylov–Bogoliubov: $\mu_n = \frac{1}{n}\sum_{k<n}(f^k)_*\eta \xrightarrow{w^*} \mu$ and $\frac{1}{n}(g \circ f^n - g) \to 0$, hence $f_*\mu = \mu$.

Theorem 1.7.6. *Krylov–Bogoliubov Invariant Measure Theorem*
Let $X \neq \varnothing$ be compact metric, let $f \in C(X,X)$, and let $\mathcal{P}(X)$ denote the Borel probability measures on X. Then $\exists \mu \in \mathcal{P}(X)$ such that $f_*\mu = \mu$.

Proof. Choose $\eta \in \mathcal{P}(X)$ and set $\mu_n := \frac{1}{n}\sum_{k=0}^{n-1} (f^k)_*\eta \in \mathcal{P}(X)$. By Corollary 6.4.7, $\exists n_j \uparrow \infty$ and a positive Radon measure μ such that $\int_X g \, d\mu_{n_j} \to \int_X g \, d\mu$ $\forall g \in C(X)$. Taking $g = 1$ gives $\mu(X) = 1$, so $\mu \in \mathcal{P}(X)$.

For $g \in C(X)$, $\int_X g \circ f \, d\mu_n - \int_X g \, d\mu_n = \frac{1}{n}\int_X (g \circ f^n - g)\, d\eta$, whose absolute value is at most $2\|g\|_\infty / n$. Passing to n_j gives $\int_X g \, d(f_*\mu) = \int_X g \, d\mu$ $\forall g \in C(X)$. Both measures are Radon, and $C_c(X) = C(X)$; hence $f_*\mu = \mu$ by Theorem 5.2.13. *Structural Commentary*: Average pushforwards; extract a weak-* limit; cancel endpoints.
Key Insight: Compactness turns orbit averages into an invariant probability. □

Proposition 1.7.7. *Ergodic Measures Are Extreme Invariant Measures*
Let X be compact metric, let $f \in C(X,X)$, let $\mathcal{P}(X)$ denote the Borel probability measures on X, and set $\mathcal{I}_f(X) := \{\lambda \in \mathcal{P}(X) : f_*\lambda = \lambda\}$. For $\mu \in \mathcal{I}_f(X)$, the following are equivalent:

(i) $\mu \in \mathrm{Ext}(\mathcal{I}_f(X))$;
(ii) f is μ-ergodic.

Proof.
(i) $\Rightarrow$ (ii) If f is not μ-ergodic, choose $A \in \mathcal{B}(X)$ with $\mu(A \triangle f^{-1}A) = 0$ and $0 < \mu(A) < 1$. Set $\nu(E) := \mu(E \cap A)/\mu(A)$ and $\rho(E) := \mu(E \cap A^c)/\mu(A^c)$. For $E \in \mathcal{B}(X)$, invariance modulo μ gives $\mu(f^{-1}E \cap A) = \mu(f^{-1}(E \cap A)) = \mu(E \cap A)$, and the same identity holds with A^c. Thus $\nu, \rho \in \mathcal{I}_f(X)$, while $\mu = \mu(A)\nu + \mu(A^c)\rho$ and $\nu(A) \neq \rho(A)$, contradicting (i).

(*ii*) $\Rightarrow$ (*i*) Let $\mu = \theta\nu + (1-\theta)\rho$ with $0 < \theta < 1$ and $\nu, \rho \in \mathcal{I}_f(X)$. Since $\theta\nu \le \mu$, by Theorem 3.2.1, $h := d\nu/d\mu$ satisfies $0 \le h \le \theta^{-1}$ μ-a.e. Invariance of ν and μ gives $\int_X (h\circ f)h\,d\mu = \int_X h\circ f\,d\nu = \int_X h\,d\nu = \int_X h^2\,d\mu$ and $\int_X (h\circ f)^2\,d\mu = \int_X h^2\,d\mu$. Hence $\int_X (h\circ f - h)^2\,d\mu = 0$. By Proposition 1.7.4, $h = c$ μ-a.e.; since $1 = \int_X h\,d\mu$, $c = 1$ and $\nu = \mu$. The convex identity then gives $\rho = \mu$.

Structural Commentary: Invariant sets split measures; invariant densities test splits.
Key Insight: Extreme invariant measures are exactly ergodic measures. □

Corollary 1.7.8. *Existence of an Ergodic Invariant Measure*
Let $X \neq \varnothing$ be compact metric, let $f \in C(X,X)$, let $\mathcal{P}(X)$ denote the Borel probability measures on X, and set $\mathcal{I}_f(X) := \{\mu \in \mathcal{P}(X) : f_*\mu = \mu\}$. Then $\exists \mu \in \mathcal{I}_f(X)$ such that f is μ-ergodic.

Proof. By Theorem 1.7.6, $\mathcal{I}_f(X) \neq \varnothing$, and it is convex. Let a net $(\mu_\alpha) \subseteq \mathcal{I}_f(X)$ converge weak-* among finite signed Radon measures to μ. Positivity on $C(X)_+$ and the identity $\int_X 1\,d\mu = 1$ pass to the limit, so $\mu \in \mathcal{P}(X)$. For $g \in C(X)$, $\int_X g\circ f\,d\mu = \lim_\alpha \int_X g\circ f\,d\mu_\alpha = \lim_\alpha \int_X g\,d\mu_\alpha = \int_X g\,d\mu$; hence $f_*\mu = \mu$ by Theorem 5.2.13. Thus $\mathcal{I}_f(X)$ is weak-* closed and $\|\lambda\|_{\mathrm{var}} = 1$ $\forall \lambda \in \mathcal{I}_f(X)$, so it is weak-* compact by Corollary 6.4.6.

By Theorem 9.2.10, choose a dense sequence $(g_j)_{j\ge1}$ in $C(X,\mathbb{R})$. Set $K_0 := \mathcal{I}_f(X)$ and, recursively, $a_j := \max\{\int_X g_j\,d\lambda : \lambda \in K_{j-1}\}$ and $K_j := \{\lambda \in K_{j-1} : \int_X g_j\,d\lambda = a_j\}$. Weak-* continuity of $\lambda \mapsto \int_X g_j\,d\lambda$ makes K_j nonempty and compact, and affinity makes it a face of K_{j-1}. Hence $K_\infty := \bigcap_{j\ge0} K_j \neq \varnothing$. If $\lambda, \nu \in K_\infty$, their integrals agree on the dense family (g_j), hence on $C(X,\mathbb{R})$. By Theorem 5.2.13, $\lambda = \nu$; write $K_\infty = \{\mu\}$.

If $\mu = \theta\lambda + (1-\theta)\nu$ with $0 < \theta < 1$ and $\lambda, \nu \in \mathcal{I}_f(X)$, the face property applied successively to $K_1, K_2, \dots$ gives $\lambda, \nu \in K_\infty$, so $\lambda = \nu = \mu$. Thus $\mu \in \mathrm{Ext}(\mathcal{I}_f(X))$, and f is μ-ergodic by Proposition 1.7.7. *Structural Commentary*: Compact nested faces isolate one extreme invariant measure.
Key Insight: Countably many observables isolate an ergodic invariant measure. □

Theorem 1.7.9. *Asymptotic Ergodic Averages*
Let $(X, \mathcal{M}, \mu)$ satisfy $0 < \mu(X) < +\infty$, and let $T : X \to X$ be measurable with $T_*\mu = \mu$. For $g \in L^1(X,\mu)$, set $U_T g := g \circ T$ and $A_n g := \frac{1}{n}\sum_{k=0}^{n-1} U_T^k g$. Then T is ergodic iff $A_n g \to \mu(X)^{-1}\int_X g\,d\mu$ μ-a.e. $\forall g \in L^1(X,\mu)$.

Proof.

(⇒) First establish the maximal inequality. For $v \in L^1(X,\mu)$, set $S_0 v := 0$ and $S_n v := \sum_{k=0}^{n-1} v\circ T^k$. For $N \ge 1$, set $M_N v := \max_{0\le n\le N} S_n v$ and $E_N := \{M_N v > 0\}$. On E_N, $v + M_N v \circ T \ge M_N v$. Since $M_N v = 0$ on E_N^c, $\int_{E_N} M_N v\,d\mu = \int_X M_N v\,d\mu$. Since $M_N v \circ T \ge 0$ and $T_*\mu = \mu$, $\int_{E_N} M_N v \circ T\,d\mu \le \int_X M_N v\,d\mu$. Integrating the pointwise inequality therefore gives $\int_{E_N} v\,d\mu \ge 0$. Since $E_N \uparrow E := \{\sup_{n\ge1} S_n v > 0\}$, dominated convergence gives $\int_E v\,d\mu \ge 0$.

Fix $g \in L^1(X,\mu)$. For $\varepsilon > 0$, $\sum_{n\ge1} \mu(|g\circ T^n| > \varepsilon n) = \sum_{n\ge1} \mu(|g| > \varepsilon n) \le \varepsilon^{-1}\int_X |g|\,d\mu$. By Theorem 5.1.6, applied with $\varepsilon = 1/m$, $m \ge 1$, $g\circ T^n/n \to 0$ μ-a.e. Hence $A_n g \circ T - A_n g = (g\circ T^n - g)/n \to 0$ μ-a.e., so $\overline{g} := \limsup_n A_n g$ and $\underline{g} := \liminf_n A_n g$ are T-invariant. By Proposition 1.7.4, $\exists a, b \in \overline{\mathbb{R}}$ such that $(\overline{g}, \underline{g}) = (a, b)$ μ-a.e. and $b \le a$.

Set $m := \mu(X)^{-1}\int_X g\,d\mu$. If $a > m$, choose $m < c < a$. Then $\limsup_n A_n(g - c) = a - c > 0$ μ-a.e., so the maximal inequality applied to $v = g - c$ gives $\int_X (g-c)\,d\mu \ge 0$, contradicting $c > m$. Thus $a \le m$. If $b < m$, choose $b < c < m$ and apply the maximal inequality to $v = c - g$; this gives $\int_X (c-g)\,d\mu \ge 0$, contradicting $c < m$. Therefore $b \ge m$, and $b \le a \le m \le b$ proves $A_n g \to m$ μ-a.e.

(⇐) If $A \in \mathcal{M}$ and $\mu(A \triangle T^{-1}A) = 0$, then $A_n \mathbf{1}_A = \mathbf{1}_A$ μ-a.e. $\forall n \ge 1$. The assumed limit gives $\mathbf{1}_A = \mu(A)/\mu(X)$ μ-a.e., so $\mu(A) \in \{0, \mu(X)\}$.

Structural Commentary: Hopf's maximal inequality squeezes invariant limsup and liminf.
Key Insight: Ergodicity collapses both asymptotic envelopes to the space mean. □

Proposition 1.7.10. *Koopman Isometry Characterization*
Let $(X, \mathcal{M}, \mu)$ satisfy $\mu(X) < +\infty$, and let $T : X \to X$ be measurable. Then $T_*\mu = \mu$ iff $\forall p \in [1, +\infty)$ and $\forall g \in L^p(X,\mu)$, the pullback $U_T g := g \circ T$ belongs to $L^p(X,\mu)$ and $\|U_T g\|_p = \|g\|_p$.

Proof.

(⇒) If $T_*\mu = \mu$, Proposition 1.7.2 applied to $|g|^p$ gives $\|U_T g\|_p^p = \int_X |g\circ T|^p\,d\mu = \int_X |g|^p\,d\mu = \|g\|_p^p$ $\forall p \in [1, +\infty)$ and $g \in L^p(X,\mu)$.
(⇐) Apply the $p = 1$ identity to $g = \mathbf{1}_E$, $E \in \mathcal{M}$: $(T_*\mu)(E) = \|\mathbf{1}_E \circ T\|_1 = \|\mathbf{1}_E\|_1 = \mu(E)$.

Structural Commentary: Test pullback norms on powers and indicators.
Key Insight: Koopman isometries encode measure preservation. □

Proposition 1.7.11. *Linear Preservation of Lebesgue Measure*
Let $n \ge 1$ and $T \in \mathcal{L}(\mathbb{R}^n)$. Then:

(i) $T_* m_n = m_n \iff T \in GL_n(\mathbb{R})$ and $|\det T| = 1$.
(ii) For $D := \mathrm{diag}(2, \frac{1}{2}) \in GL_2(\mathbb{R})$, $D_* m_2 = m_2$.

Proof.

(i) If $T_* m_n = m_n$ and T were singular, then $L := T(\mathbb{R}^n)$ would satisfy $m_n(L) = 0$ by Corollary 2.3.6, whereas $(T_* m_n)(L) = m_n(T^{-1}L) = m_n(\mathbb{R}^n) = +\infty$. Thus $T \in GL_n(\mathbb{R})$. For $E \in \mathcal{L}^n$ with $0 < m_n(E) < +\infty$, by Corollary 2.3.4, $m_n(E) = m_n(T^{-1}E) = |\det T|^{-1} m_n(E)$, so $|\det T| = 1$. Conversely, if $T \in GL_n(\mathbb{R})$ and $|\det T| = 1$, then $(T_* m_n)(E) = m_n(T^{-1}E) = m_n(E)$ $\forall E \in \mathcal{L}^n$ by the same corollary.
(ii) Since $\det D = 1$, claim (i) gives $D_* m_2 = m_2$.

Structural Commentary: Exclude singular range; apply determinant scaling to preimages.
Key Insight: Linear volume preservation is exactly unit determinant. □

Theorem 1.7.12. *Poincaré Recurrence*
Let $(X, \mathcal{M}, \mu)$ satisfy $\mu(X) < +\infty$, let $T : X \to X$ be measurable with $T_*\mu = \mu$, and let $A \in \mathcal{M}$. Set $R_A := \{x \in A : \#\{n \geq 1 : T^n x \in A\} = +\infty\}$. Then $\mu(A \setminus R_A) = 0$.

Proof. Set $E := A \cap \bigcap_{n\geq 1} T^{-n}(A^c)$, so $E \cap T^{-m}A = \varnothing$ $\forall m \geq 1$. If $x \in T^{-i}E \cap T^{-j}E$ with $0 \leq i < j$, then $T^i x \in E \cap T^{-(j-i)}E \subseteq E \cap T^{-(j-i)}A$, a contradiction. Thus $(T^{-k}E)_{k\geq 0}$ is pairwise disjoint. For $N \geq 0$, measure preservation gives $(N+1)\mu(E) = \mu(\bigcup_{k=0}^{N} T^{-k}E) \leq \mu(X)$; letting $N \to \infty$ yields $\mu(E) = 0$.

If $x \in A \setminus R_A$, let $r \geq 0$ be its last visit time to A. Then $T^r x \in E$, so $A \setminus R_A \subseteq \bigcup_{r\geq 0} T^{-r}E$. Countable subadditivity and $\mu(T^{-r}E) = \mu(E) = 0$ give $\mu(A \setminus R_A) = 0$. *Structural Commentary*: The nonreturn set is wandering; finite-return points eventually enter it.
Key Insight: Finite measure forbids positive-measure wandering sets. □

2.2 Elliptic Equations

2.3 Parabolic Equations

2.4 Hyperbolic Equations

3 Weak Solutions and Evolution Equations

3.1 Sobolev Spaces for PDE

Distributions test against smooth compactly supported functions; Sobolev spaces package weak derivatives in normed or Hilbert spaces as a bridge to PDE.

Definition 3.1.1. *Test Functions and Distributions*
Let $\Omega \subseteq \mathbb{R}^n$ be open. A *test function* is a smooth function $\varphi \in C_c^\infty(\Omega)$. A *distribution* on Ω is a continuous linear functional on the test-function space, written $u \in \mathcal{D}'(\Omega)$ and paired as $\langle u, \varphi \rangle$.

Definition 3.1.2. *Weak Derivative*
Let $u \in L^1_{\mathrm{loc}}(\Omega)$ and let α be a multi-index. A function $v \in L^1_{\mathrm{loc}}(\Omega)$ is the *weak derivative* $D^\alpha u$ if

$$\int_\Omega u\, D^\alpha \varphi \, dx = (-1)^{|\alpha|} \int_\Omega v\, \varphi \, dx \qquad \text{for every } \varphi \in C_c^\infty(\Omega).$$

Definition 3.1.3. *Sobolev Spaces*
For $1 \leq p \leq \infty$ and an integer $k \geq 0$, the Sobolev space $W^{k,p}(\Omega)$ consists of functions $u \in L^p(\Omega)$ whose weak derivatives $D^\alpha u$ lie in $L^p(\Omega)$ for every $|\alpha| \leq k$. The norm is

$$\|u\|_{W^{k,p}} := \sum_{|\alpha|\leq k} \|D^\alpha u\|_{L^p}$$

with the usual supremum modification when $p = \infty$.

3.2 Weak Solutions and Variational Methods

3.3 Evolution Equations

Part XVIII
Numerical and Stochastic Computation

1 Numerical Analysis

1.1 Floating Point and Error Analysis

1.2 Nonlinear Equations and Optimization Basics

Method 1.2.1. *Newton and Secant Iterations*
To solve $f(x) = 0$:

(i) Newton uses tangent-line zero: $x_n = x_{n-1} - \frac{f(x_{n-1})}{f'(x_{n-1})}$, $n \geq 1$ when $f'(x_{n-1}) \neq 0$.

(ii) Secant uses two-point slope: $x_n = x_{n-1} - \frac{f(x_{n-1})(x_{n-2}-x_{n-1})}{f(x_{n-2})-f(x_{n-1})}$, $n \geq 2$ when the denominator is nonzero.

These define iterates only; local convergence is proved with Taylor's theorem (Theorem 1.1.25).

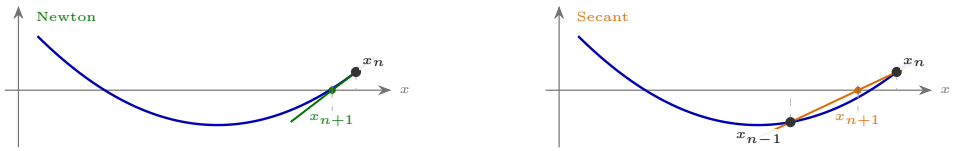

Figure 235: Newton: tangent-line zero. Secant: two-point line zero.

1.3 Interpolation and Approximation

1.4 Numerical Differentiation and Quadrature

1.5 Numerical Stability and Convergence

2 Numerical Differential Systems

2.1 Numerical ODEs

Numerical one-step methods replace the integral evolution of an initial-value problem by finitely many vector-field evaluations on a time grid.

Method 2.1.1. *Explicit Euler Method*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$, $f : U \to \mathbb{R}^n$, $(t_0, x_0) \in U$, and $T > 0$. For $x' = f(t, x)$, $x(t_0) = x_0$, choose $N \in \mathbb{N}$ with $N \geq 1$, set $h := T/N$ and $t_m := t_0 + mh$.

(i) Initialize $x_0^{(h)} := x_0$.

(ii) For $0 \leq m < N$ with $(t_m, x_m^{(h)}) \in U$, compute $x_{m+1}^{(h)} := x_m^{(h)} + hf(t_m, x_m^{(h)})$.

(iii) On each completed mesh interval, define the continuous Euler polygon by $x_h(t) := x_m^{(h)} + (t - t_m)f(t_m, x_m^{(h)})$ for $t_m \leq t \leq t_{m+1}$.

Thus $x_h' = f(t_m, x_m^{(h)})$ on each open mesh interval, while the nodes satisfy the explicit recurrence in (ii).

Theorem 2.1.2. *Uniform Error of the Euler Polygon*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, $f \in C(U, \mathbb{R}^n)$, $(t_0, x_0) \in U$, and choose $T, \delta > 0$ with $V := [t_0, t_0 + T] \times \overline{B}_\delta(x_0) \subseteq U$.
Set $M := \max_V \|f\|$, assume $MT \leq \delta$, and assume $\exists L \geq 0$ such that $\|f(t, x) - f(t, y)\| \leq L \|x - y\|$ $\forall (t, x), (t, y) \in V$.
Let $\phi \in C^1([t_0, t_0 + T], \mathbb{R}^n)$ satisfy $\phi' = f(t, \phi)$, $\phi(t_0) = x_0$, and $(t, \phi(t)) \in V$ $\forall t \in [t_0, t_0 + T]$.
For $N \in \mathbb{N}$ with $N \geq 1$, set $h := T/N$, $t_m := t_0 + mh$, $x_0^{(h)} := x_0$, $x_{m+1}^{(h)} := x_m^{(h)} + hf(t_m, x_m^{(h)})$, and $x_h(t) := x_m^{(h)} + (t - t_m)f(t_m, x_m^{(h)})$ for $t_m \leq t \leq t_{m+1}$.
Define $\Delta(h) := \sup\{\|f(s, y) - f(t, x)\| : (s, y), (t, x) \in V,\ |s - t| \leq h,\ \|y - x\| \leq Mh\}$. Then:

(i) $(t, x_h(t)) \in V$ $\forall t \in [t_0, t_0 + T]$, and $\|x_h(t) - x_h(s)\| \leq M |t - s|$ $\forall s, t \in [t_m, t_{m+1}]$, $0 \leq m < N$.
(ii) With $h = T/N$, as $N \to \infty$, $\Delta(h) \to 0$ and $\|x_h - \phi\|_\infty \leq Te^{LT}\Delta(h)$; hence $x_h \to \phi$ uniformly.
(iii) If $\exists L_0 \geq 0$ such that $\|f(t, x) - f(s, x)\| \leq L_0 |t - s|$ $\forall (t, x), (s, x) \in V$, then $\Delta(h) \leq (L_0 + LM)h$ and $\|x_h - \phi\|_\infty \leq Te^{LT}(L_0 + LM)h$.

Proof.

(i) The initial graph point (t_0, x_0) lies in V. If $\left\|x_m^{(h)} - x_0\right\| \leq mhM$, then $(t_m, x_m^{(h)}) \in V$ and $\left\|x_{m+1}^{(h)} - x_0\right\| \leq \left\|x_m^{(h)} - x_0\right\| + h\left\|f(t_m, x_m^{(h)})\right\| \leq (m + 1)hM$.
Thus induction gives $\left\|x_m^{(h)} - x_0\right\| \leq mhM$. For $t \in [t_m, t_{m+1}]$, $\|x_h(t) - x_0\| \leq M(t - t_0) \leq MT \leq \delta$. Hence the graph lies in V, and the affine slope gives the meshwise Lipschitz bound.

(ii) Let $\tau_h(t) := t_m$ for $t \in [t_m, t_{m+1})$. The Euler polygon satisfies $x_h(t) = x_0 + \int_{t_0}^t f(\tau_h(s), x_h(\tau_h(s)))\, ds$.
Uniform continuity of $f|_V$ gives $\Delta(h) \to 0$. With $e(t) := \|x_h(t) - \phi(t)\|$, item (i) gives $\|x_h(s) - x_h(\tau_h(s))\| \leq Mh$, so $e(t) \leq \int_{t_0}^t (Le(s) + \Delta(h))\, ds$.
By Lemma 1.1.20(ii), $e(t) \leq (t - t_0)e^{L(t-t_0)}\Delta(h) \leq Te^{LT}\Delta(h)$.

(iii) For pairs in the definition of $\Delta(h)$, $\|f(s, y) - f(t, x)\| \leq L \|y - x\| + L_0 |s - t| \leq (LM + L_0)h$. Combine this with (ii).

Structural Commentary: Consistency supplies $\Delta(h)$; Gronwall propagates the local defect.
Key Insight: Uniform continuity is enough for convergence; time-Lipschitz control gives first order. □

Remark 2.1.3. *Euler Step-Doubling Control*
From a node (t_m, x_m), compare the full-step prediction $z_h := x_m + hf(t_m, x_m)$ with the two-half-step prediction $z_{1/2} := x_m + \frac{h}{2}f(t_m, x_m)$, $z_{2/2} := z_{1/2} + \frac{h}{2}f(t_m + h/2, z_{1/2})$. If $\|z_h - z_{2/2}\|$ exceeds a prescribed tolerance, reduce h and repeat the step. This is a practical error indicator rather than an a priori error bound.

Method 2.1.4. *Classical Fourth-Order Runge–Kutta Method*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$, $f : U \to \mathbb{R}^n$, $h > 0$, and $(t_m, x_m) \in U$, where x_m approximates a solution of $x' = f(t, x)$ at t_m. Set $t_{m+1} := t_m + h$ and assume every displayed argument of f below lies in U.

(i) Compute $k_{1,m} := f(t_m, x_m)$ and $k_{2,m} := f(t_m + h/2, x_m + hk_{1,m}/2)$.
(ii) Compute $k_{3,m} := f(t_m + h/2, x_m + hk_{2,m}/2)$ and $k_{4,m} := f(t_m + h, x_m + hk_{3,m})$.
(iii) Update $x_{m+1} := x_m + \frac{h}{6}(k_{1,m} + 2k_{2,m} + 2k_{3,m} + k_{4,m})$.

The four stages sample two midpoint predictions and one endpoint prediction before forming the weighted increment.

Method 2.1.5. *Heun's Improved Euler Method*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$, $f : U \to \mathbb{R}^n$, $h > 0$, and $(t_m, x_m) \in U$, where x_m approximates a solution of $x' = f(t, x)$ at t_m. Set $t_{m+1} := t_m + h$ and assume the predicted endpoint used below lies in U.

(i) Predict the endpoint by $y_m := x_m + hf(t_m, x_m)$.
(ii) Correct with the averaged slopes: $x_{m+1} := x_m + \frac{h}{2}[f(t_m, x_m) + f(t_{m+1}, y_m)]$.

Thus Heun replaces Euler's single left-endpoint slope by the average of the initial slope and its predicted endpoint value.

Proposition 2.1.6. *Heun-Type One-Step Error*
Let $U \subseteq \mathbb{R} \times \mathbb{R}^n$ be open, $f \in C^2(U, \mathbb{R}^n)$, $I \subseteq \mathbb{R}$ an open interval, $t_0 \in I$, and $\phi \in C^1(I, \mathbb{R}^n)$ satisfy $(t, \phi(t)) \in U$ and $\phi'(t) = f(t, \phi(t))$ $\forall t \in I$, with $\phi(t_0) = x_0$.
Set $f_0 := f(t_0, x_0)$. Then $\exists h_* > 0$ such that, $\forall h \in (0, h_*)$, setting $t_1 := t_0 + h$ and $y_0 := x_0 + hf_0$ gives $t_1 \in I$ and $(t_1, y_0), (t_1, x_0), (t_0, y_0) \in U$. As $h \downarrow 0$:

(i) For $H_h := x_0 + \frac{h}{2}[f(t_0, x_0) + f(t_1, y_0)]$, $\|\phi(t_1) - H_h\| = O(h^3)$.
(ii) For $\widetilde{H}_h := x_0 + \frac{h}{2}[f(t_1, x_0) + f(t_0, y_0)]$, $\left\|\phi(t_1) - \widetilde{H}_h\right\| = O(h^3)$.

Proof. Set $G_0 := \partial_t f(t_0, x_0) + D_x f(t_0, x_0) f_0$. By Lemma 1.1.19, $\phi \in C^3$ locally, so $\phi(t_1) = x_0 + hf_0 + \frac{h^2}{2}G_0 + O(h^3)$.

(i) Taylor expansion of f at (t_0, x_0) gives $f(t_1, y_0) = f_0 + h\partial_t f(t_0, x_0) + hD_x f(t_0, x_0) f_0 + O(h^2) = f_0 + hG_0 + O(h^2)$.
Hence $H_h = x_0 + hf_0 + h^2 G_0/2 + O(h^3)$, which matches the expansion of $\phi(t_1)$.
(ii) Separately, $f(t_1, x_0) = f_0 + h\partial_t f(t_0, x_0) + O(h^2)$ and $f(t_0, y_0) = f_0 + hD_x f(t_0, x_0) f_0 + O(h^2)$.
Thus $\widetilde{H}_h = x_0 + hf_0 + h^2 G_0/2 + O(h^3)$, proving the second estimate.

Structural Commentary: Expand the exact flow and both predicted slopes through second order.
Key Insight: Averaging reconstructs the quadratic term of the exact solution. □

Example 2.1.7. *Euler and RK4 for Exponential Growth*
For $x' = x$, $x(0) = 1$, and $h = 0.1$, Euler gives $x_m = (1 + h)^m$, hence $x_{10} = 1.1^{10} \approx 2.5937424601$.
Classical RK4 gives $x_{m+1} = R(h)x_m$ with $R(h) = 1 + h + h^2/2 + h^3/6 + h^4/24$, so $x_{10} = R(0.1)^{10} \approx 2.7182797441$.
Since $x(1) = e \approx 2.7182818285$, the respective absolute errors at $t = 1$ are approximately 1.2454×10^{-1} and 2.0843×10^{-6}.

2.2 Geometric Numerical Integration

2.3 Finite Difference PDE Methods

2.4 Finite Element Methods

2.5 Numerical SDEs

2.6 Computational Stability Across ODE/PDE/SDE

3 Monte Carlo and Stochastic Computation

3.1 Monte Carlo Foundations

Monte Carlo methods turn integrals into averages of simulated random variables. This is especially useful when the integral is high-dimensional or when the target density is known only up to a normalizing constant.

Method 3.1.1. *Basic Monte Carlo Integration*

(i) Let $I = \int h(x) f(x)\, dx$, where f is a probability density.
(ii) For IID draws $X_1, \ldots, X_N \sim f$, define $\widehat{I}_N = N^{-1} \sum_{i=1}^{N} h(X_i)$; then $\widehat{I}_N \xrightarrow{p} I$ by the law of large numbers.
(iii) With $Y_i = h(X_i)$, set $s^2 = (N-1)^{-1} \sum_{i=1}^{N} (Y_i - \widehat{I}_N)^2$ and $\widehat{\mathrm{se}} = \frac{s}{\sqrt{N}}$.
(iv) An approximate $1 - \alpha$ Monte Carlo interval is $\widehat{I}_N \pm z_{\frac{\alpha}{2}} \widehat{\mathrm{se}}$.

Example 3.1.2. *Monte Carlo Integration from the LLN*
Let $X_1, \ldots, X_n$ be iid Uniform$(0, 1)$ and $f \in L^1([0, 1])$.
The estimator $\widehat{I}_n(f) := n^{-1} \sum_{i=1}^{n} f(X_i)$ satisfies $\widehat{I}_n(f) \xrightarrow{\mathbb{P}} \mathbb{E} f(X_1) = \int_0^1 f(x)\, dx$.
For $f(x) = (2\pi)^{-\frac{1}{2}} e^{-\frac{x^2}{2}}$ on $[0, 1]$, a 1000-point estimate near 0.3417 is consistent with $\int_0^1 f(x)\, dx \approx 0.3413$.

Example 3.1.3. *Integrating on an Interval*
For $X \sim$ Uniform(a, b), $I = \int_a^b h(x)\, dx = (b - a)\mathbb{E}[h(X)]$.
Given IID draws $X_1, \ldots, X_N \sim$ Uniform(a, b), estimate I by $\widehat{I}_N = (b - a)N^{-1} \sum_{i=1}^{N} h(X_i)$.

Example 3.1.4. *Estimating a Normal CDF*

Let $Z \sim N(0,1)$ and $\Phi(x) = \mathbb{P}(Z \le x)$. For IID draws $Z_1, \dots, Z_N \sim N(0,1)$, use $h(s) = \mathbf{1}\{s \le x\}$ and $\widehat{\Phi}(x) = N^{-1} \sum_{i=1}^{N} \mathbf{1}\{Z_i \le x\}$.

Thus $\widehat{\Phi}(x)$ is the empirical fraction of draws not exceeding x.

Method 3.1.5. *Inverse-Transform Generation*

(i) *Exponential*: if $U \sim \text{Uniform}(0,1)$ and $\lambda > 0$, then $T = -\lambda^{-1} \log(1-U) \sim \text{Exp}(\lambda)$. (or $T = -\lambda^{-1} \log U$)
(ii) *Weibull*: if $F(x) = 1 - \exp(-(\frac{x}{\alpha})^{\beta})$ for $x \ge 0$ and $\alpha, \beta > 0$,
then $F^{-1}(u) = \alpha[-\log(1-u)]^{\frac{1}{\beta}}$ and $W = \alpha[-\log(1-U)]^{\frac{1}{\beta}} \sim F$.
(iii) *Integer-valued inverse CDF*: if F is integer-valued and $U \sim \text{Uniform}(0,1)$, set $Y = \inf\{k \in \mathbb{Z} : F(k) \ge U\}$.
Equivalently $F(k-1) < U \le F(k)$. Then $F_Y = F$.

Key Insight: The simulation problem is reduced to solving $u = F(x)$ for x.

Method 3.1.6. *Rejection Sampling*

Let f be a target density on an interval $[a,b]$, possibly with infinite endpoints.
Choose an envelope M such that $M(x) \ge f(x)$ on $[a,b]$ and $A := \int_a^b M(t)\,dt < \infty$. Let $m(x) := \frac{M(x)}{A}$.

(i) Generate T with density m.
(ii) Generate $U \sim \text{Uniform}(0,1)$ independently of T.
(iii) Accept $X = T$ if $U \le \frac{f(T)}{M(T)}$; otherwise reject T and repeat.

Key Insight: Sample under an easy envelope and keep only points that fall below the target curve.

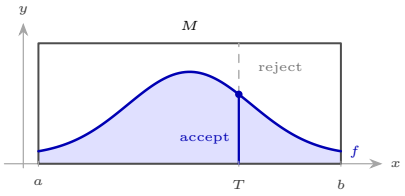

Figure 236: Rejection sample accepts when the vertical draw lies below $f(T)$.

Proposition 3.1.7. *Rejection Sampling Correctness*
Let f be a density, let $M \ge f$ with $A := \int M(x)\,dx < \infty$, and set $m := \frac{M}{A}$. If $T \sim m$, $U \sim \text{Uniform}(0,1)$ independently, and $\mathcal{A} := \{U \le \frac{f(T)}{M(T)}\}$, then $\mathbb{P}(\mathcal{A}) = \frac{1}{A}$ and $T \mid \mathcal{A}$ has density f.

Proof. For measurable B, $\mathbb{P}(T \in B, \mathcal{A}) = \int_B \frac{m(x)f(x)}{M(x)}\,dx = A^{-1} \int_B f(x)\,dx$.
Taking $B = \mathbb{R}$ gives $\mathbb{P}(\mathcal{A}) = A^{-1}$, and hence $\mathbb{P}(T \in B \mid \mathcal{A}) = \int_B f(x)\,dx$.
Structural Commentary: Acceptance reweights the envelope m back to f.
Key Insight: Conditional on acceptance, the normalized accepted density is exactly the target. □

3.2 Variance Reduction

Method 3.2.1. *Importance Sampling*

(i) For $I = \int h(x)f(x)\,dx$, choose a tractable proposal density g with $g(x) > 0$ wherever $h(x)f(x) \ne 0$.
(ii) Then $I = \int h(x)f(x)g(x)^{-1}g(x)\,dx = \mathbb{E}_g\left[\frac{h(X)f(X)}{g(X)}\right]$.
(iii) For IID draws $X_1, \dots, X_N \sim g$, use $\widehat{I}_N = N^{-1} \sum_{i=1}^{N} \frac{h(X_i)f(X_i)}{g(X_i)}$.

Remark 3.2.2. *Choosing the Proposal*
The importance weights have large, possibly infinite, variance when g is too small on regions where $|h|\,f$ is large.
Choose g to approximate the shape of $|h|\,f$ while giving it tails at least as thick as the target integrand.

Theorem 3.2.3. *Optimal Importance Density*
Let $I = \int h(x)f(x)\,dx$ and $A = \int |h(x)|\,f(x)\,dx \in (0,\infty)$.
For proposal densities g with $g(x) > 0$ wherever $|h(x)|\,f(x) > 0$, define $W_g = \frac{h(X)f(X)}{g(X)}$ for $X \sim g$.
The variance $\text{Var}_g(W_g)$ is minimised by $g^*(x) = \frac{|h(x)|f(x)}{A}$, and the minimum variance is $A^2 - I^2$.

Proof. For each admissible g, $\mathbb{E}_g W_g = I$, so $\text{Var}_g(W_g) = M(g) - I^2$, where $M(g) = \mathbb{E}_g(W_g^2) = \int \frac{h(x)^2 f(x)^2}{g(x)}\,dx$.
For any admissible g, Cauchy-Schwarz gives $A^2 = (\int |h(x)|\,f(x)g(x)^{-\frac{1}{2}} g(x)^{\frac{1}{2}}\,dx)^2 \le M(g) \int g(x)\,dx = M(g)$.
Equality holds precisely when $|h(x)|\,f(x)g(x)^{-\frac{1}{2}} = c\,g(x)^{\frac{1}{2}}$ a.e., equivalently $g(x) \propto |h(x)|\,f(x)$.
Normalization gives $g^*(x) = \frac{|h(x)|f(x)}{A}$, hence $M(g) \ge M(g^*) = A^2$ and $\text{Var}_g(W_g) \ge A^2 - I^2 = \text{Var}_{g^*}(W_{g^*})$.
Structural Commentary: Fixed mean reduces variance to second-moment minimization.
Key Insight: Cauchy-Schwarz is sharp exactly when the proposal is proportional to $|h|\,f$. □

3.3 Markov Chain Monte Carlo

Monte Carlo integration in Method 3.1.1 uses independent draws from the target density. Markov chain Monte Carlo instead constructs a Markov chain $X_0, X_1, \dots$ whose stationary density is the target f. When the chain mixes well, sample averages from the chain are used as approximations to expectations under f.

Method 3.3.1. *Metropolis-Hastings*
Let f be a target density available up to proportionality, and let $q(\cdot \mid x)$ be a tractable proposal density.
Choose X_0 arbitrarily; given $X_i = x$, define X_{i+1} as follows.

(i) Draw $Y \sim q(\cdot \mid x)$.
(ii) Set $r(x, Y) = \min\left\{\frac{f(Y)q(x|Y)}{f(x)q(Y|x)}, 1\right\}$.
(iii) Set $X_{i+1} = Y$ with probability $r(x, Y)$, and set $X_{i+1} = x$ otherwise.

Key Insight: Only ratios of f enter r, so unknown normalising constants cancel.

Proposition 3.3.2. *Detailed Balance for Metropolis-Hastings*
Let $\Phi(x, y) = f(x)q(y \mid x)$ and assume $\Phi(x, y) > 0$ iff $\Phi(y, x) > 0$.
For $x \neq y$, define $\alpha(x, y) = \min\left\{\frac{\Phi(y,x)}{\Phi(x,y)}, 1\right\}$ when $\Phi(x, y) > 0$ and $\alpha(x, y) = 0$ otherwise.
Set $p(x, y) = q(y \mid x)\alpha(x, y)$. Then $f(x)p(x, y) = f(y)p(y, x)$ for $x \neq y$.

Proof. If $\Phi(x, y) = 0$, the support condition gives $\Phi(y, x) = 0$, hence $p(x, y) = p(y, x) = 0$.
If $\Phi(x, y) > 0$, then $f(x)p(x, y) = \Phi(x, y) \min\left\{\frac{\Phi(y,x)}{\Phi(x,y)}, 1\right\} = \min\{\Phi(x, y), \Phi(y, x)\}$.
Interchanging x, y gives the same expression for $f(y)p(y, x)$, QED.
Structural Commentary: The acceptance rule symmetrizes the weighted proposal flow.
Key Insight: Both directions reduce to the same minimum of the two proposal fluxes. □

Method 3.3.3. *Random-Walk Metropolis-Hastings*

(i) Use the proposal $Y = X_i + \varepsilon_i$, where ε_i has a symmetric density.
(ii) Then $q(y \mid x) = q(x \mid y)$, so the acceptance probability is $r(x, y) = \min\left\{\frac{f(y)}{f(x)}, 1\right\}$.
(iii) For $\varepsilon_i \sim N(0, b^2)$, small b gives slow local moves, large b gives frequent rejection. Tune b for adequate mixing.

Example 3.3.4. *Cauchy Target*
For Cauchy target $f(x) = \frac{1}{\pi(1+x^2)}$ and symmetric random-walk proposal, $r(x, y) = \min\left\{\frac{1+x^2}{1+y^2}, 1\right\}$.
The proposal scale changes mixing efficiency, not the stationary target.

Method 3.3.5. *Independence Metropolis-Hastings*

(i) Use a state-independent proposal $Y \sim g$, so $q(y \mid x) = g(y)$.
(ii) The acceptance probability is $r(x, y) = \min\{\frac{f(y)g(x)}{f(x)g(y)}, 1\}$.
(iii) Choose g as a tractable approximation to the target with sufficient mass on important regions.

Method 3.3.6. *Gibbs Sampling*

(i) Let (X, Y) have joint density $f_{X,Y}$ with tractable conditionals $f_{X|Y}$ and $f_{Y|X}$.
(ii) Starting from (X_0, Y_0), iterate $X_{n+1} \sim f_{X|Y}(\cdot \mid Y_n)$ and $Y_{n+1} \sim f_{Y|X}(\cdot \mid X_{n+1})$.
(iii) In higher dimension, update one coordinate or block at a time from its full conditional.

Method 3.3.7. *Metropolis within Gibbs*

(i) If $f_{X_j|X_{-j}}$ is not directly simulable, update X_j by Metropolis-Hastings conditional on X_{-j}.
(ii) In the bivariate case, propose $Z \sim q(\cdot \mid X_n)$ and accept $X_{n+1} = Z$ with probability $\min\{\frac{f(Z,Y_n)q(X_n|Z)}{f(X_n,Y_n)q(Z|X_n)}, 1\}$.
(iii) Then update Y analogously, conditional on the newly updated X.

3.4 Sequential Monte Carlo

3.5 Rare-Event Simulation

Example 3.5.1. *Rare Tail Probability*
For $Z \sim N(0, 1)$, write $I = \mathbb{P}(Z > 3) = \int \mathbf{1}\{x > 3\} f(x)\, dx$.
If g is centered near the right tail and $X_1, \dots, X_N \sim g$, estimate I by $\widehat{I}_N = N^{-1} \sum_{i=1}^{N} \frac{\mathbf{1}\{X_i > 3\} f(X_i)}{g(X_i)}$.

3.6 Stochastic Optimization

Definition 3.6.1. *Online Estimator*
Let $(X_t)_{t \geq 1}$ be observations in $\mathcal{X}$, let $\widehat{\theta}_0 \in \Theta \subseteq \mathbb{R}^d$, let $(a_t)_{t \geq 0}$ be positive step sizes, and let $H : \Theta \times \mathcal{X} \to \mathbb{R}^d$.
$\widehat{\theta}_{t+1} := \widehat{\theta}_t + a_t H(\widehat{\theta}_t, X_{t+1})$ for $t \geq 0$.
Structural Commentary: $(\widehat{\theta}_t)$ is adapted to $\mathcal{F}_t := \sigma(\widehat{\theta}_0, X_1, \dots, X_t)$.
Key Insight: Under stationarity, analyze the recursion through $h(\theta) := \mathbb{E}H(\theta, X)$.

Method 3.6.2. *Minibatch Stochastic Gradient Descent*
Let $J_n(\theta) = n^{-1} \sum_{i=1}^{n} L(f_\theta(x_i), y_i)$, $|B_k| = b$, and $\eta_k > 0$.

(i) Sample B_k uniformly.
(ii) Compute $g_k = b^{-1} \sum_{i \in B_k} \nabla_\theta L(f_{\theta_k}(x_i), y_i)$.
(iii) Update $\theta_{k+1} = \theta_k - \eta_k g_k$.

Uniform sampling gives $\mathbb{E}[g_k \mid \theta_k] = \nabla J_n(\theta_k)$; larger b trades lower noise for higher cost.

Definition 3.6.3. *Momentum and Adaptive Methods*
Let g_k denote the stochastic gradient at θ_k; $\odot$, division, and square roots are coordinatewise.

(i) *Momentum*: $v_k = \mu v_{k-1} + g_k$ and $\theta_{k+1} = \theta_k - \eta_k v_k$, with $0 \le \mu < 1$.
(ii) *AdaGrad*: $r_k = r_{k-1} + g_k \odot g_k$ and $\theta_{k+1} = \theta_k - \frac{\eta_k g_k}{\sqrt{r_k}+\varepsilon}$.
(iii) *RMSProp*: $r_k = \rho r_{k-1} + (1-\rho) g_k \odot g_k$ and $\theta_{k+1} = \theta_k - \frac{\eta_k g_k}{\sqrt{r_k}+\varepsilon}$, with $0 < \rho < 1$.
(iv) *Adam*: update (m_k, r_k) as exponential averages of $(g_k, g_k \odot g_k)$,
set $(\widehat{m}_k, \widehat{r}_k) = (\frac{m_k}{1-\beta_1^k}, \frac{r_k}{1-\beta_2^k})$, and $\theta_{k+1} = \theta_k - \frac{\eta_k \widehat{m}_k}{\sqrt{\widehat{r}_k}+\varepsilon}$.

Part XIX
Statistical Inference and Time Series

Statistical inference turns probabilistic models into procedures for learning from data. The probability, measure-theoretic, stochastic-process, optimization, and Monte Carlo material developed in Parts 11–14 is treated here as prerequisite structure.

1 Statistical Models and Experiments

1.1 Statistical Experiments and Likelihoods

A statistical problem starts with observable data and a family of probability laws that could have generated it. The model is not the data itself; it is the mathematical language in which uncertainty about the data-generating mechanism is expressed.

Definition 1.1.1. *Statistical Experiment and Model*

(i) A *statistical experiment* is $(\mathcal{X}, \mathcal{A}, \mathcal{P})$, where $(\mathcal{X}, \mathcal{A})$ is measurable and $\mathcal{P} = \{P_\theta : \theta \in \Theta\}$ is a family of probability measures on $(\mathcal{X}, \mathcal{A})$.
(ii) Θ is the *parameter space*, $X \in \mathcal{X}$ is the *sample*, and $\mathcal{P}$ is the *statistical model*.
(iii) The model is *well specified* if the true law $P_0 \in \mathcal{P}$.
(iv) The model is *misspecified* if $P_0 \notin \mathcal{P}$.

Definition 1.1.2. *Identifiability and Functionals*

(i) The parameterization is *identifiable* if $P_\theta = P_{\theta'}$ implies $\theta = \theta'$.
(ii) A *statistical functional* is a map $T : \mathcal{P} \to \mathcal{T}$, such as $T(P) = \int x\, dP(x)$ or $T(P) = \text{median}(P)$.
(iii) In a parametric model, a *target parameter* may be a function $\psi(\theta)$ rather than the full parameter θ.

Key Insight: Estimation should target a law or functional that the experiment can actually distinguish.

Definition 1.1.3. *Dominated Models, Likelihood, Score, and Information*

(i) A model $\mathcal{P} = \{P_\theta : \theta \in \Theta\}$ is *dominated* by μ if $P_\theta \ll \mu$ for all $\theta \in \Theta$; write $p_\theta := \frac{dP_\theta}{d\mu}$.
(ii) Given x, the *likelihood* and *log-likelihood* are $L_x(\theta) := p_\theta(x)$ and $\ell_x(\theta) := \log p_\theta(x)$ when $p_\theta(x) > 0$.
(iii) If $\Theta \subseteq \mathbb{R}^d$ and differentiation is valid, the *score* is $S_\theta(X) := \nabla_\theta \ell_X(\theta)$.
(iv) The *Fisher information* is $I(\theta) := \mathbb{E}_\theta[S_\theta(X) S_\theta(X)^\top]$.

Definition 1.1.4. *Maximum Likelihood Estimator*

For likelihood $L_X(\theta)$ and log-likelihood $\ell_X(\theta)$, a *maximum likelihood estimator* is any measurable $\widehat{\theta}_n(X) \in \arg\max_{\theta \in \Theta} L_X(\theta) = \arg\max_{\theta \in \Theta} \ell_X(\theta)$; equivalently, $\widehat{\theta}_n \in \arg\min_{\theta \in \Theta} [-\ell_X(\theta)]$.

Example 1.1.5. *Bernoulli and Normal Likelihoods*

Let $X_1, \dots, X_n$ be independent observations.

(i) If $X_i \sim \text{Bernoulli}(p)$, then $L_x(p) = p^s (1-p)^{n-s}$, where $s := \sum_{i=1}^n x_i$.

(ii) If $X_i \sim N(\mu, \sigma^2)$ and σ^2 is known, then $\ell_x(\mu) = -\frac{n}{2}\log(2\pi\sigma^2) - \frac{1}{2\sigma^2}\sum_{i=1}^n (x_i - \mu)^2$, maximized at $\widehat{\mu} = \overline{x}$.

Example 1.1.6. *Multinomial Cell Probabilities*

Let $X = (X_1, \dots, X_m)$ have total count n.

(i) If $X \sim \text{Multinomial}(n; p_1, \dots, p_m)$ and $\sum_{j=1}^m p_j = 1$, then $L_x(p) \propto \prod_{j=1}^m p_j^{x_j}$ and $\widehat{p}_j = \frac{x_j}{n}$.

(ii) If $p_j = p_j(\theta)$, then $L_x(\theta) \propto \prod_{j=1}^m p_j(\theta)^{x_j}$ and $\widehat{\theta} \in \arg\max_\theta \sum_{j=1}^m x_j \log p_j(\theta)$.

Remark 1.1.7. *Likelihood as Relative Evidence*

For fixed data x, the likelihood is a function of θ, not a probability distribution on Θ.
Ratios $\frac{L_x(\theta_1)}{L_x(\theta_0)}$ compare how well two model laws explain the same observation.

1.2 Sufficiency, Exponential Families, and Local Asymptotics

The shape of a model determines which summaries of the data preserve information and which approximations become valid in large samples.

Definition 1.2.1. *Statistics, Sufficiency, and Ancillarity*

(i) A *statistic* is a measurable map $T : \mathcal{X} \to \mathcal{T}$.
(ii) T is *sufficient* if $\mathcal{L}_\theta(X \mid T)$ is independent of θ.
(iii) T is *ancillary* if $\mathcal{L}_\theta(T)$ is independent of θ.

Theorem 1.2.2. *Factorization Criterion*

Let $\mathcal{P} = \{P_\theta : \theta \in \Theta\}$ be dominated by μ, with $p_\theta := \frac{dP_\theta}{d\mu}$. A statistic $T : \mathcal{X} \to \mathcal{T}$ is sufficient iff there exist measurable $g_\theta : \mathcal{T} \to [0, \infty)$ and $h : \mathcal{X} \to [0, \infty)$ such that $p_\theta(x) = g_\theta(T(x))h(x)$ μ-a.e. for all θ.

Proof.

($\Rightarrow$) If T is sufficient, write $\nu_\theta := \mathcal{L}_\theta(T)$ and choose a θ-free kernel $K_t = \mathcal{L}_\theta(X \mid T = t)$, so $P_\theta(A) = \int K_t(A)\nu_\theta(dt)$. Choosing densities for ν_θ and for K_t on each fiber gives $p_\theta(x) = g_\theta(T(x))h(x)$.
($\Leftarrow$) If $p_\theta = g_\theta \circ T\, h$, then on the fiber $T = t$ the factor $g_\theta(t)$ cancels: for $c(t) := \int_{T^{-1}\{t\}} h\, d\mu_t > 0$, $\mathbb{P}_\theta(X \in A \mid T = t) = c(t)^{-1} \int_{A \cap T^{-1}\{t\}} h\, d\mu_t$, independent of θ.

Structural Commentary: Factorisation separates parameter information $g_\theta(T)$ from residual shape h.
Key Insight: Sufficiency keeps exactly the likelihood's θ-dependent part. □

Example 1.2.3. *Bernoulli and Normal Sufficient Statistics*
Let $X_1, \dots, X_n$ be independent and let $x = (x_1, \dots, x_n)$.

(i) If $X_i \sim \text{Bernoulli}(\theta)$, then $p_\theta(x) = \theta^s(1-\theta)^{n-s}$ with $s := \sum_i x_i$.
Hence $T = \sum_i X_i$ is sufficient for θ, and $\mathcal{L}_\theta(X \mid T = t)$ is uniform on $\{x : \sum_i x_i = t\}$.

(ii) If $X_i \sim N(\mu, \sigma^2)$ with (μ, σ^2) unknown, then $p_{\mu,\sigma^2}(x) \propto (\sigma^2)^{-\frac{n}{2}} \exp\{-\frac{\sum_i x_i^2 - 2\mu \sum_i x_i + n\mu^2}{2\sigma^2}\}$.
Hence $T = (\sum_i X_i, \sum_i X_i^2)$ is sufficient for (μ, σ^2).

Corollary 1.2.4. *Likelihood Estimators Use Sufficient Statistics*
Let $\mathcal{P} = \{P_\theta : \theta \in \Theta\}$ be dominated with densities p_θ, and let T be sufficient with $p_\theta(x) = g_\theta(T(x))h(x)$.
If $a(t) \in \arg\max_{\theta \in \Theta} g_\theta(t)$ exists, then $\widehat{\theta}(X) := a(T(X))$ is an MLE.

Proof. For fixed x, $L_x(\theta) = p_\theta(x) = h(x)g_\theta(T(x))$. If $h(x) > 0$, then $\arg\max_\theta L_x(\theta) = \arg\max_\theta g_\theta(T(x))$.
If $h(x) = 0$, then $L_x(\theta) = 0$ for all θ. Thus an MLE may be chosen as $a(T(x))$.
Structural Commentary: The θ-free factor $h(x)$ is irrelevant to maximization.
Key Insight: MLEs can depend on data only through a sufficient statistic. □

Theorem 1.2.5. *Rao–Blackwell Improvement*
Let T be sufficient and let $\widehat{\psi} \in L^2(P_\theta)$ estimate a real target $\psi(\theta)$. Choose the θ-free version $\widetilde{\psi}(T) := \mathbb{E}_\theta(\widehat{\psi} \mid T)$.
Then $\mathbb{E}_\theta \widetilde{\psi} = \mathbb{E}_\theta \widehat{\psi}$ and $\mathbb{E}_\theta(\widetilde{\psi} - \psi(\theta))^2 \le \mathbb{E}_\theta(\widehat{\psi} - \psi(\theta))^2$ for all θ, with equality iff $\widehat{\psi} = \widetilde{\psi}$ P_θ-a.s.

Proof. Sufficiency makes $\mathcal{L}_\theta(X \mid T)$ independent of θ, so $\widetilde{\psi}$ is a T-statistic. Also $\mathbb{E}_\theta \widetilde{\psi} = \mathbb{E}_\theta \widehat{\psi}$.
Since $\mathbb{E}_\theta(\widehat{\psi} - \widetilde{\psi} \mid T) = 0$ and $\widetilde{\psi} - \psi(\theta)$ is T-measurable, $\mathbb{E}_\theta[(\widehat{\psi} - \widetilde{\psi})(\widetilde{\psi} - \psi(\theta))] = 0$.
Hence $\mathbb{E}_\theta(\widehat{\psi} - \psi(\theta))^2 = \mathbb{E}_\theta(\widehat{\psi} - \widetilde{\psi})^2 + \mathbb{E}_\theta(\widetilde{\psi} - \psi(\theta))^2 \ge \mathbb{E}_\theta(\widetilde{\psi} - \psi(\theta))^2$, with equality iff $\mathbb{E}_\theta(\widehat{\psi} - \widetilde{\psi})^2 = 0$.
Structural Commentary: Rao–Blackwellization projects an estimator onto the $\sigma(T)$-measurable statistics.
Key Insight: Conditioning on a sufficient statistic preserves bias and removes residual noise. □

Definition 1.2.6. *Exponential Family*

(i) A dominated model $\{P_\eta : \eta \in \mathcal{N}\}$ is a *k-parameter exponential family* if $\mathcal{N} \subseteq \mathbb{R}^k$ and $p_\eta(x) = \exp\{\eta^\top T(x) - A(\eta)\}h(x)$.
(ii) η is the *natural parameter*, $T(X)$ is the *natural statistic*, and h is the carrier density.
(iii) $A(\eta)$ is the *log-partition function*: $A(\eta) = \log \int \exp\{\eta^\top T(x)\}h(x)\, d\mu(x)$ when finite.

Proposition 1.2.7. *Moment Identities in Full Exponential Families*
Let $p_\eta(x) = \exp\{\eta^\top T(x) - A(\eta)\}h(x)$ be a full exponential family with open natural parameter space, and assume differentiation under the integral is valid. Then $\nabla A(\eta) = \mathbb{E}_\eta T(X)$ and $\nabla^2 A(\eta) = \text{Cov}_\eta(T(X))$.

Proof. From $1 = \int p_\eta\, d\mu$, differentiation gives $0 = \int (T - \nabla A(\eta)) p_\eta\, d\mu$, hence $\nabla A(\eta) = \mathbb{E}_\eta T(X)$.
For coordinates i, j, differentiating $\mathbb{E}_\eta T_i = \int T_i p_\eta\, d\mu$ gives $\partial_j \mathbb{E}_\eta T_i = \mathbb{E}_\eta[T_i(T_j - \partial_j A(\eta))] = \text{Cov}_\eta(T_i, T_j)$, QED.
Structural Commentary: The log-partition function cumulatively encodes the natural statistic.
Key Insight: First and second derivatives of A give mean and covariance. □

Definition 1.2.8. *Local Asymptotic Normality*
For experiments $\{P_\theta^{(n)} : \theta \in \Theta \subseteq \mathbb{R}^d\}$, set $\theta_{n,h} := \theta_0 + \frac{h}{\sqrt{n}}$.

(i) The sequence is *locally asymptotically normal* at θ_0 with information $I(\theta_0)$ if,
for each fixed $h \in \mathbb{R}^d$, $\log(\frac{dP^{(n)}_{\theta_{n,h}}}{dP^{(n)}_{\theta_0}}) = h^\top \Delta_n - \frac{1}{2} h^\top I(\theta_0) h + o_{P^{(n)}_{\theta_0}}(1)$.

(ii) The *central sequence* satisfies $\Delta_n \Rightarrow N(0, I(\theta_0))$ under $P^{(n)}_{\theta_0}$.

Remark 1.2.9. *Why Local Asymptotics Matter*
LAN replaces local likelihood ratios by the Gaussian quadratic experiment $h^\top \Delta - \frac{1}{2} h^\top I(\theta_0) h$, giving normal approximations for estimators, tests, and confidence regions.

1.3 Design, Randomization, and Observational Comparisons

Comparative inference is only as meaningful as the experiment or study that produced the groups. The same two-sample statistic can estimate a causal treatment effect in a randomised experiment, describe an association in an observational study, or amplify bias if the groups were formed by a hidden mechanism.

Definition 1.3.1. *Controls, Randomisation, and Blinding*

(i) A *controlled experiment* compares $Y \mid T = 1$ and $Y \mid T = 0$ under common conditions.
(ii) *Randomisation* assigns $T \in \{0, 1\}$ so that T is independent of pre-treatment factors C by design.
(iii) *Blinding* conceals T when knowledge of treatment could affect Y or its measurement.

Definition 1.3.2. *Placebo Effect and Confounding*

(i) A *placebo effect* is variation in Y caused by belief in treatment rather than the active mechanism.
(ii) Placebos and blinding separate expectation effects from the causal effect of T.
(iii) A pre-treatment variable C is *confounded* with treatment T for response Y if $\mathcal{L}(C \mid T = 1) \neq \mathcal{L}(C \mid T = 0)$ and C affects Y.

(iv) An *observational study* compares groups without assigning T.
Group differences may reflect confounding rather than the factor of interest.

Example 1.3.3. *Mammary Artery Ligation*
A blinded trial randomised patients after preliminary incisions to ligation ($T = 1$) or sham surgery ($T = 0$). Similar outcomes show that controls remove background improvement; blinding limits placebo, observer effects.

Principle 1.3.4. *Confounding, Blocking, and Pairing*
Randomisation balances unmeasured covariates C in probability; blocking, matching, and pairing condition on known influential C before randomisation. Pairing is one-factor blocking; blocked and factorial designs extend this control to multiple factors.

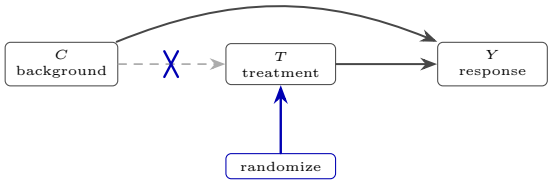

Figure 237: Randomization breaks the confounding path from C to T.

Example 1.3.5. *Uncontrolled Adjustments and Position Effects*
In the Lanarkshire milk experiment, post-randomisation movement between groups made T depend on perceived nourishment C, reintroducing selection bias; weighing children in clothes also confounded measurement with socioeconomic status. In the FD&C Red No. 40 study, cage location was systematic in sex and dose, so position effects confounded treatment comparisons; randomising or blocking cage location would protect inference.

Remark 1.3.6. *Comparative Study Checklist*
Before interpreting group comparisons, record sampling, treatment assignment T, controls, blinding, blocking or pairing factors C, dependence among repeated measurements, and the number of tested comparisons.
These determine whether the analysis supports causality, association, or hypothesis generation.

2 Estimation Theory

2.1 Estimators, Bias, Variance, and Risk

An estimator is a statistic interpreted as an answer to a target question. Its quality depends on the target, the loss function, and the model law under which performance is measured.

Definition 2.1.1. *Estimator, Loss, and Risk*
(i) A target parameter is a map $\psi : \Theta \to \Psi$.
(ii) An *estimator* of $\psi(\theta)$ is a statistic $\delta(X) \in \mathcal{D}$.
(iii) A *loss function* is $L : \Theta \times \mathcal{D} \to [0, \infty]$.
(iv) The *risk* of δ is $R(\theta, \delta) := \mathbb{E}_\theta L(\theta, \delta(X))$.
(v) For squared-error loss $L(\theta, d) = \|d - \psi(\theta)\|^2$, $R(\theta, \delta)$ is mean squared error.

Definition 2.1.2. *Sampling Distribution and Standard Error*
(i) For a statistic $T_n = T_n(X_1, \dots, X_n)$ under P_θ, its *sampling distribution* is $\mathcal{L}_\theta(T_n)$.
(ii) If $T_n \in L^2(P_\theta)$, its *standard error* is $\mathrm{SE}_\theta(T_n) := \sqrt{\mathrm{Var}_\theta(T_n)}$.
(iii) An *estimated standard error* estimates $\mathrm{SE}_\theta(T_n)$, typically by plug-in, asymptotics, or resampling.

Definition 2.1.3. *Bias, Variance, and Consistency*
For real-valued $\widehat{\psi}$, $\mathrm{Bias}_\theta(\widehat{\psi}) := \mathbb{E}_\theta\widehat{\psi} - \psi(\theta)$, and $\mathrm{Var}_\theta(\widehat{\psi}) := \mathbb{E}_\theta(\widehat{\psi} - \mathbb{E}_\theta\widehat{\psi})^2$.
(i) $\widehat{\psi}$ is *unbiased* if $\mathrm{Bias}_\theta(\widehat{\psi}) = 0$ for all θ.
(ii) $\widehat{\psi}_n$ is *consistent* at θ if $\widehat{\psi}_n \to \psi(\theta)$ in P_θ-probability.

Proposition 2.1.4. *Bias-Variance Decomposition*
Let $\widehat{\psi} \in L^2(P_\theta)$ be real-valued. Under squared-error loss, $\mathrm{MSE}_\theta(\widehat{\psi}) := \mathbb{E}_\theta(\widehat{\psi} - \psi(\theta))^2 = \mathrm{Var}_\theta(\widehat{\psi}) + \mathrm{Bias}_\theta(\widehat{\psi})^2$.

Proof. Write $\widehat{\psi} - \psi(\theta) = (\widehat{\psi} - \mathbb{E}_\theta\widehat{\psi}) + (\mathbb{E}_\theta\widehat{\psi} - \psi(\theta))$. Square, take $\mathbb{E}_\theta$ gives the identity since $\mathbb{E}_\theta(\widehat{\psi} - \mathbb{E}_\theta\widehat{\psi}) = 0$.
Structural Commentary: MSE splits into random fluctuation plus squared systematic error.
Key Insight: Accuracy requires controlling both variance and bias. □

Example 2.1.5. *Sample Mean*
If $X_1, \dots, X_n$ are independent with $\mathbb{E}X_i = \mu$ and $\mathrm{Var}(X_i) = \sigma^2 < \infty$,
then $\overline{X}_n := n^{-1} \sum_{i=1}^{n} X_i$ satisfies $\mathbb{E}\overline{X}_n = \mu$, $\mathrm{Var}(\overline{X}_n) = \frac{\sigma^2}{n}$, and $\overline{X}_n \xrightarrow{P} \mu$.

Definition 2.1.6. *Plug-In and M-Estimators*
(i) A *plug-in estimator* estimates $T(P)$ by $T(\widehat{P}_n)$, where $\widehat{P}_n$ is empirical or fitted.
(ii) An *M-estimator* satisfies $\widehat{\theta}_n \in \arg\min_{\theta \in \Theta} M_n(\theta)$ for an empirical criterion M_n.
(iii) Common choices are $M_n =$ negative log-likelihood, squared loss, or absolute loss.

Definition 2.1.7. *Location M-Estimates*
For data $x_1, \dots, x_n \in \mathbb{R}$, scale $\sigma > 0$, and loss $\Psi : \mathbb{R} \to \mathbb{R}$, $\widehat{\mu} \in \arg\min_{\mu \in \mathbb{R}} \sum_{i=1}^{n} \Psi(\frac{x_i - \mu}{\sigma})$.
Key Insight: Quadratic loss gives $\overline{x}$; absolute or subquadratic loss improves outlier resistance.

2.2 Information Bounds and Asymptotic Efficiency

Information inequalities describe the best possible local accuracy under regular models. Efficient procedures are those whose asymptotic error reaches these bounds.

Lemma 2.2.1. *Two Forms of Fisher Information*
For a regular one-parameter dominated model, let $\ell_\theta(x) := \log p_\theta(x)$ *and* $S_\theta(X) := \partial_\theta \ell_\theta(X)$.
Then $I(\theta) := \mathbb{E}_\theta S_\theta(X)^2 = -\mathbb{E}_\theta \partial_\theta^2 \ell_\theta(X)$.

Proof. Differentiating $\int p_\theta \, d\mu = 1$ gives $\mathbb{E}_\theta S_\theta = 0$.
Differentiating, $0 = \partial_\theta \mathbb{E}_\theta S_\theta = \mathbb{E}_\theta[\partial_\theta S_\theta + S_\theta^2] = \mathbb{E}_\theta[\partial_\theta^2 \ell_\theta + S_\theta^2]$, since $\partial_\theta p_\theta = S_\theta p_\theta$. Thus $I(\theta) = \mathbb{E}_\theta S_\theta^2 = -\mathbb{E}_\theta \partial_\theta^2 \ell_\theta$.
Structural Commentary: Fisher information is both score variance and expected log-likelihood curvature.
Key Insight: Normalisation forces the mean score to vanish, linking slope variance to curvature. □

Theorem 2.2.2. *Cramer–Rao Bound*
Let $X_1, \dots, X_n \sim P_\theta$ *be iid from a regular one-parameter dominated model with one-observation information* $I(\theta) > 0$. *If* $\widehat{\psi} \in L^2(P_\theta)$ *is unbiased for differentiable* $\psi(\theta)$, *then* $\operatorname{Var}_\theta(\widehat{\psi}) \geq \frac{\psi'(\theta)^2}{nI(\theta)}$.

Proof. Let $S_n(\theta) := \partial_\theta \log L_n(\theta) = \sum_{i=1}^n S_\theta(X_i)$. Regularity gives $\mathbb{E}_\theta S_n = 0$ and $\operatorname{Var}_\theta(S_n) = \mathbb{E}_\theta S_n^2 = nI(\theta)$.
Differentiating $\mathbb{E}_\theta \widehat{\psi} = \psi(\theta)$ gives $\psi'(\theta) = \mathbb{E}_\theta[\widehat{\psi} S_n] = \operatorname{Cov}_\theta(\widehat{\psi}, S_n)$.
Thus $\psi'(\theta)^2 \leq \operatorname{Var}_\theta(\widehat{\psi}) \operatorname{Var}_\theta(S_n) = \operatorname{Var}_\theta(\widehat{\psi}) nI(\theta)$ by Cauchy–Schwarz.
Structural Commentary: The score is the direction in which unbiased estimators must covary to track $\psi(\theta)$.
Key Insight: Information lower-bounds variance through Cauchy–Schwarz. □

Example 2.2.3. *Poisson Mean Attains the Bound*
For $X \sim \text{Poisson}(\lambda)$, $\ell_\lambda(X) = X \log \lambda - \lambda - \log(X!)$ and $\partial_\lambda^2 \ell_\lambda(X) = -\frac{X}{\lambda^2}$, so $I(\lambda) = -\mathbb{E}_\lambda \partial_\lambda^2 \ell_\lambda(X) = \frac{1}{\lambda}$.
For iid $X_1, \dots, X_n$, any unbiased estimator T of λ satisfies $\operatorname{Var}_\lambda(T) \geq \frac{\lambda}{n}$.
$\overline{X}$ attains equality since $\mathbb{E}\overline{X} = \lambda$ and $\operatorname{Var}(\overline{X}) = \frac{\lambda}{n}$.

Definition 2.2.4. *Asymptotic Efficiency*
For a scalar regular parameter with information $I(\theta_0) > 0$, an estimator sequence $\widehat{\theta}_n$ is *asymptotically efficient* at θ_0 if $\sqrt{n}(\widehat{\theta}_n - \theta_0) \Rightarrow N(0, I(\theta_0)^{-1})$, i.e. it attains the inverse Fisher-information variance.

Theorem 2.2.5. *Regular MLE Asymptotic Normality*
Let $X_1, \dots, X_n \sim P_{\theta_0}$ *iid in a regular one-parameter model, with* θ_0 *interior,* $I(\theta_0) > 0$, *and a consistent interior MLE* $\widehat{\theta}_n$. *Then* $\sqrt{n}(\widehat{\theta}_n - \theta_0) \Rightarrow N(0, I(\theta_0)^{-1})$.

Proof. Let $S_n(\theta) := \partial_\theta \ell_n(\theta)$ and $J_n(\theta) := -n^{-1} \partial_\theta S_n(\theta)$.
Since $S_n(\widehat{\theta}_n) = 0$, Taylor expansion gives $0 = S_n(\theta_0) - nJ_n(\widetilde{\theta}_n)(\widehat{\theta}_n - \theta_0)$ for some $\widetilde{\theta}_n$ between $\widehat{\theta}_n$ and θ_0.
Hence $\sqrt{n}(\widehat{\theta}_n - \theta_0) = J_n(\widetilde{\theta}_n)^{-1} n^{-\frac{1}{2}} S_n(\theta_0)$.
Regularity gives $J_n(\widetilde{\theta}_n) \xrightarrow{P} I(\theta_0)$ and $n^{-\frac{1}{2}} S_n(\theta_0) \Rightarrow N(0, I(\theta_0))$, so Slutsky gives the result.
Structural Commentary: Local likelihood curvature converts score noise into estimator error.
Key Insight: The MLE is asymptotically score divided by information. □

Remark 2.2.6. *Efficiency and Approximation*
Finite-sample efficiency means equality in the Cramer–Rao bound.
Asymptotic efficiency means $\sqrt{n}(\widehat{\theta}_n - \theta_0) \Rightarrow N(0, I(\theta_0)^{-1})$; finite-sample bias or boundary effects still matter.

2.3 Method of Moments and Parametric Likelihood Examples

Method 2.3.1. *Method of Moments*

(i) Let $X_1, \dots, X_n$ be independent from P_θ, and set $\mu_k(\theta) := \mathbb{E}_\theta X^k$ for $k = 1, \dots, r$.

(ii) If $\mu(\theta) = (\mu_1(\theta), \dots, \mu_r(\theta))$ identifies $\theta \in \Theta \subseteq \mathbb{R}^r$, define $\widehat{\mu}_k := n^{-1} \sum_{i=1}^n X_i^k$.

(iii) The *method of moments* estimator solves $\mu_k(\widehat{\theta}) = \widehat{\mu}_k$ for $k = 1, \dots, r$.

Key Insight: Match population moments to sample moments.

Proposition 2.3.2. *Consistency of Continuous Moment Estimates*
Let $\widehat{\mu}_n \xrightarrow{P_{\theta_0}} \mu_0$ *and let* g *be continuous at* μ_0 *with* $g(\mu_0) = \theta_0$. *Then* $\widehat{\theta}_n := g(\widehat{\mu}_n) \xrightarrow{P_{\theta_0}} \theta_0$. *Thus method-of-moments estimators are consistent whenever* $\widehat{\mu}_n \xrightarrow{P} \mu(\theta_0)$, *inversion map* $g = \mu^{-1}$ *is continuous at* $\mu(\theta_0)$.

Proof. Since $\widehat{\mu}_n \xrightarrow{P_{\theta_0}} \mu_0$ and g is continuous at μ_0, by continuous mapping theorem, $g(\widehat{\mu}_n) \xrightarrow{P_{\theta_0}} g(\mu_0) = \theta_0$.
For MoM, if the required moments are finite, the weak law gives $\widehat{\mu}_n \xrightarrow{P_{\theta_0}} \mu(\theta_0)$.
Structural Commentary: Moment consistency is convergence plus continuous inversion.
Key Insight: Estimate moments first, then pass through g. □

Example 2.3.3. *Moment Estimation for Small Open Probabilities*
Let $N \sim \text{Binomial}(m, p)$ be the number of open channels and let $S = cN$ be total current.
Then $\mathbb{E}S = cmp$, $\operatorname{Var}(S) = c^2 mp(1-p)$, and $\frac{\operatorname{Var}(S)}{\mathbb{E}S} = c(1-p) \approx c$ for small p.
Thus independent measurements estimate c by the empirical ratio $\frac{\widehat{\operatorname{Var}}(S)}{\widehat{\mathbb{E}}S}$, without knowing m.

Example 2.3.4. *Poisson Mean*
Let $X_1, \dots, X_n \sim \text{Poisson}(\lambda)$ be independent. Since $\mathbb{E}_\lambda X = \lambda$, $\widehat{\lambda}_{\text{mom}} = \overline{X}$.
Also $\ell(\lambda) = \sum_{i=1}^{n} \{X_i \log \lambda - \lambda - \log(X_i!)\}$ and $\ell'(\lambda) = \frac{S}{\lambda} - n$, where $S = \sum_i X_i$, so $\widehat{\lambda}_{\text{mle}} = \frac{S}{n} = \overline{X}$.
If true value is λ_0, then $S \sim \text{Poisson}(n\lambda_0)$. Hence $\mathbb{E}_{\lambda_0}\widehat{\lambda} = \lambda_0$, $\text{Var}_{\lambda_0}(\widehat{\lambda}) = \frac{\lambda_0}{n}$, $\text{SE}_{\lambda_0}(\widehat{\lambda}) = \sqrt{\frac{\lambda_0}{n}}$, $\widehat{\text{SE}}(\widehat{\lambda}) = \sqrt{\frac{\widehat{\lambda}}{n}}$.

Example 2.3.5. *Negative Binomial Overdispersion*
For overdispersed counts, negative-binomial mass $f(x \mid m, k) = (1 + \frac{m}{k})^{-k}\Gamma(k+x)\{x!\Gamma(k)\}^{-1}(\frac{m}{m+k})^x$, $x \in \mathbb{N}_0$,
has $\mathbb{E}X = m$ and $\text{Var}(X) = m + \frac{m^2}{k}$. By MoM $\widehat{m} = \overline{X}$, $\widehat{k} = \frac{\overline{X}^2}{\widehat{\sigma}^2 - \overline{X}}$ when $\widehat{\sigma}^2 > \overline{X}$.

Example 2.3.6. *Normal Mean and Variance*
For iid $X_i \sim N(\mu, \sigma^2)$, $\mu_1 = \mu$, $\mu_2 = \mu^2 + \sigma^2$. Thus by MoM $\widehat{\mu} = \overline{X}$; $\widehat{\sigma}^2 = n^{-1}\sum_{i=1}^{n} X_i^2 - \overline{X}^2 = n^{-1}\sum_{i=1}^{n}(X_i - \overline{X})^2$.
The normal MLEs are the same; $\widehat{\sigma}^2$ uses denominator n, not the unbiased denominator $n-1$.

Example 2.3.7. *Gamma Shape and Rate*
Let X_i be iid gamma with shape α and rate λ, so $\mathbb{E}X = \frac{\alpha}{\lambda}$ and $\text{Var}(X) = \frac{\alpha}{\lambda^2}$.
With $\widehat{\sigma}^2 := n^{-1}\sum_{i=1}^{n}(X_i - \overline{X})^2$, MoM gives $\widehat{\alpha}_{\text{mom}} = \frac{\overline{X}^2}{\widehat{\sigma}^2}$ and $\widehat{\lambda}_{\text{mom}} = \frac{\overline{X}}{\widehat{\sigma}^2}$.
The log-likelihood is $\ell(\alpha, \lambda) = n\alpha \log \lambda + (\alpha - 1)\sum_i \log X_i - \lambda \sum_i X_i - n \log \Gamma(\alpha)$.
The MLE satisfies $\widehat{\lambda} = \frac{\widehat{\alpha}}{\overline{X}}$ and $\log \widehat{\alpha} - \log \overline{X} + n^{-1}\sum_i \log X_i - \psi(\widehat{\alpha}) = 0$, where $\psi = \frac{\Gamma'}{\Gamma}$.
The MoM estimate is a natural starting value.

Example 2.3.8. *Angular Density*
Let $f(x \mid \alpha) = \frac{1+\alpha x}{2}$ on $[-1, 1]$, with $\alpha \in [-1, 1]$. Since $\mathbb{E}_\alpha X = \int_{-1}^{1} \frac{x(1+\alpha x)}{2}\,dx = \frac{\alpha}{3}$, MoM gives $\widehat{\alpha} = 3\overline{X}$.
Also $\text{Var}_\alpha(X) = \frac{1}{3} - \frac{\alpha^2}{9}$, so $\text{Var}_\alpha(\widehat{\alpha}) = 9\,\text{Var}_\alpha(\overline{X}) = \frac{3-\alpha^2}{n}$.

3 Hypothesis Testing and Confidence

3.1 Tests, Likelihood Ratios, and Error Control

Testing formalises decisions between hypotheses. The central quantities are the probability of false rejection under the null and the probability of rejection under alternatives.

Definition 3.1.1. *Hypotheses, Tests, Size, and Power*
(i) A *null hypothesis* is a subset $\Theta_0 \subseteq \Theta$ of the parameter space.
(ii) An *alternative* is a subset $\Theta_1 \subseteq \Theta$ disjoint from Θ_0, so $\Theta_0 \cap \Theta_1 = \emptyset$.
(iii) Randomised *test* is a measurable map $\varphi : \mathcal{X} \to [0, 1]$, where $\varphi(x)$ is rejection probability at observation x.
(iv) The *size* of φ is $\alpha(\varphi) = \sup_{\theta \in \Theta_0} \mathbb{E}_\theta[\varphi(X)]$.
(v) The *power function* of φ is $\beta_\varphi(\theta) = \mathbb{E}_\theta[\varphi(X)]$.

Definition 3.1.2. *Simple and Composite Hypotheses; Type Errors*
(i) A *simple* hypothesis specifies one law; a *composite* hypothesis specifies several.
(ii) A *type I error* rejects a true H_0; its probability is bounded by $\alpha(\varphi)$.
(iii) For a simple alternative P_1, a *type II error* is failure to reject H_0 under P_1, with probability $\mathbb{E}_1[1 - \varphi(X)]$.
(iv) The *power* against P_1 is $1 - \mathbb{E}_1[1 - \varphi(X)]$.

Theorem 3.1.3. *Neyman–Pearson Lemma*
Let $P_1 \ll P_0$, $\Lambda := \frac{dP_1}{dP_0}$, $\alpha \in [0, 1]$. If $c \geq 0$ and $\gamma \in [0, 1]$ make $\varphi^* := \mathbf{1}_{\{\Lambda > c\}} + \gamma \mathbf{1}_{\{\Lambda = c\}}$ satisfy $\mathbb{E}_0\varphi^* = \alpha$, then φ^* is most powerful among level-α tests: for every $\psi : \mathcal{X} \to [0, 1]$ with $\mathbb{E}_0\psi \leq \alpha$, $\mathbb{E}_1\psi \leq \mathbb{E}_1\varphi^*$.

Proof. For any level-α competitor ψ, $(\varphi^* - \psi)(\Lambda - c) \geq 0$ pointwise.
Since $dP_1 = \Lambda\, dP_0$, $\mathbb{E}_1(\varphi^* - \psi) = \mathbb{E}_0[\Lambda(\varphi^* - \psi)] \geq c\mathbb{E}_0(\varphi^* - \psi) = c(\alpha - \mathbb{E}_0\psi) \geq 0$.
Structural Commentary: Null controls size constraint, while alternative supplies power objective.
Key Insight: Use the rejection budget where $\Lambda = \frac{dP_1}{dP_0}$ is largest. □

Remark 3.1.4. *Choosing the Null*
At level a, for simple P_0 versus P_1, the *Neyman–Pearson problem* is $\sup\{\mathbb{E}_1\varphi : 0 \leq \varphi \leq 1,\ \mathbb{E}_0\varphi \leq a\}$.
Thus H_0 is the protected claim: choose it so the false-rejection probability $\mathbb{E}_0\varphi$ is the error to be bounded by a.
The choice of H_0 is substantive, not determined by $\{P_0, P_1\}$.

Definition 3.1.5. *Uniformly Most Powerful Test*
For a composite alternative Θ_1, a level-α test φ is *uniformly most powerful* if, for every $\theta \in \Theta_1$, it has power at least as large as every other level-α test at that same θ.

Example 3.1.6. *Normal Mean, Known Variance*
Let $X_1, \dots, X_n$ be independent $N(\mu, \sigma^2)$ variables with known σ^2. For $H_0 : \mu = \mu_0$ against $H_1 : \mu = \mu_1 > \mu_0$, the likelihood ratio is increasing in $\overline{X}$, so the level-α test is $\varphi^* = \mathbf{1}_{\{\overline{X} > \mu_0 + \frac{z_{1-\alpha}\sigma}{\sqrt{n}}\}}$, where $z_{1-\alpha}$ is the $N(0,1)$ quantile. Since the cutoff is independent of μ_1, φ^* is uniformly most powerful for $H_1 : \mu > \mu_0$; no single likelihood-ratio direction is uniformly most powerful for $H_1 : \mu \neq \mu_0$.

Definition 3.1.7. *Generalized Likelihood-Ratio Test*
For $H_0 : \theta \in \Theta_0 \subseteq \Theta$, the *generalized likelihood ratio* is $\lambda(x) := \frac{\sup_{\theta \in \Theta_0} L_x(\theta)}{\sup_{\theta \in \Theta} L_x(\theta)} \in [0, 1]$.
A GLR test rejects H_0 for small $\lambda(x)$, typically $\lambda(x) \leq c_\alpha$ with c_α chosen to give level α.

Theorem 3.1.8. *Large-Sample Likelihood-Ratio Calibration*

(i) Let $H_0 : \theta \in \Theta_0 \subseteq \Theta$, $\dim \Theta = d$, $\dim \Theta_0 = d_0$, $r := d - d_0$, *and* $X^{(n)} \sim P_{\theta_0}$ *with* $\theta_0 \in \Theta_0$.

(ii) Let $L_n(\theta) := e^{\ell_n(\theta)}$ *and* $\lambda_n := \dfrac{\sup_{\theta \in \Theta_0} L_n(\theta)}{\sup_{\theta \in \Theta} L_n(\theta)}$.

(iii) Assume local coordinates with $\theta_0 = 0$, $\Theta_0 = \{(u, 0) : u \in \mathbb{R}^{d_0}\}$, $h = (u, v) \in \mathbb{R}^{d_0} \times \mathbb{R}^r$, *and* $\ell_n(\frac{h}{\sqrt{n}}) - \ell_n(0) = h^\top Z_n - \frac{\|h\|^2}{2} + o_{P_{\theta_0}}(1)$, *where* $Z_n = (U_n, V_n) \Rightarrow N_d(0, I_d)$, $U_n \in \mathbb{R}^{d_0}$, $V_n \in \mathbb{R}^r$.

(iv) Then under H_0, $-2 \log \lambda_n \Rightarrow \chi^2_r$.

Proof.

(i) Since $L_n = e^{\ell_n}$, $\log \lambda_n = \sup_{\theta \in \Theta_0} \ell_n(\theta) - \sup_{\theta \in \Theta} \ell_n(\theta)$, hence $-2 \log \lambda_n = 2\{\sup_{\theta \in \Theta} \ell_n(\theta) - \sup_{\theta \in \Theta_0} \ell_n(\theta)\}$.

(ii) In the local coordinates, write $\theta = \frac{h}{\sqrt{n}}$ for the full model and $\theta = \frac{(u,0)}{\sqrt{n}}$ for the null model.

With $Q_n(h) := h^\top Z_n - \frac{\|h\|^2}{2}$ and $Q_{0,n}(u) := Q_n(u, 0) = u^\top U_n - \frac{\|u\|^2}{2}$, (iii) and cancellation of $\ell_n(0)$ give $-2 \log \lambda_n = 2\{\sup_{h \in \mathbb{R}^d} Q_n(h) - \sup_{u \in \mathbb{R}^{d_0}} Q_{0,n}(u)\} + o_{P_{\theta_0}}(1)$.

(iii) For $a \in \mathbb{R}^m$, $x^\top a - \frac{\|x\|^2}{2} = \frac{\|a\|^2}{2} - \frac{\|x-a\|^2}{2}$, so supremum over $x \in \mathbb{R}^m$ is $\frac{\|a\|^2}{2}$ at $x = a$.

Applying this with $a = Z_n$ and $a = U_n$ gives $\sup_{h \in \mathbb{R}^d} Q_n(h) = \frac{\|Z_n\|^2}{2}$ and $\sup_{u \in \mathbb{R}^{d_0}} Q_{0,n}(u) = \frac{\|U_n\|^2}{2}$,

hence $-2 \log \lambda_n = \|Z_n\|^2 - \|U_n\|^2 + o_{P_{\theta_0}}(1) = \|V_n\|^2 + o_{P_{\theta_0}}(1)$.

(iv) Since $Z_n = (U_n, V_n) \Rightarrow N_d(0, I_d)$, marginal convergence gives $V_n \Rightarrow Y$ with $Y \sim N_r(0, I_r)$.
Therefore $\|V_n\|^2 \Rightarrow \|Y\|^2 \sim \chi^2_r$ by continuous mapping, and Slutsky gives $-2 \log \lambda_n \Rightarrow \chi^2_r$.

Structural Commentary: The likelihood ratio compares unconstrained fit with null-constrained fit.
Key Insight: Wilks' statistic is the squared Gaussian fluctuation in the $r = d - d_0$ constrained directions. □

Example 3.1.9. *Two-Sided Normal Mean GLRT*
Let $X_1, \ldots, X_n$ be independent $N(\mu, \sigma^2)$ variables with known σ^2, and test $H_0 : \mu = \mu_0$ against $H_1 : \mu \neq \mu_0$.
Since $\widehat{\mu} = \overline{X}$, $\lambda(X) = \frac{L_n(\mu_0)}{L_n(\overline{X})} = \exp\{-\frac{n(\overline{X}-\mu_0)^2}{2\sigma^2}\}$, so $-2 \log \lambda(X) = \frac{n(\overline{X}-\mu_0)^2}{\sigma^2}$.
Under H_0, $\frac{\sqrt{n}(\overline{X}-\mu_0)}{\sigma} \sim N(0, 1)$; hence $-2 \log \lambda(X) \sim \chi^2_1$,
and the level-α GLR rejects iff $\frac{n(\overline{X}-\mu_0)^2}{\sigma^2} > \chi^2_{1,1-\alpha}$, equivalently $|\overline{X} - \mu_0| > \frac{z_{1-\frac{\alpha}{2}}\sigma}{\sqrt{n}}$.

Example 3.1.10. *Sign Test as a Binomial GLRT*
Let $X \sim \text{Binomial}(n, p)$ and test $H_0 : p = \frac{1}{2}$ against $H_1 : p \neq \frac{1}{2}$.
For observed x, $\widehat{p} = \frac{x}{n}$ and $\lambda(x) = \frac{L_x(\frac{1}{2})}{L_x(\widehat{p})} = \frac{(\frac{1}{2})^n}{[(\frac{x}{n})^x(1-\frac{x}{n})^{n-x}]}$, $0^0 = 1$ at $x = 0, n$.
Since $\lambda(x)$ decreases as $|x - \frac{n}{2}|$ increases, a level-α GLR rejects on the largest values of $|X - \frac{n}{2}|$, with cutoff chosen under $X \sim \text{Binomial}(n, \frac{1}{2})$; this is the two-sided sign test.

Definition 3.1.11. *p-Value*
A *p-value* for $H_0 : \theta \in \Theta_0$ is a statistic $p : \mathcal{X} \to [0, 1]$ such that $\sup_{\theta \in \Theta_0} \mathbb{P}_\theta\{p(X) \leq u\} \leq u$ for every $u \in [0, 1]$.
Then $\varphi_\alpha(X) := \mathbf{1}_{\{p(X) \leq \alpha\}}$ has size $\alpha(\varphi_\alpha) \leq \alpha$.

Proposition 3.1.12. *Continuous Null p-Values Are Uniform*
Let $H_0 : \theta \in \Theta_0$ *and let* $T : \mathcal{X} \to \mathbb{R}$ *satisfy* $\mathbb{P}_\theta(T \leq t) = F_0(t)$ *for all* $\theta \in \Theta_0$, *where* F_0 *is continuous.*
For the right-tail convention, set $p(X) := 1 - F_0(T(X))$.
Then $p(X) \sim \text{Uniform}(0, 1)$ *under every* $\theta \in \Theta_0$, *and* $\varphi_\alpha(X) := \mathbf{1}_{\{p(X) \leq \alpha\}}$ *has size* α *for* $\alpha \in [0, 1]$.

Proof. Fix $\theta \in \Theta_0$ and set $U := F_0(T(X))$.
By probability integral transform, Proposition 2.3.6, $U \sim \text{Uniform}(0, 1)$ under $\mathbb{P}_\theta$,
hence $p(X) = 1 - U \sim \text{Uniform}(0, 1)$. Thus $\mathbb{E}_\theta \varphi_\alpha = \mathbb{P}_\theta(p(X) \leq \alpha) = \alpha \ \forall \theta \in \Theta_0$, so $\alpha(\varphi_\alpha) = \sup_{\theta \in \Theta_0} \mathbb{E}_\theta \varphi_\alpha = \alpha$.

Structural Commentary: A continuous null CDF converts the statistic to a canonical uniform scale.
Key Insight: Exact calibration is the probability integral transform applied under H_0. □

Remark 3.1.13. *p-Values Are Tail Probabilities*
A p-value is a null tail probability, e.g. $p(x) = \mathbb{P}_{H_0}\{T(X) \geq T(x)\}$ for a right-tail statistic T.
It is not $\mathbb{P}(H_0 \mid x)$; posterior probabilities require priors and an alternative likelihood.

Definition 3.1.14. *Multiple-Testing Error Counts and FDR*
For a multiple-testing rule over M hypotheses.
Let M_0 be the number of true nulls and $M_1 = M - M_0$ the number of false nulls.
Let V be false rejections, S true rejections, U true nonrejections, and T false nonrejections.
The total number of discoveries is $R = V + S$.

(i) *Family-wise error rate*: $\text{FWER} := \mathbb{P}(V \geq 1)$.
(ii) *False discovery proportion*: $\text{FDP} := \frac{V}{\max(R,1)}$.
(iii) *False discovery rate*: $\text{FDR} := \mathbb{E}[\text{FDP}]$.
(iv) *Power*: One aggregate power measure is $\mathbb{E}[S]/M_1$ when $M_1 > 0$.

Thus FWER controls the chance of any false discovery.
FDR controls the expected false fraction among the reported discoveries.

Remark 3.1.15. *Error Rates*
For one test φ, size is $\alpha(\varphi) = \sup_{\theta \in \Theta_0} \mathbb{E}_\theta \varphi$. For a family of tests, let R be the number of rejections and V the number of false rejections; common targets are $\text{FWER} = \mathbb{P}\{V \geq 1\}$ and $\text{FDR} = \mathbb{E}[\frac{V}{R \vee 1}]$, while directional or selective rates replace V by the corresponding error count.

Method 3.1.16. *Fishing Expeditions and Bonferroni Control*

(i) For N null hypotheses, let R_i be the event that null i is rejected.
(ii) By the union bound, $\mathbb{P}(\bigcup_{i=1}^{N} R_i) \le \sum_{i=1}^{N} \mathbb{P}(R_i)$.
(iii) To control family-wise error at level α, test each null at level $\frac{\alpha}{N}$; then $\mathbb{P}(\text{at least one false rejection}) \le \alpha$.
(iv) Without such correction, many tests can produce small p-values even when all nulls are true.

Definition 3.1.17. *Positive FDR, Local FDR, and q-Values*

Let $Z_j = 0$ indicate a true null, $Z_j = 1$ a false null, t_j a test statistic, and Γ a rejection region.

(i) *pFDR*: For false discoveries V and discoveries R, $\mathrm{pFDR} := \mathbb{E}[V/R \mid R > 0]$.
(ii) *Mixture model*: If $\mathbb{P}(Z_j = 0) = \pi_0$, $\mathcal{L}(t_j \mid Z_j = 0) = F_0$, and $\mathcal{L}(t_j \mid Z_j = 1) = F_1$, then $\mathcal{L}(t_j) = \pi_0 F_0 + (1 - \pi_0) F_1$.
(iii) *Bayes form*: For a rejection region Γ, $\mathrm{pFDR}(\Gamma) = \mathbb{P}(Z_j = 0 \mid t_j \in \Gamma)$.
(iv) *Local FDR*: At value t_0, $\mathrm{lfdr}(t_0) := \mathbb{P}(Z_j = 0 \mid t_j = t_0)$.
(v) *q-value*: For feature j, $q_j := \inf\{\alpha : j \in \mathcal{R}_\alpha\}$, where $\mathcal{R}_\alpha$ is the discovery set at FDR level α.

Remark 3.1.18. *FDR Versus Family-Wise Error*

With false discoveries V and total discoveries R, $\mathrm{FWER} := \mathbb{P}(V \ge 1)$ controls any false rejection, while $\mathrm{FDR} := \mathbb{E}[V/\max(R, 1)]$ controls the expected false fraction among discoveries. Thus FDR is less conservative for large screening lists and measures list reliability directly.

Method 3.1.19. *Benjamini–Hochberg Step-Up Rule*

For M hypotheses with p-values $p_1, \dots, p_M$ and target level $\alpha \in (0, 1)$:

(i) *Order*: Let $p_{(1)} \le \cdots \le p_{(M)}$ be the order statistics.
(ii) *Step-up index*: Set $L := \max\{j : p_{(j)} \le \alpha j / M\}$, with $L := 0$ if the set is empty.
(iii) *Rejections*: Reject $\mathcal{R} := \{m : p_m \le p_{(L)}\}$ if $L > 0$, and reject none if $L = 0$.
(iv) *Guarantee*: If true-null p-values are independent and uniform, then $\mathrm{FDR} \le (M_0/M)\alpha \le \alpha$, where M_0 is the number of true nulls.

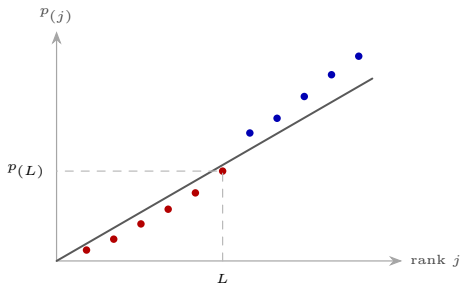

Figure 238: Benjamini–Hochberg threshold: red points reject, blue points do not; line is $\alpha j/M$.

3.2 Confidence Sets, Pivots, and Asymptotic Intervals

Confidence procedures attach uncertainty to estimators by controlling coverage probability under repeated sampling.

Definition 3.2.1. *Confidence Sets and Coverage*

A random set $C(X) \subseteq \Psi$ is a $1 - \alpha$ *confidence set* for $\psi : \Theta \to \Psi$ if $\inf_{\theta \in \Theta} \mathbb{P}_\theta\{\psi(\theta) \in C(X)\} \ge 1 - \alpha$.

The left side is the *coverage guarantee*.

Definition 3.2.2. *Pivots and Confidence Construction*

(i) A *pivot* is a statistic $Q(X, \theta)$ whose distribution under $\mathbb{P}_\theta$ is free of θ.
(ii) If constants a_α, b_α satisfy $\mathbb{P}_\theta\{a_\alpha \le Q(X, \theta) \le b_\alpha\} = 1 - \alpha$ for all $\theta \in \Theta$, then $C(X) := \{\theta \in \Theta : a_\alpha \le Q(X, \theta) \le b_\alpha\}$ is an exact $1 - \alpha$ confidence set for θ.

Corollary 3.2.3. *Hoeffding Confidence Interval for a Bernoulli Parameter*

Let $X_1, \dots, X_n$ be independent Bernoulli(p) *variables, $\widehat{p}_n := \overline{X}_n$, and $\alpha \in (0, 1)$.*

Set $\varepsilon_n := \sqrt{(2n)^{-1} \log(\frac{2}{\alpha})}$ and $C_n := [\widehat{p}_n - \varepsilon_n, \widehat{p}_n + \varepsilon_n]$.

(i) Coverage: $\mathbb{P}(p \in C_n) \ge 1 - \alpha$.
(ii) Length: $|C_n| = 2\varepsilon_n \le 0.05$ whenever $n \ge 800 \log(\frac{2}{\alpha})$.

Proof.

(i) Since $\{p \notin C_n\} = \{|\widehat{p}_n - p| > \varepsilon_n\}$, Corollary 3.3.5 gives $\mathbb{P}(p \notin C_n) \le 2e^{-2n\varepsilon_n^2} = \alpha$.
(ii) If $n \ge 800 \log(\frac{2}{\alpha})$, then $\varepsilon_n^2 \le \frac{1}{1600}$, hence $|C_n| = 2\varepsilon_n \le 0.05$.

Structural Commentary: Confidence intervals invert a concentration inequality.
Key Insight: Choose ε_n so the Hoeffding failure bound equals α. □

Proposition 3.2.4. *Test–Confidence Duality*

For each $\psi_0 \in \Psi$, let $\varphi_{\psi_0} : \mathcal{X} \to \{0, 1\}$ satisfy $\sup_{\theta : \psi(\theta) = \psi_0} \mathbb{E}_\theta \varphi_{\psi_0} \le \alpha$.

Then $C(X) := \{\psi_0 \in \Psi : \varphi_{\psi_0}(X) = 0\}$ is a $1 - \alpha$ confidence set for $\psi(\theta)$.

Proof. Fix $\theta \in \Theta$ and set $\psi_\theta := \psi(\theta)$.
By definition, $\{\psi(\theta) \notin C(X)\} = \{\varphi_{\psi_\theta}(X) = 1\}$, so $\mathbb{P}_\theta\{\psi(\theta) \notin C(X)\} = \mathbb{E}_\theta \varphi_{\psi_\theta} \le \sup_{\eta:\psi(\eta)=\psi_\theta} \mathbb{E}_\eta \varphi_{\psi_\theta} \le \alpha$.
Hence $\mathbb{P}_\theta\{\psi(\theta) \in C(X)\} \ge 1-\alpha$ for every θ, and $\inf_{\theta\in\Theta} \mathbb{P}_\theta\{\psi(\theta) \in C(X)\} \ge 1-\alpha$.
Structural Commentary: Inverting all accepted point-null tests turns non-rejection regions into a confidence set.
Key Insight: Coverage failure equals rejection of the true null value. □

Proposition 3.2.5. *Confidence–Test Converse*
Let $C(X) \subseteq \Psi$ satisfy $\inf_{\theta\in\Theta} \mathbb{P}_\theta\{\psi(\theta) \in C(X)\} \ge 1-\alpha$.
For $\psi_0 \in \Psi$, let $\varphi_{\psi_0}(X) := \mathbf{1}_{\{\psi_0 \notin C(X)\}}$ for testing $H_0 : \psi(\theta) = \psi_0$. Then φ_{ψ_0} is level α: $\sup_{\theta:\psi(\theta)=\psi_0} \mathbb{E}_\theta \varphi_{\psi_0} \le \alpha$.

Proof. Fix θ with $\psi(\theta) = \psi_0$. Then $\mathbb{E}_\theta \varphi_{\psi_0} = \mathbb{P}_\theta\{\psi_0 \notin C(X)\} = \mathbb{P}_\theta\{\psi(\theta) \notin C(X)\} = 1 - \mathbb{P}_\theta\{\psi(\theta) \in C(X)\} \le \alpha$.
Taking $\sup_{\theta:\psi(\theta)=\psi_0}$ gives the level bound.
Structural Commentary: A confidence set tests a proposed value by checking membership.
Key Insight: Rejection of ψ_0 is exactly non-coverage when ψ_0 is true. □

Remark 3.2.6. *Acceptance Regions and Confidence Regions*
For level-α point-null tests with acceptance regions $A_{\psi_0} \subseteq \mathcal{X}$, the inversion $C(X) := \{\psi_0 \in \Psi : X \in A_{\psi_0}\}$ is the set of null values not rejected at X. Conversely, any confidence set $C(X)$ induces point-null tests $\varphi_{\psi_0}(X) = \mathbf{1}_{\{\psi_0 \notin C(X)\}}$.

Definition 3.2.7. *Wald, Score, and Likelihood Intervals*
For scalar regular θ with estimator $\widehat{\theta}$, standard error $\widehat{\mathrm{se}}(\widehat{\theta})$, score U_n, and likelihood ratio $\lambda_n(\theta_0)$:

(i) *Wald*: use $\widehat{\theta} \pm z_{1-\frac{\alpha}{2}} \widehat{\mathrm{se}}(\widehat{\theta})$.
(ii) *Score*: invert $\frac{|U_n(\theta_0)|}{\sqrt{I_n(\theta_0)}} \le z_{1-\frac{\alpha}{2}}$ over θ_0.
(iii) *Likelihood*: invert $-2\log\lambda_n(\theta_0) \le \chi^2_{1,1-\alpha}$ over θ_0.

Key Insight: Wald, score, and likelihood intervals are first-order equivalent in regular models.

Example 3.2.8. *Poisson Mean Wald Interval*
Let $X_1, \dots, X_n$ be independent Poisson(λ) variables.
Then $\widehat{\lambda} = \overline{X}$ and $\frac{\sqrt{n}(\overline{X}-\lambda)}{\sqrt{\lambda}} \Rightarrow N(0,1)$, so the plug-in standard error is $\widehat{\mathrm{se}}(\widehat{\lambda}) = \sqrt{\frac{\overline{X}}{n}}$.
The Wald interval is $C_\alpha(X) = [\overline{X} - z_{1-\frac{\alpha}{2}}\sqrt{\frac{\overline{X}}{n}}, \overline{X} + z_{1-\frac{\alpha}{2}}\sqrt{\frac{\overline{X}}{n}}]$, with asymptotic coverage $1-\alpha$.

3.3 Goodness-of-Fit and Diagnostic Plots

Goodness-of-fit methods compare an observed empirical pattern with the pattern predicted by a probability model. Formal tests give calibrated evidence against a specified model, while diagnostic plots show where the model fits or fails.

Definition 3.3.1. *Multinomial Goodness-of-Fit Model*

(i) *Observed counts*: $O = (O_1, \dots, O_m)$ records cell frequencies from n trials, with $O_i \in \mathbb{N}_0$ and $\sum_{i=1}^m O_i = n$.
(ii) *Null model*: $\mathcal{M}_0 = \{p(\theta) = (p_1(\theta), \dots, p_m(\theta)) : \theta \in \Theta_0\} \subseteq \Delta_{m-1}$ is parametric.
(iii) *Saturated model*: $\Delta_{m-1} = \{p \in [0,1]^m : \sum_i p_i = 1\}$ allows every multinomial probability vector.
(iv) *Fitted counts*: if $\widehat{\theta}$ is the null MLE, then $E_i := np_i(\widehat{\theta})$ for $i = 1, \dots, m$.
(v) *Degrees of freedom*: if $\dim\Theta_0 = k$, then $\mathrm{df} = (m-1) - k = m - k - 1$.

Definition 3.3.2. *Pearson and Likelihood-Ratio Goodness-of-Fit Statistics*

(i) *Inputs*: $O = (O_1, \dots, O_m)$ are observed counts, $E = (E_1, \dots, E_m)$ are fitted null counts with $E_i > 0$, and the null model has k free parameters.
(ii) *Pearson statistic*: $X^2 := \sum_{i=1}^m \frac{(O_i - E_i)^2}{E_i}$.
(iii) *Likelihood-ratio statistic*: $G^2 := 2\sum_{i=1}^m O_i \log(\frac{O_i}{E_i})$, with $0\log(\frac{0}{E_i}) := 0$.
(iv) *Null calibration*: under the regular null model, $X^2 \Rightarrow \chi^2_{m-k-1}$ and $G^2 = -2\log\lambda(X) \Rightarrow \chi^2_{m-k-1}$.
Moreover $G^2 - X^2 = o_P(1)$ under H_0.

Example 3.3.3. *Hardy–Weinberg Fit*
For genotype cells (M, MN, N), the Hardy–Weinberg model is $p(\theta) = ((1-\theta)^2, 2\theta(1-\theta), \theta^2)$.
With $n = 1029$ and $\widehat{\theta} = 0.4247$, the observed and fitted counts are

	M	MN	N
O_i	342	500	187
E_i	340.6	502.8	185.6

Since $m = 3$ and $k = 1$, $\mathrm{df} = m - k - 1 = 1$. Pearson statistic is $X^2 = 0.0319$, so $p = \mathbb{P}\{\chi^2_1 \ge 0.0319\}$ is large.
The data give no evidence against Hardy–Weinberg equilibrium.

Method 3.3.4. *Reading Cell Contributions*

(i) Compute signed residuals $r_i := O_i - E_i$ and Pearson contributions $c_i := \frac{(O_i - E_i)^2}{E_i}$.
(ii) Large c_i identify cells driving the rejection; the sign of r_i indicates overfit or underfit in that cell.
(iii) If some E_i are small, group adjacent or tail cells before testing so the chi-square approximation is reliable.

Remark 3.3.5. *Grouped Counts and Expected Frequencies*

Let $Y_1, \dots, Y_N$ be observations, let $A_1, \dots, A_m$ partition sample space, with observed counts $O_j := \sum_{i=1}^{N} \mathbf{1}_{\{Y_i \in A_j\}}$.

Given a fitted parametric law $P_{\widehat{\theta}}$, set $p_j(\widehat{\theta}) := P_{\widehat{\theta}}(Y \in A_j)$; the fitted expected count is $E_j := N p_j(\widehat{\theta})$.
For grouped Poisson tails, $p_j(\widehat{\theta})$ is a sum of Poisson masses, $(O_1, \dots, O_m)$ is modelled as multinomial under $P_{\widehat{\theta}}$.

Example 3.3.6. *Poisson Clumps*
For grouped bacterial clump frequencies from $n = 400$ grid squares, fit $H_0 : X \sim \text{Poisson}(\lambda)$ with $\widehat{\lambda} = 2.44$ and grouped tails so E_i are adequate. The Pearson statistic is $X^2 = 75.4$ with df $= 6$, so $p = \mathbb{P}\{\chi^2_6 \geq 75.4\} < 0.005$; the largest $c_i = \frac{(O_i - E_i)^2}{E_i}$ are in the first and last cells, indicating excess small and large counts.

Definition 3.3.7. *Overdispersed Counts*
Count data are *overdispersed* relative to a Poisson model if $\text{Var}(X) > \mathbb{E}X$; empirically, this is $\widehat{\sigma}^2 > \overline{X}$.

Definition 3.3.8. *Poisson Dispersion Test*

The data is $x_1, \dots, x_n$ are independent counts and $\overline{x} := n^{-1} \sum_{i=1}^{n} x_i$.

(i) *Models*: $H_0 : x_i \sim \text{Poisson}(\lambda)$ with common λ; the saturated alternative uses separate rates λ_i.

(ii) *Likelihood-ratio statistic*: $G^2_D := 2 \sum_{i=1}^{n} x_i \log(\frac{x_i}{\overline{x}})$, with $0 \log(\frac{0}{\overline{x}}) := 0$.

(iii) *Pearson approximation*: $T := \overline{x}^{-1} \sum_{i=1}^{n} (x_i - \overline{x})^2$.

(iv) *Calibration*: under H_0, G^2_D and T are calibrated by χ^2_{n-1}
Large values indicate overdispersion relative to $\text{Var}(X) = \mathbb{E}X$.

Example 3.3.9. *Dispersion in Bacterial Clumps*
For bacterial clump counts with $n = 400$, $\overline{x} = 2.44$ and $s^2 = 4.59$, so $\frac{s^2}{\overline{x}} = 1.88 > 1$.
Dispersion statistic is $T \approx 752.7$ with df $= n - 1 = 399$, so $p = \mathbb{P}\{\chi^2_{399} \geq 752.7\} \approx 0$.
The data show strong overdispersion relative to a Poisson model.

Definition 3.3.10. *Hanging Rootograms and Chi-Grams*
Let n_j be observed bin counts and $\widehat{n}_j$ fitted counts in ordered bins.

(i) A *hanging histogram* plots raw residuals $r_j := n_j - \widehat{n}_j$, whose variance depends on $\widehat{n}_j$.

(ii) A *hanging rootogram* plots $q_j := \sqrt{n_j} - \sqrt{\widehat{n}_j}$, using $\text{Var}(\sqrt{n_j}) \approx \frac{1}{4}$ for count data.

(iii) A *hanging chi-gram* plots standardized residuals $z_j := \frac{n_j - \widehat{n}_j}{\sqrt{\widehat{n}_j}}$.

Runs of same-sign residuals, tail spikes, or systematic curvature indicate model departure.

Method 3.3.11. *Probability Plots*
Let $X_{(1)} \leq \cdots \leq X_{(n)}$ be order statistics and let F be the candidate continuous strictly increasing CDF.

(i) A *P-P plot* compares $F(X_{(k)})$ with $u_k := \frac{k}{n+1}$ for $k = 1, \dots, n$.

(ii) A *Q-Q plot* compares $X_{(k)}$ with $F^{-1}(u_k)$ for $k = 1, \dots, n$.

The model is plausible when the plotted points are approximately linear.
For $F(x) = G(\frac{x-\mu}{\sigma})$, Q-Q slope and intercept estimate σ and μ.

Method 3.3.12. *Probability Plots for Grouped Data*

Let bins boundaries $x_1 < \cdots < x_{m+1}$, counts $n_1, \dots, n_m$, total $n := \sum_{j=1}^{m} n_j$, cumulative counts $N_j := \sum_{i=1}^{j} n_i$.

Let G be the standardised CDF in the proposed location-scale family $F_{\mu,\sigma}(x) = G(\frac{x-\mu}{\sigma})$.

(i) Plot empirical boundary quantiles x_{j+1} against theoretical quantiles $G^{-1}(\frac{N_j}{n+1})$ for $j = 1, \dots, m$.

(ii) Use this grouped Q-Q plot when individual order statistics are unavailable.

Remark 3.3.13. *Grouped Normality Tests*
For binned normal-fit testing, use $X^2 = \sum_j \frac{(O_j - E_j)^2}{E_j}$ with $E_j = n\{F_{\widehat{\mu},\widehat{\sigma}}(b_{j+1}) - F_{\widehat{\mu},\widehat{\sigma}}(b_j)\}$.

The usual χ^2_{m-k-1} calibration requires $(\widehat{\mu}, \widehat{\sigma})$ from the grouped counts; ungrouped estimates change the limit.

Definition 3.3.14. *Normality Diagnostics*
Let $X_{(1)} \leq \cdots \leq X_{(n)}$, $\overline{X} := n^{-1} \sum_i X_i$, and $s^2 := n^{-1} \sum_i (X_i - \overline{X})^2$.

(i) *Normal Q-Q plot*: plot $X_{(k)}$ against $\Phi^{-1}(\frac{k}{n+1})$; normality predicts approximate linearity.

(ii) *Skewness*: $b_1 := n^{-1} \sum_{i=1}^{n} \frac{(X_i - \overline{X})^3}{s^3}$ measures asymmetry; large $|b_1|$ indicates nonnormality.

(iii) *Kurtosis*: $b_2 := n^{-1} \sum_{i=1}^{n} \frac{(X_i - \overline{X})^4}{s^4}$ measures tail weight and peakedness; normality gives $b_2 \approx 3$.

(iv) *Plot correlation*: Q-Q point correlation; small values indicate curvature.

3.4 Normal Sampling Pivots

For normal samples, the sample mean and sample variance separate exactly. This is the finite-sample source of the classical z, χ^2, and Student t pivots used in normal-theory confidence intervals and tests.

Corollary 3.4.1. *Student Pivot for a Normal Mean*
Let $X_1, \dots, X_n$ be independent; $X_i \sim N(\mu, \sigma^2)$, $\overline{X} := n^{-1} \sum_i X_i$, $S^2 := (n-1)^{-1} \sum_i (X_i - \overline{X})^2$; $\frac{\overline{X} - \mu}{\frac{S}{\sqrt{n}}} \sim t_{n-1}$.

Proof. Let $Z := \frac{\sqrt{n}(\overline{X}-\mu)}{\sigma}$ and $V := \frac{(n-1)S^2}{\sigma^2}$. By normal mean law, $Z \sim N(0,1)$. By sample-variance chi-square law, $V \sim \chi^2_{n-1}$. By mean-residual independence, $Z \perp\!\!\!\perp V$. Therefore $\frac{\overline{X}-\mu}{\frac{S}{\sqrt{n}}} = \frac{Z}{\sqrt{\frac{V}{n-1}}} \sim t_{n-1}$.

Structural Commentary: Replacing σ by S yields a Student pivot.
Key Insight: Student's t is a normal variable divided by an independent chi-square scale estimate. □

Method 3.4.2. *Exact Normal Mean Intervals*
Let $X_1, \dots, X_n$ be independent $N(\mu, \sigma^2)$ variables, with $\overline{X} := n^{-1}\sum_i X_i$ and $S^2 := (n-1)^{-1}\sum_i (X_i - \overline{X})^2$.

Below cases have exact coverage $1-\alpha$.

(i) *Known variance*: if σ is known, $C_\mu(X) = [\overline{X} - \frac{z_{1-\frac{\alpha}{2}}\sigma}{\sqrt{n}}, \overline{X} + \frac{z_{1-\frac{\alpha}{2}}\sigma}{\sqrt{n}}]$

(ii) *Unknown variance*: if σ is unknown, $C_\mu(X) = [\overline{X} - \frac{t_{n-1,1-\frac{\alpha}{2}}S}{\sqrt{n}}, \overline{X} + \frac{t_{n-1,1-\frac{\alpha}{2}}S}{\sqrt{n}}]$

(iii) *Variance*: $C_{\sigma^2}(X) = [\frac{(n-1)S^2}{\chi^2_{n-1,1-\frac{\alpha}{2}}}, \frac{(n-1)S^2}{\chi^2_{n-1,\frac{\alpha}{2}}}]$

Example 3.4.3. *Normal Mean with Known Variance*
Let $X_1, \dots, X_n$ be independent $N(\mu, \sigma^2)$ variables with known σ.
The pivot $Z_\mu := \frac{\sqrt{n}(\overline{X}-\mu)}{\sigma} \sim N(0,1)$ gives $\mathbb{P}_\mu\{|Z_\mu| \le z_{1-\frac{\alpha}{2}}\} = 1-\alpha$.
Solving for μ gives the exact interval $C_\alpha(X) = [\overline{X} - \frac{z_{1-\frac{\alpha}{2}}\sigma}{\sqrt{n}}, \overline{X} + \frac{z_{1-\frac{\alpha}{2}}\sigma}{\sqrt{n}}]$.
Test Connection: The two-sided level-α test of $H_0 : \mu = \mu_0$ rejects iff $\mu_0 \notin C_\alpha(X)$.

Example 3.4.4. *Normal Mean and Variance with Unknown Variance*
Let $X_1, \dots, X_n$ be independent $N(\mu, \sigma^2)$ variables, and set $S^2 := (n-1)^{-1}\sum_{i=1}^n (X_i - \overline{X})^2$.
The exact pivots are $T_\mu := \frac{\sqrt{n}(\overline{X}-\mu)}{S} \sim t_{n-1}$ and $W_{\sigma^2} := \frac{(n-1)S^2}{\sigma^2} \sim \chi^2_{n-1}$. Writing $t_{\nu,p}$ and $\chi^2_{\nu,p}$ for p-quantiles, pivot inversion gives $C_\mu(X) = [\overline{X} - \frac{t_{n-1,1-\frac{\alpha}{2}}S}{\sqrt{n}}, \overline{X} + \frac{t_{n-1,1-\frac{\alpha}{2}}S}{\sqrt{n}}]$ and $C_{\sigma^2}(X) = [\frac{(n-1)S^2}{\chi^2_{n-1,1-\frac{\alpha}{2}}}, \frac{(n-1)S^2}{\chi^2_{n-1,\frac{\alpha}{2}}}]$.
Both intervals have exact marginal coverage $1-\alpha$; $C_{\sigma^2}(X)$ is asymmetric because the χ^2 pivot is not symmetric.

3.5 Two-Sample Normal Inference

Two-sample inference compares the location of two response distributions. In a controlled experiment, one sample may receive a treatment and the other a control; in an observational comparison, the same formulas may be computed but their causal interpretation depends on the design.

Definition 3.5.1. *Two Independent Samples and the Location Contrast*
$X_1, \dots, X_n \sim F$ are independent, $Y_1, \dots, Y_m \sim G$ are independent, and the two samples are independent.

(i) *Means*: $\mu_X := \mathbb{E}X_i$ and $\mu_Y := \mathbb{E}Y_j$ summarize the two average levels, assuming both exist.
(ii) *Location contrast*: $\Delta := \mu_X - \mu_Y$ measures the shift from group Y to group X.
(iii) *Estimator*: $\widehat{\Delta} := \overline{X} - \overline{Y}$ estimates Δ, where $\overline{X} := n^{-1}\sum_i X_i$ and $\overline{Y} := m^{-1}\sum_j Y_j$.

Proposition 3.5.2. *Known Common Variance Pivot*
Let $X_1, \dots, X_n$ and $Y_1, \dots, Y_m$ be independent samples, $X_i \sim N(\mu_X, \sigma^2)$, $Y_j \sim N(\mu_Y, \sigma^2)$, known $\sigma > 0$.
Set $\Delta := \mu_X - \mu_Y$, $\widehat{\Delta} := \overline{X} - \overline{Y}$, and $\mathrm{se}_0 := \sigma\sqrt{n^{-1} + m^{-1}}$.

(i) $\widehat{\Delta} \sim N(\Delta, \mathrm{se}_0^2)$ and $Z := \frac{\widehat{\Delta}-\Delta}{\mathrm{se}_0} \sim N(0,1)$.
(ii) $C_\alpha(X,Y) := [\widehat{\Delta} - z_{1-\frac{\alpha}{2}}\,\mathrm{se}_0, \widehat{\Delta} + z_{1-\frac{\alpha}{2}}\,\mathrm{se}_0]$ satisfies $\mathbb{P}_\Delta\{\Delta \in C_\alpha(X,Y)\} = 1-\alpha$.

Proof.

(i) Since $\overline{X} \sim N(\mu_X, \frac{\sigma^2}{n})$, $\overline{Y} \sim N(\mu_Y, \frac{\sigma^2}{m})$, and $\overline{X} \perp\!\!\!\perp \overline{Y}$, $\widehat{\Delta} = \overline{X} - \overline{Y} \sim N(\Delta, \frac{\sigma^2}{n} + \frac{\sigma^2}{m}) = N(\Delta, \mathrm{se}_0^2)$. Standardization gives $Z \sim N(0,1)$.
(ii) By (i), $\mathbb{P}_\Delta\{|Z| \le z_{1-\frac{\alpha}{2}}\} = 1-\alpha$, equivalently $\mathbb{P}_\Delta\{\Delta \in C_\alpha(X,Y)\} = 1-\alpha$.

Structural Commentary: The contrast is a linear combination of independent sample means.
Key Insight: Known common variance gives an exact normal pivot for Δ. □

Definition 3.5.3. *Pooled Sample Variance*
Let $X_1, \dots, X_n \sim N(\mu_X, \sigma^2)$ and $Y_1, \dots, Y_m \sim N(\mu_Y, \sigma^2)$ be independent samples with common unknown σ^2.

(i) *Sample variances*: $S_X^2 := (n-1)^{-1}\sum_{i=1}^n (X_i - \overline{X})^2$ and $S_Y^2 := (m-1)^{-1}\sum_{j=1}^m (Y_j - \overline{Y})^2$.
(ii) *Pooled variance*: $S_p^2 := \frac{(n-1)S_X^2 + (m-1)S_Y^2}{n+m-2}$.
(iii) *Degrees-of-freedom weighting*: S_p^2 weights S_X^2 and S_Y^2 by $n-1$ and $m-1$, respectively.

Theorem 3.5.4. *Pooled Two-Sample Student Pivot*
Let $X_i \sim N(\mu_X, \sigma^2)$, $i = 1, \dots, n$, and $Y_j \sim N(\mu_Y, \sigma^2)$, $j = 1, \dots, m$, be mutually independent, with unknown common $\sigma^2 > 0$. Set $\Delta := \mu_X - \mu_Y$ and $\nu := n + m - 2$. Then $T := \frac{(\overline{X}-\overline{Y})-\Delta}{S_p\sqrt{n^{-1}+m^{-1}}} \sim t_\nu$.

Proof. Let $Z := \frac{(\overline{X}-\overline{Y})-\Delta}{\sigma\sqrt{n^{-1}+m^{-1}}}$ and $W := \frac{\nu S_p^2}{\sigma^2} = \frac{(n-1)S_X^2 + (m-1)S_Y^2}{\sigma^2}$.
Since $\overline{X} - \overline{Y} \sim N(\Delta, \sigma^2(n^{-1}+m^{-1}))$, $Z \sim N(0,1)$. Let $U_X := \frac{(n-1)S_X^2}{\sigma^2}$ and $U_Y := \frac{(m-1)S_Y^2}{\sigma^2}$.
By normal mean-residual independence and sample independence, Z, U_X, U_Y mutually independent,

with $U_X \sim \chi^2_{n-1}$, $U_Y \sim \chi^2_{m-1}$. Hence $W = U_X + U_Y \sim \chi^2_\nu$ and $W \perp\!\!\!\perp Z$. Since $S_p^2 = \frac{\sigma^2 W}{\nu}$, $T = \frac{Z}{\sqrt{\frac{W}{\nu}}} \sim t_\nu$.

Structural Commentary: The pooled variance combines the two residual sums of squares.
Key Insight: A common variance permits replacing σ by an independent pooled estimate. □

Method 3.5.5. *Pooled Two-Sample t Procedures*
Under the equal-variance normal model, set $\Delta := \mu_X - \mu_Y$, $\nu := n + m - 2$, and $\mathrm{se}_p := S_p\sqrt{n^{-1} + m^{-1}}$.

(i) *Interval*: $C_\alpha := [(\overline{X} - \overline{Y}) - t_{\nu,1-\frac{\alpha}{2}}\,\mathrm{se}_p, (\overline{X} - \overline{Y}) + t_{\nu,1-\frac{\alpha}{2}}\,\mathrm{se}_p]$ is exact $1-\alpha$ for Δ.
(ii) *Statistic*: for $H_0 : \Delta = 0$, use $t_0 := \frac{\overline{X}-\overline{Y}}{\mathrm{se}_p}$, with $t_0 \sim t_\nu$ under H_0.
(iii) *Rejection*: reject H_0 for $|t_0| > t_{\nu,1-\frac{\alpha}{2}}$ under $H_1 : \Delta \neq 0$
reject H_0 for $t_0 > t_{\nu,1-\alpha}$ under $H_1 : \Delta > 0$
reject H_0 for $t_0 < -t_{\nu,1-\alpha}$ under $H_1 : \Delta < 0$.
(iv) *Duality*: the two-sided test rejects iff $0 \notin C_\alpha$.

Example 3.5.6. *Latent Heat of Fusion: Two Methods*
For methods A and B, let $n_A = 13$, $n_B = 8$, $\overline{x}_A = 80.02$, $\overline{x}_B = 79.98$, $s_A = 0.024$, $s_B = 0.031$, and $S_p = 0.027$.
Then $\widehat{\Delta} = \overline{x}_A - \overline{x}_B = 0.04$, $\widehat{\mathrm{se}} = S_p\sqrt{13^{-1} + 8^{-1}} \approx 0.012$, pooled 95% interval for $\Delta = \mu_A - \mu_B$ is
$\approx (0.015, 0.065)$. For $H_0 : \Delta = 0$, $t_0 = \frac{\widehat{\Delta}}{\widehat{\mathrm{se}}} \approx 3.33$ with $\nu = 19$, strong evidence that method means differ.

Proposition 3.5.7. *Likelihood-Ratio View of the Pooled Test*
Let $X_i \sim N(\mu_X, \sigma^2)$, $i = 1, \ldots, n$, and $Y_j \sim N(\mu_Y, \sigma^2)$, $j = 1, \ldots, m$, be mutually independent, with unknown common $\sigma^2 > 0$. Set $\Delta := \mu_X - \mu_Y$, $\nu := n + m - 2$, and $T := \frac{\overline{X}-\overline{Y}}{S_p\sqrt{n^{-1}+m^{-1}}}$.
For $H_0 : \Delta = 0$ against $H_1 : \Delta \neq 0$, $\lambda(X, Y) = (1 + \frac{T^2}{\nu})^{-\frac{n+m}{2}}$.
Hence the GLR rejects for large $|T|$; at level α, reject iff $|T| > t_{\nu,1-\frac{\alpha}{2}}$.

Proof. Set $N := n+m$, $\nu := N-2$, $d := \overline{X}-\overline{Y}$, $R_1 := \sum_i (X_i - \overline{X})^2 + \sum_j (Y_j - \overline{Y})^2$, $\widehat{\mu}_0 := \frac{n\overline{X}+m\overline{Y}}{N}$, and $R_0 := \sum_i (X_i - \widehat{\mu}_0)^2 + \sum_j (Y_j - \widehat{\mu}_0)^2$.
Under H_1, $(\widehat{\mu}_X, \widehat{\mu}_Y, \widehat{\sigma}_1^2) = (\overline{X}, \overline{Y}, \frac{R_1}{N})$; under H_0, $(\widehat{\mu}, \widehat{\sigma}_0^2) = (\widehat{\mu}_0, \frac{R_0}{N})$.
The maximised Gaussian likelihood is proportional to $\widehat{\sigma}^{-N}$, hence $\lambda = (\frac{R_1}{R_0})^{\frac{N}{2}}$.
ANOVA decomposition gives $R_0 = R_1 + \{\frac{nm}{N}\}d^2$, while $T^2 = \frac{d^2}{(\frac{R_1}{\nu})(n^{-1}+m^{-1})} = \frac{\nu\{\frac{nm}{N}\}d^2}{R_1}$.
Therefore $\frac{R_0}{R_1} = 1 + \frac{T^2}{\nu}$ and $\lambda = (1 + \frac{T^2}{\nu})^{-\frac{N}{2}}$, decreasing in T^2; small λ iff large $|T|$.
Structural Commentary: The null fit adds only the between-sample mean discrepancy to the unrestricted fit.
Key Insight: The GLR depends on the data through the pooled t statistic. □

Method 3.5.8. *Unequal-Variance Two-Sample Procedure*
For independent samples without the equal-variance assumption, set $\widehat{v} := \frac{S_X^2}{n} + \frac{S_Y^2}{m}$.

(i) *Standard error*: estimate $\mathrm{Var}(\overline{X} - \overline{Y})$ by $\widehat{v}$.
(ii) *Welch statistic*: for $H_0 : \Delta = \Delta_0$, use $T_W := \frac{(\overline{X}-\overline{Y})-\Delta_0}{\sqrt{\widehat{v}}}$.
(iii) *Degrees of freedom*: calibrate T_W by t_ν, where $\nu := \frac{\widehat{v}^2}{\frac{(S_X^2/n)^2}{n-1} + \frac{(S_Y^2/m)^2}{m-1}}$.
(iv) *Use*: the procedure avoids pooling variances, at the cost of approximate calibration.

Corollary 3.5.9. *Variance Ratio Test Under Normality*
Let $X_1, \ldots, X_n \sim N(\mu_X, \sigma_X^2)$ and $Y_1, \ldots, Y_m \sim N(\mu_Y, \sigma_Y^2)$ be independent samples, with $n, m \geq 2$.
Set $\rho := \frac{\sigma_X^2}{\sigma_Y^2}$ and $R := \frac{S_X^2}{S_Y^2}$. Then $\frac{R}{\rho} \sim F_{n-1,m-1}$.

Proof. Let $U := \frac{(n-1)S_X^2}{\sigma_X^2}$ and $V := \frac{(m-1)S_Y^2}{\sigma_Y^2}$.
Normal residual chi-square laws give $U \sim \chi^2_{n-1}$ and $V \sim \chi^2_{m-1}$, and sample independence gives $U \perp\!\!\!\perp V$.
Thus $\frac{\frac{U}{n-1}}{\frac{V}{m-1}} = \frac{R}{\rho} \sim F_{n-1,m-1}$. If $H_0 : \rho = 1$, then $R \sim F_{n-1,m-1}$, yielding exact normal-theory tests and confidence intervals for ρ; the calibration is normality-sensitive.
Structural Commentary: The comparison standardises two independent residual variance estimates.
Key Insight: Normality turns each sample variance into an independent chi-square pivot. □

Method 3.5.10. *Approximate Power for Balanced Two-Sample z Tests*
For planning, assume balanced samples of size n, known common σ, and target effect $\Delta := \mu_X - \mu_Y > 0$.

(i) *Statistic*: use $Z := \frac{\overline{X}-\overline{Y}}{\sigma\sqrt{\frac{2}{n}}}$ and reject two-sided at level α when $|Z| > z_{1-\frac{\alpha}{2}}$.
(ii) *Shift*: under $\Delta > 0$, $Z \sim N(\delta, 1)$ with $\delta := (\frac{\Delta}{\sigma})\sqrt{\frac{n}{2}}$.
(iii) *Power*: $\pi(\Delta) := 1 - \Phi(z_{1-\frac{\alpha}{2}} - \delta) + \Phi(-z_{1-\frac{\alpha}{2}} - \delta)$.
(iv) *Sample size*: if the lower-tail term is negligible, target power $1-\beta$ gives $n \approx \frac{2\sigma^2(z_{1-\frac{\alpha}{2}} + z_{1-\beta})^2}{\Delta^2}$.

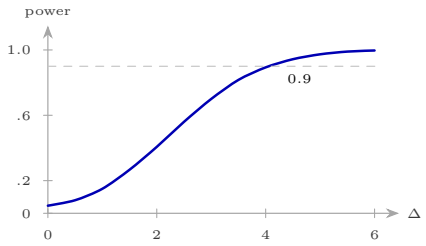

Figure 239: Power rises as the detectable mean difference Δ increases.

Remark 3.5.11. *Transformations and Normal Diagnostics*
Normal-theory two-sample procedures are often CLT-robust for large samples, but small skewed or outlier-prone samples require diagnostics. Transformations may stabilize spread and improve symmetry, but they change the estimand, e.g. a log-scale mean difference corresponds to a ratio-scale comparison.

3.6 Paired-Sample Inference

Paired comparisons arise when observations are naturally matched: before and after measurements on the same unit, littermates, matched subjects, or two measurement methods applied to the same specimen. Pairing changes the stochastic structure because the two samples are no longer independent.

Definition 3.6.1. *Paired Differences*

(i) *Pairs*: (X_i, Y_i), $i = 1, \dots, n$, are independent across i; dependence within each pair is allowed.

(ii) *Differences*: $D_i := X_i - Y_i$ and $\overline{D} := n^{-1} \sum_{i=1}^{n} D_i$.

(iii) *Mean*: if $\mathbb{E}X_i = \mu_X$ and $\mathbb{E}Y_i = \mu_Y$, then $\mathbb{E}D_i = \mu_X - \mu_Y$.

(iv) *Variance*: if $\mathrm{Var}(X_i) = \sigma_X^2$, $\mathrm{Var}(Y_i) = \sigma_Y^2$, and $\mathrm{Cov}(X_i, Y_i) = \sigma_{XY}$, then $\mathrm{Var}(D_i) = \sigma_X^2 + \sigma_Y^2 - 2\sigma_{XY}$.

Proposition 3.6.2. *Variance Effect of Pairing*
Let (X_i, Y_i), $i = 1, \dots, n$, *be independent pairs with* $\mathrm{Var}(X_i) = \sigma_X^2$, $\mathrm{Var}(Y_i) = \sigma_Y^2$, *and* $\mathrm{Corr}(X_i, Y_i) = \rho$.
Set $D_i := X_i - Y_i$ *and* $\overline{D} := n^{-1} \sum_i D_i$. *Then* $\mathrm{Var}(\overline{D}) = n^{-1}(\sigma_X^2 + \sigma_Y^2 - 2\rho\sigma_X\sigma_Y)$.

Proof. Since $\mathrm{Cov}(X_i, Y_i) = \rho\sigma_X\sigma_Y$, $\mathrm{Var}(D_i) = \mathrm{Var}(X_i - Y_i) = \sigma_X^2 + \sigma_Y^2 - 2\rho\sigma_X\sigma_Y$.
Independence across pairs gives $\mathrm{Var}(\overline{D}) = n^{-2} \sum_i \mathrm{Var}(D_i) = \frac{\mathrm{Var}(D_i)}{n}$.

If $\sigma_X = \sigma_Y = \sigma$, substitution gives $\mathrm{Var}(\overline{D}) = \frac{2\sigma^2(1-\rho)}{n}$; independent unpaired samples of size n per group have $\mathrm{Var}(\overline{X} - \overline{Y}) = \frac{2\sigma^2}{n}$, so the paired-to-unpaired variance ratio is $1 - \rho$.
Structural Commentary: Pairing replaces two marginal measurements by one within-pair contrast.
Key Insight: Positive within-pair correlation cancels shared variation and lowers variance. □

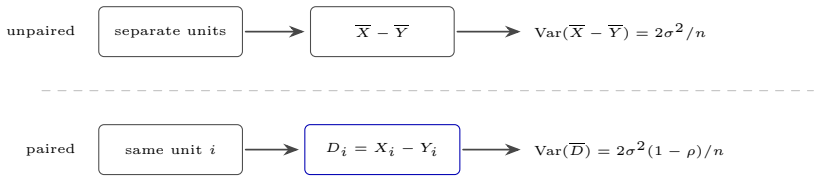

Figure 240: Pairing cancels shared variation; positive within-pair correlation lowers variance.

Method 3.6.3. *Paired t Procedure*
Let $D_1, \dots, D_n \sim N(\mu_D, \sigma_D^2)$, where $\mu_D := \mu_X - \mu_Y$.

(i) *Variance*: $S_D^2 := (n-1)^{-1} \sum_{i=1}^{n} (D_i - \overline{D})^2$.

(ii) *Pivot*: $T := \frac{\overline{D} - \mu_D}{S_D/\sqrt{n}} \sim t_{n-1}$.

(iii) *Interval*: $C_\alpha := [\overline{D} - \frac{t_{n-1,1-\frac{\alpha}{2}} S_D}{\sqrt{n}}, \overline{D} + \frac{t_{n-1,1-\frac{\alpha}{2}} S_D}{\sqrt{n}}]$ is exact $1 - \alpha$ for μ_D.

(iv) *Test*: for $H_0 : \mu_D = 0$, reject two-sided at level α iff $|\overline{D}| > \frac{t_{n-1,1-\frac{\alpha}{2}} S_D}{\sqrt{n}}$.

For large n, use same rule by CLT; for small nonnormal differences, prefer rank or sign methods.

Example 3.6.4. *Platelet Aggregation Before and After Smoking*
For $n = 11$ before-after platelet measurements, let $D_i = \text{after}_i - \text{before}_i$ with $\overline{D} = 10.27$ and $\frac{S_D}{\sqrt{11}} = 2.40$.
Then $t_0 = \frac{\overline{D}}{\frac{S_D}{\sqrt{11}}} = 4.28$ with $\nu = 10$, so $p < 0.01$ two-sided; a 90% confidence interval is approximately $(5.9, 14.6)$, indicating a positive mean increase after smoking.

Example 3.6.5. *Mercury Measurement Methods*
For $n = 25$ paired mercury measurements, let $D_i = M_{1i} - M_{2i}$ with $\overline{D} = 0.04$ and $S_D = 0.116$.
Then $t_0 = \frac{\overline{D}}{\frac{S_D}{\sqrt{25}}} = 1.724$ with $\nu = 24$, giving $p \approx 0.094$ two-sided.
Plot of D_i against measurement level should be checked: level-dependent discrepancies not captured by $\overline{D}$ alone.

Remark 3.6.6. *Pairing Is Not Extra Independent Sampling*
If unit i contributes repeated measurements $Z_{i1}, \dots, Z_{ik}$, independence is across units, not within unit.
Treating all nk observations as iid ignores within-unit dependence and overstates the effective sample size.

4 Decision Theory

4.1 Loss, Risk, Bayes, and Minimax Rules

Decision theory compares statistical procedures by their consequences, not only by their formulas. The same data model can lead to different optimal rules under different loss functions.

Definition 4.1.1. *Statistical Decision Problem and Risk*

(i) *Problem*: a statistical decision problem is $(\{P_\theta : \theta \in \Theta\}, \mathcal{A}, L)$ with $L : \Theta \times \mathcal{A} \to [0, \infty]$.
(ii) *Rule*: a decision rule is a measurable $\delta : \mathcal{X} \to \mathcal{A}$.
(iii) *Risk*: $R(\theta, \delta) := \mathbb{E}_\theta[L(\theta, \delta(X))]$.

Definition 4.1.2. *Bayes Risk, Minimaxity, and Admissibility*

(i) *Bayes risk*: for prior Π on Θ, $r(\Pi, \delta) := \int R(\theta, \delta)\, d\Pi(\theta)$.
(ii) *Bayes rule*: δ_Π is Bayes if $r(\Pi, \delta_\Pi) = \inf_\delta r(\Pi, \delta)$.
(iii) *Maximum risk*: $M(\delta) := \sup_{\theta \in \Theta} R(\theta, \delta)$; $\delta^\star$ is minimax if $M(\delta^\star) = \inf_\delta M(\delta)$.
(iv) *Admissibility*: δ inadmissible if $\exists \delta'$ with $R(\theta, \delta') \le R(\theta, \delta)\ \forall \theta$ and $<$ for some θ; otherwise δ admissible.

Proposition 4.1.3. *Posterior Risk Characterization*
Let Π be a prior, let $\Pi(\cdot \mid x)$ be a posterior, and set $\rho_x(a) := \int L(\theta, a)\, d\Pi(\theta \mid x)$.
If a measurable selector $\delta_\Pi(x) \in \arg\min_{a \in \mathcal{A}} \rho_x(a)$ exists, then δ_Π is Bayes: $r(\Pi, \delta_\Pi) = \inf_\delta r(\Pi, \delta)$.

Proof. By iterated expectation, $r(\Pi, \delta) = \mathbb{E}_\Pi[\rho_X(\delta(X))]$, where X has the prior predictive law.
Since $\rho_x(\delta_\Pi(x)) \le \rho_x(\delta(x))\ \forall$ rule δ and almost every x, $r(\Pi, \delta_\Pi) \le r(\Pi, \delta)\ \forall \delta$. Thus $r(\Pi, \delta_\Pi) = \inf_\delta r(\Pi, \delta)$.
Structural Commentary: Bayes risk is the prior-predictive average of posterior risks.
Key Insight: Global Bayes optimization reduces to pointwise posterior-risk minimization. □

Example 4.1.4. *Bayes Rules Under Common Losses*
For a real parameter and posterior distribution $\Pi(\cdot \mid x)$:

(i) Squared-error loss is minimized by the posterior mean.
(ii) Absolute-error loss is minimized by a posterior median.
(iii) Zero-one loss on a finite action set is minimized by a posterior mode.

Remark 4.1.5. *Least Favorable Priors*
If a prior $\Pi^\star$ has Bayes risk equal to the minimax value, then any Bayes rule for $\Pi^\star$ with constant risk on the support of $\Pi^\star$ is minimax. Such priors are called least favorable.

4.2 Shrinkage, Empirical Bayes, and Regularization

Risk can often be reduced by intentionally pulling noisy estimates toward a structured target. The price is bias; the benefit is variance reduction.

Definition 4.2.1. *Shrinkage Estimator*

(i) *Input*: let $\widehat{\theta} = \widehat{\theta}(X)$ be a data-based estimator.
(ii) *Target*: choose θ_{tar} as a reference value or lower-complexity model.
(iii) *Weight*: let $a(X) \in [0, 1]$ control the amount of shrinkage.
(iv) *Estimator*: $\delta(X) := a(X)\widehat{\theta} + \{1 - a(X)\}\theta_{\text{tar}}$.

Example 4.2.2. *Ridge Regression as Shrinkage*
For design matrix X, response y, and $\lambda \ge 0$, ridge regression sets $\widehat{\beta}_\lambda \in \arg\min_\beta \{\|y - X\beta\|_2^2 + \lambda \|\beta\|_2^2\}$.

If $X^\top X$ is invertible, $\widehat{\beta}_\lambda = (X^\top X + \lambda I)^{-1} X^\top y$, shrinking $\widehat{\beta}_{\text{LS}}$ toward 0 most in weak eigendirections.

Theorem 4.2.3. *James–Stein Phenomenon*
Let $X \sim \mathcal{N}_d(\theta, \sigma^2 I_d)$ with $d \ge 3$, known σ^2, and squared-error risk $R(\theta, \delta) := \mathbb{E}_\theta \|\delta(X) - \theta\|^2$.
Define $\delta_{\text{JS}}(X) := (1 - \frac{(d-2)\sigma^2}{\|X\|^2})X$ for $X \ne 0$, with arbitrary value at $X = 0$.
Then $R(\theta, \delta_{\text{JS}}) < R(\theta, X) = d\sigma^2$ for every $\theta \in \mathbb{R}^d$.

Proof. Let $a := (d-2)\sigma^2$ and $g(x) := -\frac{ax}{\|x\|^2}$, so $\delta_{\text{JS}}(X) = X + g(X)$.
Stein's identity gives $R(\theta, X + g) = d\sigma^2 + \mathbb{E}_\theta[\|g(X)\|^2 + 2\sigma^2 \nabla \cdot g(X)]$.
For $x \ne 0$, $\|g(x)\|^2 = \frac{a^2}{\|x\|^2}$ and $\nabla \cdot g(x) = -\frac{a(d-2)}{\|x\|^2}$.
Thus $R(\theta, \delta_{\text{JS}}) = d\sigma^2 - (d-2)^2\sigma^4 \mathbb{E}_\theta[\|X\|^{-2}] < d\sigma^2$, with $\mathbb{E}_\theta[\|X\|^{-2}] < \infty$ since $d \ge 3$.
Structural Commentary: Shrinkage trades bias toward 0 for enough variance reduction to lower total risk.
Key Insight: In dimension $d \ge 3$, the usual estimator X is inadmissible under squared-error loss. □

Definition 4.2.4. *Empirical Bayes*

(i) *Hierarchy*: $\theta_i \mid \eta \sim \Pi_\eta$ and $X_i \mid \theta_i \sim P_{\theta_i}$ for $i = 1, \dots, m$.
(ii) *Hyperparameter*: estimate η by $\widehat{\eta} = \widehat{\eta}(X_1, \dots, X_m)$ from the marginal law of the data.
(iii) *Plug-in Bayes rule*: use the Bayes rule computed under $\Pi_{\widehat{\eta}}$.

Remark 4.2.5. *Regularization as Decision-Theoretic Structure*
Penalization, shrinkage, and empirical Bayes impose structure to reduce risk, typically by trading increased bias for reduced variance. The criterion is $R(\theta, \delta)$, not unbiasedness.

5 Bayesian Inference

5.1 Priors, Posteriors, and Conjugacy

Bayesian inference treats unknown parameters as uncertain quantities and updates a prior distribution by the likelihood supplied by the data.

Definition 5.1.1. *Prior, Posterior, and Predictive Distribution*
Let Π be a prior on Θ and $p_\theta(x)$ a dominated likelihood.

(i) *Prior*: Π encodes uncertainty about $\theta \in \Theta$ before observing x.
(ii) *Evidence*: $m(x) := \int_\Theta p_\vartheta(x)\, d\Pi(\vartheta)$, assumed finite and positive.
(iii) *Posterior*: $d\Pi(\theta \mid x) := \frac{p_\theta(x)\, d\Pi(\theta)}{m(x)}$.
(iv) *Predictive*: for future X_{new}, $\mathbb{P}(X_{\text{new}} \in A \mid x) = \int_\Theta P_\theta(A)\, d\Pi(\theta \mid x)$.

Definition 5.1.2. *Conjugate Prior Family*

(i) *Conjugacy*: $\{\Pi_\eta : \eta \in H\}$ is conjugate if $\Pi_\eta(\cdot \mid x) = \Pi_{\eta(x)}$ for some $\eta(x) \in H$.

Proposition 5.1.3. *Posterior Odds and Likelihood Ratios*
Let H_0, H_1 be simple hypotheses with $\mathbb{P}(H_i) = \pi_i > 0$ and likelihood $p_i(x) = p(x \mid H_i)$ for $i = 0, 1$.
For $m(x) := \pi_0 p_0(x) + \pi_1 p_1(x) > 0$, $\mathbb{P}(H_i \mid x) = \frac{\pi_i p_i(x)}{m(x)}$ and $\frac{\mathbb{P}(H_0 \mid x)}{\mathbb{P}(H_1 \mid x)} = (\frac{\pi_0}{\pi_1})(\frac{p_0(x)}{p_1(x)})$.

Proof. Bayes' rule gives $\mathbb{P}(H_i \mid x) = \frac{\pi_i p_i(x)}{m(x)}$ for $i = 0, 1$. Therefore $\frac{\mathbb{P}(H_0 \mid x)}{\mathbb{P}(H_1 \mid x)} = \frac{\frac{\pi_0 p_0(x)}{m(x)}}{\frac{\pi_1 p_1(x)}{m(x)}} = (\frac{\pi_0}{\pi_1})(\frac{p_0(x)}{p_1(x)})$.

Structural Commentary: Posterior odds factor as prior odds times the data likelihood ratio.
Key Insight: Bayes updating multiplies odds by $\frac{p_0(x)}{p_1(x)}$. □

Example 5.1.4. *Beta–Binomial Updating*
If $X \mid p \sim \text{Binomial}(n, p)$ and $p \sim \text{Beta}(a, b)$, then $p \mid X = x \sim \text{Beta}(a + x, b + n - x)$.
Thus $\mathbb{E}[p \mid x] = \frac{a+x}{a+b+n}$, a weighted average of $\frac{a}{a+b}$ and $\frac{x}{n}$.

Example 5.1.5. *Gamma–Poisson Updating*
Let $X_1, \dots, X_n \mid \lambda$ be iid Poisson(λ) and $\lambda \sim \text{Gamma}(\alpha, \nu)$ in rate form.
Writing $s := \sum_{i=1}^{n} x_i$, the posterior kernel is $\pi(\lambda \mid x) \propto \lambda^{\alpha+s-1} e^{-(\nu+n)\lambda}$, hence $\lambda \mid x \sim \text{Gamma}(\alpha + s, \nu + n)$.
Thus $\mathbb{E}[\lambda \mid x] = \frac{\alpha+s}{\nu+n}$, $\text{Var}(\lambda \mid x) = \frac{\alpha+s}{(\nu+n)^2}$, $\text{mode}(\lambda \mid x) = \frac{\alpha+s-1}{\nu+n}$ if $\alpha + s > 1$.

Example 5.1.6. *Normal Mean with Normal Prior*
Let $X_1, \dots, X_n \mid \mu$ be iid $N(\mu, \sigma^2)$ with known σ^2, and let $\mu \sim N(m_0, \tau_0^2)$.
Then $\mu \mid X \sim N(m_n, \tau_n^2)$, where $\tau_n^{-2} = \tau_0^{-2} + n\sigma^{-2}$ and $m_n = \tau_n^2(\tau_0^{-2} m_0 + n\sigma^{-2}\overline{X})$.

Example 5.1.7. *Known Mean and Unknown Precision*
Let $X_1, \dots, X_n \mid \xi$ be iid $N(\theta_0, \xi^{-1})$ with known θ_0, and let $\xi \sim \text{Gamma}(\alpha, \lambda)$ in rate form.
Writing $q := \sum_{i=1}^{n} (x_i - \theta_0)^2$, the posterior is $\xi \mid x \sim \text{Gamma}(\alpha + \frac{n}{2}, \lambda + \frac{q}{2})$.
With a flat gamma prior, $\sigma^2 = \xi^{-1}$ centers near the MLE $\frac{q}{n}$.

Definition 5.1.8. *Improper Prior*
An *improper prior* is a σ-finite prior measure Π on Θ with $\Pi(\Theta) = \infty$. For likelihood $p_\theta(x)$, it is usable only when $0 < m_\Pi(x) := \int_\Theta p_\theta(x)\, d\Pi(\theta) < \infty$, in which case $d\Pi(\theta \mid x) := \frac{p_\theta(x)\, d\Pi(\theta)}{m_\Pi(x)}$ is a proper posterior.

Remark 5.1.9. *Conditioning Viewpoint*
Bayesian updating is conditioning under the joint law $dP(\theta, x) = p_\theta(x)\, d\Pi(\theta)\, dx$; the posterior $\Pi(\cdot \mid x)$ is a regular conditional law of θ given $X = x$.

5.2 Computation, Prediction, and Asymptotic Bayes

Except in conjugate models, posterior summaries are integrals that usually require approximation. Monte Carlo and optimization methods from numerical computation become statistical tools here.

Remark 5.2.1. *Bayesian Integrals as a Motivation*
For prior density $\pi(\theta)$ and likelihood $\mathcal{L}(\theta)$, write $Z = \int \mathcal{L}(u)\pi(u)\, du$.
Then $\pi(\theta \mid X^n) = Z^{-1}\mathcal{L}(\theta)\pi(\theta)$ and $\mathbb{E}[\theta \mid X^n] = Z^{-1} \int \theta\, \mathcal{L}(\theta)\pi(\theta)\, d\theta$.
For $\theta = (\theta_1, \dots, \theta_k)$, high-dimensional marginalisation is often analytically impractical.

Definition 5.2.2. *Bayesian Credible Set*
Let $\Pi(\cdot \mid x)$ be the posterior on Θ.

(i) *Credible set*: $C(x) \subseteq \Theta$ has credibility $1 - \alpha$ if $\Pi(C(x) \mid x) \geq 1 - \alpha$.
(ii) *Conditioning*: credibility is a posterior probability conditional on the observed data x.

Definition 5.2.3. *Posterior Monte Carlo Integration*
Let $\Pi(\cdot \mid x)$ be the posterior on Θ.

(i) *Monte Carlo sample*: let $\theta^{(1)}, \dots, \theta^{(M)}$ be draws, or approximate draws, from $\Pi(\cdot \mid x)$.
(ii) *Posterior mean*: for integrable g, $\int g(\theta)\, d\Pi(\theta \mid x) \approx M^{-1} \sum_{m=1}^{M} g(\theta^{(m)})$.
(iii) *Dependent draws*: MCMC uses dependent samples but targets the same posterior integrals.

Method 5.2.4. *Simulating a Posterior Function*

(i) Let $\delta = g(p_1, \dots, p_k)$ be the posterior target.

(ii) Draw posterior samples $(P_1^{(i)}, \dots, P_k^{(i)})$ for $i = 1, \dots, N$.

(iii) Set $\delta^{(i)} = g(P_1^{(i)}, \dots, P_k^{(i)})$, use empirical distribution of $\delta^{(i)}$ to estimate posterior distribution of δ.

Example 5.2.5. *Two Binomial Proportions*

Suppose $X \sim \text{Binomial}(n, p_1)$ and $Y \sim \text{Binomial}(m, p_2)$ are independent, with independent flat priors on p_1, p_2.
Then $p_1 \mid X \sim \text{Beta}(X+1, n-X+1)$ and $p_2 \mid Y \sim \text{Beta}(Y+1, m-Y+1)$.
For $\delta = p_2 - p_1$, draw $P_1^{(i)} \sim \text{Beta}(X+1, n-X+1)$ and $P_2^{(i)} \sim \text{Beta}(Y+1, m-Y+1)$, set $\delta^{(i)} = P_2^{(i)} - P_1^{(i)}$, and summarize the empirical distribution of $\delta^{(i)}$.

Method 5.2.6. *Gibbs Sampling from Full Conditionals*

(i) *Kernel*: unknown mean θ, precision ξ, flat-prior posterior satisfies $\pi(\theta, \xi \mid x) \propto \xi^{\frac{n}{2}-1} \exp\{-\frac{\xi}{2} \sum_i (x_i - \theta)^2\}$.

(ii) *Decomposition*: $\sum_i (x_i - \theta)^2 = \sum_i (x_i - \overline{x})^2 + n(\theta - \overline{x})^2$.

(iii) *Mean conditional*: $\theta \mid \xi, x \sim N(\overline{x}, (n\xi)^{-1})$.

(iv) *Precision conditional*: $\xi \mid \theta, x \sim \text{Gamma}(\frac{n}{2}, \frac{1}{2} \sum_i (x_i - \theta)^2)$ in rate form.

(v) *Gibbs sampler*: alternate conditionals; post-burn-in averages estimate posterior summaries.

Method 5.2.7. *Laplace Approximation*

(i) *Setup*: let $\pi_n(\theta \mid x) \propto \exp\{-n q_n(\theta)\}$, with interior minimiser $\widehat{\theta}$.

(ii) *Curvature*: set $H_n(\widehat{\theta}) := \nabla^2 q_n(\widehat{\theta})$, assumed positive definite.

(iii) *Quadratic approximation*: $q_n(\theta) \approx q_n(\widehat{\theta}) + \frac{1}{2}(\theta - \widehat{\theta})^\top H_n(\widehat{\theta})(\theta - \widehat{\theta})$.

(iv) *Normal approximation*: $\Pi(\cdot \mid x) \approx N(\widehat{\theta}, \{n H_n(\widehat{\theta})\}^{-1})$.

Theorem 5.2.8. *Bernstein–von Mises Principle*

Let $X_1, \dots, X_n \sim P_{\theta_0}$ in a regular d-dimensional model with nonsingular information $I(\theta_0)$.
Assume the prior density π is positive and continuous near θ_0, and let $\widehat{\theta}_n$ be an efficient center.
Then $\Pi(\sqrt{n}(\theta - \widehat{\theta}_n) \in \cdot \mid X_1, \dots, X_n) \Rightarrow N_d(0, I(\theta_0)^{-1})$ in P_{θ_0}-probability.

Proof. Set $h := \sqrt{n}(\theta - \widehat{\theta}_n)$. Local asymptotic normality gives $\ell_n(\widehat{\theta}_n + \frac{h}{\sqrt{n}}) - \ell_n(\widehat{\theta}_n) = -\frac{1}{2} h^\top I(\theta_0) h + o_{P_{\theta_0}}(1)$ uniformly on bounded h. Prior continuity gives $\frac{\pi(\widehat{\theta}_n + \frac{h}{\sqrt{n}})}{\pi(\theta_0)} \to 1$ in P_{θ_0}-probability on bounded h.
After normalization, the posterior density of h converges to the $N_d(0, I(\theta_0)^{-1})$ density, with tail mass outside bounded sets negligible. Thus the displayed posterior weak convergence holds.
Structural Commentary: Locally, the likelihood is quadratic and the prior is flat to first order.
Key Insight: In regular finite-dimensional models, posterior uncertainty is asymptotically frequentist normal. □

Remark 5.2.9. *Alignment and Limits*

In regular fixed-dimensional models, Bayesian credible sets based on the Bernstein–von Mises normal approximation have asymptotic frequentist coverage. This alignment can fail in high-dimensional, nonparametric, weakly identified, or boundary problems, where the prior may remain first-order relevant.

5.3 Bayesian Normal Comparisons

The normal two-sample model also has a Bayesian interpretation. With diffuse priors, the resulting posterior formulas resemble frequentist t intervals, but the conditioning and interpretation are different.

Definition 5.3.1. *Common-Precision Two-Sample Normal Model*

(i) *Common-Precision Model*: $\theta = (\mu_X, \mu_Y, \xi) \in \mathbb{R}^2 \times (0, \infty)$ with shared precision $\xi = \sigma^{-2}$ and variance ξ^{-1}.

(ii) *Conditional model*: Given (μ_X, μ_Y, ξ), the variables $X_1, \dots, X_n, Y_1, \dots, Y_m$ are independent, with $X_i \mid (\mu_X, \xi) \sim N(\mu_X, \xi^{-1})$ and $Y_j \mid (\mu_Y, \xi) \sim N(\mu_Y, \xi^{-1})$.

(iii) *Improper prior*: $\pi(\mu_X, \mu_Y, \xi) \propto \xi^{-1}$ on $\mu_X, \mu_Y \in \mathbb{R}$ and $\xi > 0$.

(iv) *Observed data*: Write $x = (x_1, \dots, x_n)$ and $y = (y_1, \dots, y_m)$.

(v) *Sample means*: $\overline{x} := n^{-1} \sum_{i=1}^n x_i$ and $\overline{y} := m^{-1} \sum_{j=1}^m y_j$.

(vi) *Sample variances*: $s_X^2 := (n-1)^{-1} \sum_{i=1}^n (x_i - \overline{x})^2$ and $s_Y^2 := (m-1)^{-1} \sum_{j=1}^m (y_j - \overline{y})^2$.

(vii) *Pooled variance*: $s_p^2 := \frac{(n-1)s_X^2 + (m-1)s_Y^2}{m+n-2}$.

(viii) *Posterior kernel*: $\pi(\mu_X, \mu_Y, \xi \mid x, y) \propto \xi^{\frac{m+n}{2}-1} \exp\left\{-\frac{\xi}{2}\left[\sum_{i=1}^n (x_i - \mu_X)^2 + \sum_{j=1}^m (y_j - \mu_Y)^2\right]\right\}$.

Proposition 5.3.2. *Conditional Posterior Factors*

For $n, m \geq 2$, put $\nu := m + n - 2$ and take Gamma *shape-rate.*
In the common-precision model, $\pi(\mu_X, \mu_Y, \xi \mid x, y) = \pi(\mu_X \mid \xi, x, y)\pi(\mu_Y \mid \xi, x, y)\pi(\xi \mid x, y)$,
where $(\mu_X, \mu_Y) \mid \xi, x, y \sim N(\overline{x}, (n\xi)^{-1}) \otimes N(\overline{y}, (m\xi)^{-1})$ and $\xi \mid x, y \sim \text{Gamma}(\frac{\nu}{2}, \frac{\nu s_p^2}{2})$. $\mu_X \perp\!\!\!\perp \mu_Y \mid (\xi, x, y)$.

Proof. Let $S_X(\mu_X) := \sum_{i=1}^n (x_i - \mu_X)^2$, $S_Y(\mu_Y) := \sum_{j=1}^m (y_j - \mu_Y)^2$, and $A := (n-1)s_X^2 + (m-1)s_Y^2 = \nu s_p^2$.
Completing squares gives $S_X(\mu_X) = (n-1)s_X^2 + n(\mu_X - \overline{x})^2$ and $S_Y(\mu_Y) = (m-1)s_Y^2 + m(\mu_Y - \overline{y})^2$.
Thus $\pi(\mu_X, \mu_Y, \xi \mid x, y) \propto \xi^{\frac{m+n}{2}-1} \exp\{-\frac{\xi A}{2}\} \exp\{-\frac{n\xi(\mu_X - \overline{x})^2}{2}\} \exp\{-\frac{m\xi(\mu_Y - \overline{y})^2}{2}\}$.

For fixed ξ, last two factors are independent normal kernels for μ_X, μ_Y with variances $(n\xi)^{-1}$, $(m\xi)^{-1}$.
Also $\int \exp\{-\frac{n\xi(\mu_X-\overline{x})^2}{2}\}\,d\mu_X \propto (n\xi)^{-\frac{1}{2}}$ and $\int \exp\{-\frac{m\xi(\mu_Y-\overline{y})^2}{2}\}\,d\mu_Y \propto (m\xi)^{-\frac{1}{2}}$.
Hence marginalising μ_X, μ_Y leaves $\pi(\xi \mid x, y) \propto \xi^{\frac{\nu}{2}-1}\exp\{-\frac{\xi\nu s_p^2}{2}\}$.
Structural Commentary: Completing squares isolates location kernels and pooled residual $A = \nu s_p^2$.
Key Insight: Marginalising μ_X, μ_Y leaves the pooled gamma law for ξ. □

Proposition 5.3.3. *Posterior t Law for a Mean Difference*
In the common-precision model with $n, m \geq 2$, set $\Delta := \mu_X - \mu_Y$, $d := \overline{x} - \overline{y}$, $c := n^{-1} + m^{-1}$, $\nu := m + n - 2$, and $T := \frac{\Delta - d}{s_p\sqrt{c}}$. Then $T \mid x, y \sim t_\nu$.

Proof. By Proposition 5.3.2, $\Delta \mid \xi, x, y \sim N(d, \frac{c}{\xi})$ and $\xi \mid x, y \sim \text{Gamma}(\frac{\nu}{2}, \frac{\nu s_p^2}{2})$.
Equivalently, take independent $E \sim N(0,1)$, $V \sim \chi^2_\nu$, $\xi = \frac{V}{\nu s_p^2}$, $\Delta = d + \sqrt{\frac{c}{\xi}}\,E$. Thus $T = \frac{\Delta - d}{s_p\sqrt{c}} = \frac{E}{\sqrt{\frac{V}{\nu}}}$, QED.
Structural Commentary: Normal given ξ; Student after mixing over ξ.
Key Insight: The t law is exactly a standard normal divided by an independent estimated-scale factor $\sqrt{\frac{V}{\nu}}$. □

Remark 5.3.4. *Same Algebra, Different Conditioning*
The statistic has the same algebra as the pooled two-sample t pivot in Theorem 3.5.4: frequentist inference treats Δ as fixed and X, Y as random, whereas the posterior treats x, y as fixed and $\Delta \mid x, y$ as random.

Example 5.3.5. *Latent Heat Posterior Comparison*
For method contrast $\Delta = \mu_X - \mu_Y$, the common-precision posterior gives $\mathbb{P}(\Delta > 0 \mid X, Y) \approx 0.998$ and posterior interval $\mathbb{P}(0.015 \leq \Delta \leq 0.065 \mid X, Y) \approx 0.95$, numerically matching the pooled normal-theory interval.

6 Nonparametric and High-Dimensional Statistics

6.1 Empirical Processes, Density, and Regression Smoothing

Nonparametric statistics replaces finite-dimensional parameter assumptions by smoothness, shape, sparsity, or complexity restrictions.

Definition 6.1.1. *Empirical Measure and Empirical Process*
Let $X_1, \ldots, X_n$ be observations in $(\mathcal{X}, \mathcal{A})$ with reference law P.

(i) *Empirical measure*: $\widehat{P}_n := n^{-1}\sum_{i=1}^n \delta_{X_i}$, so $\widehat{P}_n f = n^{-1}\sum_{i=1}^n f(X_i)$.

(ii) *Empirical process*: For measurable $\mathcal{F}$, $\mathbb{G}_n(f) := \sqrt{n}(\widehat{P}_n f - Pf)$ for $f \in \mathcal{F}$.

Proposition 6.1.2. *Fixed-Point Behavior of the Empirical CDF*
Let $X_1, \ldots, X_n$ be independent with common CDF F.
For $x \in \mathbb{R}$, set $I_i(x) := \mathbf{1}_{(-\infty, x]}(X_i)$ and $F_n(x) := n^{-1}\sum_{i=1}^n I_i(x)$. Then, for each fixed $x \in \mathbb{R}$:

(i) Law: $nF_n(x) \sim \text{Binomial}(n, F(x))$.
(ii) Mean: $\mathbb{E}F_n(x) = F(x)$.
(iii) Variance: $\text{Var}(F_n(x)) = n^{-1}F(x)(1 - F(x))$.

Proof. Fix $x \in \mathbb{R}$ and put $p := F(x)$ and $I_i := I_i(x)$.

(i) Since $I_i \sim \text{Bernoulli}(p)$ independently, $nF_n(x) = \sum_{i=1}^n I_i \sim \text{Binomial}(n, p)$.

(ii) Linearity gives $\mathbb{E}F_n(x) = n^{-1}\sum_{i=1}^n \mathbb{E}I_i = n^{-1}np = p = F(x)$.

(iii) Independence gives $\text{Var}(F_n(x)) = n^{-2}\sum_{i=1}^n \text{Var}(I_i) = n^{-2}np(1-p) = n^{-1}F(x)(1 - F(x))$.

Structural Commentary: Pointwise, $F_n(x) = n^{-1}\sum_{i=1}^n I_i(x)$ with $I_i(x) \sim \text{Bernoulli}(F(x))$ independently.
Key Insight: The empirical CDF at one point is a normalised binomial count. □

Remark 6.1.3. *Pointwise and Simultaneous CDF Uncertainty*
Proposition 6.1.2 is pointwise: x is fixed and $F_n(x)$ is a normalised binomial count.
Simultaneous uncertainty controls $\|F_n - F\|_\infty := \sup_x |F_n(x) - F(x)|$, yielding bands and diagnostics.

Proposition 6.1.4. *Two-Point Covariance of the Empirical CDF*
Let $X_1, \ldots, X_n$ be independent with common CDF F.
For $w \in \mathbb{R}$, set $I_i(w) := \mathbf{1}_{(-\infty, w]}(X_i)$, $F_n(w) := n^{-1}\sum_{i=1}^n I_i(w)$. For $u, v \in \mathbb{R}$, put $m := \min\{u, v\}$. Then:

(i) Covariance: $\text{Cov}\big(F_n(u), F_n(v)\big) = n^{-1}\big(F(m) - F(u)F(v)\big)$.
(ii) Sign: $\text{Cov}\big(F_n(u), F_n(v)\big) \geq 0$.

Proof. Fix $u, v \in \mathbb{R}$ and set $m := \min\{u, v\}$.

(i) *Covariance*: $\text{Cov}(F_n(u), F_n(v)) = n^{-2}\sum_{i,j}\text{Cov}(I_i(u), I_j(v))$.

For $i \neq j$ the term is 0 by independence, while for $i = j$,
$\text{Cov}(I_i(u), I_i(v)) = \mathbb{E}[I_i(u)I_i(v)] - \mathbb{E}I_i(u)\mathbb{E}I_i(v) = F(m) - F(u)F(v)$.
Hence $\text{Cov}(F_n(u), F_n(v)) = n^{-1}(F(m) - F(u)F(v))$.

(ii) *Sign*: If $u \le v$, then $F(m) - F(u)F(v) = F(u)(1 - F(v)) \ge 0$.
If $v \le u$, then $F(m) - F(u)F(v) = F(v)(1 - F(u)) \ge 0$.

Structural Commentary: $F_n(u)$ and $F_n(v)$ average iid Bernoulli pairs, so covariance scales by $1/n$.
Key Insight: Cross-index independence leaves only the same-observation overlap $\{X_i \le m\}$. □

Theorem 6.1.5. *Glivenko–Cantelli Theorem*
Let $X_1, X_2, \dots$ be i.i.d. real variables with CDF F, and set $\widehat{F}_n(t) := n^{-1} \sum_{i=1}^{n} \mathbf{1}_{\{X_i \le t\}}$.

Then $\sup_{t \in \mathbb{R}} \left|\widehat{F}_n(t) - F(t)\right| \to 0$ almost surely.

Proof. Add independent $R_i \sim \mathrm{Unif}[0,1]$ and set $U_i := F(X_i-) + R_i\{F(X_i) - F(X_i-)\}$.
Then U_i are i.i.d. Unif$[0,1]$, and with $H_n(u) := n^{-1} \sum_i \mathbf{1}_{\{U_i \le u\}}$ one has $\widehat{F}_n(t) = H_n(F(t))$ a.s.

Hence $\sup_t \left|\widehat{F}_n(t) - F(t)\right| \le \sup_{0 \le u \le 1} |H_n(u) - u|$.
Fix $k \ge 1$, $u_j := \frac{j}{k}$, let $M_{n,k} := \max_{0 \le j \le k} |H_n(u_j) - u_j|$.
By the SLLN, $M_{n,k} \to 0$ a.s. If $u_{j-1} \le u \le u_j$, monotonicity gives $H_n(u_{j-1}) - u_j \le H_n(u) - u \le H_n(u_j) - u_{j-1}$,
Hence $\sup_{0 \le u \le 1} |H_n(u) - u| \le M_{n,k} + k^{-1}$, and $\limsup_{n \to \infty} \sup_{0 \le u \le 1} |H_n(u) - u| \le k^{-1}$ a.s. $\forall k$. Let $k \to \infty$.

Structural Commentary: Finite-grid SLLN plus monotonicity gives uniform CDF control.
Key Insight: Monotonicity bounds between-grid drift by the mesh. □

Proposition 6.1.6. *Approximate Variance of a Sample Quantile*
Let $Y_1, \dots, Y_n$ be iid with continuous CDF F and density f. Fix $p \in (0,1)$, set $x_p := F^{-1}(p)$ with $f(x_p) > 0$, choose k with $\frac{k}{n+1} \approx p$, and put $\widehat{x}_p := Y_{(k)}$. Then:

(i) Probability Scale: $U_{(k)} := F(Y_{(k)})$ has kth uniform order-statistic law. $\mathrm{Var}(U_{(k)}) = \frac{k(n+1-k)}{(n+1)^2(n+2)} \approx \frac{p(1-p)}{n}$.

(ii) Quantile Scale: $\mathrm{Var}(\widehat{x}_p) \approx \frac{p(1-p)}{n f(x_p)^2}$.

Proof.
(i) By probability integral transform, $U_i := F(Y_i)$ are iid Uniform$(0,1)$, $U_{(k)} = F(Y_{(k)})$.
Theorem 4.1.4 gives the stated exact variance, hence $\mathrm{Var}(U_{(k)}) \approx \frac{p(1-p)}{n}$ when $\frac{k}{n+1} \approx p$.
(ii) Let $g := F^{-1}$. Since $g'(p) = \frac{1}{f(x_p)}$ and $\widehat{x}_p = g(U_{(k)})$, delta approximation $g(U_{(k)}) \approx g(p) + g'(p)(U_{(k)} - p)$
gives $\mathrm{Var}(\widehat{x}_p) \approx g'(p)^2 \mathrm{Var}(U_{(k)}) \approx \frac{p(1-p)}{n f(x_p)^2}$.

Structural Commentary: Quantile variance is probability-scale variance multiplied by $(F^{-1})'(p)^2$.
Key Insight: Low density near x_p inflates sample-quantile variability by $1/f(x_p)^2$. □

Proposition 6.1.7. *Distribution-Free Median Interval*
Let $X_1, \dots, X_n$ be independent with continuous CDF F and median η, so $F(\eta) = \frac{1}{2}$.
Let $X_{(1)} \le \cdots \le X_{(n)}$ and $1 \le k \le \lfloor \frac{n}{2} \rfloor$. Then:

(i) Interval: $C_k := [X_{(k)}, X_{(n-k+1)}]$.

(ii) Coverage: $\mathbb{P}(\eta \in C_k) = 1 - \frac{1}{2^{n-1}} \sum_{j=0}^{k-1} \binom{n}{j}$.

Proof.
(i) Let $B_- := \sum_{i=1}^{n} \mathbf{1}_{\{X_i < \eta\}}$, $B_+ := \sum_{i=1}^{n} \mathbf{1}_{\{X_i > \eta\}}$. By continuity, $B_- + B_+ = n$ a.s. and $B_- \sim \mathrm{Binomial}(n, \frac{1}{2})$.
(ii) $\eta \notin C_k$ iff $B_- < k$ or $B_+ < k$. Since $k \le \lfloor \frac{n}{2} \rfloor$, these two events are disjoint.
(iii) By symmetry, $\mathbb{P}(\eta \notin C_k) = 2\mathbb{P}(B_- < k) = 2 \sum_{j=0}^{k-1} \binom{n}{j} 2^{-n} = \frac{1}{2^{n-1}} \sum_{j=0}^{k-1} \binom{n}{j}$, so $\mathbb{P}(\eta \in C_k) = 1 - \frac{1}{2^{n-1}} \sum_{j=0}^{k-1} \binom{n}{j}$.

Structural Commentary: The coverage depends only on the binomial count of observations below η, not on F.
Key Insight: Continuity turns median coverage into a symmetric binomial tail. □

Definition 6.1.8. *Kernel Density Estimator*
(i) *Kernel and bandwidth*: Let $\int K(u)\,du = 1$ and $h > 0$.
(ii) *Estimator*: For data $X_1, \dots, X_n$, $\widehat{f}_h(x) := (nh)^{-1} \sum_{i=1}^{n} K(\frac{x - X_i}{h})$.

Larger h lowers variance and raises bias; smaller h does the reverse.

Definition 6.1.9. *Nonparametric Regression*
(i) *Model*: $Y = m(X) + \varepsilon$ with $\mathbb{E}[\varepsilon \mid X] = 0$, so $m(x) = \mathbb{E}[Y \mid X = x]$.
(ii) *Weights*: For kernel K and bandwidth $h > 0$, set $w_i(x) := K(\frac{x - X_i}{h})$.
(iii) *Estimator*: If $\sum_i w_i(x) > 0$, define $\widehat{m}_h(x) := \frac{\sum_{i=1}^{n} w_i(x) Y_i}{\sum_{i=1}^{n} w_i(x)}$.

Definition 6.1.10. *Kernel-Weighted Local Average*
Let $(X_i, Y_i)_{i=1}^n$ be regression data and fix a query point x_0.
(i) *Local kernel*: For a nonnegative profile D and width $h_\lambda(x_0) > 0$, set $K_\lambda(x_0, x) := D(\|x - x_0\| / h_\lambda(x_0))$.

(ii) *Estimator*: If $\sum_{i=1}^{n} K_\lambda(x_0, X_i) > 0$, local-constant (Nadaraya–Watson) estimate is $\widehat{m}(x_0) := \frac{\sum_{i=1}^{n} K_\lambda(x_0, X_i) Y_i}{\sum_{i=1}^{n} K_\lambda(x_0, X_i)}$.

Metric windows set $h_\lambda(x_0) = \lambda$; nearest-neighbor windows set $h_\lambda(x_0) = \operatorname{dist}(x_0, X_{(k)}(x_0))$.

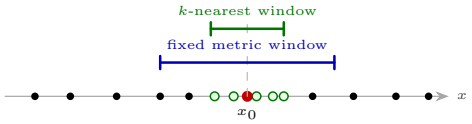

Figure 241: Fixed metric and k-nearest windows around x_0.

Example 6.1.11. *Common Local-Smoothing Kernels*
In one dimension, common compact profiles are $D_E(t) := \frac{3}{4}(1-t^2)\mathbf{1}_{\{|t|\le 1\}}$ for Epanechnikov smoothing and $D_T(t) := (1-|t|^3)^3\mathbf{1}_{\{|t|\le 1\}}$ for tri-cube smoothing. Both have support $[-1,1]$; Gaussian profiles have full support, and normalization constants cancel in regression-weight averages but matter for density estimation.

Method 6.1.12. *Local Linear Regression Smoothing*
Fix x_0 and bandwidth $h > 0$.

(i) *Weighted fit*: Set $(\widehat{\beta}_0(x_0), \widehat{\beta}_1(x_0)) \in \operatorname*{argmin}_{\beta_0,\beta_1} \sum_{i=1}^{n} (Y_i - \beta_0 - \beta_1(X_i - x_0))^2 K(\frac{X_i - x_0}{h})$.

(ii) *Estimate*: Define $\widehat{m}_h(x_0) := \widehat{\beta}_0(x_0)$.

Smaller h gives a more variable fit; larger h gives more bias.

Method 6.1.13. *Local Polynomial Regression*
Fix a query point $x_0 \in \mathbb{R}^p$ and degree $d \in \mathbb{N}_0$.

(i) *Basis*: Let $\mathcal{A}_d := \{\alpha \in \mathbb{N}_0^p : |\alpha| \le d\}$ and $b_d(u) := (u^\alpha)_{\alpha\in\mathcal{A}_d}$, where $u^\alpha := \prod_{j=1}^{p} u_j^{\alpha_j}$.

(ii) *Weights*: Set $K_i(x_0) := K_\lambda(x_0, X_i)$.

(iii) *Weighted fit*: For $\beta = (\beta_\alpha)_{\alpha\in\mathcal{A}_d}$, choose $\widehat{\beta}(x_0) \in \operatorname*{argmin}_{\beta\in\mathbb{R}^{|\mathcal{A}_d|}} \sum_{i=1}^{n} K_i(x_0)(Y_i - b_d(X_i - x_0)^\top\beta)^2$.

(iv) *Estimator*: With $\mathbf{0} \in \mathcal{A}_d$ the constant multi-index, define $\widehat{m}_d(x_0) := \widehat{\beta}_{\mathbf{0}}(x_0)$.

$d = 0$ is local constant; $d = 1$ is local linear with boundary correction.
Larger d trades lower curvature bias for higher variance.

Proposition 6.1.14. *Equivalent Kernel Moments*
Fix $x_0 \in \mathbb{R}$ and set $u_i := X_i - x_0$, $K_i := K_\lambda(x_0, X_i)$, $z_i := (1, u_i)^\top$, $Z := (z_1^\top, \dots, z_n^\top)^\top$, $W := \operatorname{diag}(K_1, \dots, K_n)$, $Y := (Y_1, \dots, Y_n)^\top$, and $G := Z^\top W Z$.
Assume G is nonsingular, let $e_1 := (1,0)^\top$, $\widehat{\beta}(x_0) := G^{-1}Z^\top WY$, and $\widehat{m}(x_0) := e_1^\top\widehat{\beta}(x_0)$.

(i) Equivalent weights: $\widehat{m}(x_0) = \sum_{i=1}^{n} \ell_i(x_0) Y_i$ with $\ell_i(x_0) := K_i z_i^\top G^{-1} e_1$.

(ii) Moment constraints: $\sum_{i=1}^{n} \ell_i(x_0) = 1$ and $\sum_{i=1}^{n} u_i \ell_i(x_0) = 0$.

(iii) Affine reproduction: If $Y_i = a + bX_i$, then $\widehat{m}(x_0) = a + bx_0$.

Proof.

(i) *Equivalent weights*: The weighted criterion $(Y - Z\beta)^\top W(Y - Z\beta)$ has normal equations $G\widehat{\beta} = Z^\top WY$, so $\widehat{\beta} = G^{-1}Z^\top WY$. Since G^{-1} is symmetric, $\widehat{m}(x_0) = e_1^\top G^{-1}Z^\top WY = \sum_{i=1}^{n} K_i e_1^\top G^{-1} z_i Y_i = \sum_{i=1}^{n} \ell_i(x_0) Y_i$.

(ii) *Moment constraints*: With $\ell(x_0) := (\ell_1(x_0), \dots, \ell_n(x_0))^\top = WZG^{-1}e_1$, $Z^\top\ell(x_0) = Z^\top WZG^{-1}e_1 = e_1$, hence $\sum_i \ell_i(x_0) = 1$ and $\sum_i u_i \ell_i(x_0) = 0$.

(iii) *Affine reproduction*: If $Y_i = a + bX_i = (a + bx_0) + bu_i$, then $\widehat{m}(x_0) = (a + bx_0)\sum_i \ell_i(x_0) + b\sum_i u_i\ell_i(x_0) = a + bx_0$.

Structural Commentary: Weighted projection onto $\operatorname{span}\{1, x - x_0\}$ imposes two weight moments.
Key Insight: $Z^\top\ell = e_1$ encodes constant reproduction and zero first moment. □

Definition 6.1.15. *Structured Kernel Metric*
Fix $x_0, x \in \mathbb{R}^p$, bandwidth $\lambda > 0$, profile $D \ge 0$, and a positive semidefinite matrix $A \succeq 0$.

(i) *Quadratic scale*: Define $\rho_A(x, x_0) := (x - x_0)^\top A(x - x_0)$.

(ii) *Kernel*: Set $K_{\lambda,A}(x_0, x) := D(\rho_A(x, x_0)/\lambda)$.

A sets coordinate weights, correlations, and active directions.
Standardise predictors first since ρ_A is unit-dependent.

Method 6.1.16. *Local Likelihood and Varying Coefficients*
Let $\ell_i(\theta)$ be the log-likelihood contribution of observation i under parameter θ.

(i) *Local likelihood*: At target x_0, set $K_i(x_0) := K_\lambda(x_0, X_i)$ and choose $\widehat{\theta}(x_0) \in \operatorname*{argmax}_\theta \sum_{i=1}^{n} K_i(x_0)\ell_i(\theta)$.

(ii) *Local parameterisation*: In generalised models, replace a constant natural parameter by $\eta_i(\gamma; x_0) := b_d(X_i - x_0)^\top\gamma$ and maximize $\sum_i K_i(x_0)\ell_i(\eta_i(\gamma; x_0))$ over γ.

(iii) *Varying coefficients*: For predictors (U, Z) with $U \in \mathbb{R}^q$, model $m(U, Z) := \alpha(Z) + \sum_{r=1}^{q} \beta_r(Z) U_r$.

(iv) *Local fit*: At z_0, choose $(\widehat{\alpha}, \widehat{\beta}) \in \operatorname{argmin}_{a,b} \sum_i K_\lambda(z_0, Z_i)(Y_i - a - b^\top U_i)^2$ and set $(\widehat{\alpha}(z_0), \widehat{\beta}(z_0)) := (\widehat{\alpha}, \widehat{\beta})$.

The coefficients are ordinary regression coefficients locally in U, but functions of the index variable Z.

Remark 6.1.17. *Bandwidth, Boundaries, and Dimension*
Let $N_\lambda(x_0) := \{i : K_\lambda(x_0, X_i) > 0\}$ and $n_\lambda(x_0) := |N_\lambda(x_0)|$.

(i) *Bias–variance*: Larger λ usually increases $n_\lambda(x_0)$, lowering variance, raising bias; smaller λ does reverse.
(ii) *Windows*: Metric windows fix radius; k-nearest-neighbor windows choose $\lambda(x_0)$ so that $n_{\lambda(x_0)}(x_0) \approx k$.
(iii) *Dimension*: In $\mathbb{R}^p$, neighborhoods must expand with p to keep $n_\lambda(x_0)$ stable, reducing local resolution.
(iv) *Cost*: Without indexing, one query evaluates $K_\lambda(x_0, X_i)$ for all i, costing $O(n)$.

Method 6.1.18. *Bandwidth Choice by Leave-One-Out Cross-Validation*

(i) *Candidates*: Fix bandwidths $h_1, \dots, h_M > 0$.

(ii) *Leave-one-out score*: Let $\widehat{m}_{h_k,-i}$ be local linear fit excluding (X_i, Y_i). Set $\mathrm{CV}(h_k) := \sum_{i=1}^{n} (Y_i - \widehat{m}_{h_k,-i}(X_i))^2$.

(iii) *Selection*: Choose $\widehat{h} \in \operatorname{argmin}_{1 \le k \le M} \mathrm{CV}(h_k)$, with a visual smoothness check.

Remark 6.1.19. *Complexity Control*
For a function class $\mathcal{F}$, estimation is stable when $\sup_{f \in \mathcal{F}} \left| \widehat{P}_n f - P f \right|$ is small with high probability or a.s.
Smoothness and entropy control this supremum in place of finite dimension.

6.2 Sparse High-Dimensional Inference

High-dimensional statistics studies regimes where the number of candidate parameters is comparable to, or much larger than, the sample size. Estimation is possible only after adding structure.

Definition 6.2.1. *High-Dimensional Regime and Sparsity*

(i) *High dimension*: A sequence has dimension $p = p_n$, often with $p_n \gg n$.
(ii) *Sparsity*: For $\theta \in \mathbb{R}^p$, $\|\theta\|_0 := |\{j : \theta_j \neq 0\}|$; θ is s-sparse if $\|\theta\|_0 \le s$.

Definition 6.2.2. *Lasso Estimator*

(i) *Lasso*: For $y = X\beta_0 + \varepsilon$ and $\lambda \ge 0$, $\widehat{\beta}_\lambda \in \arg\min_{\beta \in \mathbb{R}^p} \{(2n)^{-1} \|y - X\beta\|_2^2 + \lambda \|\beta\|_1\}$.

The convex ℓ^1 penalty promotes sparsity.

Definition 6.2.3. *Restricted Eigenvalue Condition*

(i) *Restricted eigenvalue*: For $S \subseteq [p] := \{1, \dots, p\}$, $C(S) := \{v : \|v_{S^c}\|_1 \le 3 \|v_S\|_1\}$, and $\kappa > 0$,
X satisfies $\mathrm{RE}(S, \kappa)$ if $n^{-\frac{1}{2}} \|Xv\|_2 \ge \kappa \|v_S\|_2$ for all $v \in C(S)$.

Theorem 6.2.4. *Basic Lasso Rate Form*
Let $y = X\beta_0 + \varepsilon$, $S := \mathrm{supp}(\beta_0)$, $|S| \le s$, and let $\widehat{\beta}_\lambda$ be any lasso solution.
If X satisfies $\mathrm{RE}(S, \kappa)$ and $\lambda > 0$ with $\lambda \ge 2 \left\| \frac{X^\top \varepsilon}{n} \right\|_\infty$, then $n^{-1} \left\| X(\widehat{\beta}_\lambda - \beta_0) \right\|_2^2 \le \frac{9 s \lambda^2}{\kappa^2}$ and $\left\| \widehat{\beta}_\lambda - \beta_0 \right\|_1 \le \frac{12 s \lambda}{\kappa^2}$.

Proof. Set $\delta := \widehat{\beta}_\lambda - \beta_0$. The lasso optimality inequality gives $(2n)^{-1} \|X\delta\|_2^2 + \lambda \|\beta_0 + \delta\|_1 \le n^{-1} \varepsilon^\top X \delta + \lambda \|\beta_0\|_1$.
Since $\lambda \ge 2 \left\| \frac{X^\top \varepsilon}{n} \right\|_\infty$, $n^{-1} \varepsilon^\top X \delta \le \frac{\lambda}{2} \|\delta\|_1$, and since $\beta_{0,S^c} = 0$, $\|\beta_0\|_1 - \|\beta_0 + \delta\|_1 \le \|\delta_S\|_1 - \|\delta_{S^c}\|_1$.
Thus $(2n)^{-1} \|X\delta\|_2^2 + \frac{\lambda}{2} \|\delta_{S^c}\|_1 \le \frac{3\lambda}{2} \|\delta_S\|_1$, so $\delta \in C(S)$. By $\mathrm{RE}(S, \kappa)$, $\|\delta_S\|_1 \le \sqrt{s} \|\delta_S\|_2 \le \frac{\sqrt{s} \|X\delta\|_2}{\kappa \sqrt{n}}$.
Hence $n^{-1} \|X\delta\|_2^2 \le \frac{3\lambda \sqrt{s} \|X\delta\|_2}{\kappa \sqrt{n}}$, giving $n^{-1} \|X\delta\|_2^2 \le \frac{9 s \lambda^2}{\kappa^2}$; also $\|\delta\|_1 \le 4 \|\delta_S\|_1 \le \frac{12 s \lambda}{\kappa^2}$.
Structural Commentary: Basic inequality plus RE converts score control into prediction and ℓ^1 error bounds.
Key Insight: The ℓ^1 penalty forces the error into the RE cone. □

Method 6.2.5. *Featurewise Two-Sample Screening*
Let x_{ij} be feature $j \in [M]$ for observation i, with groups C_1, C_2 and $n_\ell := |C_\ell|$.

(i) *Group means*: For $\ell \in \{1, 2\}$, set $\bar{x}_{\ell j} := n_\ell^{-1} \sum_{i \in C_\ell} x_{ij}$.

(ii) *Pooled scale*: Set $\widehat{\sigma}_j^2 := (n_1 + n_2 - 2)^{-1} \{ \sum_{i \in C_1} (x_{ij} - \bar{x}_{1j})^2 + \sum_{i \in C_2} (x_{ij} - \bar{x}_{2j})^2 \}$ and $\mathrm{se}_j := \widehat{\sigma}_j \sqrt{n_1^{-1} + n_2^{-1}}$.

(iii) *Statistic*: Define $t_j := (\bar{x}_{2j} - \bar{x}_{1j}) / \mathrm{se}_j$; large $|t_j|$ flags a featurewise mean shift.
(iv) *Family*: Screening acts on $\{t_j : 1 \le j \le M\}$, so error control targets the family, not a single statistic.

Remark 6.2.6. *Statistical and Computational Structure*
High-dimensional inference couples concentration bounds, convex optimization, and selection error control; computation and statistics are part of the same guarantee.

6.3 Rank-Based Comparative Tests

Rank methods replace numerical values by their relative order. They are invariant under strictly increasing transformations and reduce the influence of extreme observations, which makes them natural companions to the two-sample and paired t procedures.

Definition 6.3.1. *Mann–Whitney and Rank-Sum Statistics*
Let $X_1, \dots, X_n \sim F$ and $Y_1, \dots, Y_m \sim G$ be independent continuous samples.
Rank the pooled observations increasingly.

(i) *Pooled size*: $N := m + n$.
(ii) *Y-ranks*: $R_j^Y := \operatorname{rank}(Y_j)$ in the pooled sample.
(iii) *Rank sum*: $T_Y := \sum_{j=1}^{m} R_j^Y$.
(iv) *Mann–Whitney statistic*: $U_Y := T_Y - \frac{m(m+1)}{2}$.

Under continuity, $U_Y = \sum_{i=1}^{n} \sum_{j=1}^{m} \mathbf{1}_{\{X_i < Y_j\}}$ a.s., so U_Y counts cross-sample pairs with $Y_j > X_i$.

Theorem 6.3.2. *Null Mean and Variance of the Rank Sum*
Let $X_1, \dots, X_n \sim F$ and $Y_1, \dots, Y_m \sim G$ be independent continuous samples.
Let rank-sum T_Y and Mann–Whitney statistic U_Y. Assume $F = G$ and set $N := m + n$.

(i) Rank law: $T_Y = \sum_{r \in A} r$, where A is uniform over all m-subsets of $\{1, \dots, N\}$.
(ii) Rank-sum moments: $\mathbb{E}T_Y = \frac{m(N+1)}{2}$ and $\operatorname{Var}(T_Y) = \frac{mn(N+1)}{12}$.
(iii) Mann–Whitney moments: $\mathbb{E}U_Y = \frac{mn}{2}$ and $\operatorname{Var}(U_Y) = \frac{mn(N+1)}{12}$.

Proof.

(i) Continuity gives no ties and $F = G$ makes labels exchangeable, so the Y-rank set $A \subseteq \{1, \dots, N\}$ is uniform over all m-subsets and $T_Y = \sum_{r \in A} r$.
(ii) For ranks $1, \dots, N$, $\bar{r} = \frac{N+1}{2}$ and $S_r^2 = \frac{N^2-1}{12}$; sampling m ranks without replacement gives $\mathbb{E}T_Y = m\bar{r} = \frac{m(N+1)}{2}$ and $\operatorname{Var}(T_Y) = \frac{mS_r^2(N-m)}{N-1} = \frac{mn(N+1)}{12}$.
(iii) Since $U_Y = T_Y - \frac{m(m+1)}{2}$, shifting by a constant gives $\mathbb{E}U_Y = \frac{m(N+1)}{2} - \frac{m(m+1)}{2} = \frac{mn}{2}$ and $\operatorname{Var}(U_Y) = \operatorname{Var}(T_Y) = \frac{mn(N+1)}{12}$.

Structural Commentary: Under $F = G$, ranks reduce to simple random sampling without replacement.
Key Insight: U_Y is just a centered rank sum, so only the mean shifts. □

Method 6.3.3. *Mann–Whitney Test*
Given independent samples $X_1, \dots, X_n \sim F$ and $Y_1, \dots, Y_m \sim G$, test $H_0 : F = G$:

(i) *Compute*: Pool and rank $m + n$ observations, use midranks for ties. Compute T_Y, $U_Y = T_Y - \frac{m(m+1)}{2}$.
(ii) *Calibrate*: For small m, n, enumerate m-subsets of $\{1, \dots, m+n\}$ to get the exact null law.
For large m, n, use $Z := \frac{U_Y - \frac{mn}{2}}{\sqrt{\frac{mn(m+n+1)}{12}}} \approx N(0,1)$, with tie correction when needed.
(iii) *Decide*: Compute the relevant one- or two-sided tail probability under the chosen null law.
Reject H_0 at level α when $p \le \alpha$.

Example 6.3.4. *Latent Heat Data by Ranks*
For the latent-heat data, take $m = 8$, $n = 13$, $N = 21$, and midranks for ties.
The smaller-sample rank sum is $R = 51$, its complement is $R' = m(N+1) - R = 125$, and $R^* = \min(R, R') = 51$.
Under equality of the two method distributions, $\mu_T = \frac{m(N+1)}{2} = 88$ and $\sigma_T = \sqrt{\frac{mn(N+1)}{12}} \approx 13.8$,
hence $z = \frac{R - \mu_T}{\sigma_T} \approx -2.68$ and the two-sided normal p-value is ≈ 0.007.
The exact rank-sum test therefore rejects equality at level 0.01.

Definition 6.3.5. *Mann–Whitney Effect Probability*
Let $X \sim F$ and $Y \sim G$ be independent, with samples $X_1, \dots, X_n$ and $Y_1, \dots, Y_m$.

(i) *Effect probability*: $\pi := \mathbb{P}(X < Y)$.
(ii) *Estimator*: $\widehat{\pi} := (mn)^{-1} \sum_{i=1}^{n} \sum_{j=1}^{m} \mathbf{1}_{\{X_i < Y_j\}} = \frac{U_Y}{mn}$.

Thus π is the probability that a random Y exceeds a random X.

Method 6.3.6. *Shift Intervals from Pairwise Differences*
Assume the shift model $G(x) = F(x - \Delta)$.

(i) *Compute*: Set $D_{ij} := Y_j - X_i$ and order $D_{(1)} \le \cdots \le D_{(mn)}$.
(ii) *Calibrate*: Choose k so the two-sided rank test accepts a candidate shift when $k \le U_Y(\Delta) \le mn - k$.
(iii) *Invert*: Report $[D_{(k)}, D_{(mn-k+1)}]$ as the inverted shift interval.

The Hodges–Lehmann point estimate is $\widehat{\Delta}_{HL} := \operatorname{median}\{D_{ij} : 1 \le i \le n, 1 \le j \le m\}$.

Definition 6.3.7. *Signed-Rank Statistic*
Let $D_1, \dots, D_n$ be paired differences.

(i) *Nonzero index set*: $I := \{i : D_i \neq 0\}$.
(ii) *Absolute ranks*: $R_i := \operatorname{rank}(|D_i|)$ among $\{|D_\ell| : \ell \in I\}$, using midranks for ties.
(iii) *Signed-rank statistic*: $W_+ := \sum_{i \in I} R_i \mathbf{1}_{\{D_i > 0\}}$.

Theorem 6.3.8. *Signed-Rank Mean and Variance*
Under the signed-rank null, assume no zero differences and no ties in $|D_i|$.

(i) Mean: $\mathbb{E}W_+ = \frac{n(n+1)}{4}$.

(ii) Variance: $\mathrm{Var}(W_+) = \frac{n(n+1)(2n+1)}{24}$.

Proof. Let $\mathcal{R}$ be the absolute-rank information and let I_k indicate positivity at absolute-rank k.
Then $W_+ = \sum_{k=1}^{n} kI_k$ and, under symmetry, $I_k \mid \mathcal{R}$ are independent Bernoulli($\frac{1}{2}$).

(i) *Mean*: $\mathbb{E}(W_+ \mid \mathcal{R}) = \frac{1}{2}\sum_{k=1}^{n} k = \frac{n(n+1)}{4}$; the right side is deterministic, hence $\mathbb{E}W_+ = \frac{n(n+1)}{4}$.

(ii) *Variance*: $\mathrm{Var}(W_+ \mid \mathcal{R}) = \frac{1}{4}\sum_{k=1}^{n} k^2 = \frac{n(n+1)(2n+1)}{24}$, while $\mathbb{E}(W_+ \mid \mathcal{R})$ is deterministic.

Total variance gives $\mathrm{Var}(W_+) = \frac{n(n+1)(2n+1)}{24}$.

Structural Commentary: Condition on absolute ranks; only independent fair signs remain.
Key Insight: W_+ is a weighted sum of Bernoulli signs with weights $1, \ldots, n$. □

Method 6.3.9. *Signed-Rank Test*
For paired differences D_i, test $H_0 : D_i \overset{d}{=} -D_i$.

(i) *Compute*: Discard zero differences, rank nonzero $|D_i|$ using midranks for ties, and compute W_+.
(ii) *Calibrate*: Conditional on the nonzero absolute ranks, enumerate the 2^r sign assignments, where $r := |I|$, to get the null law of W_+.
(iii) *Decide*: Compute the relevant tail probability and reject H_0 at level α when $p \le \alpha$.

The sign test is the coarser paired alternative using only signs, not ranks.

Example 6.3.10. *Paired Rank Analyses*
Two paired-rank calculations are:

(i) *Platelet data*: With one negative signed rank, use W_-; exact signed-rank test rejects symmetry at 0.01.
(ii) *Mercury data*: Dropping one zero difference and using midranks gives $n = 24$ and $W_+ = 194.5$. Under H_0, $\mathbb{E}_0 W_+ = \frac{24\cdot 25}{4} = 150$ and $\mathrm{Var}_0(W_+) = \frac{24\cdot 25\cdot 49}{24} = 1225$, so $Z = \frac{194.5-150}{35} \approx 1.27$ and two-sided $p \approx 0.20$; there is no strong evidence of a systematic shift.

Remark 6.3.11. *Rank Tests and Normal Theory*
Rank tests use order information, require no normal model, and are robust to outliers; under normal models their efficiency relative to t tests is often close to 1.

7 Time Series Models

7.1 Stationarity, Autocovariance, and Linear Processes

Time-series statistics studies data ordered by time, where dependence is part of the signal rather than a nuisance to be removed. The process-level notions of strict and weak stationarity are fixed in Definition 4.5.1.

Definition 7.1.1. *Autocorrelation, Partial Autocorrelation, and Spectral Density*
Let $(X_t)_{t\in\mathbb{Z}}$ be weakly stationary with autocovariance $\gamma(h) := \mathrm{Cov}(X_t, X_{t-h})$ and $\gamma(0) > 0$.
For $h \ge 2$ and $t \in \mathbb{Z}$, set $\mathcal{H}_{t,h} := \mathrm{span}\{1, X_{t-1}, \ldots, X_{t-h+1}\}$ let $P_{t,h}$ be L^2-orthogonal projection onto $\mathcal{H}_{t,h}$.
Assume $\mathrm{Var}(X_t - P_{t,h}X_t) > 0$ and $\mathrm{Var}(X_{t-h} - P_{t,h}X_{t-h}) > 0$ $\forall h \ge 2,\ t \in \mathbb{Z}$.

(i) *Autocorrelation function*: $\rho : \mathbb{Z} \to [-1, 1]$, $\rho(h) := \frac{\gamma(h)}{\gamma(0)}$.

(ii) *Partial autocorrelation function*: $\alpha : \mathbb{N}_0 \to [-1, 1]$, $\alpha(0) := 1$, $\alpha(1) := \frac{\gamma(1)}{\gamma(0)}$, and $\alpha(h) := \mathrm{Corr}(X_t - P_{t,h}X_t, X_{t-h} - P_{t,h}X_{t-h})$ $\forall h \ge 2,\ t \in \mathbb{Z}$.

(iii) *Spectral density*: If $\sum_{h\in\mathbb{Z}} |\gamma(h)| < \infty$, $f_X : [-\pi, \pi] \to \mathbb{C}$, $f_X(\lambda) := (2\pi)^{-1} \sum_{h\in\mathbb{Z}} \gamma(h)e^{-ih\lambda}$ $\forall \lambda \in [-\pi, \pi]$.

Definition 7.1.2. *White Noise and Linear Process*
Let $\sigma^2 \ge 0$, $\mu \in \mathbb{R}$, and $(\psi_j)_{j\ge 0} \subset \mathbb{R}$ satisfy $\sum_{j=0}^{\infty} |\psi_j| < \infty$; all processes below are real-valued, indexed by $\mathbb{Z}$.

(i) *White noise*: $(\varepsilon_t)_{t\in\mathbb{Z}} \subset L^2$, $\mathbb{E}\varepsilon_t = 0$ and $\mathrm{Var}(\varepsilon_t) = \sigma^2$ $\forall t \in \mathbb{Z}$, and $\mathrm{Cov}(\varepsilon_t, \varepsilon_s) = 0$ $\forall s, t \in \mathbb{Z}$ with $s \ne t$.

(ii) *Linear process*: $(X_t)_{t\in\mathbb{Z}}$ satisfies $X_t = \mu + \sum_{j=0}^{\infty} \psi_j \varepsilon_{t-j}$ $\forall t \in \mathbb{Z}$ for some $(\varepsilon_t)_{t\in\mathbb{Z}}$ satisfying (i).

Structural Commentary: $\sum_j |\psi_j| < \infty$ gives an L^2-stable one-sided innovation filter.

Example 7.1.3. *Autoregression of Order One*
Let $(\varepsilon_t)_{t\in\mathbb{Z}}$ be white noise, variance σ^2, $|\phi| < 1$. For $X_t = \phi X_{t-1} + \varepsilon_t$, stationary solution is $X_t = \sum_{j=0}^{\infty} \phi^j \varepsilon_{t-j}$.
Thus $\gamma(h) = \mathrm{Cov}(X_t, X_{t-h}) = \frac{\sigma^2\phi^{|h|}}{1-\phi^2}$, $\rho(h) = \frac{\gamma(h)}{\gamma(0)} = \phi^{|h|}$. Autocorrelation decays geometrically at rate $|\phi|$.

Remark 7.1.4. *Process-Level Prerequisites*
Time-series inference uses filtrations $(\mathcal{F}_t)$, adapted X_t, predictors $\mathbb{E}(X_{t+h} \mid \mathcal{F}_t)$, martingale differences ε_t, and stationarity or ergodicity assumptions.

7.2 ARIMA, State-Space, and Volatility Models

Classical time-series models combine deterministic filters, stochastic innovations, and likelihood-based estimation.

Definition 7.2.1. *ARMA Model*
Let $p, q \in \mathbb{N}_0$, $\phi_i \in \mathbb{R}$ $(1 \le i \le p)$, $\theta_j \in \mathbb{R}$ $(1 \le j \le q)$, and let B denote the backshift, $(BX)_t = X_{t-1}$.
Set $\phi(z) := 1 - \sum_{i=1}^{p} \phi_i z^i$ and $\theta(z) := 1 + \sum_{j=1}^{q} \theta_j z^j$; empty sums are zero.
$(X_t)_{t\in\mathbb{Z}}$ is ARMA(p, q) with innovations $(\varepsilon_t)_{t\in\mathbb{Z}}$ iff (ε_t) is white noise and $\phi(B)X_t = \theta(B)\varepsilon_t$ $\forall t \in \mathbb{Z}$.
Structural Commentary: Causal iff $\phi(z) \neq 0$ for $|z| \le 1$; invertible iff $\theta(z) \neq 0$ for $|z| \le 1$.
Key Insight: AR roots control recursion; MA roots control innovation recovery.

Definition 7.2.2. *ARIMA Model*
Let $p, q, d \in \mathbb{N}_0$, $\phi_i \in \mathbb{R}$ $(1 \le i \le p)$, $\theta_j \in \mathbb{R}$ $(1 \le j \le q)$, and let B denote the backshift.
Set $\Delta^d := (1 - B)^d$, $\phi(z) := 1 - \sum_{i=1}^{p} \phi_i z^i$, and $\theta(z) := 1 + \sum_{j=1}^{q} \theta_j z^j$.
$(X_t)_{t\in\mathbb{Z}}$ is ARIMA(p, d, q) with innovations $(\varepsilon_t)_{t\in\mathbb{Z}}$ iff (ε_t) is white noise and $\phi(B)\Delta^d X_t = \theta(B)\varepsilon_t$ $\forall t \in \mathbb{Z}$.
Structural Commentary: $Y_t := \Delta^d X_t$ satisfies ARMA(p, q) with the same innovations.
Key Insight: $d > 0$ shifts stationarity from X_t to $\Delta^d X_t$.

Definition 7.2.3. *Filtering Problem*
Let $(Z_t, Y_t)_{t\ge1}$ be a hidden-state model with state space $(E, \mathcal{E})$, and set $\mathcal{F}_t^Y := \sigma(Y_1, \dots, Y_t)$.
For $A \in \mathcal{E}$, $\pi_t(A) := \mathbb{P}(Z_t \in A \mid \mathcal{F}_t^Y)$; the task is recursive propagation or approximation of $(\pi_t)_{t\ge1}$.
Structural Commentary: (π_t) is an $\mathcal{F}_t^Y$-adapted probability-kernel-valued process.
Key Insight: Conditioning converts hidden dynamics into an observable belief-state recursion.

Definition 7.2.4. *Linear Gaussian State-Space Model*
Let $m, r, n \in \mathbb{N}$, $F \in \mathbb{R}^{m\times m}$, $G \in \mathbb{R}^{m\times r}$, $H \in \mathbb{R}^{n\times m}$, and $Q \in \mathbb{R}^{r\times r}$, $R \in \mathbb{R}^{n\times n}$ with $Q, R \succeq 0$.
Let (η_t) and (ε_t) be mutually independent Gaussian noises with $\eta_t \sim N(0, Q)$ and $\varepsilon_t \sim N(0, R)$.
Let α_0 be independent Gaussian. $(\alpha_t, Y_t)_{t\in\mathbb{N}_0}$ is *linear Gaussian state-space* iff
$\alpha_t \in \mathbb{R}^m$, $Y_t \in \mathbb{R}^n$, $\alpha_{t+1} = F\alpha_t + G\eta_t$, $Y_t = H\alpha_t + \varepsilon_t$ $\forall t \in \mathbb{N}_0$.
Key Insight: With $\mathcal{F}_t^Y := \sigma(Y_0, \dots, Y_t)$, Kalman filtering recurses $(a_t, P_t) := (\mathbb{E}(\alpha_t \mid \mathcal{F}_t^Y), \mathrm{Var}(\alpha_t \mid \mathcal{F}_t^Y))$.

Definition 7.2.5. *ARCH and GARCH Volatility*
Let $p, q \in \mathbb{N}_0$, $\omega > 0$, $\alpha_1, \dots, \alpha_q, \beta_1, \dots, \beta_p \ge 0$, and let $(z_t)_{t\in\mathbb{Z}}$ be standardized white noise.
All processes below are real-valued and indexed by $\mathbb{Z}$; set $A := \sum_{i=1}^{q} \alpha_i + \sum_{j=1}^{p} \beta_j$.

(i) *ARCH(q)*: $(X_t, \sigma_t)_{t\in\mathbb{Z}}$, $\sigma_t \ge 0$, satisfies $X_t = \sigma_t z_t$ and $\sigma_t^2 = \omega + \sum_{i=1}^{q} \alpha_i X_{t-i}^2$ $\forall t \in \mathbb{Z}$.

(ii) *GARCH(p, q)*: $(X_t, \sigma_t)_{t\in\mathbb{Z}}$, $\sigma_t \ge 0$, satisfies $X_t = \sigma_t z_t$ and $\sigma_t^2 = \omega + \sum_{i=1}^{q} \alpha_i X_{t-i}^2 + \sum_{j=1}^{p} \beta_j \sigma_{t-j}^2$ $\forall t \in \mathbb{Z}$.

Structural Commentary: $\omega > 0$, $\alpha_i, \beta_j \ge 0$ force $\sigma_t^2 \ge 0$; by stationary GARCH, $A < 1$ has $\mathbb{E}X_t^2 = \frac{\omega}{1-A}$.

Remark 7.2.6. *Likelihood by Filtering*
If one-step densities exist, likelihood filtering has $S_t = \mathcal{T}_\vartheta(S_{t-1}, W_t)$ and $\ell_T(\vartheta) = \sum_{t=1}^{T} \log p_\vartheta(W_t \mid S_{t-1})$.
Inference depends on stability of S_t.

Method 7.2.7. *Estimating a Finite Transition Matrix*

(i) Observe finite homogeneous chain $X_0, \dots, X_n$, let $n_{ij} := \sum_{t=0}^{n-1} \mathbf{1}\{X_t = i, X_{t+1} = j\}$, $n_i := \sum_j n_{ij}$.

(ii) The row likelihood is proportional to $\prod_j p_{ij}^{n_{ij}}$ subject to $\sum_j p_{ij} = 1$.

(iii) If $n_i > 0$, the rowwise MLE is $\widehat{p}_{ij} = \frac{n_{ij}}{n_i}$.

(iv) If $n_i = 0$, row i is not identifiable without a convention or prior.

8 Sequential Inference and Resampling

8.1 Resampling, Bootstrap, and Permutation Methods

Resampling methods approximate sampling distributions by recomputing statistics on data-generated pseudo-samples.

Definition 8.1.1. *Nonparametric Bootstrap*
For $X_{1:n} \sim P^{\otimes n}$, set $\widehat{P}_n := n^{-1} \sum_{i=1}^{n} \delta_{X_i}$. Conditional on $X_{1:n}$, let $X_{1:n}^* \sim \widehat{P}_n^{\otimes n}$ and $\widehat{P}_n^* := n^{-1} \sum_{i=1}^{n} \delta_{X_i^*}$.
For any law functional T, $\mathcal{L}(T(\widehat{P}_n^*) - T(\widehat{P}_n) \mid X_{1:n})$ approximates $\mathcal{L}(T(\widehat{P}_n) - T(P))$.
Key Insight: P is replaced by $\widehat{P}_n$ before pseudo-sampling.

Method 8.1.2. *Bootstrap Standard Error*
Let $\widehat{\psi} = s(X_{1:n})$ be observed statistic, $\mathcal{R}_*(X_{1:n})$ be the chosen bootstrap law on pseudo-samples, $B \ge 2$.

(i) *Resample*: $X_{1:n}^{*b} \sim \mathcal{R}_*(X_{1:n})$ for $b = 1, \dots, B$.

(ii) *Recompute*: $\widehat{\psi}^{*b} := s(X_{1:n}^{*b})$ for $b = 1, \dots, B$.

(iii) *Estimate*: $\widehat{\mathrm{se}}_*(\widehat{\psi}) := \{(B-1)^{-1} \sum_{b=1}^{B} (\widehat{\psi}^{*b} - \overline{\psi}^*)^2\}^{\frac{1}{2}}$, where $\overline{\psi}^* := B^{-1} \sum_{b=1}^{B} \widehat{\psi}^{*b}$.

Method 8.1.3. *Bootstrap Variability for Location Summaries*
Let $T = T(x_1, \dots, x_n)$ be a location summary and let $B \geq 1$.

(i) *Resample*: For $1 \leq b \leq B$, draw $x_1^{*(b)}, \dots, x_n^{*(b)}$ iid from $\widehat{F}_n := n^{-1} \sum_{i=1}^{n} \delta_{x_i}$.

(ii) *Recompute*: Set $T_b^* := T(x_1^{*(b)}, \dots, x_n^{*(b)})$ and $\overline{T}^* := B^{-1} \sum_{b=1}^{B} T_b^*$.

(iii) *Spread*: Estimate variability by $\widehat{\mathrm{se}}_*(T) := \left((B-1)^{-1} \sum_{b=1}^{B} (T_b^* - \overline{T}^*)^2 \right)^{1/2}$.

Key Insight: This is useful for medians and trimmed means, where analytic standard errors can be tail-sensitive.

Definition 8.1.4. *Parametric Bootstrap*
Let $\{P_\theta : \theta \in \Theta\}$ be parametric model for $X_{1:n} := (X_1, \dots, X_n)$, let $\widehat{\theta} := \widehat{\theta}(X_{1:n})$, and let S be a statistic.
$X_1^*, \dots, X_n^* \mid X_{1:n} \sim P_{\widehat{\theta}}^{\otimes n}$, and $\mathcal{L}(S(X_{1:n}^*) \mid X_{1:n})$ is the fitted-model resampling law for $S(X_{1:n})$.

Key Insight: The model class $\{P_\theta\}$ is retained; only θ is replaced by $\widehat{\theta}$.

Method 8.1.5. *Parametric Bootstrap Standard Errors and Intervals*
Let $\{P_\theta : \theta \in \Theta\}$ be parametric model, $\widehat{\psi} := s(X_{1:n})$ estimate $\psi(\theta)$, fix $B \geq 2$, fix confidence level $1 - \alpha$.

(i) *Fit*: $\widehat{\theta} := \widehat{\theta}(X_{1:n})$.

(ii) *Simulate*: $X_{1:n}^{*b} \sim P_{\widehat{\theta}}^{\otimes n}$ and $\widehat{\psi}^{*b} := s(X_{1:n}^{*b})$ for $b = 1, \dots, B$.

(iii) *Standard error*: $\widehat{\mathrm{se}}_*(\widehat{\psi}) := \{(B-1)^{-1} \sum_{b=1}^{B} (\widehat{\psi}^{*b} - \overline{\psi}^*)^2\}^{\frac{1}{2}}$, where $\overline{\psi}^* := B^{-1} \sum_{b=1}^{B} \widehat{\psi}^{*b}$.

(iv) *Pivotal interval*: for empirical quantiles $q_{\frac{\alpha}{2}}^*$ and $q_{1-\frac{\alpha}{2}}^*$ of $\{\widehat{\psi}^{*b} - \widehat{\psi}\}_{b=1}^B$, use $[\widehat{\psi} - q_{1-\frac{\alpha}{2}}^*, \widehat{\psi} - q_{\frac{\alpha}{2}}^*]$.

The percentile interval uses empirical quantiles of $\{\widehat{\psi}^{*b}\}_{b=1}^B$ directly.
The pivotal and percentile intervals coincide when the bootstrap error law is symmetric about 0.

Remark 8.1.6. *Plug-In Monte Carlo*
The parametric bootstrap estimates model-dependent quantities by replacing the unknown parameter with its estimate before simulation. If $h(X, \theta)$ is a loss, error indicator, or other accuracy summary, then Monte Carlo from $P_{\widehat{\theta}}$ approximates $\mathbb{E}_\theta h(X, \theta)$ by the empirical average of $h(X^{*b}, \widehat{\theta})$.

Definition 8.1.7. *Permutation Test*
Let a finite group G act on the sample space $\mathcal{X}$, let P_0 satisfy $gX \overset{\text{dist}}{=} X$ under P_0 $\forall g \in G$, and let $T : \mathcal{X} \to \mathbb{R}$ be a test statistic. With U_G uniform on G and independent of X, $\mathcal{L}(T(U_G X) \mid X)$, the empirical law on $\{T(gX) : g \in G\}$, is the reference law for tail probabilities.

Key Insight: Calibration follows from the invariance $gX \overset{\text{dist}}{=} X$ under P_0.

Method 8.1.8. *Permutation Plug-In FDR Estimate*
Let t_j be observed statistics for $j \in [M]$, and let $t_j^{(k)}$ be the statistic after label permutation $k \in [K]$.

(i) *Observed discoveries*: For cutpoint $C > 0$, set $R_{\text{obs}}(C) := \sum_{j=1}^{M} \mathbf{1}_{\{|t_j| > C\}}$.

(ii) *Null discoveries*: Estimate the expected false discoveries by $\widehat{\mathbb{E}}(V; C) := K^{-1} \sum_{k=1}^{K} \sum_{j=1}^{M} \mathbf{1}_{\{|t_j^{(k)}| > C\}}$.

(iii) *Plug-in FDR*: If $R_{\text{obs}}(C) > 0$, set $\widehat{\mathrm{FDR}}(C) := \widehat{\mathbb{E}}(V; C) / R_{\text{obs}}(C)$.

(iv) *Permutation p-values*: Use $\{t_j^{(k)}\}$ to compare $|t_j|$ with featurewise or pooled permutation null statistics.

Remark 8.1.9. *Asymmetric Cutpoints and SAM*
Let $t_{(1)} \leq \cdots \leq t_{(M)}$ and $\bar{t}_{(j)}^0 := K^{-1} \sum_{k=1}^{K} t_{(j)}^{(k)}$, where $t_{(j)}^{(k)}$ is the jth ordered permutation statistic.
For $d_j := t_{(j)} - \bar{t}_{(j)}^0$, $a > 0$, set $c_+(a) := \min\{t_{(j)} : d_j > a\}$, $c_-(a) := \max\{t_{(j)} : d_j < -a\}$ when nonempty.
Reject $t_j \in A(c_-, c_+) := (-\infty, c_-] \cup [c_+, \infty)$, estimate FDR by Method 8.1.8, $A(c_-, c_+)$ replace $\{|t| > C\}$.

Remark 8.1.10. *Validity Depends on the Resampling Law*
Bootstrap validity is asymptotic; permutation validity is finite-sample exact under invariance; both require the resampling law to match the target sampling variation.

8.2 Sequential Experiments, Filtering, and Online Inference

Sequential methods update decisions as observations arrive. They must account for optional stopping, adaptive sampling, and computational constraints.

Definition 8.2.1. *Sequential Test and Stopping Time*
Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space, let $I \subseteq \mathbb{N}_0$ be a time index, let $(\mathcal{F}_t)_{t \in I}$ be a filtration, and let $(D, \mathcal{D})$ be a decision space. For any $\tau : \Omega \to I \cup \{\infty\}$, set $\mathcal{F}_\tau := \{A \in \mathcal{F} : A \cap \{\tau \leq t\} \in \mathcal{F}_t \ \forall t \in I\}$.

(i) *Stopping time*: $\tau : \Omega \to I \cup \{\infty\}$ satisfies $\{\tau \leq t\} \in \mathcal{F}_t$ $\forall t \in I$.

(ii) *Sequential test*: (τ, d) with τ a stopping time and $d : (\Omega, \mathcal{F}_\tau) \to (D, \mathcal{D})$ measurable.

Key Insight: Stop and decide using only pre-stopping information.

Definition 8.2.2. *Sequential Probability Ratio Test*
Let P_0 and P_1 be simple iid models with one-observation densities p_0 and p_1 for $(X_t)_{t \geq 1}$,
let $\Lambda_0 := 1$, $\Lambda_t := \prod_{i=1}^{t} \frac{p_1(X_i)}{p_0(X_i)}$, and choose $0 < A < B < \infty$.
$\tau := \inf\{t \geq 1 : \Lambda_t \in (0, A] \cup [B, \infty)\}$, with terminal decision $d_\tau = P_0$ on $\{\Lambda_\tau \leq A\}$ and $d_\tau = P_1$ on $\{\Lambda_\tau \geq B\}$.
Key Insight: First exit of $\log \Lambda_t$ from $(\log A, \log B)$ converts cumulative likelihood evidence into a stopping rule.

Remark 8.2.3. *Sequential Cross-References*
Sequential inference uses filtrations and martingales from stochastic processes, stability of recursions from dynamical systems, and simulation methods from Monte Carlo computation.

8.3 Two-Sample Resampling Methods

Two-sample resampling procedures must preserve the source of randomness relevant to the question. Bootstrap procedures usually resample within groups to estimate sampling variability under the fitted empirical distributions; permutation procedures pool labels when the null asserts exchangeability.

Method 8.3.1. *Two-Sample Nonparametric Bootstrap*

Let $x_{1:n}$ and $y_{1:m}$ be independent samples from F and G, let $\widehat{F}_n := n^{-1}\sum_{i=1}^{n}\delta_{x_i}$ and $\widehat{G}_m := m^{-1}\sum_{j=1}^{m}\delta_{y_j}$.

Let $T(F,G)$ be a two-sample functional, and fix $B \geq 2$.

(i) *Resample*: $x^{*b}_{1:n} \sim \widehat{F}_n^{\otimes n}$ and $y^{*b}_{1:m} \sim \widehat{G}_m^{\otimes m}$ independently for $b = 1,\dots,B$.

(ii) *Recompute*: with $\widehat{F}^{*b}_n := n^{-1}\sum_{i=1}^{n}\delta_{x_i^{*b}}$ and $\widehat{G}^{*b}_m := m^{-1}\sum_{j=1}^{m}\delta_{y_j^{*b}}$, set $\widehat{T}^{*b} := T(\widehat{F}^{*b}_n, \widehat{G}^{*b}_m)$.

(iii) *Summarize*: $s^*_T := \mathrm{sd}\{\widehat{T}^{*b} : 1 \leq b \leq B\}$; $I^*_{1-\alpha} := [q^*_{\frac{\alpha}{2}}, q^*_{1-\frac{\alpha}{2}}]$, where q^*_γ is the empirical γ-quantile.

This is the two-sample version of Method 8.1.2.

Example 8.3.2. *Bootstrap for $\pi = \mathbb{P}(X < Y)$*
Let $x_{1:n} \sim F^{\otimes n}$ and $y_{1:m} \sim G^{\otimes m}$ independently.
Set $\widehat{F}_n := n^{-1}\sum_{i=1}^{n}\delta_{x_i}$, $\widehat{G}_m := m^{-1}\sum_{j=1}^{m}\delta_{y_j}$, and $\widehat{\pi} := (mn)^{-1}\sum_{i=1}^{n}\sum_{j=1}^{m}\mathbf{1}_{\{x_i<y_j\}}$.
For $b = 1,\dots,B$, draw $x^{*b}_{1:n} \sim \widehat{F}_n^{\otimes n}$ and $y^{*b}_{1:m} \sim \widehat{G}_m^{\otimes m}$ independently.
Set $\widehat{\pi}^{*b} := (mn)^{-1}\sum_{i=1}^{n}\sum_{j=1}^{m}\mathbf{1}_{\{x_i^{*b}<y_j^{*b}\}}$, and use $s^*_\pi := \mathrm{sd}\{\widehat{\pi}^{*b} : 1 \leq b \leq B\}$.
Key Insight: Separate resampling targets $F \otimes G$ variation; rank-sum calibration imposes $F = G$.

Method 8.3.3. *Bootstrap for a Hodges–Lehmann Shift*
For independent samples $x_{1:n}$ and $y_{1:m}$ and $B \geq 2$, set $\widehat{\Delta}_{\mathrm{HL}} := \mathrm{median}\{y_j - x_i : 1 \leq i \leq n,\ 1 \leq j \leq m\}$, resample the two groups separately for $b = 1,\dots,B$, and use the empirical spread or quantiles of the recomputed medians $\widehat{\Delta}^{*b}_{\mathrm{HL}}$ for a standard error or interval.

Method 8.3.4. *Permutation Test for a Difference of Means*

Let $x_{1:n}$ be control responses, let $y_{1:m}$ be treatment responses, set $\overline{x} := n^{-1}\sum_{i=1}^{n}x_i$ and $\overline{y} := m^{-1}\sum_{j=1}^{m}y_j$.

Let $z_{1:N}$ with $N = n + m$ be the pooled responses, and set $T_{\mathrm{obs}} := \overline{y} - \overline{x}$.
Let H_0 denote no treatment effect, set $\mathcal{S}_{m,N} := \{S \subseteq \{1,\dots,N\} : |S| = m\}$, and use $S \mid H_0 \sim \mathrm{Unif}(\mathcal{S}_{m,N})$.

(i) *Relabel*: $S \in \mathcal{S}_{m,N}$, by enumeration or Monte Carlo draws from $\mathrm{Unif}(\mathcal{S}_{m,N})$.

(ii) *Recompute*: $T^*_S := m^{-1}\sum_{i\in S}z_i - n^{-1}\sum_{i\notin S}z_i$.

(iii) *Calibrate*: $p_{\mathrm{exact}} := \binom{N}{m}^{-1}\#\{S \in \mathcal{S}_{m,N} : |T^*_S| \geq |T_{\mathrm{obs}}|\}$, Monte Carlo approximation if $\binom{N}{m}$ large.

Remark 8.3.5. *Permutation and Rank Tests*
The permutation test for means and the Mann–Whitney test both use the randomization principle that, under the null, labels are exchangeable. They differ in the statistic: the permutation mean test uses the numerical values and is sensitive to outliers, while the Mann–Whitney test first replaces values by ranks.

Part XX
Statistical Data Analysis and Applied Models

Applied statistical analysis organizes data summaries, sampling designs, contingency tables, designed experiments, and regression models into reusable workflows. The inferential tools of Part 15 supply the testing, estimation, and uncertainty language used here.

1 Survey Sampling

1.1 Finite Population Parameters and Simple Random Sampling

Survey sampling treats a finite population as fixed and the sample-selection mechanism as random. The inferential target is often a population mean, total, or proportion, while the random variables come from the sampling design.

Definition 1.1.1. *Finite Population Parameters*
Let $U := \{1, \dots, N\}$ and fix $x_i \in \mathbb{R}$, $i \in U$.

(i) *Population mean*: $\mu := \frac{1}{N} \sum_{i=1}^{N} x_i$.

(ii) *Population total*: $\tau := \sum_{i=1}^{N} x_i = N\mu$.

(iii) *Population variance*: $\sigma^2 := \frac{1}{N} \sum_{i=1}^{N} (x_i - \mu)^2 = \frac{1}{N} \sum_{i=1}^{N} x_i^2 - \mu^2$.

(iv) *Population proportion*: $\{x_i : i \in U\} \subseteq \{0, 1\} \implies p := \mu = \frac{1}{N} \sum_{i=1}^{N} x_i$ and $\sigma^2 = p(1-p)$.

Definition 1.1.2. *Simple Random Sampling*
Let $U := \{1, \dots, N\}$, $1 \le n \le N$, and fix $x_i \in \mathbb{R}$, $i \in U$.
Let S be a random n-element subset of U; for a random ordering $J_1, \dots, J_n$ of S, set $X_k := x_{J_k}$.

(i) *Simple random sample*: $\mathbb{P}(S = s) = \frac{1}{\binom{N}{n}}$, $\forall s \subseteq U$ with $|s| = n$.

(ii) *Sample mean*: $\overline{X} := \frac{1}{n} \sum_{i=1}^{n} X_i$.

(iii) *Total estimator*: $T := N\overline{X}$.

(iv) *Sample proportion*: $\{x_i : i \in U\} \subseteq \{0, 1\} \implies \widehat{p} := \overline{X}$.

Method 1.1.3. *Sequential Simple Random Sampling*
Fix target size $n \ge 1$, assume terminal stream length is $N \ge n$, N unknown while streaming.
Population units arrive sequentially as $1, \dots, N$. Let $S_t \subseteq \{1, \dots, t\}$ denote current reservoir after t arrivals.

(i) *Initialize*: for $1 \le t \le n$, set $S_t = \{1, \dots, t\}$.
(ii) *Admit*: for $t > n$, draw $B_t \sim \text{Bernoulli}(\frac{n}{t})$.
(iii) *Update*: if $B_t = 0$, set $S_t = S_{t-1}$; if $B_t = 1$, draw $J_t \mid S_{t-1} \sim \text{Unif}(S_{t-1})$ and set $S_t = (S_{t-1} \setminus \{J_t\}) \cup \{t\}$.
(iv) *Output*: after the stream ends, return S_N.

Then for every $t \ge n$, $S_t \sim \text{Unif}\{s \subseteq \{1, \dots, t\} : |s| = n\}$.
Hence S_N is a simple random sample without replacement.

Example 1.1.4. *Capture–Recapture Likelihood*
Suppose t population units are tagged and a later sample of size m contains $r > 0$ tagged units.
For population size n, likelihood is $L_n = \frac{\binom{t}{r}\binom{n-t}{m-r}}{\binom{n}{m}}$. Since $\frac{L_n}{L_{n-1}} = \frac{(n-t)(n-m)}{n(n-t-m+r)}$, L_n increases for $n < \frac{mt}{r}$ and decreases for $n > \frac{mt}{r}$.
Hence $\widehat{n} = \lfloor \frac{mt}{r} \rfloor$; for $(t, m, r) = (10, 20, 4)$, $\widehat{n} = 50$.

Lemma 1.1.5. *Law of One Sample Position*
Let $U := \{1, \dots, N\}$, $1 \le n \le N$, fix $x_a \in \mathbb{R}$ for $a \in U$.
Let $\mu := \frac{1}{N} \sum_{a=1}^{N} x_a$, $\sigma^2 := \frac{1}{N} \sum_{a=1}^{N} (x_a - \mu)^2$, $S \sim \text{Unif}\{s \subseteq U : |s| = n\}$.
If $(J_1, \dots, J_n)$ is a random ordering of S, set $X_k := x_{J_k}$.
Let $\zeta_1, \dots, \zeta_m$ be distinct values in $\{x_a : a \in U\}$, let $n_j := \#\{a \in U : x_a = \zeta_j\}$. For each $k \in \{1, \dots, n\}$:

(i) Distribution: the selected value X_k has the finite-population law $\mathbb{P}(X_k = \zeta_j) = \frac{n_j}{N}$ for $j = 1, \dots, m$.
(ii) Moments: the finite-population law has mean $\mathbb{E}X_k = \mu$ and variance $\text{Var}(X_k) = \sigma^2$.

Proof.

(i) For every $a \in U$, $\mathbb{P}(J_k = a) = \frac{1}{N}$, so $\mathbb{P}(X_k = \zeta_j) = \sum_{a : x_a = \zeta_j} \mathbb{P}(J_k = a) = \frac{n_j}{N}$.

(ii) From (i), $\mathbb{E}X_k = \frac{1}{N} \sum_{a=1}^{N} x_a = \mu$. By finite-population law, $\text{Var}(X_k) = \frac{1}{N} \sum_{a=1}^{N} (x_a - \mu)^2 = \sigma^2$.

Structural Commentary: Each sample position is marginally uniform on U.
Key Insight: Without replacement changes joint dependence, not the one-position marginal distribution. □

Theorem 1.1.6. *Unbiased SRS Estimators*
Let $U := \{1, \dots, N\}$, $1 \le n \le N$, fix $x_a \in \mathbb{R}$ for $a \in U$.
Set $\mu := \frac{1}{N} \sum_{a=1}^{N} x_a$, $\tau := \sum_{a=1}^{N} x_a = N\mu$. Let $S \sim \text{Unif}\{s \subseteq U : |s| = n\}$.
Given random ordering $(J_1, \dots, J_n)$ of S, set $X_k := x_{J_k}$, $\overline{X} := \frac{1}{n} \sum_{k=1}^{n} X_k$, and $T := N\overline{X}$. Then:

(i) Mean estimator: the sample mean is design-unbiased for the finite-population mean, $\mathbb{E}\overline{X} = \mu$.

(ii) Total estimator: the expansion estimator is design-unbiased for the finite-population total, $\mathbb{E}T = \tau$.

Proof.

(i) For each k, $\mathbb{P}(J_k = a) = \frac{1}{N}\ \forall a \in U$, so $\mathbb{E}X_k = \frac{1}{N}\sum_{a=1}^{N} x_a = \mu$. By linearity $\mathbb{E}\overline{X} = \frac{1}{n}\sum_{k=1}^{n}\mathbb{E}X_k = \mu$.

(ii) Since $T = N\overline{X}$, $\mathbb{E}T = N\mathbb{E}\overline{X} = N\mu = \tau$.

Structural Commentary: $T = N\overline{X}$ rescales the mean estimate.
Key Insight: Equal position marginals give unbiasedness; independence is unnecessary. □

Lemma 1.1.7. *Negative Dependence Without Replacement*
Let $U := \{1, \dots, N\}$, $2 \le n \le N$, fix $x_a \in \mathbb{R}$ for $a \in U$.
Set $\mu := \frac{1}{N}\sum_{a=1}^{N} x_a$, $\tau := \sum_{a=1}^{N} x_a$, $\sigma^2 := \frac{1}{N}\sum_{a=1}^{N}(x_a - \mu)^2$. Let $S \sim \mathrm{Unif}\{s \subseteq U : |s| = n\}$.
For random ordering $(J_1, \dots, J_n)$ of S, set $X_k := x_{J_k}$. If $i, j \in \{1, \dots, n\}$ and $i \ne j$, then $\mathrm{Cov}(X_i, X_j) = -\frac{\sigma^2}{N-1}$.

Proof. Let $(Y_1, \dots, Y_N)$ be a uniformly random ordering of $(x_1, \dots, x_N)$.
Each Y_a has variance σ^2, and symmetry gives $\mathrm{Cov}(Y_a, Y_b) = \gamma$ for $a \ne b$.
Since $\sum_{a=1}^{N} Y_a = \tau$ is fixed, $0 = \mathrm{Var}(\sum_{a=1}^{N} Y_a) = N\sigma^2 + N(N-1)\gamma$.
Thus $\gamma = -\frac{\sigma^2}{N-1}$, and (X_i, X_j) has same law as any two distinct positions in full random ordering.
Structural Commentary: A fixed total forces negative pairwise covariance.
Key Insight: Without replacement, one large draw leaves less for the rest. □

Theorem 1.1.8. *Variance and Finite Population Correction*
Let $U := \{1, \dots, N\}$, $N > 1$, $1 \le n \le N$, fix $x_a \in \mathbb{R}$ for $a \in U$.
Set $\mu := \frac{1}{N}\sum_{a=1}^{N} x_a$ and $\sigma^2 := \frac{1}{N}\sum_{a=1}^{N}(x_a - \mu)^2$. Let $S \sim \mathrm{Unif}\{s \subseteq U : |s| = n\}$.
For a random ordering $(J_1, \dots, J_n)$ of S, set $X_k := x_{J_k}$, $\overline{X} := \frac{1}{n}\sum_{k=1}^{n} X_k$, and $T := N\overline{X}$. Then:

(i) Mean variance: the sample mean has design variance $\mathrm{Var}(\overline{X}) = \frac{\sigma^2}{n}\left(\frac{N-n}{N-1}\right) = \frac{\sigma^2}{n}\left(1 - \frac{n-1}{N-1}\right)$.
(ii) Total variance: the total estimator has design variance $\mathrm{Var}(T) = N^2\,\mathrm{Var}(\overline{X})$.

Proof.

(i) Each X_k has variance σ^2. Let $(Y_1, \dots, Y_N)$ be a uniformly random ordering of $(x_1, \dots, x_N)$, set $\tau := \sum_{a=1}^{N} x_a$, and let γ be the common covariance of Y_a, Y_b for $a \ne b$.
Since $\sum_{a=1}^{N} Y_a = \tau$, $0 = \mathrm{Var}(\sum_{a=1}^{N} Y_a) = N\sigma^2 + N(N-1)\gamma$, so $\gamma = -\frac{\sigma^2}{N-1}$.
Therefore $\mathrm{Var}(\overline{X}) = \frac{1}{n^2}\left(n\sigma^2 + n(n-1)\left[-\frac{\sigma^2}{N-1}\right]\right) = \frac{\sigma^2}{n}\left(1 - \frac{n-1}{N-1}\right)$.

(ii) The total estimator satisfies $T = N\overline{X}$, so $\mathrm{Var}(T) = \mathrm{Var}(N\overline{X}) = N^2\,\mathrm{Var}(\overline{X})$.

Structural Commentary: The factor $\frac{N-n}{N-1}$ is the *finite population correction*.
Key Insight: Averaging gives $\frac{1}{n}$ scaling; without replacement subtracts negative covariance. □

Corollary 1.1.9. *Estimated Standard Errors*
Let $U := \{1, \dots, N\}$, $1 < n \le N$, fix $x_a \in \mathbb{R}$ for $a \in U$, and let $S \sim \mathrm{Unif}\{s \subseteq U : |s| = n\}$. For a random ordering $(J_1, \dots, J_n)$ of S, set $X_k := x_{J_k}$, $\overline{X} := \frac{1}{n}\sum_{k=1}^{n} X_k$, $T := N\overline{X}$, and $s^2 := \frac{1}{n-1}\sum_{k=1}^{n}(X_k - \overline{X})^2$.
Then practical plug-in estimated variances are:

(i) Mean: the plug-in estimated variance of the sample mean is $s^2_{\overline{X}} = \frac{s^2}{n}\left(1 - \frac{n}{N}\right)$.
(ii) Total: the plug-in estimated variance of the total estimator is $s^2_T = N^2 s^2_{\overline{X}}$.
(iii) Proportion: if $x_a \in \{0, 1\}\ \forall a \in U$ and $\widehat{p} := \overline{X}$, then plug-in estimated variance of $\widehat{p}$ is $s^2_{\widehat{p}} = \frac{\widehat{p}(1-\widehat{p})}{n-1}\left(1 - \frac{n}{N}\right)$.

Proof. Set $c_N := 1 - \frac{n}{N}$.

(i) Replace unknown finite-population variance by s^2, correction by c_N gives $s^2_{\overline{X}} = (\frac{s^2}{n})c_N = \frac{s^2}{n}(1 - \frac{n}{N})$.

(ii) Since $T = N\overline{X}$, variance scales quadratically, so $s^2_T = N^2 s^2_{\overline{X}}$.

(iii) If $X_k \in \{0, 1\}$ and $\widehat{p} = \overline{X}$, then $s^2 = \frac{1}{n-1}\sum_{k=1}^{n}(X_k - \widehat{p})^2 = \frac{1}{n-1}(n\widehat{p} - n\widehat{p}^2) = \frac{n\widehat{p}(1-\widehat{p})}{n-1}$.
Substituting this into (i) gives $s^2_{\widehat{p}} = \frac{\widehat{p}(1-\widehat{p})c_N}{n-1} = \frac{\widehat{p}(1-\widehat{p})}{n-1}(1 - \frac{n}{N})$.

Structural Commentary: Plug-in SEs use s^2 and the $1 - \frac{n}{N}$ correction.
Key Insight: Binary-data variance depends only on $\widehat{p}$. □

Example 1.1.10. *Finite Population Correction in a Hospital Survey*
For a finite population of $N = 393$ hospitals, let x_i denote discharges and suppose the finite-population standard deviation is $\sigma \approx 589.7$. Under simple random sampling without replacement with $n = 32$, the sample-mean standard deviation is $\sigma_{\overline{X}} = \frac{\sigma}{\sqrt{n}}\sqrt{1 - \frac{n-1}{N-1}} \approx \frac{589.7}{\sqrt{32}}\sqrt{1 - \frac{31}{392}} \approx 100.0$. Since $\frac{n}{N} = \frac{32}{393}$ is small, the finite-population correction is near 1, and the standard error is mainly governed by the $\frac{1}{\sqrt{n}}$ averaging scale.

1.2 Normal Approximation and Confidence Intervals

The exact design formulas in Theorem 1.1.8 give the center and scale of the sampling distribution. For large samples, a normal approximation turns those formulas into error probabilities and confidence intervals.

Method 1.2.1. *Normal Approximation for SRS*

(i) Let $U := \{1, \dots, N\}$, $N > 1$, $1 \le n \le N$, $x_i \in \mathbb{R}$ for $i \in U$, and $S \sim \text{Unif}\{s \subseteq U : |s| = n\}$.

(ii) For a random ordering $(J_1, \dots, J_n)$ of S, set $X_k := x_{J_k}$, $\overline{X} := n^{-1} \sum_{k=1}^{n} X_k$, $T := N\overline{X}$, $\mu := N^{-1} \sum_{i=1}^{N} x_i$, $\sigma^2 := N^{-1} \sum_{i=1}^{N} (x_i - \mu)^2$, $\tau := N\mu$, and $\sigma^2_{\overline{X}} := \frac{\sigma^2}{n} \left(\frac{N-n}{N-1}\right)$.

(iii) Let Φ be the standard normal cdf. For large n, use $\overline{X} \approx N(\mu, \sigma^2_{\overline{X}})$.

(iv) If $\sigma_{\overline{X}} > 0$, then $\mathbb{P}(|\overline{X} - \mu| \le \delta) \approx 2\Phi(\frac{\delta}{\sigma_{\overline{X}}}) - 1$ for $\delta > 0$, and $T - \tau = N(\overline{X} - \mu) \approx N(0, N^2\sigma^2_{\overline{X}})$.

Method 1.2.2. *Approximate SRS Confidence Intervals*

(i) Let S be an SRS without replacement, with targets μ, τ and estimators $\overline{X}, T$.

(ii) Fix $0 < \alpha < 1$, let Φ be the standard normal cdf, set $z(\frac{\alpha}{2}) := \Phi^{-1}(1 - \frac{\alpha}{2})$, and use plug-in SEs $s_{\overline{X}}, s_T$, and, when binary, $s_{\widehat{p}}$.

(iii) $\text{CI}_{1-\alpha}(\mu) = \overline{X} \pm z(\frac{\alpha}{2}) s_{\overline{X}}$ and $\text{CI}_{1-\alpha}(\tau) = T \pm z(\frac{\alpha}{2}) s_T$.

(iv) In the dichotomous case, with population proportion p and sample proportion $\widehat{p}$, use $\text{CI}_{1-\alpha}(p) = \widehat{p} \pm z(\frac{\alpha}{2}) s_{\widehat{p}}$.

(v) Intervals are random before sampling; after observation, parameters are fixed and coverage is procedural.

Example 1.2.3. *Generic SRS Intervals*

Suppose finite population has $N = 8000$ units. Simple random sample of $n = 100$ gives $\overline{X} = 1.6$ for variable with sample standard deviation $s = 0.8$. Use $z(0.025) \approx 1.96$, suppose sample gives $\widehat{p} = 0.12$ for binary attribute.

(i) *Mean*: $s_{\overline{X}} = \frac{s}{\sqrt{n}} \sqrt{1 - \frac{n}{N}} = \frac{0.8}{10} \sqrt{1 - \frac{100}{8000}} \approx 0.0795$, then 95% CI for μ is $1.6 \pm 1.96(0.0795) = (1.44, 1.76)$.

(ii) *Total*: $T = N\overline{X} = 8000(1.6) = 12800$ and $s_T = N s_{\overline{X}} \approx 636$, then 95% CI for τ is $(11553, 14047)$.

(iii) *Proportion*: $s_{\widehat{p}} = \sqrt{\frac{\widehat{p}(1-\widehat{p})}{n-1} \left(1 - \frac{n}{N}\right)} = \sqrt{\frac{0.12(0.88)}{99} \left(1 - \frac{100}{8000}\right)} \approx 0.0325$, then 95% CI for p is $(0.056, 0.184)$.
The estimated attribute total is $N\widehat{p} = 960$ with $N s_{\widehat{p}} \approx 260$ and interval $(451, 1469)$.

These intervals quantify SRS uncertainty for fixed finite-population quantities.

Method 1.2.4. *Sample Size from Desired Half-Width*

(i) Fix $0 < \alpha < 1$, half-width $h > 0$, planning SD $\sigma > 0$, and planned size n.
Let Φ be the standard normal cdf and set $z(\frac{\alpha}{2}) := \Phi^{-1}(1 - \frac{\alpha}{2})$.

(ii) Ignoring the finite population correction, $h \approx z(\frac{\alpha}{2}) \frac{\sigma}{\sqrt{n}}$ gives $n \approx \left(\frac{z(\frac{\alpha}{2})\sigma}{h}\right)^2$.

(iii) For total based on population proportion over N units, use planning value $p_0 \in [0, 1]$, SE $N\sqrt{\frac{p_0(1-p_0)}{n}}$.

(iv) With negligible finite population correction, halving interval width requires roughly $4n$ observations.

1.3 Ratio Estimation

Ratio estimation uses an auxiliary variable whose population mean or total is known. It is especially useful when the auxiliary variable is strongly correlated with the target variable.

Definition 1.3.1. *Population and Sample Ratios*

Let $U := \{1, \dots, N\}$ and fixed pairs $(x_i, y_i) \in \mathbb{R}^2$, $i \in U$.

Set $\mu_x := \frac{1}{N} \sum_{i=1}^{N} x_i$, $\mu_y := \frac{1}{N} \sum_{i=1}^{N} y_i$, $\tau_x := \sum_{i=1}^{N} x_i$, and $\tau_y := \sum_{i=1}^{N} y_i$, with $\mu_x \neq 0$.

For SRS pairs $(X_i, Y_i)_{i=1}^n$, set $\overline{X} := \frac{1}{n} \sum_{i=1}^{n} X_i$ and $\overline{Y} := \frac{1}{n} \sum_{i=1}^{n} Y_i$, with $\overline{X} \neq 0$.

(i) *Population ratio*: $r := \sum_{i=1}^{N} y_i / \sum_{i=1}^{N} x_i = \frac{\mu_y}{\mu_x}$.

(ii) *Sample ratio*: $R := \frac{\overline{Y}}{\overline{X}}$.

(iii) *Ratio mean estimator*: $\overline{Y}_R := \mu_x R$ when μ_x is known.

(iv) *Ratio total estimator*: $T_R := \tau_x R$ when τ_x is known.

Key Insight: $\{i \in U : x_i = 0\} = \emptyset$ does not imply $r = \frac{1}{N} \sum_{i=1}^{N} \frac{y_i}{x_i}$.

Definition 1.3.2. *Population Covariance and Correlation*

Let $U := \{1, \dots, N\}$ and fixed pairs $(x_i, y_i) \in \mathbb{R}^2$, $i \in U$.

Set $\mu_x := \frac{1}{N} \sum_{i=1}^{N} x_i$, $\mu_y := \frac{1}{N} \sum_{i=1}^{N} y_i$, $\sigma_x^2 := \frac{1}{N} \sum_{i=1}^{N} (x_i - \mu_x)^2$, and $\sigma_y^2 := \frac{1}{N} \sum_{i=1}^{N} (y_i - \mu_y)^2$.

For sample pairs $(X_i, Y_i)_{i=1}^n$, set $\overline{X} := \frac{1}{n} \sum_{i=1}^{n} X_i$ and $\overline{Y} := \frac{1}{n} \sum_{i=1}^{n} Y_i$.

(i) *Population covariance*: $\sigma_{xy} := \frac{1}{N} \sum_{i=1}^{N} (x_i - \mu_x)(y_i - \mu_y)$.

(ii) *Population correlation*: $\rho := \frac{\sigma_{xy}}{\sigma_x \sigma_y}$ when $\sigma_x, \sigma_y > 0$.

(iii) *Sample covariance*: $s_{xy} := \frac{1}{n-1} \sum_{i=1}^{n} (X_i - \overline{X})(Y_i - \overline{Y})$.

Theorem 1.3.3. *Approximate Moments of the Ratio Estimator*
Let $U := \{1, \dots, N\}$, $N > 1$, $1 \le n \le N$, and let $(x_a, y_a) \in \mathbb{R}^2$ be fixed for $a \in U$.
Set $\lambda_n := \frac{1}{n}(1 - \frac{n-1}{N-1})$, $\mu_x := \frac{1}{N}\sum_{a=1}^{N} x_a$, $\mu_y := \frac{1}{N}\sum_{a=1}^{N} y_a$, $r := \frac{\mu_y}{\mu_x}$
with $\mu_x \neq 0$, $\sigma_x^2 := \frac{1}{N}\sum_{a=1}^{N}(x_a - \mu_x)^2$, $\sigma_y^2 := \frac{1}{N}\sum_{a=1}^{N}(y_a - \mu_y)^2$, and $\sigma_{xy} := \frac{1}{N}\sum_{a=1}^{N}(x_a - \mu_x)(y_a - \mu_y)$.
Let $S \sim \mathrm{Unif}\{s \subseteq U : |s| = n\}$, let $(J_1, \dots, J_n)$ be a random ordering of S, set $(X_k, Y_k) := (x_{J_k}, y_{J_k})$, $\overline{X} := \frac{1}{n}\sum_{k=1}^{n} X_k$, $\overline{Y} := \frac{1}{n}\sum_{k=1}^{n} Y_k$,
and $R := \frac{\overline{Y}}{\overline{X}}$ on $\{\overline{X} \neq 0\}$. The subscript d denotes design moments.

(i) Variance: first-order Taylor gives $\mathrm{Var}_d(R) \approx \frac{\lambda_n}{\mu_x^2}(r^2\sigma_x^2 + \sigma_y^2 - 2r\sigma_{xy})$.
(ii) Mean: second-order Taylor gives $\mathbb{E}_d R \approx r + \frac{\lambda_n}{\mu_x^2}(r\sigma_x^2 - \sigma_{xy})$.

Proof. Let $(A_q, B_q)_{q=1}^N$ be a uniformly random ordering of the population pairs; the ordered sample has the law of the first n entries. For $q \neq r$, write $\gamma_x := \mathrm{Cov}_d(A_q, A_r)$, $\gamma_y := \mathrm{Cov}_d(B_q, B_r)$, and $\gamma_{xy} := \mathrm{Cov}_d(A_q, B_r)$.
The fixed sums give $0 = \mathrm{Var}_d(\sum_{q=1}^{N} A_q) = N\sigma_x^2 + N(N-1)\gamma_x$, $0 = \mathrm{Var}_d(\sum_{q=1}^{N} B_q) = N\sigma_y^2 + N(N-1)\gamma_y$,
and $0 = \mathrm{Cov}_d(\sum_{q=1}^{N} A_q, \sum_{q=1}^{N} B_q) = N\sigma_{xy} + N(N-1)\gamma_{xy}$.
Hence $\gamma_x = -\frac{\sigma_x^2}{N-1}$, $\gamma_y = -\frac{\sigma_y^2}{N-1}$, $\gamma_{xy} = -\frac{\sigma_{xy}}{N-1}$, $V_x := \mathrm{Var}_d(\overline{X}) = \lambda_n\sigma_x^2$, $V_y := \mathrm{Var}_d(\overline{Y}) = \lambda_n\sigma_y^2$,
and $C_{xy} := \mathrm{Cov}_d(\overline{X}, \overline{Y}) = \lambda_n\sigma_{xy}$. Let $\Sigma := \begin{pmatrix} V_x & C_{xy} \\ C_{xy} & V_y \end{pmatrix}$.
For $g(x, y) = \frac{y}{x}$ and $\mu := (\mu_x, \mu_y)$, $g(\mu) = r$, $\nabla g(\mu) = (-\frac{r}{\mu_x}, \frac{1}{\mu_x})^\top$, and $H_g(\mu) = \begin{pmatrix} 2r/\mu_x^2 & -1/\mu_x^2 \\ -1/\mu_x^2 & 0 \end{pmatrix}$.

(i) *Variance*: $\mathrm{Var}_d(R) \approx \nabla g(\mu)^\top \Sigma \nabla g(\mu) = \frac{\lambda_n}{\mu_x^2}(r^2\sigma_x^2 + \sigma_y^2 - 2r\sigma_{xy})$.
(ii) *Mean*: $\mathbb{E}_d R \approx g(\mu) + \frac{1}{2}\operatorname{tr}(H_g(\mu)\Sigma) = r + \frac{\lambda_n}{\mu_x^2}(r\sigma_x^2 - \sigma_{xy})$.

Structural Commentary: The ratio estimator is locally linear for variance and locally quadratic for bias.
Key Insight: Ratio variance is scaled residual variation in $Y - rX$. □

Corollary 1.3.4. *Estimated Standard Error of a Ratio*
Let $U := \{1, \dots, N\}$, $N > 1$, $1 < n \le N$, and let $(x_a, y_a) \in \mathbb{R}^2$ be fixed for $a \in U$.
Set $\lambda_n := \frac{1}{n}(1 - \frac{n-1}{N-1})$, $\mu_x := \frac{1}{N}\sum_{a=1}^{N} x_a$, $\tau_x := \sum_{a=1}^{N} x_a$, $\tau_y := \sum_{a=1}^{N} y_a$, and $r := \frac{\tau_y}{\tau_x}$ with $\tau_x \neq 0$.
Let $S \sim \mathrm{Unif}\{s \subseteq U : |s| = n\}$. For a random ordering $(J_1, \dots, J_n)$ of S,
set $(X_i, Y_i) := (x_{J_i}, y_{J_i})$, $\overline{X} := \frac{1}{n}\sum_{i=1}^{n} X_i$, and $\overline{Y} := \frac{1}{n}\sum_{i=1}^{n} Y_i$.
Assume $\overline{X} \neq 0$ and set $R := \frac{\overline{Y}}{\overline{X}}$, $s_x^2 := \frac{1}{n-1}\sum_{i=1}^{n}(X_i - \overline{X})^2$, $s_y^2 := \frac{1}{n-1}\sum_{i=1}^{n}(Y_i - \overline{Y})^2$, $s_{xy} := \frac{1}{n-1}\sum_{i=1}^{n}(X_i - \overline{X})(Y_i - \overline{Y})$, and $q_R := R^2 s_x^2 + s_y^2 - 2Rs_{xy}$. If $0 < \alpha < 1$ and $z(\frac{\alpha}{2}) := \Phi^{-1}(1 - \frac{\alpha}{2})$ for the standard normal cdf Φ, then:

(i) Ratio variance: $s_R^2 := \frac{\lambda_n}{\overline{X}^2} q_R$ estimates $\mathrm{Var}_d(R)$.
(ii) Ratio interval: $\mathrm{CI}_{1-\alpha}(r) := R \pm z(\frac{\alpha}{2}) s_R$.
(iii) Mean and total: for $\overline{Y}_R := \mu_x R$ and $T_R := \tau_x R$, $\mathrm{SE}(\overline{Y}_R) = |\mu_x|\, s_R$ and $\mathrm{SE}(T_R) = |\tau_x|\, s_R$ when the corresponding auxiliary constant is known.

Proof.

(i) The plug-in map $(\mu_x, r, \sigma_x^2, \sigma_y^2, \sigma_{xy}) \mapsto (\overline{X}, R, s_x^2, s_y^2, s_{xy})$ in Theorem 1.3.3 yields $\widehat{\mathrm{Var}}_d(R) = \frac{\lambda_n}{\overline{X}^2}(R^2 s_x^2 + s_y^2 - 2Rs_{xy}) = s_R^2$.
(ii) If $Z_R := (R - r)/s_R \approx \mathcal{N}(0, 1)$, then $\mathbb{P}_d(|Z_R| \le z(\frac{\alpha}{2})) \approx 1 - \alpha$, equivalently $r \in R \pm z(\frac{\alpha}{2}) s_R$.
(iii) For known c, $\widehat{\mathrm{Var}}_d(cR) = c^2 s_R^2$, so $\mathrm{SE}(cR) = |c|\, s_R$; set $c = \mu_x$ and $c = \tau_x$.

Structural Commentary: Plug in sample moments to estimate the ratio variance.
Key Insight: Ratio uncertainty is residual uncertainty in $Y - RX$. □

Method 1.3.5. *When the Ratio Estimate Helps*
Let $U = \{1, \dots, N\}$ contain fixed pairs (x_i, y_i) with $\mu_x, \mu_y > 0$, $\sigma_x, \sigma_y > 0$, σ_{xy}, $\rho := \frac{\sigma_{xy}}{\sigma_x \sigma_y}$, and $r := \frac{\mu_y}{\mu_x}$.
For an SRS $(X_k, Y_k)_{k=1}^n$, set $\overline{X} := \frac{1}{n}\sum_{k=1}^{n} X_k$, $\overline{Y} := \frac{1}{n}\sum_{k=1}^{n} Y_k$, $R := \frac{\overline{Y}}{\overline{X}}$, and $\overline{Y}_R := \mu_x R$.
Ignoring finite-population corrections:

(i) *Variances*: $V_0 := \mathrm{Var}(\overline{Y}) = \frac{\sigma_y^2}{n}$ and $V_R^* := \frac{1}{n}(r^2\sigma_x^2 + \sigma_y^2 - 2r\sigma_{xy})$ approximate $\mathrm{Var}(\overline{Y}_R)$.
(ii) *Improvement*: $V_R^* < V_0 \iff 2\sigma_{xy} > r\sigma_x^2 \iff 2\rho\sigma_y > r\sigma_x$.
(iii) *Coefficient form*: with $C_x := \frac{\sigma_x}{\mu_x}$ and $C_y := \frac{\sigma_y}{\mu_y}$, $V_R^* < V_0 \iff \rho > \frac{1}{2}\frac{C_x}{C_y}$.
(iv) *Favorable case*: large positive ρ and small C_x/C_y.

Example 1.3.6. *Mortgage-Payment Ratio*
For an SRS of $n = 100$ recent house buyers, let Y_i be monthly mortgage payment and X_i gross income.
Suppose $\overline{X} = 3100$, $\overline{Y} = 868$, $s_x = 1200$, $s_y = 250$, and $\widehat{\rho} := s_{xy}/(s_x s_y) = 0.85$.

(i) *Ratio*: $R = \frac{\overline{Y}}{\overline{X}} = \frac{868}{3100} = 0.28$.
(ii) *Variance input*: $q := R^2 s_x^2 + s_y^2 - 2R\widehat{\rho} s_x s_y \approx 32596$.

(iii) *Standard error*: ignoring the finite-population correction, $s_R \approx \frac{\sqrt{q}}{\sqrt{100}\,\overline{X}} \approx 0.00582$.
(iv) *Interval*: $\mathrm{CI}_{0.95}(r) = R \pm 1.96 s_R \approx 0.28 \pm 1.96(0.00582) = (0.269, 0.291)$.

Thus the population mortgage-payment-to-income ratio is about 28%.

Remark 1.3.7. *Bias and Resampling Corrections*
For SRS from fixed pairs (x_i, y_i), set $R := \overline{Y}/\overline{X}$, $\overline{Y}_R := \mu_x R$, and $T_R := \tau_x R$.
(i) Since $g(x,y) = y/x$ is nonlinear, generally $\mathbb{E}_d R \neq r$, hence $\mathbb{E}_d \overline{Y}_R \neq \mu_y$ and $\mathbb{E}_d T_R \neq \tau_y$.
(ii) Bias corrections target $B_d(R) := \mathbb{E}_d R - r$; use resampling when Taylor bias matters.

1.4 Stratified Random Sampling

Stratified sampling partitions the population into subpopulations and samples within each one. It can guarantee representation of important groups and can reduce variance when strata are internally homogeneous or have different means.

Definition 1.4.1. *Strata and the Stratified Mean*

Let U be a finite population, $L \geq 1$, nonempty subsets $U_1, \ldots, U_L \subseteq U$, $N_l := |U_l|$, $N := \sum_{l=1}^{L} N_l$,
and fixed values $x_{il} \in \mathbb{R}$ for $i = 1, \ldots, N_l$, $l = 1, \ldots, L$.
For stratum samples of sizes n_l, write sampled values as X_{il}, $i = 1, \ldots, n_l$.

(i) *Strata*: $U = \bigsqcup_{l=1}^{L} U_l$.
(ii) *Stratum weight*: $W_l := \frac{N_l}{N}$.
(iii) *Stratum mean*: $\mu_l := \frac{1}{N_l} \sum_{i=1}^{N_l} x_{il}$.
(iv) *Stratum variance*: $\sigma_l^2 := \frac{1}{N_l} \sum_{i=1}^{N_l} (x_{il} - \mu_l)^2$.
(v) *Stratum sample mean*: $\overline{X}_l := \frac{1}{n_l} \sum_{i=1}^{n_l} X_{il}$.
(vi) *Stratified mean*: $\overline{X}_s := \sum_{l=1}^{L} W_l \overline{X}_l$.

Structural Commentary: With $\mu := \frac{1}{N} \sum_{l=1}^{L} \sum_{i=1}^{N_l} x_{il}$, $\mu = \sum_{l=1}^{L} W_l \mu_l$.

Theorem 1.4.2. *Mean and Variance of the Stratified Estimate*

Let $L \geq 1$, $N_l > 1$, $1 \leq n_l \leq N_l$, $N := \sum_{l=1}^{L} N_l$, $W_l := \frac{N_l}{N}$, and $\lambda_l := \frac{1}{n_l}(1 - \frac{n_l - 1}{N_l - 1})$.

For fixed $x_{il} \in \mathbb{R}$, $i = 1, \ldots, N_l$, $l = 1, \ldots, L$, set $\mu_l := \frac{1}{N_l} \sum_{i=1}^{N_l} x_{il}$, $\sigma_l^2 := \frac{1}{N_l} \sum_{i=1}^{N_l} (x_{il} - \mu_l)^2$, and $\mu := \sum_{l=1}^{L} W_l \mu_l$.

Independently sample $S_l \sim \mathrm{Unif}\{s \subseteq \{1, \ldots, N_l\} : |s| = n_l\}$; for random orderings $(J_{il})_{i=1}^{n_l}$ of S_l, set $X_{il} := x_{J_{il},l}$, $\overline{X}_l := \frac{1}{n_l} \sum_{i=1}^{n_l} X_{il}$,

and $\overline{X}_s := \sum_{l=1}^{L} W_l \overline{X}_l$. Let $\mathbb{E}_d, \mathrm{Var}_d$ denote design moments.

(i) Mean: $\mathbb{E}_d \overline{X}_s = \mu$.
(ii) Variance: $\mathrm{Var}_d(\overline{X}_s) = \sum_{l=1}^{L} W_l^2 \lambda_l \sigma_l^2$.
(iii) Small fractions: if $n_l/N_l \ll 1$ for all l, then $\mathrm{Var}_d(\overline{X}_s) \approx \sum_{l=1}^{L} W_l^2 \frac{\sigma_l^2}{n_l}$.

Proof.

(i) For $a \in \{1, \ldots, N_l\}$, $\mathbb{P}_d(J_{il} = a) = 1/N_l$, hence $\mathbb{E}_d X_{il} = \mu_l$, $\mathbb{E}_d \overline{X}_l = \mu_l$, and $\mathbb{E}_d \overline{X}_s = \sum_{l=1}^{L} W_l \mu_l = \mu$.

(ii) Independence across strata gives $\mathrm{Var}_d(\overline{X}_s) = \sum_{l=1}^{L} W_l^2 \mathrm{Var}_d(\overline{X}_l)$.

For stratum l, let $(Y_{1,l}, \ldots, Y_{N_l,l})$ uniformly order $\{x_{il} : 1 \leq i \leq N_l\}$, put $\gamma_l := \mathrm{Cov}_d(Y_{a,l}, Y_{b,l})$ for $a \neq b$.

As $\sum_{a=1}^{N_l} Y_{a,l}$ is fixed, $0 = N_l \sigma_l^2 + N_l(N_l - 1)\gamma_l$, so $\gamma_l = -\frac{\sigma_l^2}{N_l - 1}$, $\mathrm{Var}_d(\overline{X}_l) = \frac{1}{n_l^2}(n_l \sigma_l^2 + n_l(n_l - 1)\gamma_l) = \lambda_l \sigma_l^2$.

(iii) If $n_l/N_l \ll 1$, then $1 - \frac{n_l - 1}{N_l - 1} \approx 1$, so $\lambda_l \sigma_l^2 \approx \sigma_l^2/n_l$.

Structural Commentary: Stratified estimation is a weighted sum of independent within-stratum estimators.
Key Insight: Independent strata make variance add as $\sum_l W_l^2 \mathrm{Var}_d(\overline{X}_l)$. □

Corollary 1.4.3. *Totals and Estimated Variances*

Let $L \geq 1$, $N_l > 1$, $1 < n_l \leq N_l$, $N := \sum_{l=1}^{L} N_l$, $W_l := \frac{N_l}{N}$, and $f_l := n_l/N_l$.

Fix $x_{il} \in \mathbb{R}$ for $i = 1, \ldots, N_l$, $l = 1, \ldots, L$, set $\mu_l := \frac{1}{N_l} \sum_{i=1}^{N_l} x_{il}$, $\mu := \sum_{l=1}^{L} W_l \mu_l$, and $\tau := N\mu$.

Assume independently $S_l \sim \mathrm{Unif}\{s \subseteq \{1, \ldots, N_l\} : |s| = n_l\}$; for random orderings $(J_{il})_{i=1}^{n_l}$ of S_l.

Set $X_{il} := x_{J_{il},l}$, $\overline{X}_l := \frac{1}{n_l} \sum_{i=1}^{n_l} X_{il}$, $\overline{X}_s := \sum_{l=1}^{L} W_l \overline{X}_l$, $T_s := N\overline{X}_s$, and $s_l^2 := \frac{1}{n_l - 1} \sum_{i=1}^{n_l} (X_{il} - \overline{X}_l)^2$.

For $0 < \alpha < 1$, let $z(\frac{\alpha}{2}) := \Phi^{-1}(1 - \frac{\alpha}{2})$.

(i) Total moments: $\mathbb{E}_d T_s = \tau$ and $\mathrm{Var}_d(T_s) = N^2 \mathrm{Var}_d(\overline{X}_s)$.

(ii) Estimated mean variance: $s^2_{\overline{X}_s} := \sum_{l=1}^{L} W_l^2(1-f_l)\frac{s_l^2}{n_l}$.

(iii) Intervals: $\mathrm{CI}_{1-\alpha}(\mu) = \overline{X}_s \pm z(\frac{\alpha}{2})s_{\overline{X}_s}$ *and* $\mathrm{CI}_{1-\alpha}(\tau) = T_s \pm z(\frac{\alpha}{2})Ns_{\overline{X}_s}$.

Proof.

(i) Since $T_s = N\overline{X}_s$ and $\tau = N\mu$, Theorem 1.4.2 gives $\mathbb{E}_d T_s = N\mu = \tau$ and $\mathrm{Var}_d(T_s) = N^2\,\mathrm{Var}_d(\overline{X}_s)$.

(ii) Let $S_l^2 := \frac{1}{N_l-1}\sum_{i=1}^{N_l}(x_{il}-\mu_l)^2$. Then $\mathrm{Var}_d(\overline{X}_l) = \frac{(1-f_l)S_l^2}{n_l}$, $\mathbb{E}_d s_l^2 = S_l^2$, so $S_l^2 \mapsto s_l^2$; $s^2_{\overline{X}_s} = \sum_{l=1}^{L} W_l^2(1-f_l)\frac{s_l^2}{n_l}$.

(iii) With $\frac{\overline{X}_s-\mu}{s_{\overline{X}_s}} \approx \mathcal{N}(0,1)$, inversion gives $\mathrm{CI}_{1-\alpha}(\mu)$; multiplying by N gives $\mathrm{CI}_{1-\alpha}(\tau)$.

Structural Commentary: Totals and intervals scale the stratified mean.
Key Insight: Estimated variance adds weighted stratum variances. □

Theorem 1.4.4. *Neyman Allocation*

Let $L \geq 1$, $W_l > 0$, $\sum_{l=1}^{L} W_l = 1$, $\sigma_l > 0$, $S_\sigma := \sum_{k=1}^{L} W_k\sigma_k$, *and* $n > 0$.

On $\mathcal{A} := \{(n_1,\dots,n_L) \in (0,\infty)^L : \sum_{l=1}^{L} n_l = n\}$, *set* $V(n_1,\dots,n_L) := \sum_{l=1}^{L}\frac{W_l^2\sigma_l^2}{n_l}$.

Then V *has the unique minimiser* $n_l^* := n\frac{W_l\sigma_l}{S_\sigma}$, $l = 1,\dots,L$.

Proof. V is strictly convex on $(0,\infty)^L$ since $\partial_{ll}V = \frac{2W_l^2\sigma_l^2}{n_l^3} > 0$ and $\partial_{lm}V = 0$ for $l \neq m$.

For $\mathcal{L}(n,\lambda) := V(n) + \lambda(\sum_{l=1}^{L} n_l - n)$, the first-order equations are $-\frac{W_l^2\sigma_l^2}{n_l^2} + \lambda = 0$, hence $n_l = \frac{W_l\sigma_l}{\sqrt{\lambda}}$.
The constraint gives $\frac{1}{\sqrt{\lambda}} = \frac{n}{S_\sigma}$, so $n_l = n_l^*$; strict convexity gives uniqueness.
Structural Commentary: The constrained optimum balances marginal variance reduction across strata.
Key Insight: A stratum receives more sample not only when it is large, but also when it is internally variable. □

Corollary 1.4.5. *Allocation Comparisons*

Let $L \geq 1$, $W_l > 0$, $\sum_{l=1}^{L} W_l = 1$, $\mu_l \in \mathbb{R}$, $\sigma_l > 0$, $\mu := \sum_{l=1}^{L} W_l\mu_l$, $\overline{\sigma} := \sum_{l=1}^{L} W_l\sigma_l$, *and* $n > 0$.

Ignoring finite-population corrections, let $\overline{X}_{so}$ *be the optimal-allocation stratified mean,* $\overline{X}_{sp}$ *the proportional-allocation stratified mean with* $n_l = nW_l$, *and* $\overline{X}$ *the ordinary SRS mean.*

(i) Allocation variances: $\mathrm{Var}(\overline{X}_{so}) \approx \frac{\overline{\sigma}^2}{n}$ *and* $\mathrm{Var}(\overline{X}_{sp}) \approx \frac{1}{n}\sum_{l=1}^{L} W_l\sigma_l^2$.

(ii) Optimal-allocation gain: $\mathrm{Var}(\overline{X}_{sp}) - \mathrm{Var}(\overline{X}_{so}) \approx \frac{1}{n}\sum_{l=1}^{L} W_l(\sigma_l-\overline{\sigma})^2$.

(iii) Proportional-allocation gain: $\mathrm{Var}(\overline{X}) - \mathrm{Var}(\overline{X}_{sp}) \approx \frac{1}{n}\sum_{l=1}^{L} W_l(\mu_l-\mu)^2$.

Proof.

(i) With finite-population corrections suppressed, $\mathrm{Var}(\overline{X}_s) \approx \sum_{l=1}^{L}\frac{W_l^2\sigma_l^2}{n_l}$. Neyman allocation gives $n_l = \frac{nW_l\sigma_l}{\overline{\sigma}}$, hence $\mathrm{Var}(\overline{X}_{so}) \approx \frac{\overline{\sigma}^2}{n}$; proportional allocation $n_l = nW_l$ gives $\mathrm{Var}(\overline{X}_{sp}) \approx \frac{1}{n}\sum_{l=1}^{L} W_l\sigma_l^2$.

(ii) Since $\sum_{l=1}^{L} W_l = 1$, $\sum_{l=1}^{L} W_l\sigma_l^2 - \overline{\sigma}^2 = \sum_{l=1}^{L} W_l(\sigma_l-\overline{\sigma})^2$.

(iii) For ordinary SRS, $\mathrm{Var}(\overline{X}) \approx \frac{1}{n}\{\sum_{l=1}^{L} W_l\sigma_l^2 + \sum_{l=1}^{L} W_l(\mu_l-\mu)^2\}$; subtract the proportional-allocation variance.

Structural Commentary: Proportional handles means; optimal also handles spreads.
Key Insight: Mean gaps help stratification; spread gaps help Neyman allocation. □

Example 1.4.6. *Four-Stratum Stratification Summary*
Let $N = 393$ and strata $l \in \{A,B,C,D\}$ have rounded summaries $(N_l) = (98,98,98,99)$, $(W_l) = (.249,.249,.249,.251)$, $(\mu_l) = (182.9, 526.5, 956.3, 1591.2)$, and $(\sigma_l) = (103.4, 204.8, 243.5, 419.2)$. Let n be the total sample size, ignore finite-population corrections, and write $\overline{X}_s$ for the stratified mean.

(i) *Equal allocation*: if $n_l = n/4$, then $\mathrm{Var}(\overline{X}_s) \approx \sum_{l=1}^{4} W_l^2\sigma_l^2/(n/4) \approx 72042.6/n$, so $\mathrm{SE}(\overline{X}_s) \approx 268.4/\sqrt{n}$.

(ii) *SRS benchmark*: with overall standard deviation $\sigma \approx 589.7$, $\mathrm{SE}(\overline{X}) \approx 589.7/\sqrt{n}$.

(iii) *Neyman allocation*: $a_l := \frac{W_l\sigma_l}{\sum_{k=1}^{4} W_k\sigma_k} \approx (.106,.210,.250,.434)$ for (A,B,C,D).

Stratification reduces variance, and Neyman allocation assigns the largest share to the stratum with largest σ_l.

Remark 1.4.7. *Model Limits and Other Designs*
For a finite-population survey:

(i) *Systematic*: fixed-interval sampling after a random start is SRS-like only when list order is noninformative; periodic order can bias selection.

(ii) *Cluster*: sampling groups lowers cost but can inflate variance when within-cluster correlation is positive.

(iii) *Scope*: design-based SEs measure random selection variation, not nonresponse, coverage error, selection bias, interviewer effects, or wording effects.

2 Exploratory Data Analysis and Data Summaries

2.1 Empirical Distribution and Survival Summaries

Exploratory summaries first treat the observed values as a batch of numbers. A stochastic model may later explain their variability, but the displays themselves are useful before a model has been chosen.

Definition 2.1.1. *Empirical CDF and Empirical Survival Function*
Let $x_1, \dots, x_n \in \mathbb{R}$ be data; for survival summaries assume $x_i \geq 0$ for $1 \leq i \leq n$.

(i) *Empirical CDF*: $F_n : \mathbb{R} \to [0,1]$, $F_n(x) := n^{-1}\#\{i \in \{1,\dots,n\} : x_i \leq x\}$.
(ii) *Empirical Survival Function*: $S_n : [0,\infty) \to [0,1]$, $S_n(t) := 1 - F_n(t) = n^{-1}\#\{i \in \{1,\dots,n\} : x_i > t\}$.

Key Insight: F_n and S_n encode complementary empirical tails, with $S_n(t) = 1 - F_n(t)$ for $t \geq 0$.

Remark 2.1.2. *Step-Function Convention*
Let $v_1 < \cdots < v_m$ be the distinct observed values, with multiplicities $r_1, \dots, r_m$. Then F_n is right-continuous, constant on each component of $\mathbb{R} \setminus \{v_1, \dots, v_m\}$, and has jump $\Delta F_n(v_j) = \frac{r_j}{n}$.

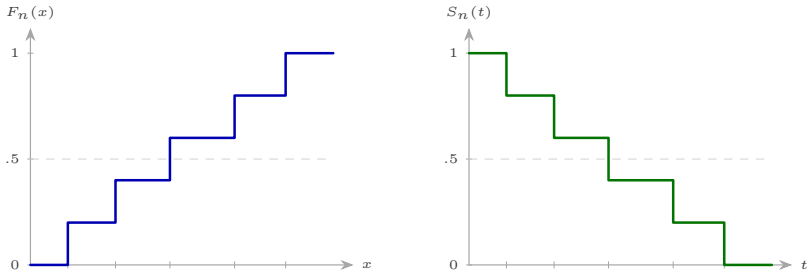

Figure 242: Empirical CDF (blue) rises as empirical survival (green) falls.

Method 2.1.3. *Empirical Log-Survival Plot*
Suppose $0 \leq T_{(1)} < \cdots < T_{(n)}$ and there are no ties. Set $p_i := \frac{i}{n+1}$ and $y_i := \log(1 - p_i)$.

(i) *Plot*: Draw $P^{(n)}_{\log S} := \{(T_{(i)}, y_i) : 1 \leq i \leq n\}$; using $n+1$ keeps y_n finite.
(ii) *Hazard Reading*: Since $(\log S)' = -h$, more negative local slopes indicate larger hazards.
(iii) *Tail Variability*: $\mathrm{Var}(\log[1 - F_n(t)]) \approx n^{-1}\frac{F(t)}{1-F(t)}$, which grows as $F(t) \uparrow 1$.

2.2 Quantile and Shape Displays

Distributional shape can be read from cumulative displays, density displays, or quantile comparisons. These views emphasize different questions: cumulative proportion, local concentration, and relative change between two distributions.

Definition 2.2.1. *Quantile–Quantile Plot*
Let F and G be continuous strictly increasing CDFs with quantile inverses $F^{-1}, G^{-1} : (0,1) \to \mathbb{R}$. For equal-sized batches $x_1, \dots, x_n$ and $y_1, \dots, y_n$, let $x_{(1)} \leq \cdots \leq x_{(n)}$ and $y_{(1)} \leq \cdots \leq y_{(n)}$.

(i) *Q–Q Plot*: $Q_{F,G} := \{(F^{-1}(p), G^{-1}(p)) : 0 < p < 1\} \subseteq \mathbb{R}^2$.
(ii) *Empirical Q–Q Plot*: $Q^{(n)}_{x,y} := \{(x_{(i)}, y_{(i)}) : 1 \leq i \leq n\} \subseteq \mathbb{R}^2$.

Key Insight: $(u, v) \in Q_{F,G}$ implies $F(u) = G(v)$, so plotted pairs match common cumulative probability levels.

Proposition 2.2.2. *Location and Scale Effects in Q–Q Plots*
Let F, G be continuous strictly increasing CDFs.
Set $x_p := F^{-1}(p)$, $y_p := G^{-1}(p)$ for $p \in (0,1)$, and $Q_{F,G} := \{(x_p, y_p) : 0 < p < 1\}$. Then:
(i) Location: If $y_p = x_p + h$ $\forall p \in (0,1)$ with $h \in \mathbb{R}$, then $G(y) = F(y - h)$ $\forall y \in \mathbb{R}$, $Q_{F,G} \subseteq \{(x,y) : y = x + h\}$.
(ii) Scale: If $y_p = cx_p$ $\forall p \in (0,1)$ with $c > 0$, then $G(y) = F(\frac{y}{c})$ $\forall y \in \mathbb{R}$, $Q_{F,G} \subseteq \{(x,y) : y = cx\}$.

Proof.
(i) *Location*: Fix $y \in \mathbb{R}$ and set $p := G(y)$. Then $p \in (0,1)$, $y = y_p = x_p + h$, and $x_p = y - h$, so $G(y) = p = F(x_p) = F(y - h)$. Also $(x_p, y_p) \in Q_{F,G}$ implies $y_p = x_p + h$.
(ii) *Scale*: Fix $y \in \mathbb{R}$ and set $p := G(y)$. Then $p \in (0,1)$, $y = y_p = cx_p$, and $x_p = \frac{y}{c}$, so $G(y) = p = F(x_p) = F(\frac{y}{c})$. Also $(x_p, y_p) \in Q_{F,G}$ implies $y_p = cx_p$.

Structural Commentary: A Q–Q plot is the graph of the quantile transport $F^{-1}(p) \mapsto G^{-1}(p)$.
Key Insight: Straight Q–Q lines encode location shifts and scale changes. □

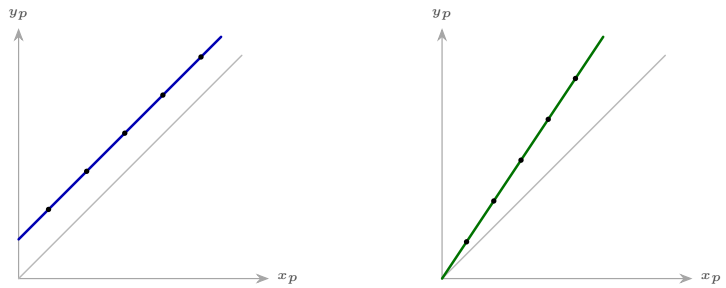

Figure 243: Q–Q lines: blue $y = x + h$ for location shift, green $y = cx$ for scale change.

Example 2.2.3. *Normal and Exponential Q–Q Lines*
For $p \in (0,1)$, set $x_p := F^{-1}(p)$ and $y_p := G^{-1}(p)$.

(i) *Normal Location*: If $F = N(0,1)$ and $G = N(1,1)$, then $y_p = x_p + 1$, so the Q–Q line is $y = x + 1$.
(ii) *Normal Location–Scale*: If $F = N(0,1)$ and $G = N(1,4)$, then $y_p = 1 + 2x_p$, so the Q–Q line is $y = 1 + 2x$.
(iii) *Exponential Rates*: If $F = \text{Exp}(\lambda_1)$ and $G = \text{Exp}(\lambda_2)$, then $x_p = -\frac{\log(1-p)}{\lambda_1}$ and $y_p = -\frac{\log(1-p)}{\lambda_2} = \frac{\lambda_1}{\lambda_2} x_p$, so the Q–Q line is $y = \frac{\lambda_1}{\lambda_2} x$.

Method 2.2.4. *Interpolated Empirical Quantiles*
Let $X_{(1)} \le \cdots \le X_{(n)}$ and set $p_k := \frac{k}{n+1}$ for $1 \le k \le n$.

(i) *Grid*: Assign $X_{(k)}$ to probability p_k.
(ii) *Interpolation*: If $p_k \le p \le p_{k+1}$ for $1 \le k < n$, set $\lambda := \frac{p - p_k}{p_{k+1} - p_k} = (n+1)p - k$, $\widehat{x}_p := (1-\lambda)X_{(k)} + \lambda X_{(k+1)}$.
(iii) *Q–Q Use*: For unequal samples, evaluate both interpolated quantile functions on a common grid $p \in (0,1)$.

Definition 2.2.5. *Histogram, Density Display, and Stem-and-Leaf Plot*
Let $x_1, \ldots, x_n \in \mathbb{R}$ be data. For disjoint intervals $B_1, \ldots, B_m$ with widths $w_j > 0$.
Set $N_j := \#\{i \in \{1, \ldots, n\} : x_i \in B_j\}$. Let K be a kernel, $h > 0$, and $b > 0$ be a chosen scale.

(i) *Histogram*: $H_j^c := N_j$, $H_j^p := \frac{N_j}{n}$, or $H_j^d := \frac{N_j}{n w_j}$ on B_j.
(ii) *Density Display*: $\widehat{f}_h : \mathbb{R} \to [0, \infty)$, $\widehat{f}_h(x) := (nh)^{-1} \sum_{i=1}^{n} K(\frac{x - x_i}{h})$.
(iii) *Stem-and-Leaf Plot*: (s_i, ℓ_i) satisfies $x_i = b s_i + \ell_i$, $s_i \in \mathbb{Z}$, $\ell_i \in [0, b)$.
Entries with common s_i are printed together in increasing s_i.

Structural Commentary: For density-scaled heights $H_j^d = \frac{N_j}{n w_j}$, $\sum_j H_j^d w_j = 1$ when the bins cover the sample. *Key Insight*: Smaller w_j or h retains more local variation; larger w_j or h increases smoothing.

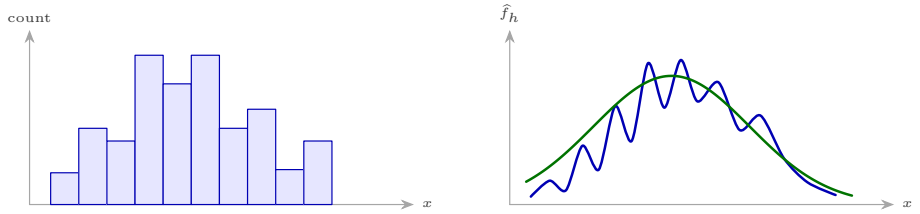

Figure 244: Shape displays: narrow bins at left; small h (blue) is rougher than large h (green).

Remark 2.2.6. *What Shape Displays Preserve*

(i) *ECDF*: Preserves ranks and supports direct quantile reading.
(ii) *Histogram*: Preserves bin counts (N_j), not exact values.
(iii) *Kernel Estimate*: Preserves smoothed local mass; bandwidth h controls resolution.
(iv) *Stem–Leaf*: Preserves coarse shape and recoverable numerical values.

2.3 Location, Scale, and Robust Summaries

Numerical summaries compress a batch more aggressively than a plot. They should therefore be chosen with attention to the feature being summarized and to the influence of extreme observations.

Definition 2.3.1. *Location Summaries for a Batch*
Let $x_1, \ldots, x_n \in \mathbb{R}$ have order statistics $x_{(1)} \le \cdots \le x_{(n)}$.
When a trim fraction is used, let $0 \le \alpha < \frac{1}{2}$ and $m_\alpha := \lfloor n\alpha \rfloor$.

(i) *Arithmetic Mean*: $\overline{x} := n^{-1} \sum_{i=1}^{n} x_i$.
(ii) *Median*: $\widetilde{x} := x_{\left(\frac{n+1}{2}\right)}$ if n is odd, and $\widetilde{x} := \frac{x_{\left(\frac{n}{2}\right)} + x_{\left(\frac{n}{2}+1\right)}}{2}$ if n is even.
(iii) $100\alpha\%$ *Trimmed Mean*: $\overline{x}_\alpha := (n - 2m_\alpha)^{-1} \sum_{i=m_\alpha+1}^{n-m_\alpha} x_{(i)}$.

Structural Commentary: Under $x_i \mapsto x_i + \Delta$, $\overline{x} \mapsto \overline{x} + \frac{\Delta}{n}$; $\widetilde{x}$ and $\overline{x}_\alpha$ depend only on central order statistics.
Key Insight: Extreme magnitudes affect $\overline{x}$ directly, but affect $\widetilde{x}$ and $\overline{x}_\alpha$ mainly through rank changes.

Remark 2.3.2. *Outliers and Center*
Replacing one x_i by M sends $\overline{x}$ to $\overline{x} + \frac{M - x_i}{n}$, hence unbounded as $M \to \pm\infty$.
Once an observation is extreme, moving it farther outward leaves $\widetilde{x}$ unchanged and leaves $\overline{x}_\alpha$ unchanged if it remains trimmed. This is descriptive robustness, not an independence or model.

Remark 2.3.3. *Compare More Than One Center*
Let $\mathcal{C} := \{\overline{x}, \widetilde{x}, \overline{x}_\alpha, \widehat{\mu}_\Psi\}$. For symmetric light-tailed data, range($\mathcal{C}$) is typically small; a large range signals skewness, heavy tails, outliers, or mixture structure.

Definition 2.3.4. *Dispersion Summaries*
Let $x_1, \ldots, x_n \in \mathbb{R}$ have mean $\overline{x}$, median $\widetilde{x}$, and selected sample quartiles Q_1, Q_3.

(i) *Sample Variance*: $s^2 := (n-1)^{-1} \sum_{i=1}^{n} (x_i - \overline{x})^2$.
(ii) *Sample Standard Deviation*: $s := \sqrt{s^2}$.
(iii) *Interquartile Range*: $\mathrm{IQR} := Q_3 - Q_1$.
(iv) *Median Absolute Deviation*: $\mathrm{MAD} := \mathrm{median}\{|x_i - \widetilde{x}| : 1 \le i \le n\}$.

Structural Commentary: s^2 is residual-based; IQR and MAD are order-based.
Key Insight: A single extreme value can dominate s, but not IQR or MAD unless it changes central ranks.

Remark 2.3.5. *Normal Scale Calibrations*
For approximately normal data, $\frac{\mathrm{IQR}}{1.35}$ and $\frac{\mathrm{MAD}}{0.675}$ are common robust scale estimates for the normal standard deviation. The constants calibrate the population normal IQR and median absolute deviation to σ.

2.4 Boxplots, Scatterplots, and Relationship Summaries

Boxplots and scatterplots are compact exploratory displays. A boxplot summarizes one batch or compares several batches; a scatterplot displays relationships between paired variables.

Method 2.4.1. *Boxplot Construction*
A standard boxplot is built from the median, lower quartile Q_1, upper quartile Q_3, and $\mathrm{IQR} = Q_3 - Q_1$:

(i) Draw a box from Q_1 to Q_3 and mark the median inside the box.
(ii) Draw whiskers to the most extreme observations lying within 1.5 IQR of the nearer quartile.
(iii) Mark observations beyond the whiskers individually as possible outliers.

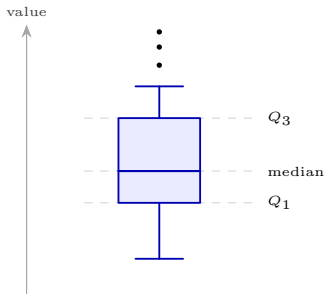

Figure 245: Boxplot: box Q_1 to Q_3, line median, dots possible outliers.

Remark 2.4.2. *Comparing Batches with Boxplots*

(i) *Location*: Differences in medians M_g indicate group shifts.
(ii) *Spread*: Differences in $\mathrm{IQR}_g = Q_{3,g} - Q_{1,g}$ indicate central-spread changes.
(iii) *Tails*: Unequal whiskers or one-sided outliers indicate skewness or tail imbalance.

Definition 2.4.3. *Scatterplot, Pearson Correlation, and Rank Correlation*
Let $(x_i, y_i) \in \mathbb{R}^2$ for $1 \le i \le n$, set $\overline{x} := n^{-1} \sum_{i=1}^{n} x_i$ and $\overline{y} := n^{-1} \sum_{i=1}^{n} y_i$.
Let R_i, S_i be chosen ranks of x_i, y_i, using average ranks for ties.
Set $\overline{R} := n^{-1} \sum_{i=1}^{n} R_i$ and $\overline{S} := n^{-1} \sum_{i=1}^{n} S_i$. Set $a_i := x_i - \overline{x}$, $b_i := y_i - \overline{y}$, $u_i := R_i - \overline{R}$, and $v_i := S_i - \overline{S}$.
Let $S_{xx} := \sum_i a_i^2$, $S_{yy} := \sum_i b_i^2$, $S_{xy} := \sum_i a_i b_i$, $S_{RR} := \sum_i u_i^2$, $S_{SS} := \sum_i v_i^2$, and $S_{RS} := \sum_i u_i v_i$.

(i) *Scatterplot*: $P := \{(x_i, y_i) : 1 \le i \le n\} \subset \mathbb{R}^2$, displayed in the xy-plane.
(ii) *Pearson Correlation Coefficient*: if $S_{xx} S_{yy} > 0$, $r := \frac{S_{xy}}{\sqrt{S_{xx} S_{yy}}}$.
(iii) *Rank Correlation Coefficient*: if $S_{RR} S_{SS} > 0$, $r_{\mathrm{rank}} := \frac{S_{RS}}{\sqrt{S_{RR} S_{SS}}}$.

Structural Commentary: r is affine-scale invariant; r_{rank} is monotone-transform invariant.
Key Insight: r measures linear association; r_{rank} measures rank association.

Method 2.4.4. *Scatterplot Diagnostics*
For paired data $P = \{(x_i, y_i) : 1 \le i \le n\}$:

(i) *Raw Plot*: Inspect P for outliers, curvature, clusters, and nonconstant spread.
(ii) *Transform*: If scale obscures structure, compare $(g(x_i), h(y_i))$ for domain-meaningful g, h such as log.

(iii) *Correlation*: Use r only when the displayed relation is approximately linear.
(iv) *Multiple Variables*: For $z_i \in \mathbb{R}^d$ with $d > 2$, inspect all pairwise plots before relying on pairwise summaries.

Example 2.4.5. *Changing Scale Can Reveal Structure*
If $x_i > 0$ and $\max_i x_i / \min_i x_i \gg 1$, the raw plot $P = \{(x_i, y_i)\}$ may compress variation. The transformed plot $P_{\log} := \{(\log x_i, y_i)\}$ can reveal monotone or linear structure, and generally $r(P_{\log}) \neq r(P)$ because Pearson correlation depends on the chosen coordinates.

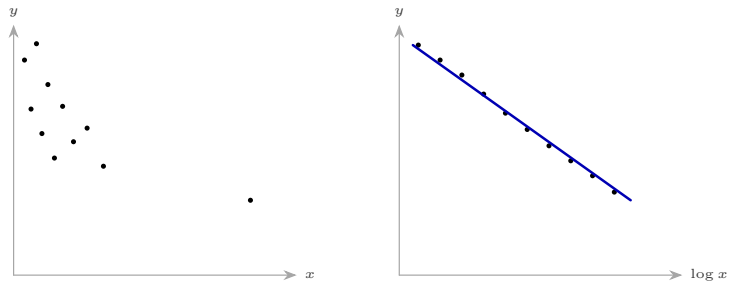

Figure 246: Scatterplots: raw x compresses points; $\log x$ reveals a linear trend.

Remark 2.4.6. *Exploration Before Formal Inference*
Exploratory displays choose the inferential target: transformations $g(X)$, influential subsets, comparable spreads IQR_g, and data-quality checks should be settled before intervals, tests, or models are trusted.

3 Categorical Data Analysis

3.1 Fisher's Exact Test and Fixed Margins

Categorical data record counts in classes rather than measurements on a continuous scale. In a two-way table, the rows and columns encode two classifications, and the cells record how many units fall in each cross-classification. The probability model is therefore built from multinomial and hypergeometric count laws rather than from normal sampling pivots.

Definition 3.1.1. *Two-Way Contingency Table*
Let $I, J \in \mathbb{N}$ and $n_{ij} \in \mathbb{N}_0$ for $1 \le i \le I$, $1 \le j \le J$. Set $n_{i\cdot} := \sum_{j=1}^{J} n_{ij}$, $n_{\cdot j} := \sum_{i=1}^{I} n_{ij}$, and $n_{\cdot\cdot} := \sum_{i=1}^{I}\sum_{j=1}^{J} n_{ij}$.
For corresponding random counts, write N_{ij} and use capitalized totals.
(i) *Two-way contingency table*: $(n_{ij})_{1\le i\le I,\ 1\le j\le J}$, indexed by row and column classifications.
(ii) *Margins*: $\{n_{i\cdot} : 1 \le i \le I\}$, $\{n_{\cdot j} : 1 \le j \le J\}$, and $n_{\cdot\cdot}$.
Structural Commentary: Fixed-margin exact tests condition on the margins of random table $N = (N_{ij})$.

Method 3.1.2. *Fisher's Exact Test for a 2×2 Table*
Let a 2×2 table have fixed margins

	1	2	Total
1	N_{11}	N_{12}	$n_{1\cdot}$
2	N_{21}	N_{22}	$n_{2\cdot}$
Total	$n_{\cdot 1}$	$n_{\cdot 2}$	$n_{\cdot\cdot}$

Let R_1, R_2 be fixed disjoint row sets with $|R_i| = n_{i\cdot}$.
Let C be the random column-1 set with $|C| = n_{\cdot 1}$, and set $\Omega_0 := \{A \subseteq R_1 \cup R_2 : |A| = n_{\cdot 1}\}$.
(i) $H_0 : \mathbb{P}_0(C = A) = \binom{n_{\cdot\cdot}}{n_{\cdot 1}}^{-1}$ $\forall A \in \Omega_0$.
(ii) $N_{11} = |C \cap R_1|$, $N_{12} = n_{1\cdot} - N_{11}$, $N_{21} = n_{\cdot 1} - N_{11}$, and $N_{22} = n_{2\cdot} - n_{\cdot 1} + N_{11}$.
(iii) $\mathcal{S} := \{x \in \mathbb{Z} : 0 \le x \le n_{1\cdot},\ 0 \le n_{\cdot 1} - x \le n_{2\cdot}\}$ and $p_0(x) := \mathbb{P}_0(N_{11} = x) = \dfrac{\binom{n_{1\cdot}}{x}\binom{n_{2\cdot}}{n_{\cdot 1}-x}}{\binom{n_{\cdot\cdot}}{n_{\cdot 1}}}$, $x \in \mathcal{S}$.
(iv) $p_+(x_{\mathrm{obs}}) := \sum_{x\in\mathcal{S}:x\ge x_{\mathrm{obs}}} p_0(x)$, $p_-(x_{\mathrm{obs}}) := \sum_{x\in\mathcal{S}:x\le x_{\mathrm{obs}}} p_0(x)$, and $p_2(x_{\mathrm{obs}}) := \sum_{x\in\mathcal{S}:p_0(x)\le p_0(x_{\mathrm{obs}})} p_0(x)$.
Reject when the selected value is $\le \alpha$.

Example 3.1.3. *Promotion Decisions and Fixed Margins*
In randomised label experiment with 24 male-labeled,24 female-labeled files, the observed table is

	Male	Female	Total
Promote	21	14	35
Hold file	3	10	13
Total	24	24	48

Under H_0 and fixed margins $(35, 13)$, $(24, 24)$, N_{11} satisfies $\mathbb{P}_0(N_{11} = x) = \dfrac{\binom{35}{x}\binom{13}{24-x}}{\binom{48}{24}}$, $x \in \mathcal{S} := \{11, \dots, 24\}$.
At level 0.05, $R^{(2)}_{0.05} := \{11, 12, 13, 14, 21, 22, 23, 24\}$; since $x_{\mathrm{obs}} = 21 \in R^{(2)}_{0.05}$, reject H_0.

Remark 3.1.4. *What Is Exact Here*
For $N = (N_{ij})$ and $\mathcal{M} := (\{N_{i\cdot}\}_i, \{N_{\cdot j}\}_j)$, exactness means evaluating $\mathcal{L}_0(N \mid \mathcal{M})$ without asymptotics. Conditioning is design-justified when $\mathcal{M}$ is ancillary to H_0; rejection interpretation is design-dependent.

3.2 Chi-Square Tests for Contingency Tables

For an $I \times J$ table with observed counts n_{ij} and fitted null counts E_{ij}, use $X^2 := \sum_{i=1}^{I} \sum_{j=1}^{J} (n_{ij} - E_{ij})^2 / E_{ij}$; in contingency tables, E_{ij} is determined by the row-column null model.

Definition 3.2.1. *Homogeneity of Multinomial Distributions*

Let $I, J \in \mathbb{N}$, $[K] := \{1, \dots, K\}$, and $\Delta_{I-1} := \{\pi \in [0,1]^I : \sum_{i=1}^{I} \pi_i = 1\}$.

For independent columns $j \in [J]$, let $(N_{1j}, \dots, N_{Ij}) \sim \text{Multinomial}(n_{\cdot j}; \pi_{1j}, \dots, \pi_{Ij})$ with observed counts n_{ij}.
The column multinomial laws are *homogeneous* iff $H_0 : \exists \pi \in \Delta_{I-1}$ with $\pi_{ij} = \pi_i \ \forall (i,j) \in [I] \times [J]$; under H_0, π_i is the common category probability.

Proposition 3.2.2. *Common Probability MLE Under Homogeneity*

Let $I, J \in \mathbb{N}$, $[K] := \{1, \dots, K\}$, $\Delta_{I-1} := \{\pi \in [0,1]^I : \sum_{i=1}^{I} \pi_i = 1\}$, and $N_{\cdot j} := (N_{1j}, \dots, N_{Ij})$, independently for $j \in [J]$. Under H_0, $N_{\cdot j} \sim \text{Multinomial}(n_{\cdot j}; \pi)$ for a common $\pi \in \Delta_{I-1}$.

With observed counts n_{ij}, set $n_{i\cdot} := \sum_{j=1}^{J} n_{ij}$ and $n_{\cdot\cdot} := \sum_{i=1}^{I} n_{i\cdot} > 0$.

Then $\widehat{\pi}_i = \frac{n_{i\cdot}}{n_{\cdot\cdot}}$ and $E_{ij} = n_{\cdot j} \widehat{\pi}_i = \frac{n_{i\cdot} n_{\cdot j}}{n_{\cdot\cdot}}$ for $(i,j) \in [I] \times [J]$.

Proof. Up to factors independent of π, $L(\pi) \propto \prod_{j=1}^{J} \prod_{i=1}^{I} \pi_i^{n_{ij}} = \prod_{i=1}^{I} \pi_i^{n_{i\cdot}}$, hence $\ell(\pi) = \sum_{i=1}^{I} n_{i\cdot} \log \pi_i$ on Δ_{I-1}.

Stationarity of $\ell(\pi) + \lambda(1 - \sum_{i=1}^{I} \pi_i)$ gives $\frac{n_{i\cdot}}{\pi_i} - \lambda = 0$ when $n_{i\cdot} > 0$ and $\widehat{\pi}_i = 0$ when $n_{i\cdot} = 0$,
Normalisation gives $\lambda = n_{\cdot\cdot}$ and $\widehat{\pi}_i = \frac{n_{i\cdot}}{n_{\cdot\cdot}}$. Therefore $E_{ij} = \mathbb{E}_{\widehat{\pi}} N_{ij} = n_{\cdot j} \widehat{\pi}_i$.
Structural Commentary: H_0 reduces IJ cell probabilities to one shared $\pi \in \Delta_{I-1}$.
Key Insight: $\widehat{\pi}$ is the pooled row proportion, and E_{ij} redistributes each column total by $\widehat{\pi}_i$. □

Definition 3.2.3. *Homogeneity Fitted Counts*
Let $I, J \in \mathbb{N}$, $[K] := \{1, \dots, K\}$, and let $n_{ij} \in \mathbb{N}_0$ for $(i,j) \in [I] \times [J]$.
Set $n_{i\cdot} := \sum_{j=1}^{J} n_{ij}$, $n_{\cdot j} := \sum_{i=1}^{I} n_{ij}$, $n_{\cdot\cdot} := \sum_{i=1}^{I} \sum_{j=1}^{J} n_{ij} > 0$, and $\widehat{\pi}_i := \frac{n_{i\cdot}}{n_{\cdot\cdot}}$.
The homogeneity *fitted counts* are $E_{ij} := n_{\cdot j} \widehat{\pi}_i = \frac{n_{i\cdot} n_{\cdot j}}{n_{\cdot\cdot}}$ for $(i,j) \in [I] \times [J]$.

Method 3.2.4. *Pearson Test of Homogeneity*
Let $I, J \in \mathbb{N}$, $[K] := \{1, \dots, K\}$, and let $n_{ij} \in \mathbb{N}_0$ for $(i,j) \in [I] \times [J]$.
Set $n_{i\cdot} := \sum_{j=1}^{J} n_{ij}$, $n_{\cdot j} := \sum_{i=1}^{I} n_{ij}$, $n_{\cdot\cdot} := \sum_{i=1}^{I} \sum_{j=1}^{J} n_{ij} > 0$, and $E_{ij} := \frac{n_{i\cdot} n_{\cdot j}}{n_{\cdot\cdot}}$. Assume $E_{ij} > 0$ for cells used.

(i) *Statistic*: $X^2 := \sum_{i=1}^{I} \sum_{j=1}^{J} \frac{(n_{ij} - E_{ij})^2}{E_{ij}}$.

(ii) *Calibration*: If $n_{\cdot\cdot}$ large, $\min_{i,j} E_{ij}$ not small, then $X^2 \overset{H_0}{\approx} \chi^2_\nu$; $\nu := J(I-1) - (I-1) = (I-1)(J-1)$.
(iii) *Decision*: Reject H_0 at level α when $\mathbb{P}\{\chi^2_{(I-1)(J-1)} \geq X^2_{\text{obs}}\} \leq \alpha$.

Example 3.2.5. *Word Counts by Text Group*
Let $W = \{a, an, this, that, with, without\}$, let $G_1, \dots, G_4$ be text groups. Observed word-count table n_{wj} is

Word	G_1	G_2	G_3	G_4
a	147	186	101	83
an	25	26	11	29
this	32	39	15	15
that	94	105	37	22
with	59	74	28	43
without	18	10	10	4
Total	375	440	202	196

For $C_A := \{1, 2, 3\}$, by homogeneity test: $X^2_A = 12.27$, $\nu_A = (6-1)(3-1) = 10$, $p_A = \mathbb{P}\{\chi^2_{10} \geq 12.27\} \approx 0.27$.
Pooling C_A and comparing it with $C_B := \{4\}$ gives $X^2_{A,B} = 32.81$, $\nu_{A,B} = 6 - 1 = 5$, and $p_{A,B} < 0.001$.
$w \in \{an, that\}$ gives the largest Pearson contributions, localising nonhomogeneity by row.

Definition 3.2.6. *Independence in a Contingency Table*
Let $I, J \in \mathbb{N}$, $[K] := \{1, \dots, K\}$, and $N = (N_{ij}) \sim \text{Multinomial}(n; (\pi_{ij})_{[I] \times [J]})$ with $n > 0$, observed counts n_{ij}.
Set $\pi_{i\cdot} := \sum_{j=1}^{J} \pi_{ij}$, $\pi_{\cdot j} := \sum_{i=1}^{I} \pi_{ij}$, $n_{i\cdot} := \sum_{j=1}^{J} n_{ij}$, and $n_{\cdot j} := \sum_{i=1}^{I} n_{ij}$.
Rows and columns are *independent* iff $H_0 : \pi_{ij} = \pi_{i\cdot} \pi_{\cdot j} \ \forall (i,j) \in [I] \times [J]$; then $\widehat{\pi}_{ij} := \frac{n_{i\cdot} n_{\cdot j}}{n^2}$ and $E_{ij} := \frac{n_{i\cdot} n_{\cdot j}}{n}$.

Method 3.2.7. *Pearson Test of Independence*
Let $I, J \in \mathbb{N}$, $[K] := \{1, \dots, K\}$, and let $n_{ij} \in \mathbb{N}_0$ for $(i,j) \in [I] \times [J]$.
Set $n := \sum_{i=1}^{I} \sum_{j=1}^{J} n_{ij} > 0$, $n_{i\cdot} := \sum_{j=1}^{J} n_{ij}$, $n_{\cdot j} := \sum_{i=1}^{I} n_{ij}$, and $E_{ij} := \frac{n_{i\cdot} n_{\cdot j}}{n}$. Assume $E_{ij} > 0$ for cells used.

(i) *Statistic*: $X^2 := \sum_{i=1}^{I} \sum_{j=1}^{J} \frac{(n_{ij} - E_{ij})^2}{E_{ij}}$.

(ii) *Calibration*: If n is large and $\min_{i,j} E_{ij}$ is not small, then $X^2 \overset{H_0}{\approx} \chi^2_\nu$ with $\nu := (I-1)(J-1)$.
(iii) *Decision*: Reject H_0 at level α when $\mathbb{P}\{\chi^2_\nu \geq X^2_{\text{obs}}\} \leq \alpha$.

(iv) *Degrees of Freedom*: $\nu = (IJ-1) - ((I-1)+(J-1)) = (I-1)(J-1)$.

Example 3.2.8. *Binary Classifications*
Let $n = 1436$, $[n] := \{1, \dots, n\}$, and $(A_k, B_k) \in \{a_1, a_2\} \times \{b_1, b_2\}$ for $k \in [n]$.
Set $n_{ij} := \#\{k \in [n] : A_k = a_i,\ B_k = b_j\}$ and $E_{ij} := \frac{n_{i\cdot} n_{\cdot j}}{n}$. The observed and independence-fitted tables are

n_{ij}

$a_i \backslash b_j$	b_1	b_2	Total
a_1	550	61	611
a_2	681	144	825
Total	1231	205	1436

E_{ij}

$a_i \backslash b_j$	b_1	b_2
a_1	523.8	87.2
a_2	707.2	117.8

Under $H_0 : A \perp B$, $X^2 = \sum_{i=1}^{2} \sum_{j=1}^{2} \frac{(n_{ij} - E_{ij})^2}{E_{ij}} = 16.01$, $\nu = 1$, and $p < 0.001$; reject H_0.
Thus $A \not\perp B$; absent randomised A, inference is associative, not causal.

Remark 3.2.9. *Homogeneity Versus Independence*
Both tests use $E_{ij} = \frac{n_{i\cdot} n_{\cdot j}}{n_{\cdot\cdot}}$, $X^2 = \sum_{i=1}^{I} \sum_{j=1}^{J} \frac{(n_{ij} - E_{ij})^2}{E_{ij}}$, and $\nu = (I-1)(J-1)$.

(i) *Homogeneity*: $N_{\cdot j} \sim \text{Multinomial}(n_{\cdot j}; \pi_{\cdot j})$ independently for $j \in [J]$, with fixed $n_{\cdot j}$, $H_0 : \pi_{\cdot 1} = \cdots = \pi_{\cdot J}$.
(ii) *Independence*: $N \sim \text{Multinomial}(n_{\cdot\cdot}; (\pi_{ij})_{[I]\times[J]})$ with $H_0 : \pi_{ij} = \pi_{i\cdot}\pi_{\cdot j}\ \forall (i,j) \in [I] \times [J]$.

If $\pi_{\cdot j} > 0$, then independence iff $\pi_{i|j} := \frac{\pi_{ij}}{\pi_{\cdot j}} = \pi_{i\cdot}\ \forall (i,j) \in [I] \times [J]$.

Method 3.2.10. *Likelihood-Ratio Version*
Let $I, J \in \mathbb{N}$, $[K] := \{1, \dots, K\}$, and let $n_{ij} \in \mathbb{N}_0$ with null fitted counts E_{ij} for $(i,j) \in [I] \times [J]$.
Set $n_{\cdot\cdot} := \sum_{i=1}^{I} \sum_{j=1}^{J} n_{ij} > 0$ and $\nu := (I-1)(J-1)$.
Let H_0 be the homogeneity or independence null producing E_{ij}, and assume $E_{ij} > 0$ whenever $n_{ij} > 0$.

(i) *Statistic*: $G^2 := 2 \sum_{i=1}^{I} \sum_{j=1}^{J} n_{ij} \log\left(\frac{n_{ij}}{E_{ij}}\right)$.
(ii) *Zero Counts*: $n_{ij} = 0$ contributes 0 to G^2.
(iii) *Calibration*: Under the large-sample likelihood-ratio conditions of Theorem 3.1.8, $G^2 \overset{H_0}{\approx} \chi^2_\nu$.
(iv) *Decision*: Reject H_0 at level α when $\mathbb{P}\{\chi^2_\nu \geq G^2_{\text{obs}}\} \leq \alpha$.

3.3 Matched Pairs and McNemar's Test

Matched categorical data require a different table from unmatched samples. The pair, not the individual measurement, is the independent sampling unit.

Definition 3.3.1. *Matched Binary Pair Table*
Let $(Y_k^{(1)}, Y_k^{(2)}) \in \{0,1\}^2$ for $k \in [n]$, and set $R_k := Y_k^{(1)} + 1$, $S_k := Y_k^{(2)} + 1$.
For $(r,s) \in \{1,2\}^2$, set $n_{rs} := \#\{k \in [n] : (R_k, S_k) = (r,s)\}$, so $n = \sum_{r=1}^{2} \sum_{s=1}^{2} n_{rs}$.

(i) *Matched Binary Pair Table*: $N := (n_{rs})_{(r,s)\in\{1,2\}^2}$.
(ii) *Concordant Cells*: $C := \{(r,s) \in \{1,2\}^2 : r = s\} = \{(1,1),(2,2)\}$; counts $(n_{rs})_{(r,s)\in C} = (n_{11}, n_{22})$.
(iii) *Discordant Cells*: $D := \{(r,s) \in \{1,2\}^2 : r \neq s\} = \{(1,2),(2,1)\}$; counts $(n_{rs})_{(r,s)\in D} = (n_{12}, n_{21})$.
Key Insight: (n_{12}, n_{21}) determines marginal change; (n_{11}, n_{22}) records agreement.

Definition 3.3.2. *Marginal Homogeneity for Matched Pairs*
Let $\pi = (\pi_{rs})_{(r,s)\in\{1,2\}^2} \in [0,1]^4$ satisfy $\sum_{r=1}^{2} \sum_{s=1}^{2} \pi_{rs} = 1$. Set $\pi_{r\cdot} := \sum_{s=1}^{2} \pi_{rs}$ and $\pi_{\cdot s} := \sum_{r=1}^{2} \pi_{rs}$.
The matched-pair law is *marginally homogeneous* iff $H_0 : (\pi_{1\cdot}, \pi_{2\cdot}) = (\pi_{\cdot 1}, \pi_{\cdot 2})$, equivalently $\pi_{12} = \pi_{21}$.
Key Insight: H_0 constrains only the discordant probabilities π_{12}, π_{21}.

Method 3.3.3. *McNemar's Test*
Let $n_{rs} \in \mathbb{N}_0$ and cell probabilities π_{rs} for $(r,s) \in \{1,2\}^2$, with $n := \sum_{r=1}^{2} \sum_{s=1}^{2} n_{rs} > 0$. Set $d := n_{12} + n_{21}$.

(i) *Null*: $H_0 : \pi_{12} = \pi_{21}$.
(ii) *MLE Under H_0*: $\widehat{\pi}_{11} = \frac{n_{11}}{n}$, $\widehat{\pi}_{22} = \frac{n_{22}}{n}$, and $\widehat{\pi}_{12} = \widehat{\pi}_{21} = \frac{d}{2n}$.
(iii) *Statistic*: If $d > 0$, $X^2 := \frac{(n_{12} - n_{21})^2}{d}$.
(iv) *Calibration*: If d is large, then $X^2 \overset{H_0}{\approx} \chi^2_1$.
(v) *Decision*: Reject H_0 at level α when $\mathbb{P}\{\chi^2_1 \geq X^2_{\text{obs}}\} \leq \alpha$.

Example 3.3.4. *Matched Case-Control Pairs*
In a matched case-control study, 85 cases were each paired with one control, and a binary exposure was recorded for both members of each pair.

	Control	
Case	Unexposed	Exposed
Unexposed	37	7
Exposed	15	26

An unmatched chi-square test treats cases and controls as independent samples.
McNemar's test uses only discordant pairs; here $X^2 = (7-15)^2/(7+15) = 2.91$ and $p \approx 0.09$, so accounting for the matching weakens the evidence of an exposure difference.

Example 3.3.5. *Matched Case-Crossover Exposure*
In a matched case-crossover study, each subject is observed during an event window and a comparable control window, with a binary exposure recorded in both windows.

Event window	Control window		
	Exposed	Unexposed	Total
Exposed	13	157	170
Unexposed	24	505	529
Total	37	662	699

The discordant counts are 157 and 24, so $X^2 = (157-24)^2/(157+24) = 97.7$, giving strong evidence that exposure prevalence differs between the two windows. This does not by itself establish causation, since time-varying covariates may affect both exposure and event risk.

Remark 3.3.6. *Matched Does Not Mean Independent*
McNemar's null hypothesis is marginal homogeneity, not independence of paired responses. Thus the analysis must preserve the matching structure rather than treat the two margins as independent samples.

3.4 Odds Ratios and Case-Control Sampling

Odds ratios summarize association in a binary exposure–binary outcome table. They are especially useful because the same cross-product ratio can be estimated under several sampling designs, including retrospective case-control designs where risks themselves cannot be estimated.

Definition 3.4.1. *Odds and Odds Ratio*
Let A satisfy $0 < \mathbb{P}(A) < 1$.
Let X and D be binary exposure and disease events with $0 < \mathbb{P}(X) < 1$ and $0 < \mathbb{P}(D \mid X), \mathbb{P}(D \mid \overline{X}) < 1$.

(i) *Odds*: $\operatorname{odds}(A) := \frac{\mathbb{P}(A)}{1-\mathbb{P}(A)}$.
(ii) *Odds ratio*: $\Delta := \frac{\operatorname{odds}(D|X)}{\operatorname{odds}(D|\overline{X})}$.

Structural Commentary: If $o = \operatorname{odds}(A)$, then $\mathbb{P}(A) = \frac{o}{1+o}$; $p \mapsto p/(1-p)$ is a bijection $(0,1) \to (0,\infty)$.

Proposition 3.4.2. *Cross-Product Formula*
Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space, let $X, D \in \mathcal{F}$, and set $X_0 := \overline{X}$, $X_1 := X$, $D_0 := \overline{D}$, $D_1 := D$.
Let $\pi_{ij} := \mathbb{P}(X_i \cap D_j) > 0$ for $i, j \in \{0,1\}$, with margins $\pi_{i\cdot} := \pi_{i0} + \pi_{i1}$ and $\pi_{\cdot j} := \pi_{0j} + \pi_{1j}$.

	$\overline{D}$	D	
$\overline{X}$	π_{00}	π_{01}	$\pi_{0\cdot}$
X	π_{10}	π_{11}	$\pi_{1\cdot}$
	$\pi_{\cdot 0}$	$\pi_{\cdot 1}$	1

With $\Delta := \frac{\operatorname{odds}(D|X)}{\operatorname{odds}(D|\overline{X})}$, the cross-product identity is $\Delta = \frac{\pi_{11}\pi_{00}}{\pi_{01}\pi_{10}}$.

Proof. Since $\pi_{1\cdot} = \pi_{10} + \pi_{11}$ and $\pi_{0\cdot} = \pi_{00} + \pi_{01}$, $\mathbb{P}(D \mid X) = \frac{\pi_{11}}{\pi_{1\cdot}}$ and $1 - \mathbb{P}(D \mid X) = \frac{\pi_{10}}{\pi_{1\cdot}}$, so $\operatorname{odds}(D \mid X) = \frac{\pi_{11}}{\pi_{10}}$.
Similarly, $\operatorname{odds}(D \mid \overline{X}) = \frac{\pi_{01}}{\pi_{00}}$. Hence $\Delta = \frac{\frac{\pi_{11}}{\pi_{10}}}{\frac{\pi_{01}}{\pi_{00}}} = \frac{\pi_{11}\pi_{00}}{\pi_{01}\pi_{10}}$.
Structural Commentary: $\pi_{1\cdot}, \pi_{0\cdot}$ enter conditional probabilities but cancel after passage to odds.
Key Insight: Δ equals diagonal product $\pi_{11}\pi_{00}$ divided by off-diagonal product $\pi_{01}\pi_{10}$. □

Method 3.4.3. *Estimating an Odds Ratio by Design*
Let $N = (n_{ij})_{i,j\in\{0,1\}}$ be a 2×2 table for (X_i, D_j), where $X_1 := X$, $X_0 := \overline{X}$, $D_1 := D$, and $D_0 := \overline{D}$.
Assume $n_{ij} > 0$, set $n_{i\cdot} := n_{i0} + n_{i1}$, $n_{\cdot j} := n_{0j} + n_{1j}$, $n := \sum_{i=0}^{1}\sum_{j=0}^{1} n_{ij}$.

(i) *Simple Random Sampling*: $\widehat{\pi}_{ij} := \frac{n_{ij}}{n}$ estimates π_{ij}; hence $\widehat{\Delta} := \frac{n_{00}n_{11}}{n_{01}n_{10}}$ estimates Δ.
(ii) *Prospective Sampling*: $n_{0\cdot}, n_{1\cdot}$ fixed; $\frac{n_{01}}{n_{0\cdot}}$, $\frac{n_{11}}{n_{1\cdot}}$ estimate $\mathbb{P}(D \mid \overline{X})$, $\mathbb{P}(D \mid X)$; $\mathbb{P}(X)$ not identified.
(iii) *Retrospective Case-Control Sampling*: $n_{\cdot 0}, n_{\cdot 1}$ are fixed; disease risks are not identified, but $\widehat{\Delta} = \frac{n_{11}}{n_{01}} / \frac{n_{10}}{n_{00}}$ is estimable from exposure odds.

Key Insight: Design-fixed margins cancel in $\widehat{\Delta}$, so odds ratio is estimable even when risks or margins are not.

Example 3.4.4. *Unmatched Case-Control Odds Ratio*
Consider an unmatched case-control table with binary exposure:

	Exposed	Unexposed
Case	67	34
Control	43	64

The estimated odds ratio is $\widehat{\Delta} = \frac{67\cdot 64}{43\cdot 34)} = 2.93$, indicating a positive exposure–disease association.

Method 3.4.5. *Parametric Bootstrap for an Odds-Ratio Standard Error*
Let $a, b, c, d \in \mathbb{N}$ denote the observed counts in rows $D, \overline{D}$ and columns $X, \overline{X}$: $a := n_{DX}$, $b := n_{D\overline{X}}$, $c := n_{\overline{D}X}$, and $d := n_{\overline{D}\overline{X}}$. Set $m_D := a + b$, $m_{\overline{D}} := c + d$, $\widehat{p}_D := \frac{a}{m_D}$, $\widehat{p}_{\overline{D}} := \frac{c}{m_{\overline{D}}}$, and $\widehat{\Delta} := \frac{ad}{bc}$.

(i) *Bootstrap Law*: For $r \in [R]$, draw independently $A_r^* \sim \operatorname{Binomial}(m_D, \widehat{p}_D)$ and $C_r^* \sim \operatorname{Binomial}(m_{\overline{D}}, \widehat{p}_{\overline{D}})$.
(ii) *Replicate*: If $0 < A_r^* < m_D$ and $0 < C_r^* < m_{\overline{D}}$, set $\widehat{\Delta}_r^* := \frac{A_r^*(m_{\overline{D}} - C_r^*)}{(m_D - A_r^*)C_r^*}$.
(iii) *Standard Error*: With $\overline{\Delta}^* := \frac{1}{R}\sum_{r=1}^{R}\widehat{\Delta}_r^*$, set $\widehat{\operatorname{se}}_*(\widehat{\Delta}) := \left(\frac{1}{R-1}\sum_{r=1}^{R}(\widehat{\Delta}_r^* - \overline{\Delta}^*)^2\right)^{1/2}$.

Key Insight: Resample exposure counts conditional on fixed row totals; $\operatorname{sd}\{(\widehat{\Delta}_r^*)_{r\in[R]}\}$ estimates $\operatorname{se}(\widehat{\Delta})$.

Remark 3.4.6. *Odds Ratios Are Not Automatically Risks*
The odds ratio $\Delta = \text{odds}(D \mid X)/\text{odds}(D \mid \overline{X})$ differs from risk contrasts such as $\mathbb{P}(D \mid X) - \mathbb{P}(D \mid \overline{X})$.
In retrospective sampling, $n_{\cdot 0}, n_{\cdot 1}$ are design-fixed, absolute risks are not identified without population margins; Δ remains estimable because those margins cancel in the cross-product ratio.

3.5 Higher-Order Tables and Sampling Design

Two-way tables are the simplest categorical-data structure. Higher-order tables introduce several possible notions of dependence: full independence, conditional independence given a third factor, marginal homogeneity, and interactions among factors.

Definition 3.5.1. *Two-Way Log-Linear Form*
Let $I, J \in \mathbb{N}$ and let $\pi_{ij} > 0$ be two-way cell probabilities for $1 \le i \le I$, $1 \le j \le J$,
with $\pi_{i\cdot} := \sum_{j=1}^{J} \pi_{ij}$, $\pi_{\cdot j} := \sum_{i=1}^{I} \pi_{ij}$, $\alpha_i := \log \pi_{i\cdot}$, and $\beta_j := \log \pi_{\cdot j}$.

(i) *Independence form*: $\pi_{ij} = \pi_{i\cdot}\pi_{\cdot j}$ $\forall 1 \le i \le I$, $1 \le j \le J \iff \log \pi_{ij} = \alpha_i + \beta_j$ $\forall 1 \le i \le I$, $1 \le j \le J$.
(ii) *Interaction terms*: $\gamma_{ij} := \log \pi_{ij} - \alpha_i - \beta_j$, giving $\log \pi_{ij} = \alpha_i + \beta_j + \gamma_{ij}$.

Key Insight: $\gamma_{ij} = 0$ $\forall 1 \le i \le I$, $1 \le j \le J \iff \pi_{ij} = \pi_{i\cdot}\pi_{\cdot j}$ $\forall 1 \le i \le I$, $1 \le j \le J$.

Remark 3.5.2. *Three-Way Interactions*
Let $\pi_{ijk} > 0$ for $(i, j, k) \in [I] \times [J] \times [K]$. A log-linear model with all two-factor interactions and no three-factor interaction is $\log \pi_{ijk} = \mu + \alpha_i + \beta_j + \eta_k + \delta_{ij} + \varepsilon_{ik} + \gamma_{jk}$.
The absent term λ_{ijk} encodes the constraint of no third-order interaction; nested models are compared by deleting interaction terms and using the corresponding loss of degrees of freedom.

Example 3.5.3. *Graduate Admissions and Aggregation*
In the Berkeley admissions example, the aggregate admission rate for men was higher than for women.
Within the six listed majors, however, women were not consistently admitted at lower rates.
The apparent aggregate disadvantage was driven by application patterns: women applied more often to majors with lower admission rates. Major was therefore confounded with sex in the observational comparison.

Principle 3.5.4. *Choose the Test from the Sampling Mechanism*
For a contingency table $N = (n_{ij})$, let $n_{i\cdot}$ and $n_{\cdot j}$ denote row and column margins.
Select the test from the design-fixed quantities:

(i) *Fixed Margins*: If $(n_{i\cdot})$ and $(n_{\cdot j})$ are fixed in a 2×2 table, use Fisher's exact test.
(ii) *Independent Samples*: If rows are independent multinomial samples with fixed $(n_{i\cdot})$, test homogeneity of column probabilities.
(iii) *Single Multinomial Sample*: If $N \sim \text{Multinomial}(n, (\pi_{ij}))$, test independence, i.e. $\pi_{ij} = \pi_{i\cdot}\pi_{\cdot j}$.
(iv) *Matched Pairs*: If observations are paired counts n_{rs}, test marginal homogeneity using discordant cells.
(v) *Case-Control Sampling*: If $(n_{\cdot 0}, n_{\cdot 1})$ are fixed by disease status, estimate odds ratios. Absolute risks require population margins.

Key Insight: The same numeric table can encode different null hypotheses under different sampling laws.

Remark 3.5.5. *Use Counts, Not Percentages*
Let $Q(O, E) := \sum_i \frac{(O_i - E_i)^2}{E_i}$. Pearson's chi-square calibration applies to counts: $Q(O/n, E/n) = \frac{1}{n} Q(O, E)$ and $Q(100O/n, 100E/n) = \frac{100}{n} Q(O, E)$. Thus relative frequencies or percentages give a rescaled statistic unless the original count scale is restored.

4 Analysis of Variance and Designed Experiments

4.1 One-Way Layouts and the F Test

Analysis of variance compares several mean levels by splitting total variation into variation within treatment groups and variation between treatment groups. The method is a multisample continuation of the equal-variance two-sample procedure, with design and randomisation assumptions kept explicit.

Definition 4.1.1. *Balanced One-Way Layout*
For $I, J \in \mathbb{N}$, one factor has levels $i = 1, \dots, I$, each with exactly J independent replicates Y_{ij}, $j = 1, \dots, J$.
The normal fixed-effects model satisfies $Y_{ij} = \mu + \alpha_i + \varepsilon_{ij}$, $\sum_{i=1}^{I} \alpha_i = 0$, and independent errors $\varepsilon_{ij} \sim N(0, \sigma^2)$.

Structural Commentary: $\mathbb{E}Y_{ij} = \mu + \alpha_i$, and $\sum_{i=1}^{I} \alpha_i = 0$ identifies μ as the average treatment mean.

Key Insight: $H_0 : \alpha_i = 0$ $\forall i$ iff all treatment means are equal.

Definition 4.1.2. *One-Way Sums of Squares*
For a balanced one-way layout, set $\overline{Y}_{i\cdot} := \frac{1}{J} \sum_{j=1}^{J} Y_{ij}$ and $\overline{Y}_{\cdot\cdot} := \frac{1}{IJ} \sum_{i=1}^{I} \sum_{j=1}^{J} Y_{ij}$.

(i) *Total*: $SS_{\text{tot}} := \sum_{i=1}^{I} \sum_{j=1}^{J} (Y_{ij} - \overline{Y}_{\cdot\cdot})^2$; grand-mean dispersion.
(ii) *Within-treatment*: $SS_W := \sum_{i=1}^{I} \sum_{j=1}^{J} (Y_{ij} - \overline{Y}_{i\cdot})^2$; residual dispersion within treatments.
(iii) *Between-treatment*: $SS_B := J \sum_{i=1}^{I} (\overline{Y}_{i\cdot} - \overline{Y}_{\cdot\cdot})^2$; treatment-mean dispersion scaled by J.

Key Insight: $SS_{\text{tot}} = SS_W + SS_B$ separates within-treatment noise from between-treatment mean differences.

Proposition 4.1.3. *One-Way Sum-of-Squares Decomposition*
For $I, J \in \mathbb{N}$ and observations Y_{ij}, set $\overline{Y}_{i\cdot} := \frac{1}{J}\sum_j Y_{ij}$, $\overline{Y}_{\cdot\cdot} := \frac{1}{IJ}\sum_i\sum_j Y_{ij}$,

$SS_{\text{tot}} := \sum_i\sum_j (Y_{ij} - \overline{Y}_{\cdot\cdot})^2$, $SS_W := \sum_i\sum_j (Y_{ij} - \overline{Y}_{i\cdot})^2$, and $SS_B := J\sum_i (\overline{Y}_{i\cdot} - \overline{Y}_{\cdot\cdot})^2$. Then $SS_{\text{tot}} = SS_W + SS_B$.

Proof. Set $r_{ij} := Y_{ij} - \overline{Y}_{i\cdot}$ and $b_i := \overline{Y}_{i\cdot} - \overline{Y}_{\cdot\cdot}$. Then $Y_{ij} - \overline{Y}_{\cdot\cdot} = r_{ij} + b_i$ and $\sum_j r_{ij} = 0\ \forall i$.

Thus $SS_{\text{tot}} = \sum_i\sum_j (r_{ij} + b_i)^2 = \sum_i\sum_j r_{ij}^2 + 2\sum_i b_i \sum_j r_{ij} + J\sum_i b_i^2 = SS_W + SS_B$.

Structural Commentary: $Y_{ij} - \overline{Y}_{\cdot\cdot} = r_{ij} + b_i$, where $r_{ij} := Y_{ij} - \overline{Y}_{i\cdot}$ and $b_i := \overline{Y}_{i\cdot} - \overline{Y}_{\cdot\cdot}$.
Key Insight: $\sum_j r_{ij} = 0\ \forall i$ annihilates the cross term $2\sum_i b_i \sum_j r_{ij}$. □

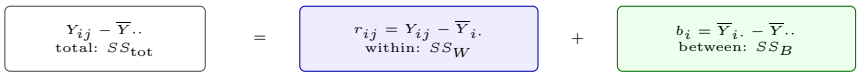

Figure 247: Squaring and summing gives $SS_{\text{tot}} = SS_W + SS_B$; large MS_B/MS_W suggests treatment effects.

Theorem 4.1.4. *Expected One-Way Sums of Squares*
For $I, J \in \mathbb{N}$, let $Y_{ij} = \mu + \alpha_i + \varepsilon_{ij}$, $1 \le i \le I$, $1 \le j \le J$, with $\sum_i \alpha_i = 0$, independent errors satisfying

$\mathbb{E}\varepsilon_{ij} = 0$, $\mathrm{Var}(\varepsilon_{ij}) = \sigma^2$. Set $\overline{Y}_{i\cdot} := \frac{1}{J}\sum_j Y_{ij}$, $\overline{Y}_{\cdot\cdot} := \frac{1}{IJ}\sum_i\sum_j Y_{ij}$.

Then $SS_W := \sum_i\sum_j (Y_{ij} - \overline{Y}_{i\cdot})^2$, $SS_B := J\sum_i (\overline{Y}_{i\cdot} - \overline{Y}_{\cdot\cdot})^2$; $\mathbb{E}(SS_W) = I(J-1)\sigma^2$

and $\mathbb{E}(SS_B) = (I-1)\sigma^2 + J\sum_i \alpha_i^2$. Hence $S_p^2 := \frac{SS_W}{I(J-1)}$ satisfies $\mathbb{E}S_p^2 = \sigma^2$.

Proof. For fixed i, Lemma 3.2.8 with $\mu_{ij} = \mu + \alpha_i$ gives $\mathbb{E}\sum_j (Y_{ij} - \overline{Y}_{i\cdot})^2 = (J-1)\sigma^2$, hence $\mathbb{E}SS_W = I(J-1)\sigma^2$.

For $\overline{Y}_{i\cdot}$, $\mathbb{E}\overline{Y}_{i\cdot} = \mu + \alpha_i$, $\mathrm{Var}(\overline{Y}_{i\cdot}) = \frac{\sigma^2}{J}$, and $\frac{1}{I}\sum_i (\mu + \alpha_i) = \mu$. By Lemma 3.2.8, $(\overline{Y}_{i\cdot})_{i=1}^I$ gives

$\mathbb{E}\sum_i (\overline{Y}_{i\cdot} - \overline{Y}_{\cdot\cdot})^2 = \sum_i \alpha_i^2 + \frac{I-1}{J}\sigma^2$, so $\mathbb{E}SS_B = J\sum_i \alpha_i^2 + (I-1)\sigma^2$. Thus $\mathbb{E}S_p^2 = \frac{\mathbb{E}SS_W}{I(J-1)} = \sigma^2$.
Structural Commentary: $\mathbb{E}SS_W$ depends only on σ^2; $\mathbb{E}SS_B$ adds $J\sum_i \alpha_i^2$.
Key Insight: Under $\alpha_i = 0\ \forall i$, $\mathbb{E}\{\frac{SS_B}{I-1}\} = \mathbb{E}\{\frac{SS_W}{I(J-1)}\} = \sigma^2$. □

Theorem 4.1.5. *Normal-Theory One-Way F Test*
For $I, J \in \mathbb{N}$, let $Y_{ij} = \mu + \alpha_i + \varepsilon_{ij}$, $1 \le i \le I$, $1 \le j \le J$, with $\sum_i \alpha_i = 0$ and independent errors $\varepsilon_{ij} \sim N(0, \sigma^2)$.

Set $\overline{Y}_{i\cdot} := \frac{1}{J}\sum_j Y_{ij}$, $\overline{Y}_{\cdot\cdot} := \frac{1}{IJ}\sum_i\sum_j Y_{ij}$, $SS_W := \sum_i\sum_j (Y_{ij} - \overline{Y}_{i\cdot})^2$, $SS_B := J\sum_i (\overline{Y}_{i\cdot} - \overline{Y}_{\cdot\cdot})^2$.
$MS_W := \frac{SS_W}{I(J-1)}$, $MS_B := \frac{SS_B}{I-1}$; $\frac{SS_W}{\sigma^2} \sim \chi^2_{I(J-1)}$.
If $H_0 : \alpha_i = 0\ \forall i$, then $\frac{SS_B}{\sigma^2} \sim \chi^2_{I-1}$, $SS_B \perp\!\!\!\perp SS_W$, $F := \frac{MS_B}{MS_W} \sim F_{I-1, I(J-1)}$.

Proof. Let $C_m := \mathrm{Id}_m - m^{-1}\mathbf{1}_m\mathbf{1}_m^\top$, so $C_m^2 = C_m = C_m^\top$ and $\mathrm{rank}\, C_m = m - 1$.
For each i, $Z_i := \frac{1}{\sigma}(Y_{i1} - \mu - \alpha_i, \ldots, Y_{iJ} - \mu - \alpha_i)^\top \sim N_J(0, \mathrm{Id}_J)$ independently,
$\frac{1}{\sigma^2}\sum_j (Y_{ij} - \overline{Y}_{i\cdot})^2 = Z_i^\top C_J Z_i \sim \chi^2_{J-1}$. Summing over independent treatments gives $\frac{SS_W}{\sigma^2} \sim \chi^2_{I(J-1)}$.
Under H_0, $\widetilde{Z} := \sqrt{J}\sigma^{-1}(\overline{Y}_{1\cdot} - \mu, \ldots, \overline{Y}_{I\cdot} - \mu)^\top \sim N_I(0, \mathrm{Id}_I)$, and $\frac{SS_B}{\sigma^2} = \widetilde{Z}^\top C_I \widetilde{Z} \sim \chi^2_{I-1}$.
For each i, $C_J Z_i \perp\!\!\!\perp \mathbf{1}_J^\top Z_i$ by orthogonal normal components.
Hence $SS_W \perp\!\!\!\perp (\overline{Y}_{1\cdot}, \ldots, \overline{Y}_{I\cdot})$ and $SS_W \perp\!\!\!\perp SS_B$. Thus $F = \frac{SS_B}{I-1} / \frac{SS_W}{I(J-1)} = \frac{MS_B}{MS_W} \sim F_{I-1, I(J-1)}$.
Structural Commentary: $IJ = 1 + I(J-1) + (I-1)$ partitions df into mean, residual, and contrast subspaces.
Key Insight: Under H_0, MS_B and MS_W are independent σ^2 estimators, so $\frac{MS_B}{MS_W}$ has an F law. □

Example 4.1.6. *Generic Balanced One-Way ANOVA*
Let $I = 7$, $J = 10$, and $Y_{ij} = \mu_i + \varepsilon_{ij}$ with independent errors $\varepsilon_{ij} \sim N(0, \sigma^2)$. Suppose the ANOVA table is

Component	*df*	*SS*	*MS*	*F*
Treatment	6	.125	.021	5.66
Error	63	.231	.0037	
Total	69	.356		

Then $F = 5.66$ has null law $F_{6,63}$, $p = \mathbb{P}(F_{6,63} \ge 5.66) < .01$, and $H_0 : \mu_1 = \cdots = \mu_7$ is rejected at level .01.
If diagnostics are adequate, between-treatment variation exceeds within-treatment noise.

Method 4.1.7. *Unequal Sample Sizes*

For $I \in \mathbb{N}$, treatment i has observations Y_{ij}, $1 \le j \le J_i$, with $J_i \in \mathbb{N}$ and $N := \sum_{i=1}^I J_i$.

(i) $\overline{Y}_{i\cdot} := \frac{1}{J_i}\sum_{j=1}^{J_i} Y_{ij}$ and $\overline{Y}_{\cdot\cdot} := \frac{1}{N}\sum_{i=1}^I\sum_{j=1}^{J_i} Y_{ij}$.

(ii) $SS_W := \sum_{i=1}^I\sum_{j=1}^{J_i} (Y_{ij} - \overline{Y}_{i\cdot})^2$, $SS_B := \sum_{i=1}^I J_i(\overline{Y}_{i\cdot} - \overline{Y}_{\cdot\cdot})^2$, $SS_{\text{tot}} := \sum_{i=1}^I\sum_{j=1}^{J_i} (Y_{ij} - \overline{Y}_{\cdot\cdot})^2$
satisfy $SS_{\text{tot}} = SS_W + SS_B$.

(iii) $\mathrm{df}_W = N - I$ and $\mathrm{df}_B = I - 1$.

(iv) If $Y_{ij} = \mu_i + \varepsilon_{ij}$ with independent $\varepsilon_{ij} \sim N(0, \sigma^2)$ and $H_0 : \mu_1 = \cdots = \mu_I$, then $F := \frac{\frac{SS_B}{I-1}}{\frac{SS_W}{N-I}} \sim F_{I-1,N-I}$.

Corollary 4.1.8. *Two Treatments Give $F = t^2$*
Let $X_1, \ldots, X_n$ and $Y_1, \ldots, Y_m$ be independent normal samples with common variance, means $\overline{X}, \overline{Y}$, pooled variance $S_p^2 := \frac{SS_W}{n+m-2}$, and $t := \frac{\overline{X}-\overline{Y}}{S_p\sqrt{n^{-1}+m^{-1}}}$. The one-way ANOVA statistic for the two groups satisfies $F = t^2$.

Proof. Let $N := n + m$ and $\overline{Z} := \frac{n\overline{X}+m\overline{Y}}{N}$. Then $SS_B = n(\overline{X} - \overline{Z})^2 + m(\overline{Y} - \overline{Z})^2 = \frac{nm}{N}(\overline{X} - \overline{Y})^2$.
Since $df_B = 1$ and $MS_W = \frac{SS_W}{N-2} = S_p^2$, $F = \frac{SS_B}{MS_W} = \frac{(\overline{X}-\overline{Y})^2}{S_p^2(n^{-1}+m^{-1})} = t^2$.
Structural Commentary: Two groups leave one between-group contrast.
Key Insight: ANOVA squares the pooled t contrast. □

The same one-way decomposition also supports a random-effects interpretation, where groups are sampled from a population of possible group levels rather than fixed in advance.

Definition 4.1.9. *Balanced One-Way Random Effects Model*
A *balanced one-way random-effects model* has I groups and common replication J, with $Y_{ij} = \mu + A_i + \varepsilon_{ij}$ for $1 \le i \le I$, $1 \le j \le J$, independent A_i satisfying $\mathbb{E}A_i = 0$ and $\mathrm{Var}(A_i) = \sigma_A^2$, and independent errors ε_{ij} independent of (A_i) with $\mathbb{E}\varepsilon_{ij} = 0$ and $\mathrm{Var}(\varepsilon_{ij}) = \sigma_\varepsilon^2$.
Structural Commentary: $\mathrm{Var}(Y_{ij}) = \sigma_A^2 + \sigma_\varepsilon^2$, and $\mathrm{Cov}(Y_{ij}, Y_{ij'}) = \sigma_A^2$ for $j \ne j'$ within the same group.

Proposition 4.1.10. *Random-Effects Expected Mean Squares*
Assume $Y_{ij} = \mu + A_i + \varepsilon_{ij}$ for $1 \le i \le I$, $1 \le j \le J$, with independent A_i and ε_{ij}, $\mathbb{E}A_i = \mathbb{E}\varepsilon_{ij} = 0$, $\mathrm{Var}(A_i) = \sigma_A^2$, and $\mathrm{Var}(\varepsilon_{ij}) = \sigma_\varepsilon^2$. Then $\mathbb{E}(MS_W) = \sigma_\varepsilon^2$ and $\mathbb{E}(MS_B) = \sigma_\varepsilon^2 + J\sigma_A^2$.
The method-of-moments estimators are $\widehat{\sigma}_\varepsilon^2 = MS_W$ and $\widehat{\sigma}_A^2 = \frac{MS_B - MS_W}{J}$, truncated at 0 if required.

Proof. Condition on (A_i). Since $Y_{ij} - \overline{Y}_{i\cdot} = \varepsilon_{ij} - \overline{\varepsilon}_{i\cdot}$, $\mathbb{E}(SS_W \mid A) = I(J-1)\sigma_\varepsilon^2$, hence $\mathbb{E}(MS_W) = \sigma_\varepsilon^2$.
Also $\overline{Y}_{i\cdot} = \mu + A_i + \overline{\varepsilon}_{i\cdot}$ has variance $\sigma_A^2 + \frac{\sigma_\varepsilon^2}{J}$.
Hence the one-way between mean square satisfies $\mathbb{E}(MS_B) = J\,\mathrm{Var}(\overline{Y}_{i\cdot}) = \sigma_\varepsilon^2 + J\sigma_A^2$.
Solving these two moment equations gives the estimators.
Structural Commentary: Within estimates error; between adds group heterogeneity.
Key Insight: The excess $MS_B - MS_W$ estimates $J\sigma_A^2$. □

Example 4.1.11. *Dye Strength Batch Variation*
Suppose $I = 6$ batches each have $J = 6$ subsamples, with $\overline{y}_{\cdot\cdot} = 93.61$
and batch means $(92.00, 90.50, 91.25, 98.25, 91.17, 98.50)$.
Given $SS_B = 415.47$ and $SS_W = 134.08$, the mean squares are $MS_B = 83.09$ and $MS_W = 4.47$.
The moment estimates are $\widehat{\sigma}_\varepsilon^2 = MS_W = 4.47$ and $\widehat{\sigma}_A^2 = \frac{MS_B - MS_W}{6} = 13.10$.
Batch variation dominates measurement-error variation.

Remark 4.1.12. *Assumptions and Robustness*
For $Y_{ij} = \mu_i + \varepsilon_{ij}$, the one-way F calibration assumes independent $\varepsilon_{ij} \sim N(0, \sigma^2)$. Balance softens variance heterogeneity; clustered, paired, blocked, or repeated data require dependence modeling.

4.2 Multiple Comparisons After ANOVA

The one-way F test assesses $H_0 : \mu_1 = \cdots = \mu_I$; after rejection, inference targets contrasts $\mu_a - \mu_b$ with error control over the chosen comparison family.

Definition 4.2.1. *Studentized Range Quantile*
Let $Q_{I,\nu}$ denote a random variable with the studentized range distribution for I treatment means and ν error degrees of freedom. The *studentized range quantile* is $q_{I,\nu}(\alpha) := \inf\{q \in \mathbb{R} : \mathbb{P}(Q_{I,\nu} > q) \le \alpha\}$.
Structural Commentary: Balanced Tukey comparisons use pooled scale S_p.

Method 4.2.2. *Tukey Pairwise Comparisons*
In a balanced normal one-way layout, let $\mathcal{P} := \{(a,b) : 1 \le a < b \le I\}$, $\nu := I(J-1)$, and $h_\alpha := q_{I,\nu}(\alpha)S_p/\sqrt{J}$.

(i) For $(a,b) \in \mathcal{P}$, the simultaneous $100(1-\alpha)\%$ confidence interval for $\mu_a - \mu_b$ is $(\overline{Y}_{a\cdot} - \overline{Y}_{b\cdot}) \pm h_\alpha$.
(ii) Reject $H_{0,ab} : \mu_a = \mu_b$ iff $\left|\overline{Y}_{a\cdot} - \overline{Y}_{b\cdot}\right| > h_\alpha$.

Simultaneity over $\mathcal{P}$ uses the studentized range cutoff.

Example 4.2.3. *Generic Tukey Pairwise Calculation*
Consider a balanced one-way layout with $I = 7$, $J = 10$, $S_p = .06$, and ordered sample means
$(\overline{Y}_{1\cdot}, \overline{Y}_{3\cdot}, \overline{Y}_{7\cdot}, \overline{Y}_{2\cdot}, \overline{Y}_{5\cdot}, \overline{Y}_{6\cdot}, \overline{Y}_{4\cdot}) = (4.062, 4.003, 3.998, 3.997, 3.957, 3.955, 3.920)$.
With $q_{7,60}(.05) = 4.31$, the Tukey half-width is $h_{.05} = 4.31(.06)/\sqrt{10} \approx .082$.
Rejected pairs at simultaneous level .05 are $(1,4), (1,5), (1,6), (3,4)$; remaining pairwise nulls not rejected.

Method 4.2.4. *Bonferroni Pairwise Comparisons*
Let $\mathcal{C} \subseteq \{(a,b) : 1 \le a < b \le I\}$ be the planned pairwise family with $|\mathcal{C}| = k$.
Set $\nu := N - I$ and $h_{ab} := t_{\nu,1-\alpha/(2k)}S_p\sqrt{1/J_a + 1/J_b}$.

(i) For $(a,b) \in \mathcal{C}$, the Bonferroni confidence interval for $\mu_a - \mu_b$ is $(\overline{Y}_{a\cdot} - \overline{Y}_{b\cdot}) \pm h_{ab}$.
(ii) Reject $H_{0,ab} : \mu_a = \mu_b$ iff $\left|\overline{Y}_{a\cdot} - \overline{Y}_{b\cdot}\right| > h_{ab}$.

The family satisfies FWER $\le \alpha$ and allows unequal treatment sizes through J_a, J_b.

Example 4.2.5. *Generic Bonferroni Pairwise Calculation*
For $I = 7$ treatments and $k = \binom{7}{2} = 21$ planned pairwise comparisons at $\alpha = .05$, take $t_{60,1-.05/(2\cdot 21)} \approx 3.16$.
The resulting simultaneous 95% Bonferroni half-width is $h \approx .085$.
Rejected pairwise nulls are $(1,4), (1,5), (1,6)$; all other planned pairwise nulls are not rejected.

Remark 4.2.6. *The Global Test Does Not Name the Difference*
Rejecting $H_0 : \mu_1 = \cdots = \mu_I$ establishes only $\exists\, a < b$ with $\mu_a \neq \mu_b$.
It does not identify such pairs or provide simultaneous sign guarantees.
Select Tukey, Bonferroni, or planned-contrast procedures according to the preassigned comparison family.

4.3 Rank-Based One-Way ANOVA

When normality or outlier sensitivity is a concern, a one-way comparison can be made after replacing observations by pooled ranks.

Definition 4.3.1. *Kruskal–Wallis Ranks*
Let $\mathcal{Y} := \{Y_{ij} : 1 \le i \le I, 1 \le j \le J_i\}$ be an unequal-size one-way sample with $N := \sum_{i=1}^{I} J_i$.
Assign increasing pooled ranks to $\mathcal{Y}$, averaging ranks over ties.

(i) *Pooled rank*: $R_{ij} := \mathrm{rank}_{\mathrm{pool}}(Y_{ij})$.

(ii) *Treatment mean rank*: $\overline{R}_{i\cdot} := \frac{1}{J_i} \sum_{j=1}^{J_i} R_{ij}$.

(iii) *Grand mean rank*: $\overline{R}_{\cdot\cdot} := \frac{N+1}{2}$.

Method 4.3.2. *Kruskal–Wallis Test*
Let $SS_B^{(R)} := \sum_{i=1}^{I} J_i(\overline{R}_{i\cdot} - \overline{R}_{\cdot\cdot})^2$ and $K := \frac{12}{N(N+1)} SS_B^{(R)} = \frac{12}{N(N+1)} \sum_{i=1}^{I} J_i \overline{R}_{i\cdot}^2 - 3(N+1)$.

(i) The exact null law enumerates all allocations of pooled ranks to group sizes $J_1, \ldots, J_I$.

(ii) For moderate samples, $K \overset{H_0}{\approx} \chi^2_{I-1}$.

(iii) Reject $H_0 : F_1 = \cdots = F_I$ at level α when $\mathbb{P}\{\chi^2_{I-1} \ge K_{\mathrm{obs}}\} \le \alpha$.

Example 4.3.3. *Generic Kruskal–Wallis Rank Calculation*
For $I = 7$ groups, suppose the pooled ranks give $K_{\mathrm{obs}} = 29.51$.
Using $K \overset{H_0}{\approx} \chi^2_6$, the tail probability satisfies $\mathbb{P}\{\chi^2_6 \ge 29.51\} < .005$.
Reject $H_0 : F_1 = \cdots = F_7$; the group response distributions are not all equal.

Corollary 4.3.4. *Two Groups Recover Mann–Whitney*
For $I = 2$, let $T_i := \sum_{j=1}^{J_i} R_{ij}$ and $N = J_1 + J_2$. Then $K = \frac{12}{J_1 J_2 (N+1)} \left(T_1 - \frac{J_1(N+1)}{2}\right)^2$, so the Kruskal–Wallis rejection order is the two-sided Mann–Whitney rank-sum order.

Proof. Let $G := \frac{N+1}{2}$. Since $T_1 + T_2 = NG$, $\overline{R}_{1\cdot} - G = \frac{T_1 - J_1 G}{J_1}$ and $\overline{R}_{2\cdot} - G = -\frac{T_1 - J_1 G}{J_2}$.
Hence $SS_B^{(R)} = (T_1 - J_1 G)^2 (\frac{1}{J_1} + \frac{1}{J_2}) = \frac{N(T_1 - J_1 G)^2}{J_1 J_2}$, and the formula for K follows.
Since $U_1 = T_1 - \frac{J_1(J_1+1)}{2}$ is affine in T_1, both tests order evidence by $|T_1 - J_1 G|$.
Structural Commentary: Two groups leave one rank contrast.
Key Insight: K is a squared centered rank sum. □

Method 4.3.5. *Rank-Based Follow-Up Comparisons*
After rejecting global rank null, let $\mathcal{C} \subseteq \{(a,b) : 1 \le a < b \le I\}$ be planned follow-up family with $|\mathcal{C}| = k$.

(i) For $(a,b) \in \mathcal{C}$, test $H_{0,ab} : F_a = F_b$ by a two-sample rank-sum statistic and let p_{ab} be its two-sided p-value.

(ii) Reject $H_{0,ab}$ iff $p_{ab} \le \frac{\alpha}{k}$, equivalently $k p_{ab} \le \alpha$.

(iii) The selected family satisfies FWER $\le \alpha$ and is most efficient when $\mathcal{C}$ is fixed before inspection.

Remark 4.3.6. *What Rank ANOVA Tests*
The null is $H_0 : F_1 = \cdots = F_I$, not merely $\mu_1 = \cdots = \mu_I$. Under comparable distributional shapes, rejection is read as a location difference; the rank form avoids normality and reduces sensitivity to extremes.

4.4 Two-Way Layouts and Interaction

A two-way layout studies two factors at once. It estimates main effects for each factor and checks whether the effect of one factor changes across levels of the other.

Definition 4.4.1. *Two-Way Additive Parametrization*
For one observation Y_{ij} at factor levels $i = 1, \ldots, I$ and $j = 1, \ldots, J$,
set $\overline{Y}_{i\cdot} := J^{-1} \sum_{j=1}^{J} Y_{ij}$, $\overline{Y}_{\cdot j} := I^{-1} \sum_{i=1}^{I} Y_{ij}$, and $\overline{Y}_{\cdot\cdot} := (IJ)^{-1} \sum_{i=1}^{I} \sum_{j=1}^{J} Y_{ij}$.

(i) *Intercept*: $\widehat{\mu} := \overline{Y}_{\cdot\cdot}$.

(ii) *Factor A, B coefficient*: $\widehat{\alpha}_i := \overline{Y}_{i\cdot} - \overline{Y}_{\cdot\cdot}$, $1 \le i \le I$ and $\widehat{\beta}_j := \overline{Y}_{\cdot j} - \overline{Y}_{\cdot\cdot}$, $1 \le j \le J$.

(iii) *Additive fitted value*: $\widehat{Y}_{ij} := \widehat{\mu} + \widehat{\alpha}_i + \widehat{\beta}_j$.

(iv) *Interaction residual*: $\widehat{\delta}_{ij} := Y_{ij} - \overline{Y}_{i\cdot} - \overline{Y}_{\cdot j} + \overline{Y}_{\cdot\cdot}$, so $Y_{ij} = \widehat{\mu} + \widehat{\alpha}_i + \widehat{\beta}_j + \widehat{\delta}_{ij}$.

Structural Commentary: Exact fits satisfy zero-sum effects and margins: $\sum_i \widehat{\alpha}_i = \sum_j \widehat{\beta}_j = \sum_i \widehat{\delta}_{ij} = \sum_j \widehat{\delta}_{ij} = 0$.

Remark 4.4.2. *Interaction and Parallel Profiles*
Under additivity, $\widehat{Y}_{ij} - \widehat{Y}_{i'j} = \widehat{\alpha}_i - \widehat{\alpha}_{i'}$ is independent of j, so factor-A profiles are parallel across B. Nonparallel profiles indicate $\delta_{ij} \neq 0$ structure: the contrast between factor levels depends on the conditioning level.

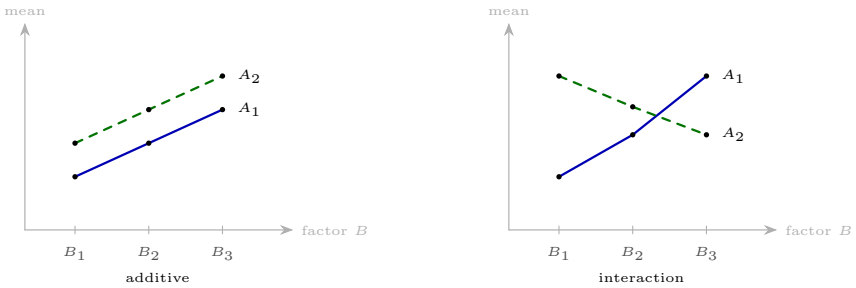

Figure 248: Parallel profiles indicate additivity; changing gaps indicate interaction.

Definition 4.4.3. *Balanced Two-Way Normal Model*
A *balanced two-way normal fixed-effects model* observes Y_{ijk} for $1 \le i \le I$, $1 \le j \le J$, $1 \le k \le K$, with common cell size $K > 1$, and assumes $Y_{ijk} = \mu + \alpha_i + \beta_j + \delta_{ij} + \varepsilon_{ijk}$ for mutually independent $\varepsilon_{ijk} \sim N(0, \sigma^2)$,
under $\sum_i \alpha_i = \sum_j \beta_j = 0$, $\sum_i \delta_{ij} = 0\ \forall j$, and $\sum_j \delta_{ij} = 0\ \forall i$.
Key Insight: $\delta_{ij} = 0\ \forall (i,j)$ iff the cell means are additive in the two factors.

Definition 4.4.4. *Two-Way Sums of Squares*
Let Y_{ijk} be balanced observations for $1 \le i \le I$, $1 \le j \le J$, $1 \le k \le K$.

(i) *Means*: $\overline{Y}_{ij\cdot} := \frac{1}{K}\sum_k Y_{ijk}$, $\overline{Y}_{i\cdot\cdot} := \frac{1}{JK}\sum_j\sum_k Y_{ijk}$, $\overline{Y}_{\cdot j\cdot} := \frac{1}{IK}\sum_i\sum_k Y_{ijk}$, $\overline{Y}_{\cdots} := \frac{1}{IJK}\sum_i\sum_j\sum_k Y_{ijk}$.

(ii) *Between-cell components*: $SS_A := JK\sum_i(\overline{Y}_{i\cdot\cdot} - \overline{Y}_{\cdots})^2$, $SS_B := IK\sum_j(\overline{Y}_{\cdot j\cdot} - \overline{Y}_{\cdots})^2$,
and $SS_{AB} := K\sum_i\sum_j(\overline{Y}_{ij\cdot} - \overline{Y}_{i\cdot\cdot} - \overline{Y}_{\cdot j\cdot} + \overline{Y}_{\cdots})^2$.

(iii) *Within-cell and total*: $SS_E := \sum_i\sum_j\sum_k(Y_{ijk} - \overline{Y}_{ij\cdot})^2$, $SS_{\text{tot}} := \sum_i\sum_j\sum_k(Y_{ijk} - \overline{Y}_{\cdots})^2$,
and $SS_{\text{tot}} = SS_A + SS_B + SS_{AB} + SS_E$.

Structural Commentary: Orthogonal projections split total variation.

Theorem 4.4.5. *Expected Two-Way Sums of Squares*
Assume $Y_{ijk} = \mu + \alpha_i + \beta_j + \delta_{ij} + \varepsilon_{ijk}$ with independent $\varepsilon_{ijk} \sim N(0,\sigma^2)$,
and $\sum_i \alpha_i = \sum_j \beta_j = 0$, $\sum_i \delta_{ij} = 0\ \forall j$; $\sum_j \delta_{ij} = 0\ \forall i$.

(i) $\mathbb{E}(SS_A) = (I-1)\sigma^2 + JK\sum_i \alpha_i^2$.

(ii) $\mathbb{E}(SS_B) = (J-1)\sigma^2 + IK\sum_j \beta_j^2$.

(iii) $\mathbb{E}(SS_{AB}) = (I-1)(J-1)\sigma^2 + K\sum_i\sum_j \delta_{ij}^2$.

(iv) $\mathbb{E}(SS_E) = IJ(K-1)\sigma^2$.

Proof. Let $Y = m + \varepsilon \in \mathbb{R}^{IJK}$ with $m_{ijk} = \mu + \alpha_i + \beta_j + \delta_{ij}$ and $\varepsilon \sim N(0, \sigma^2 I_{IJK})$.
For an orthogonal projection P, $\mathbb{E}\,\|PY\|^2 = \|Pm\|^2 + \sigma^2 \operatorname{rank} P$.

(i) $P_A m$ has value α_i repeated over j,k, so $\|P_A m\|^2 = JK\sum_i \alpha_i^2$ and $\operatorname{rank} P_A = I - 1$.

(ii) $P_B m$ has value β_j repeated over i,k, so $\|P_B m\|^2 = IK\sum_j \beta_j^2$ and $\operatorname{rank} P_B = J - 1$.

(iii) $P_{AB} m$ has value δ_{ij} repeated over k, so $\|P_{AB} m\|^2 = K\sum_i\sum_j \delta_{ij}^2$ and $\operatorname{rank} P_{AB} = (I-1)(J-1)$.

(iv) P_E centers within cells; since m_{ijk} is constant in k for fixed (i,j), $P_E m = 0$ and $\operatorname{rank} P_E = IJ(K-1)$.

Applying the projection identity to P_A, P_B, P_{AB}, P_E gives the four expectations.
Structural Commentary: Balanced orthogonality separates noise degrees of freedom from effect energy.
Key Insight: Each expectation is σ^2 times rank plus squared signal norm. □

Theorem 4.4.6. *Two-Way Normal-Theory F Tests*
Assume observations Y_{ijk} for $1 \le i \le I$, $1 \le j \le J$, $1 \le k \le K$ satisfy $Y_{ijk} = \mu + \alpha_i + \beta_j + \delta_{ij} + \varepsilon_{ijk}$
with independent $\varepsilon_{ijk} \sim N(0,\sigma^2)$, $\sum_i \alpha_i = \sum_j \beta_j = 0$, $\sum_i \delta_{ij} = 0\ \forall j$, and $\sum_j \delta_{ij} = 0\ \forall i$.
Let $d_E := IJ(K-1)$ and $MS_E := \frac{SS_E}{d_E}$.

(i) $SS_A, SS_B, SS_{AB}, SS_E$ are independent, and $\frac{SS_E}{\sigma^2} \sim \chi^2_{d_E}$.

(ii) Under $H_A : \alpha_i = 0\ \forall i$, $\frac{SS_A}{\sigma^2} \sim \chi^2_{I-1}$; under $H_B : \beta_j = 0\ \forall j$, $\frac{SS_B}{\sigma^2} \sim \chi^2_{J-1}$;
under $H_{AB} : \delta_{ij} = 0\ \forall (i,j)$, $\frac{SS_{AB}}{\sigma^2} \sim \chi^2_{(I-1)(J-1)}$.

(iii) $F_A := \frac{\frac{SS_A}{I-1}}{MS_E} \sim F_{I-1,d_E}$ under H_A, $F_B := \frac{\frac{SS_B}{J-1}}{MS_E} \sim F_{J-1,d_E}$ under H_B,
and $F_{AB} := \frac{\frac{SS_{AB}}{(I-1)(J-1)}}{MS_E} \sim F_{(I-1)(J-1),d_E}$ under H_{AB}.

Proof.

(i) Vectorise $Y = m + \varepsilon \in \mathbb{R}^{IJK}$ with $\varepsilon \sim N(0, \sigma^2 I_{IJK})$.
Let P_A, P_B, P_{AB}, P_E be the mutually orthogonal projections onto the factor-A, factor-B, interaction, and within-cell subspaces, so $SS_R = \|P_R Y\|^2$ for $R \in \{A, B, AB, E\}$.

Orthogonal projections of a spherical normal vector are independent, and $\frac{\|P_R Y\|^2}{\sigma^2} \sim \chi^2_{d_R}(\lambda_R)$ with $d_R = \operatorname{rank} P_R$ and $\lambda_R = \frac{\|P_R m\|^2}{\sigma^2}$. Since $d_E = IJ(K-1)$ and $\lambda_E = 0$, claim (i) follows.

(ii) Here $d_A = I-1$, $d_B = J-1$, and $d_{AB} = (I-1)(J-1)$. Under H_A, H_B, H_{AB} respectively, $\lambda_A, \lambda_B, \lambda_{AB}$ vanish, so the central chi-square laws in claim (ii) follow.

(iii) In each null case the numerator chi-square in claim (ii) is independent of SS_E by claim (i); dividing by its degrees of freedom and by $\frac{SS_E}{d_E} = MS_E$ gives the stated F ratios in claim (iii).

Structural Commentary: Balanced normal ANOVA is an orthogonal Gaussian projection decomposition.
Key Insight: Null effects remove noncentrality, leaving independent chi-square ratios. □

Example 4.4.7. *Generic Transformed Two-Way ANOVA*
Consider balanced two-way study with factor A having 2 levels, factor B having 3 levels, $K = 18$ observations per cell. After log transformation stabilises cell spread, ANOVA table on transformed scale is

Source	*df*	*SS*	*MS*	*F*
Factor A	1	2.074	2.074	5.99
Factor B	2	15.588	7.794	22.53
Interaction	2	.810	.405	1.17
Error	102	35.296	.346	
Total	107	53.768		

For factor A, $F_A = 5.99$ gives $p < .025$, and an estimated log contrast .28 corresponds to the original-scale multiplier $e^{.28} \approx 1.32$ with approximate interval $(1.06, 1.65)$. For interaction, $F_{AB} = 1.17$ gives $p = .31$, so there is no strong evidence that the A contrast depends on the level of B.

Remark 4.4.8. *Transformations and Diagnostics*
Two-way ANOVA inherits the normal-theory assumptions of the one-way model. Residual plots, normal probability plots, profile plots, and plots of cell spread against cell mean help decide whether a transformation is needed. A transformation can stabilize variance and improve symmetry, but it also changes additive effects on the transformed scale into multiplicative or otherwise nonlinear effects on the original scale.

Remark 4.4.9. *Factorial Economy and Incomplete Designs*
Factorial designs use each observation to estimate multiple factor contrasts and interactions.
As the factor set grows, full factorials may be replaced by fractional factorials that omit cells while preserving chosen estimable effects; when blocks cannot contain all treatments, incomplete block designs retain partial blocking without all block-treatment pairs.

4.5 Randomised Blocks and Friedman's Test

Randomised block designs compare treatments within relatively homogeneous blocks. Blocking removes major background variation from the treatment comparison, much as pairing removes shared variation.

Definition 4.5.1. *Randomised Block Design*
A randomised block design has J blocks, each containing one experimental unit for each of the I treatments; within every block, treatments are assigned by an independent random permutation.
The additive block model is $Y_{ij} = \mu + \alpha_i + \beta_j + \varepsilon_{ij}$ for $1 \le i \le I$, $1 \le j \le J$, with $\sum_i \alpha_i = \sum_j \beta_j = 0$.

Key Insight: Blocks absorb heterogeneity; $\alpha_i - \alpha_{i'}$ is a within-block treatment contrast.

Method 4.5.2. *Randomized Block F Test*
Treat $Y_{ij} = \mu + \alpha_i + \beta_j + \varepsilon_{ij}$ as a two-way layout with one observation per treatment-block cell and no interaction.

(i) Define $MS_A := \frac{SS_A}{I-1}$, $MS_B := \frac{SS_B}{J-1}$, and $MS_{AB} := \frac{SS_{AB}}{(I-1)(J-1)}$.

(ii) Under additivity, $\mathbb{E}(MS_A) = \sigma^2 + \frac{J}{I-1}\sum_i \alpha_i^2$, $\mathbb{E}(MS_B) = \sigma^2 + \frac{I}{J-1}\sum_j \beta_j^2$, and $\mathbb{E}(MS_{AB}) = \sigma^2$.

(iii) Test $H_0 : \alpha_1 = \cdots = \alpha_I = 0$ by $F := \frac{MS_A}{MS_{AB}}$.

(iv) Under the normal additive null, $F \sim F_{I-1,(I-1)(J-1)}$.

Remark 4.5.3. *Interaction in a Block Design*
If $\delta_{ij} \neq 0$, then MS_{AB} estimates σ^2 plus treatment-block interaction energy.
The denominator of $F = \frac{MS_A}{MS_{AB}}$ is inflated, so the additive-model treatment test is conservative.

Example 4.5.4. *Generic Randomized Block ANOVA*
Suppose $I = 7$ treatments are compared across $J = 10$ blocks, with each block receiving all treatments in randomized order. The randomized-block ANOVA table is

Source	*df*	*SS*	*MS*	*F*
Treatments	6	53013	8835	2.85
Blocks	9	103280	11476	3.71
Interaction	54	167130	3095	
Total	69	323422		

$F = 2.85$ on $(6, 54)$ degrees of freedom gives $p < .025$, rejecting equal treatment effects.
Blocking isolates nuisance block heterogeneity.

Method 4.5.5. *Friedman's Rank Test for Blocks*
For observations Y_{ij} from treatment i in block j, rank $Y_{1j}, \ldots, Y_{Ij}$ within each block.

(i) Let R_{ij} be within-block rank, use average ranks for ties, set $\overline{R}_{i\cdot} := \frac{1}{J}\sum_j R_{ij}$, $\overline{R}_{\cdot\cdot} := \frac{I+1}{2}$.

(ii) Define $Q := \frac{12J}{I(I+1)}\sum_i (\overline{R}_{i\cdot} - \overline{R}_{\cdot\cdot})^2$.

(iii) Under $H_0 : F_1 = \cdots = F_I$, use $Q \overset{H_0}{\approx} \chi^2_{I-1}$ for moderate J.

(iv) Reject at level α when $\mathbb{P}\{\chi^2_{I-1} \ge Q_{\text{obs}}\} \le \alpha$.

Example 4.5.6. *Generic Friedman Rank Calculation*
For $I = 7$ treatments, suppose the average within-block ranks are

Treatment	T_1	T_2	T_3	T_4	T_5	T_6	T_7
Average rank	5.10	4.90	2.30	3.50	3.05	4.90	4.25

With $\overline{R}_{\cdot\cdot} = 4$, $\sum_i (\overline{R}_{i\cdot} - \overline{R}_{\cdot\cdot})^2 = 6.935$ and $Q = 14.86$.
Using $Q \overset{H_0}{\approx} \chi^2_6$, the tail probability is below .025, so the treatment response distributions are not all equal.

Corollary 4.5.7. *Two Treatments Recover the Sign Test*
For $I = 2$, set $D_j := Y_{1j} - Y_{2j}$ and $B := \#\{j : D_j > 0\}$. Friedman's statistic is a function of B alone, so the two-treatment Friedman test is equivalent to the paired sign test.

Proof. Ignoring ties, $R_{1j} = 2\mathbf{1}_{\{D_j>0\}} + \mathbf{1}_{\{D_j<0\}} = 1 + \mathbf{1}_{\{D_j>0\}}$.
Hence $\sum_j R_{1j} = J + B$, so $\overline{R}_{1\cdot}$, $\overline{R}_{2\cdot}$, and Q are determined by B.
Under H_0, signs are exchangeable and $B \sim \mathrm{Bin}(J, 1/2)$, which is the paired sign-test calibration.
Structural Commentary: Two within-block ranks encode only the sign of D_j.
Key Insight: The rank-sum statistic collapses to a binomial sign count. □

5 Linear Models and Regression

5.1 Least Squares Curve Fitting and Linearization

Least squares begins as a geometric fitting rule and becomes a statistical model only after assumptions are made about the errors. The optimization step is asymmetric in the two plotted variables: ordinary regression measures vertical prediction errors.

Definition 5.1.1. *Least-Squares Fit to a Parametric Family*
Let $[n] := \{1, \dots, n\}$, let $(x_i, y_i)_{i\in[n]} \subseteq \mathcal{X} \times \mathbb{R}$, let $\Theta \subseteq \mathbb{R}^p$, and let $m : \mathcal{X} \times \Theta \to \mathbb{R}$.

(i) *Criterion*: $S : \Theta \to [0, \infty)$, $S(\theta) := \sum_{i=1}^{n} \big(y_i - m(x_i; \theta)\big)^2$.

(ii) *Estimate*: $\widehat{\theta} \in \arg\min_{\theta\in\Theta} S(\theta)$.

(iii) *Residual*: $\widehat{e}_i := y_i - m(x_i; \widehat{\theta})$, $i \in [n]$.

Key Insight: $y_i = m(x_i; \widehat{\theta}) + \widehat{e}_i$, so $\widehat{e}_i > 0$ iff $y_i > m(x_i; \widehat{\theta})$.

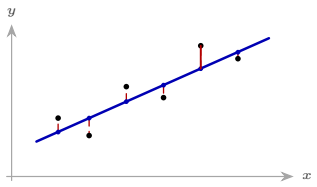

Figure 249: Least squares minimizes squared vertical residuals.

Definition 5.1.2. *Linear in the Parameters*
Let $\mathcal{X}$ be an input set, let $\Theta \subseteq \mathbb{R}^p$, and let $m : \mathcal{X} \times \Theta \to \mathbb{R}$. m is linear in β if and only if
$\exists$ fixed maps $\phi_0, \dots, \phi_{p-1} : \mathcal{X} \to \mathbb{R}$ with $m(x; \beta) = \sum_{j=0}^{p-1} \beta_j \phi_j(x)$ $\forall x \in \mathcal{X}$ and $\beta \in \Theta$.

Structural Commentary: Polynomial regression uses $\phi_j(x) = x^j$ and estimates only the coefficients β_j.

Proposition 5.1.3. *Least-Squares Line*
Let $[n] := \{1, \dots, n\}$, $(x_i, y_i)_{i\in[n]} \subseteq \mathbb{R}^2$, $\overline{x} := \frac{1}{n}\sum_{i=1}^{n} x_i$, $\overline{y} := \frac{1}{n}\sum_{i=1}^{n} y_i$, assume $D := \sum_{i=1}^{n} (x_i - \overline{x})^2 > 0$.

For $b = (b_0, b_1) \in \mathbb{R}^2$, set $S(b) := \sum_{i=1}^{n} (y_i - b_0 - b_1 x_i)^2$.

Then $\exists! \widehat{\beta} = (\widehat{\beta}_0, \widehat{\beta}_1) \in \arg\min_{b\in\mathbb{R}^2} S(b)$; $\widehat{y}(x) := \widehat{\beta}_0 + \widehat{\beta}_1 x$ satisfies $\widehat{\beta}_1 = \frac{1}{D}\sum_{i=1}^{n} (x_i - \overline{x})(y_i - \overline{y})$, $\widehat{\beta}_0 = \overline{y} - \widehat{\beta}_1 \overline{x}$.

Proof. Set $u_i := x_i - \overline{x}$, $v_i := y_i - \overline{y}$, and $c(b) := b_0 + b_1\overline{x} - \overline{y}$.
Since $\sum_{i=1}^{n} u_i = \sum_{i=1}^{n} v_i = 0$, $S(b) = \sum_{i=1}^{n} (v_i - b_1 u_i)^2 + n c(b)^2$.
Thus $c(\widehat{\beta}) = 0$, so $\widehat{\beta}_0 = \overline{y} - \widehat{\beta}_1\overline{x}$, and $\widehat{\beta}_1$ uniquely minimizes $Q(t) := \sum_{i=1}^{n} (v_i - t u_i)^2$.
Since $Q'(t) = -2\sum_{i=1}^{n} u_i(v_i - t u_i)$ and $\sum_{i=1}^{n} u_i^2 = D > 0$, the unique critical point is $t = \frac{1}{D}\sum_{i=1}^{n} u_i v_i$.
Structural Commentary: The fitted line passes through $(\overline{x}, \overline{y})$.
Key Insight: Centering turns the slope into covariance divided by variance. □

Example 5.1.4. *Linear and Nonlinear Parameters*
For fixed $\omega = (\omega_1, \omega_2)$, $f_{\theta,\omega}(t) := A\cos(\omega_1 t) + B\sin(\omega_1 t) + C\cos(\omega_2 t) + D\sin(\omega_2 t) = \theta^t \phi_\omega(t)$
with $\theta = (A, B, C, D)^t$ and $\phi_\omega(t) = (\cos(\omega_1 t), \sin(\omega_1 t), \cos(\omega_2 t), \sin(\omega_2 t))^t$.
Estimating ω makes $f_{\theta,\omega}$ nonlinear in (θ, ω).
For fixed $\lambda = (\alpha, \beta)$, $g_{\eta,\lambda}(t) := Ae^{-\alpha t} + Be^{-\beta t} = \eta^t \psi_\lambda(t)$ with $\eta = (A, B)^t$ and $\psi_\lambda(t) = (e^{-\alpha t}, e^{-\beta t})^t$.
Estimating λ makes $g_{\eta,\lambda}$ nonlinear in (η, λ).

Method 5.1.5. *Linearizing Transformations*
Let $[n] := \{1, \dots, n\}$, $K > 0$, $C > 0$, $e_A \in \mathbb{R}$, $T > 0$, and $\alpha(T) := C \exp\left(-\frac{e_A}{KT}\right)$.
For observations $(T_i, \alpha_i)_{i \in [n]} \subset (0, \infty)^2$, set $x := \frac{1}{T}$, $z := \log \alpha(T)$, $x_i := \frac{1}{T_i}$, and $z_i := \log \alpha_i$.

(i) $z = a + bx$ with $a := \log C$ and $b := -\frac{e_A}{K}$.

(ii) $(\widehat{a}, \widehat{b}) \in \underset{(a,b) \in \mathbb{R}^2}{\arg\min} \sum_{i=1}^{n} (z_i - a - bx_i)^2$, $\widehat{C} := e^{\widehat{a}}$, and $\widehat{e}_A := -K\widehat{b}$.

(iii) $\widehat{\varepsilon}_i := z_i - \widehat{a} - \widehat{b}x_i$ is diagnosed against x_i and $\widehat{z}_i := \widehat{a} + \widehat{b}x_i$.
Systematic structure indicates misspecification on the transformed scale.

5.2 Simple Linear Regression Inference and Diagnostics

Simple linear regression adds a noise model to the least-squares line. The x_i values are treated as fixed design points, and randomness enters through the observed responses.

Definition 5.2.1. *Standard Simple Linear Regression Model*
Let $[n] := \{1, \dots, n\}$, let $x_i \in \mathbb{R}$ be fixed for $i \in [n]$, let $\beta_0, \beta_1 \in \mathbb{R}$, and let $\sigma^2 > 0$.

(i) *Standard model*: $Y_i = \beta_0 + \beta_1 x_i + e_i$, $\mathbb{E}e_i = 0$, $\mathrm{Var}(e_i) = \sigma^2$, and $\mathrm{Cov}(e_i, e_j) = 0$ for $i \neq j$, $i, j \in [n]$.

(ii) *Normal model*: $Y_i = \beta_0 + \beta_1 x_i + e_i$ with $e_1, \dots, e_n$ independent and $e_i \sim N(0, \sigma^2)$, $i \in [n]$.

Structural Commentary: $(x_i)_{i \in [n]}$ is fixed; randomness enters through $(e_i)_{i \in [n]}$.

Theorem 5.2.2. *Mean and Variance of the Simple Regression Coefficients*
Let $[n] := \{1, \dots, n\}$, let $x_i \in \mathbb{R}$, and set $\overline{x} := \frac{1}{n} \sum_{i=1}^{n} x_i$ and $D := \sum_{i=1}^{n} (x_i - \overline{x})^2 > 0$.
Let $\beta := (\beta_0, \beta_1)$ and assume $Y_i = \beta_0 + \beta_1 x_i + e_i$, $\mathbb{E}e_i = 0$, $\mathrm{Var}(e_i) = \sigma^2$, and $\mathrm{Cov}(e_i, e_j) = 0$ for $i \neq j$.
If $\widehat{\beta} = (\widehat{\beta}_0, \widehat{\beta}_1)$ minimizes $\sum_{i=1}^{n} (Y_i - b_0 - b_1 x_i)^2$ over $b = (b_0, b_1) \in \mathbb{R}^2$, then $\mathbb{E}\widehat{\beta} = \beta$; $\mathrm{Var}(\widehat{\beta}) = \sigma^2 \begin{pmatrix} \frac{1}{n} + \frac{\overline{x}^2}{D} & -\frac{\overline{x}}{D} \\ -\frac{\overline{x}}{D} & \frac{1}{D} \end{pmatrix}$.

Proof. Set $u_i := x_i - \overline{x}$ and $\overline{e} := \frac{1}{n} \sum_{i=1}^{n} e_i$.

Proposition 5.1.3 gives $\widehat{\beta}_1 - \beta_1 = D^{-1} \sum_{i=1}^{n} u_i e_i$ and $\widehat{\beta}_0 - \beta_0 = \overline{e} - \overline{x}(\widehat{\beta}_1 - \beta_1)$.

Because $\sum_{i=1}^{n} u_i = 0$, $\mathbb{E}(\widehat{\beta} - \beta) = 0$, $\mathrm{Var}(\widehat{\beta}_1) = D^{-2} \sum_{i=1}^{n} u_i^2 \sigma^2 = \frac{\sigma^2}{D}$, $\mathrm{Cov}(\overline{e}, \widehat{\beta}_1) = \frac{1}{n} D^{-1} \sum_{i=1}^{n} u_i \sigma^2 = 0$, and $\mathrm{Var}(\overline{e}) = \frac{\sigma^2}{n}$. Therefore $\mathrm{Var}(\widehat{\beta}_0) = \frac{\sigma^2}{n} + \frac{\overline{x}^2 \sigma^2}{D}$ and $\mathrm{Cov}(\widehat{\beta}_0, \widehat{\beta}_1) = -\frac{\overline{x}\sigma^2}{D}$.
Structural Commentary: The slope is a fixed linear combination of the responses.
Key Insight: Centering the design isolates the uncertainty in the slope. □

Definition 5.2.3. *Residual Sum of Squares and Error Scale*
Let $[n] := \{1, \dots, n\}$ with $n > 2$, and let $\widehat{y}_i = \widehat{\beta}_0 + \widehat{\beta}_1 x_i$ for $i \in [n]$.

(i) *Residual Sum of Squares*: $\mathrm{RSS} := \sum_{i=1}^{n} (Y_i - \widehat{y}_i)^2$.

(ii) *Error Scale*: $s^2 := \frac{\mathrm{RSS}}{n-2}$ and $s := \sqrt{s^2}$.

Key Insight: $n - 2$ subtracts the fitted coefficients $\widehat{\beta}_0, \widehat{\beta}_1$.

Corollary 5.2.4. *Simple Regression t Intervals and Tests*
Let $n > 2$, $[n] := \{1, \dots, n\}$, $\alpha \in (0, 1)$, $\beta \in \mathbb{R}^2$, $\sigma^2 > 0$, $x = (x_1, \dots, x_n)^t \in \mathbb{R}^n$, $X := (\mathbf{1}, x) \in \mathbb{R}^{n \times 2}$ with $\mathrm{rank}(X) = 2$, $Y = X\beta + e$, and $e \sim N(0, \sigma^2 I_n)$.
Set $\widehat{\beta} := (X^t X)^{-1} X^t Y$, $s^2 := \frac{\|Y - X\widehat{\beta}\|_2^2}{n-2}$, $\overline{x} := \frac{1}{n} \sum_{i=1}^{n} x_i$, $D := \sum_{i=1}^{n} (x_i - \overline{x})^2$, $c_0 := \frac{1}{n} + \frac{\overline{x}^2}{D}$, and $c_1 := D^{-1}$.
For $j \in \{0, 1\}$ and $\beta_{j0} \in \mathbb{R}$, set $s_{\widehat{\beta}_j} := s\sqrt{c_j}$.
Then $T_j := \frac{\widehat{\beta}_j - \beta_j}{s_{\widehat{\beta}_j}} \sim t_{n-2}$, $C_j(Y) := [\widehat{\beta}_j - t_{n-2,1-\frac{\alpha}{2}} s_{\widehat{\beta}_j}, \widehat{\beta}_j + t_{n-2,1-\frac{\alpha}{2}} s_{\widehat{\beta}_j}]$ satisfies $\mathbb{P}_\beta(\beta_j \in C_j(Y)) = 1 - \alpha$,
and the two-sided level-α test of $H_0 : \beta_j = \beta_{j0}$ rejects iff $\left| \frac{\widehat{\beta}_j - \beta_{j0}}{s_{\widehat{\beta}_j}} \right| > t_{n-2,1-\frac{\alpha}{2}}$.

Proof. Let $P := X(X^t X)^{-1} X^t$, $M := I - P$, and $G := (X^t X)^{-1} = (g_{jk})_{j,k=0}^{1}$.
Then $\widehat{\beta} - \beta = GX^t e$, $g_{00} = c_0$, $g_{11} = c_1$, $\mathrm{Var}(\widehat{\beta}_j) = \sigma^2 c_j$, and $Z_j := \frac{\widehat{\beta}_j - \beta_j}{\sigma\sqrt{c_j}} \sim N(0, 1)$.
Also $\frac{(n-2)s^2}{\sigma^2} = \frac{e^t M e}{\sigma^2}$, $M = M^t = M^2$, $\mathrm{rank}(M) = n - 2$, and $MX = 0$, hence $U := \frac{(n-2)s^2}{\sigma^2} \sim \chi^2_{n-2}$ and $\mathrm{Cov}(GX^t e, Me) = GX^t \sigma^2 M = 0$. Joint normality gives $Z_j \perp U$, so $T_j = \frac{Z_j}{\sqrt{\frac{U}{n-2}}} \sim t_{n-2}$.
The interval and rejection rule follow from $\mathbb{P}(|T_j| \leq t_{n-2,1-\frac{\alpha}{2}}) = 1 - \alpha$.
Structural Commentary: $T_j = \frac{Z_j}{\sqrt{\frac{U}{n-2}}}$ with $Z_j \sim N(0, 1)$, $U \sim \chi^2_{n-2}$, and $Z_j \perp U$.
Key Insight: Normality and orthogonal residual projection make replacing σ by s exact. □

Example 5.2.5. *Calibration by Peak Area*
Let $[n] := \{1, \dots, n\}$, with known standard concentrations x_i and measured peak areas A_i, $i \in [n]$.
Fit $A_i = \beta_0 + \beta_1 x_i + e_i$ by least squares, giving $\widehat{A}(x) = \widehat{\beta}_0 + \widehat{\beta}_1 x$.
For a new area A_*, the inverse calibration estimate is $\widehat{x}_* := \frac{A_* - \widehat{\beta}_0}{\widehat{\beta}_1}$ when $\widehat{\beta}_1 \neq 0$.
In the reported fit, $\widehat{\beta}_0 = .0729$, $\widehat{\beta}_1 = 10.77$, $s = .068$, $\mathrm{se}(\widehat{\beta}_0) = .0297$, and $\mathrm{se}(\widehat{\beta}_1) = .27$, hence $t_0 = 2.45$, $t_1 = 40.20$, and the reported

95% intervals are $C_0 = (.011, .135)$ and $C_1 = (10.21, 11.33)$.
Thus $\widehat{\beta}_1 > 0$ makes peak area a monotone calibration signal.

Definition 5.2.6. *Homoscedastic and Heteroscedastic Errors*
Let $[n] := \{1, \dots, n\}$, let $e = (e_1, \dots, e_n)^t$ be errors at design points x_i, and set $v_i := \mathrm{Var}(e_i)$.

(i) *Homoscedastic*: $\exists \sigma^2 \geq 0$ with $v_i = \sigma^2$, $i \in [n]$.
(ii) *Heteroscedastic*: $\exists i, j \in [n]$ with $v_i \neq v_j$.

Key Insight: $\mathrm{Var}(e) \neq \sigma^2 I_n$ invalidates formulas requiring $\mathrm{Var}(e) = \sigma^2 I_n$.

Method 5.2.7. *Residual Diagnostics*
After fitting a regression, examine residuals against the fitted values and against important predictors.

(i) A random horizontal band supports the chosen mean form.
(ii) Curvature suggests a transformation or added nonlinear term.
(iii) Changing spread suggests heteroscedasticity.
(iv) A normal probability plot checks large departures from normality and possible outliers.
(v) Points with extreme x values may have high leverage and can strongly affect the fitted line.

These checks refine the modeling assumptions; they do not replace them.

Example 5.2.8. *Diagnostic Patterns*
Let $[n] := \{1, \dots, n\}$, $r_i := Y_i - \widehat{Y}_i$, $f_i := \widehat{Y}_i$, $\ell_i \in \mathcal{G}$,
$m_r(x) := \mathbb{E}(r_i \mid x_i = x)$, $v_r(f) := \mathrm{Var}(r_i \mid f_i = f)$, and $m_a := \mathbb{E}(r_i \mid \ell_i = a)$.

(i) $m_r \not\equiv 0$ or m_r non-affine; transform variables or add nonlinear terms.
(ii) v_r nonconstant; transform Y_i or use heteroscedastic errors.
(iii) $\exists a, b \in \mathcal{G}$ with $m_a \neq m_b$ or $\exists i \neq j$ with $\mathrm{Cov}(r_i, r_j \mid \ell_i = \ell_j) \neq 0$; add group effects or correlated errors.

Proposition 5.2.9. *Correlation and the Regression Line*
Let $[n] := \{1, \dots, n\}$, *let* $(x_i, y_i) \in \mathbb{R}^2$ *for* $i \in [n]$.
Set $\overline{x} := \frac{1}{n}\sum_{i=1}^n x_i$, $\overline{y} := \frac{1}{n}\sum_{i=1}^n y_i$, $s_{xx} := \frac{1}{n}\sum_{i=1}^n (x_i - \overline{x})^2$, $s_{yy} := \frac{1}{n}\sum_{i=1}^n (y_i - \overline{y})^2$, $s_{xy} := \frac{1}{n}\sum_{i=1}^n (x_i - \overline{x})(y_i - \overline{y})$.
If $s_{xx}, s_{yy} > 0$, $r := \frac{s_{xy}}{\sqrt{s_{xx} s_{yy}}}$, $(\widehat{\beta}_0, \widehat{\beta}_1)$ *minimizes* $\sum_{i=1}^n (y_i - b_0 - b_1 x_i)^2$ *over* $(b_0, b_1) \in \mathbb{R}^2$,
and $\widehat{y}(x) := \widehat{\beta}_0 + \widehat{\beta}_1 x$, *then* $\widehat{\beta}_1 = \frac{s_{xy}}{s_{xx}}$, $r = \widehat{\beta}_1 \sqrt{\frac{s_{xx}}{s_{yy}}}$, *and* $\frac{\widehat{y}(x) - \overline{y}}{\sqrt{s_{yy}}} = r \frac{x - \overline{x}}{\sqrt{s_{xx}}}$.

Proof. Set $D := \sum_{i=1}^n (x_i - \overline{x})^2 = n s_{xx}$ and $N := \sum_{i=1}^n (x_i - \overline{x})(y_i - \overline{y}) = n s_{xy}$.
Proposition 5.1.3 gives $\widehat{\beta}_1 = \frac{N}{D} = \frac{s_{xy}}{s_{xx}}$ and $\widehat{\beta}_0 = \overline{y} - \widehat{\beta}_1 \overline{x}$.
Hence $r = \frac{s_{xy}}{\sqrt{s_{xx} s_{yy}}} = \widehat{\beta}_1 \sqrt{\frac{s_{xx}}{s_{yy}}}$ and $\widehat{y}(x) - \overline{y} = \widehat{\beta}_1 (x - \overline{x})$, so $\frac{\widehat{y}(x) - \overline{y}}{\sqrt{s_{yy}}} = r \frac{x - \overline{x}}{\sqrt{s_{xx}}}$.
Structural Commentary: $z_x := \frac{x - \overline{x}}{\sqrt{s_{xx}}}$ and $z_{\widehat{y}} := \frac{\widehat{y}(x) - \overline{y}}{\sqrt{s_{yy}}}$ give $z_{\widehat{y}} = r z_x$.
Key Insight: $\widehat{\beta}_1 = \frac{s_{xy}}{s_{xx}}$ becomes $r = \frac{s_{xy}}{\sqrt{s_{xx} s_{yy}}}$ after standardising both coordinates. □

Remark 5.2.10. *Regression to the Mean*
With $s_{xx}, s_{yy} > 0$ and $0 < r < 1$, set $z_x := \frac{x - \overline{x}}{\sqrt{s_{xx}}}$ and $z_{\widehat{y}} := \frac{\widehat{y}(x) - \overline{y}}{\sqrt{s_{yy}}}$.
Proposition 5.2.9 gives $z_{\widehat{y}} = r z_x$, hence $|z_{\widehat{y}}| < |z_x|$ for $z_x \neq 0$.

5.3 Matrix Linear Models and Normal Equations

Matrix notation separates the geometry of least squares from the statistical assumptions on the errors. It also makes multiple regression a direct extension of simple regression.

Definition 5.3.1. *Fixed-Design Linear Model*
Let $Y \in \mathbb{R}^n$, $X \in \mathbb{R}^{n \times p}$, $\beta, b \in \mathbb{R}^p$, and $e \in \mathbb{R}^n$.

(i) *Model*: $Y = X\beta + e$.
(ii) *Least-Squares Estimator*: $\widehat{\beta} \in \arg\min_{b \in \mathbb{R}^p} \|Y - Xb\|_2^2$.

Structural Commentary: An intercept is encoded by $X_{\cdot 1} = \mathbf{1}$.

Theorem 5.3.2. *Normal Equations for the Linear Model*
Let $Y \in \mathbb{R}^n$, $X \in \mathbb{R}^{n \times p}$, *and* $Q(b) := \|Y - Xb\|_2^2$ *for* $b \in \mathbb{R}^p$.

(i) $\widehat{\beta} \in \arg\min_{b \in \mathbb{R}^p} Q(b)$ *iff* $X^t X \widehat{\beta} = X^t Y$.
(ii) If $\mathrm{rank}(X) = p$, *then* $X^t X$ *is invertible and* $\arg\min_{b \in \mathbb{R}^p} Q(b) = \{(X^t X)^{-1} X^t Y\}$.

Proof.

(i) ($\Rightarrow$) If $\widehat{\beta}$ minimizes Q, then $\forall (t, h) \in \mathbb{R} \times \mathbb{R}^p$, $0 \leq Q(\widehat{\beta} + th) - Q(\widehat{\beta}) = 2th^t X^t (X\widehat{\beta} - Y) + t^2 \|Xh\|_2^2$.
Hence $\forall h \in \mathbb{R}^p$, $h^t X^t (X\widehat{\beta} - Y) = 0$, so $X^t X \widehat{\beta} = X^t Y$.
(i) ($\Leftarrow$) If $X^t X \widehat{\beta} = X^t Y$, then $\forall h \in \mathbb{R}^p$, $Q(\widehat{\beta} + h) - Q(\widehat{\beta}) = \|Xh\|_2^2 \geq 0$, so $\widehat{\beta}$ minimizes Q.
(ii) If $\mathrm{rank}(X) = p$, then $\forall u \in \mathbb{R}^p \setminus \{0\}$, $u^t X^t X u = \|Xu\|_2^2 > 0$, so $X^t X$ is invertible.
Applying (i) gives $\arg\min_{b \in \mathbb{R}^p} Q(b) = \{(X^t X)^{-1} X^t Y\}$.

Structural Commentary: $\widehat{Y} = X\widehat{\beta}$ and $\widehat{e} = Y - \widehat{Y}$ satisfy $X^t \widehat{e} = 0$, hence $\widehat{e} \perp \mathrm{col}(X)$.
Key Insight: The projection $\widehat{Y} \in \mathrm{col}(X)$ is unique; $\mathrm{rank}(X) = p$ makes $b \mapsto Xb$ injective, so $\widehat{\beta}$ is unique. □

Method 5.3.3. *Projection View of Least Squares*

(i) *Full rank*: If $\operatorname{rank}(X) = d$, define $H := X(X^\top X)^{-1}X^\top$ and $\widehat{y} := Hy$.
(ii) *Projection*: H is the orthogonal projection onto $\operatorname{col}(X)$; hence $y - \widehat{y} \perp \operatorname{col}(X)$.
(iii) *Rank deficiency*: If $\operatorname{rank}(X) < d$, $\widehat{\beta}$ may be nonunique, but $\widehat{y} = \operatorname{proj}_{\operatorname{col}(X)} y$ is unique.

Rank deficiency affects coefficient representation, not least-squares fitted values.

Definition 5.3.4. *Hat Matrix, Fitted Values, and Residuals*
Assume $Y \in \mathbb{R}^n$, $X \in \mathbb{R}^{n\times p}$, $\operatorname{rank}(X) = p$, $\widehat{\beta} = (X^tX)^{-1}X^tY$, and $I = I_n$.

(i) *Hat Matrix*: $P := X(X^tX)^{-1}X^t$.
(ii) *Fitted Values*: $\widehat{Y} := X\widehat{\beta} = PY$.
(iii) *Residuals*: $\widehat{e} := Y - \widehat{Y} = (I - P)Y$.

Key Insight: $\operatorname{range}(P) = \operatorname{col}(X)$ and $PY = \widehat{Y}$.

Proposition 5.3.5. *Projection Properties of the Hat Matrix*
Let $Y \in \mathbb{R}^n$, $X \in \mathbb{R}^{n\times p}$ with $\operatorname{rank}(X) = p$, $I = I_n$, $P := X(X^tX)^{-1}X^t$, $\widehat{Y} := PY$, and $\widehat{e} := (I - P)Y$.
Then $P = P^t = P^2$, $I - P = (I - P)^t = (I - P)^2$, $\operatorname{range}(P) = \operatorname{col}(X)$, $\widehat{Y} = P_{\operatorname{col}(X)}Y$, and $X^t\widehat{e} = 0$.

Proof. Since $(X^tX)^t = X^tX$, $P^t = X((X^tX)^{-1})^tX^t = P$, and $P^2 = X(X^tX)^{-1}X^tX(X^tX)^{-1}X^t = P$.
Hence $(I - P)^t = I - P$ and $(I - P)^2 = I - 2P + P^2 = I - P$.
If $z = Xb \in \operatorname{col}(X)$, then $Pz = X(X^tX)^{-1}X^tXb = z$; also $\operatorname{range}(P) \subseteq \operatorname{col}(X)$, so $\operatorname{range}(P) = \operatorname{col}(X)$.
Finally, $X^t\widehat{e} = X^t(I - P)Y = X^tY - X^tX(X^tX)^{-1}X^tY = 0$, so $\widehat{e} \perp \operatorname{col}(X)$ and $\widehat{Y} = P_{\operatorname{col}(X)}Y$.
Structural Commentary: $P = P_{\operatorname{col}(X)}$ and $I - P = P_{\operatorname{col}(X)^\perp}$.
Key Insight: Fitting decomposes $Y = PY + (I - P)Y = \widehat{Y} + \widehat{e}$ with $\widehat{Y} \perp \widehat{e}$. □

Theorem 5.3.6. *Unbiased Estimate of the Error Variance*
Let $Y = X\beta + e$ with $Y, e \in \mathbb{R}^n$, $X \in \mathbb{R}^{n\times p}$, $\beta \in \mathbb{R}^p$, $\operatorname{rank}(X) = p$, $\mathbb{E}e = 0$, and $\operatorname{Var}(e) = \sigma^2 I_n$.
Set $P := X(X^tX)^{-1}X^t$, $\widehat{Y} := PY$, $\widehat{e} := Y - \widehat{Y}$, and $s^2 := \frac{\|\widehat{e}\|_2^2}{n-p}$. Then $\mathbb{E}\|\widehat{e}\|_2^2 = (n - p)\sigma^2$ and $\mathbb{E}s^2 = \sigma^2$.

Proof. Let $M := I_n - P$. Since $PX = X$, $\widehat{e} = MY = M(X\beta + e) = Me$.
Since $M = M^t = M^2$, $\|\widehat{e}\|_2^2 = e^tM^tMe = e^tMe$. For fixed $A \in \mathbb{R}^{n\times n}$ and centered e with $\operatorname{Var}(e) = \sigma^2 I_n$,
$\mathbb{E}(e^tAe) = \operatorname{tr}(A\sigma^2 I_n) = \sigma^2 \operatorname{tr}(A)$. Thus $\mathbb{E}\|\widehat{e}\|_2^2 = \sigma^2 \operatorname{tr}(M)$,
and $\operatorname{tr}(M) = n - \operatorname{tr}(P) = n - \operatorname{tr}((X^tX)^{-1}X^tX) = n - p$. Therefore $\mathbb{E}s^2 = \frac{1}{n-p}\mathbb{E}\|\widehat{e}\|_2^2 = \sigma^2$.
Structural Commentary: $M = I_n - P = P_{\operatorname{col}(X)^\perp}$ and $\operatorname{tr}(M) = n - p$.
Key Insight: $\widehat{e} = Me$, so residual variation is noise projected onto the $n - p$ directions orthogonal to $\operatorname{col}(X)$. □

Definition 5.3.7. *Standardized Residual*
Let $[n] := \{1, \dots, n\}$, $Y \in \mathbb{R}^n$, $X \in \mathbb{R}^{n\times p}$ with $\operatorname{rank}(X) = p$, $P = (p_{ij}) := X(X^tX)^{-1}X^t$, $\widehat{Y} := PY$, $\widehat{e} := Y - \widehat{Y}$, $s^2 := \frac{\|\widehat{e}\|_2^2}{n-p}$, and $s > 0$. The *standardized residual* is $r_i := \frac{\widehat{e}_i}{s\sqrt{1-p_{ii}}}$ for $i \in [n]$.
Key Insight: Under $\operatorname{Var}(e) = \sigma^2 I_n$, $\operatorname{Var}(\widehat{e}_i) = \sigma^2(1 - p_{ii})$.

Proposition 5.3.8. *Residuals Are Uncorrelated with Fitted Values*
Let $Y = X\beta + e$ with $Y, e \in \mathbb{R}^n$, $X \in \mathbb{R}^{n\times p}$, $\beta \in \mathbb{R}^p$, $\operatorname{rank}(X) = p$, and $\operatorname{Var}(e) = \sigma^2 I_n$.
Set $P := X(X^tX)^{-1}X^t$, $\widehat{Y} := PY$, and $\widehat{e} := (I_n - P)Y$. Then $\operatorname{Cov}(\widehat{e}, \widehat{Y}) = 0$.

Proof. Since $\operatorname{Cov}(Y) = \operatorname{Cov}(e) = \sigma^2 I_n$ and $P = P^t = P^2$,
$\operatorname{Cov}(\widehat{e}, \widehat{Y}) = (I_n - P)\operatorname{Cov}(Y)P^t = \sigma^2(I_n - P)P = \sigma^2(P - P^2) = 0$.
Structural Commentary: $\widehat{Y} = PY$ and $\widehat{e} = (I_n - P)Y$ are images of Y under complementary projections.
Key Insight: Spherical error covariance makes orthogonal projection components uncorrelated. □

5.4 Inference, Prediction, and Multiple Regression

Once the linear model is written in matrix form, standard errors for coefficients and predictions are consequences of linear transformations of random vectors.

Theorem 5.4.1. *Mean and Covariance of Least-Squares Estimates*
Let $Y = X\beta + e$ with $Y, e \in \mathbb{R}^n$, $X \in \mathbb{R}^{n\times p}$, $\beta \in \mathbb{R}^p$, $\operatorname{rank}(X) = p$, $\mathbb{E}e = 0$, and $\operatorname{Var}(e) = \sigma^2 I_n$.
Set $\widehat{\beta} := (X^tX)^{-1}X^tY$. Then $\mathbb{E}\widehat{\beta} = \beta$ and $\operatorname{Var}(\widehat{\beta}) = \sigma^2(X^tX)^{-1}$.

Proof. Let $A := (X^tX)^{-1}X^t$. Since $AX = I_p$, $\widehat{\beta} = A(X\beta + e) = \beta + Ae$.
Hence $\mathbb{E}\widehat{\beta} = \beta + A\mathbb{E}e = \beta$, and $\operatorname{Var}(\widehat{\beta}) = A\operatorname{Var}(e)A^t = \sigma^2(X^tX)^{-1}X^tX(X^tX)^{-1} = \sigma^2(X^tX)^{-1}$.
Structural Commentary: $\widehat{\beta} - \beta = (X^tX)^{-1}X^te$ is a fixed linear transformation of e.
Key Insight: X^tX controls precision: $\operatorname{Var}(\widehat{\beta}) = \sigma^2(X^tX)^{-1}$. □

Method 5.4.2. *Coefficient Inference in a Normal Linear Model*
Let $Y = X\beta + e$, $e \sim N_n(0, \sigma^2 I_n)$, $X \in \mathbb{R}^{n\times p}$ with $\operatorname{rank}(X) = p$, $\widehat{\beta} := (X^tX)^{-1}X^tY$,
$s^2 := \frac{1}{n-p}\left\|Y - X\widehat{\beta}\right\|_2^2$, $C = (c_{jk}) := (X^tX)^{-1}$, $j \in \{1, \dots, p\}$, and $\alpha \in (0, 1)$.

(i) *Standard Error*: $s_{\widehat{\beta}_j} := s\sqrt{c_{jj}}$.
(ii) *Pivot*: $T_j := \frac{\widehat{\beta}_j - \beta_j}{s_{\widehat{\beta}_j}} \sim t_{n-p}$.
(iii) *Confidence Interval*: $C_{j,1-\alpha} := \left[\widehat{\beta}_j - t_{n-p,1-\frac{\alpha}{2}}s_{\widehat{\beta}_j}, \widehat{\beta}_j + t_{n-p,1-\frac{\alpha}{2}}s_{\widehat{\beta}_j}\right]$.
(iv) *Test Statistic*: For $H_0 : \beta_j = \beta_{j0}$, $t_j := \frac{\widehat{\beta}_j - \beta_{j0}}{s_{\widehat{\beta}_j}}$.

If a coefficient CLT holds, $T_j \approx N(0,1)$.

Remark 5.4.3. *Linear-Model Inference After Selection*

Under fixed-design $y = X\beta + \varepsilon$, $\varepsilon \sim N(0, \sigma^2 I_n)$, and $\operatorname{rank}(X) = d$, $\widehat{\beta} \sim N(\beta, \sigma^2 (X^\top X)^{-1})$ and $\widehat{\sigma}^2 := \frac{\|y - X\widehat{\beta}\|_2^2}{n-d}$.
These give standard errors, t or asymptotic z statistics, and nested-model F tests when X is fixed in advance.
After data-driven selection of X or the model, these standard errors ignore selection.

Proposition 5.4.4. *Conditional Coverage Implies Unconditional Coverage*
Let $C(X,Y)$ be a confidence set for β_j, $\alpha \in (0,1)$, and $F := \{\operatorname{rank}(X) = p\}$.
If $\mathbb{P}(F) = 1$ and $\mathbb{P}(\beta_j \in C(X,Y) \mid X) = 1 - \alpha$ on F, then $\mathbb{P}(\beta_j \in C(X,Y)) = 1 - \alpha$.

Proof. Set $A := \{\beta_j \in C(X,Y)\}$. Since $\mathbb{P}(F) = 1$, $\mathbb{P}(A) = \mathbb{E}[\mathbb{P}(A \mid X)] = \mathbb{E}[(1-\alpha)\mathbf{1}_F + \mathbb{P}(A \mid X)\mathbf{1}_{F^c}] = 1 - \alpha$. *Structural Commentary*: $\mathbb{P}(F) = 1$ and $\mathbb{P}(A \mid X) = 1 - \alpha$ on F.
Key Insight: $\mathbb{P}(A \mid X) = 1 - \alpha$ a.s. implies $\mathbb{P}(A) = 1 - \alpha$. □

Proposition 5.4.5. *Mean Response at a New Design Point*
Let $Y = X\beta + e$ with $Y, e \in \mathbb{R}^n$, $X \in \mathbb{R}^{n \times p}$, $\beta \in \mathbb{R}^p$, $\operatorname{rank}(X) = p$, and $e \sim N_n(0, \sigma^2 I_n)$.
Set $\widehat{\beta} := (X^tX)^{-1}X^tY$, $s^2 := \frac{1}{n-p}\left\|Y - X\widehat{\beta}\right\|_2^2$, $x_0 \in \mathbb{R}^p$, $c_0 := x_0^t(X^tX)^{-1}x_0 > 0$,
$\mu_0 := x_0^t\beta$, $\widehat{\mu}_0 := x_0^t\widehat{\beta}$, $s_{\widehat{\mu}_0} := s\sqrt{c_0}$, and $\alpha \in (0,1)$. Then $\mathbb{E}\widehat{\mu}_0 = \mu_0$, $\operatorname{Var}(\widehat{\mu}_0) = \sigma^2 c_0$, $T_0 := \frac{\widehat{\mu}_0 - \mu_0}{s_{\widehat{\mu}_0}} \sim t_{n-p}$,
and $C_{0,1-\alpha} := \left[\widehat{\mu}_0 - t_{n-p,1-\frac{\alpha}{2}} s_{\widehat{\mu}_0}, \widehat{\mu}_0 + t_{n-p,1-\frac{\alpha}{2}} s_{\widehat{\mu}_0}\right]$ has coverage $1 - \alpha$ for μ_0.

Proof. Let $A := (X^tX)^{-1}X^t$, $P := XA$, and $M := I_n - P$.
Since $AX = I_p$, $\widehat{\mu}_0 - \mu_0 = x_0^tA(X\beta + e) - x_0^t\beta = x_0^tAe$, so $\mathbb{E}\widehat{\mu}_0 = \mu_0$ and $\operatorname{Var}(\widehat{\mu}_0) = x_0^tA(\sigma^2 I_n)A^tx_0 = \sigma^2 c_0$.
Normality gives $Z := \frac{\widehat{\mu}_0 - \mu_0}{\sigma\sqrt{c_0}} \sim N(0,1)$.

Since $M = M^t = M^2$, $\operatorname{rank}(M) = n - p$, and $MA^tx_0 = 0$, $Z \perp U := \frac{e^tMe}{\sigma^2} = \frac{(n-p)s^2}{\sigma^2} \sim \chi^2_{n-p}$.
Thus $T_0 = \frac{Z}{\sqrt{U/(n-p)}} \sim t_{n-p}$, and $\mathbb{P}(\mu_0 \in C_{0,1-\alpha}) = \mathbb{P}(|T_0| \le t_{n-p,1-\frac{\alpha}{2}}) = 1 - \alpha$.

Structural Commentary: $\widehat{\mu}_0 - \mu_0 = x_0^t(X^tX)^{-1}X^te$ and $s^2 = \frac{e^t(I_n - P)e}{n-p}$ use orthogonal components of e.
Key Insight: Estimating a mean response adds uncertainty only through $c_0 = x_0^t(X^tX)^{-1}x_0$. □

Corollary 5.4.6. *Prediction Interval for a New Observation*
Let $Y = X\beta + e$ with $Y, e \in \mathbb{R}^n$, $X \in \mathbb{R}^{n \times p}$, $\beta \in \mathbb{R}^p$, $\operatorname{rank}(X) = p$, and $e \sim N_n(0, \sigma^2 I_n)$.
Let $x_0 \in \mathbb{R}^p$, $e_0 \sim N(0, \sigma^2)$ with $e_0 \perp e$, and $Y_0 := x_0^t\beta + e_0$.
Set $\widehat{\beta} := (X^tX)^{-1}X^tY$, $\widehat{\mu}_0 := x_0^t\widehat{\beta}$, $s^2 := \frac{\|Y - X\widehat{\beta}\|_2^2}{n-p}$, $c_0 := x_0^t(X^tX)^{-1}x_0$, $s_{\text{pred}} := s\sqrt{1 + c_0}$, and $\alpha \in (0,1)$.
Then $\operatorname{Var}(Y_0 - \widehat{\mu}_0) = \sigma^2(1 + c_0)$, $T_{\text{pred}} := \frac{Y_0 - \widehat{\mu}_0}{s_{\text{pred}}} \sim t_{n-p}$,
and $I_{0,1-\alpha} := \left[\widehat{\mu}_0 - t_{n-p,1-\frac{\alpha}{2}} s_{\text{pred}}, \widehat{\mu}_0 + t_{n-p,1-\frac{\alpha}{2}} s_{\text{pred}}\right]$ has coverage $1 - \alpha$ for Y_0.

Proof. Let $A := (X^tX)^{-1}X^t$, $P := XA$, and $M := I_n - P$.
Since $AX = I_p$, $Y_0 - \widehat{\mu}_0 = e_0 - x_0^tAe$, so $\operatorname{Var}(Y_0 - \widehat{\mu}_0) = \sigma^2 + \sigma^2 x_0^tAA^tx_0 = \sigma^2(1 + c_0)$.
Normality gives $Z := \frac{Y_0 - \widehat{\mu}_0}{\sigma\sqrt{1+c_0}} \sim N(0,1)$. Since $AM = 0$, $Z \perp U := \frac{e^tMe}{\sigma^2} = \frac{(n-p)s^2}{\sigma^2} \sim \chi^2_{n-p}$.
Thus $T_{\text{pred}} = \frac{Z}{\sqrt{U/(n-p)}} \sim t_{n-p}$, and $\mathbb{P}(Y_0 \in I_{0,1-\alpha}) = \mathbb{P}(|T_{\text{pred}}| \le t_{n-p,1-\frac{\alpha}{2}}) = 1 - \alpha$.
Structural Commentary: $Y_0 - \widehat{\mu}_0 = e_0 - x_0^t(X^tX)^{-1}X^te$ combines future noise and estimation error.
Key Insight: Prediction variance is mean-response variance plus irreducible noise, $\sigma^2 c_0 + \sigma^2$. □

Definition 5.4.7. *Multiple Regression Coefficients*

Let $[n] := \{1, \dots, n\}$, $z_i = (x_{i1}, \dots, x_{i,p-1}) \in \mathbb{R}^{p-1}$ for $i \in [n]$, $u_1, \dots, u_{p-1}$ be the standard basis of $\mathbb{R}^{p-1}$, and $m(z) := \beta_0 + \sum_{k=1}^{p-1} \beta_k z_k$
In $Y_i = m(z_i) + e_i$, the *multiple regression coefficient* β_k satisfies $\forall z \in \mathbb{R}^{p-1}$ and $\forall \delta \in \mathbb{R}$, $m(z + \delta u_k) - m(z) = \delta\beta_k$ for $k \in \{1, \dots, p-1\}$.
Structural Commentary: Polynomial regression replaces z_i by transformed design columns such as z_{ik}^2.

Definition 5.4.8. *Coefficient of Determination*

Let $[n] := \{1, \dots, n\}$, $Y, \widehat{Y} \in \mathbb{R}^n$, $\overline{Y} := n^{-1}\sum_{i=1}^n Y_i$, $\mathbf{1} \in \operatorname{col}(X)$, and $\sum_{i=1}^n (Y_i - \overline{Y})^2 > 0$.

(i) *Residual Sum of Squares*: $\text{RSS} := \sum_{i=1}^n (Y_i - \widehat{Y}_i)^2$.

(ii) *Total Sum of Squares*: $\text{TSS} := \sum_{i=1}^n (Y_i - \overline{Y})^2$.

(iii) *Coefficient of Determination*: $R^2 := 1 - \frac{\text{RSS}}{\text{TSS}}$.

Structural Commentary: $R^2 = \operatorname{corr}(Y, \widehat{Y})^2$ for an intercept model.
Key Insight: $R^2 = \frac{\text{TSS} - \text{RSS}}{\text{TSS}}$ is the observed response variation removed by the fitted model.

Remark 5.4.9. *Adjusted Coefficients*
Let X_{-j} be X without column x_j, and set $z_j := (I - \operatorname{proj}_{\operatorname{col}(X_{-j})})x_j$.
Then $\widehat{\beta}_j = \frac{z_j^\top y}{z_j^\top z_j}$, the simple-regression coefficient of y on the adjusted predictor z_j.
Thus $\widehat{\beta}_j$ uses only the part of x_j left after adjusting for other predictors.
If $x_j \approx \operatorname{col}(X_{-j})$, then $\|z_j\|_2$ is small and $\widehat{\beta}_j$ is unstable; this is collinearity.

Remark 5.4.10. *Collinearity and Interpretation*
Let X_{-j} be X without column $X_{\cdot j}$, set $d_j := \operatorname{dist}(X_{\cdot j}, \operatorname{col}(X_{-j}))$, and let $C = (c_{kl}) := (X^tX)^{-1}$.
If $0 < d_j \ll \|X_{\cdot j}\|_2$, then X^tX is nearly singular and $s_{\widehat{\beta}_j} = s\sqrt{c_{jj}}$ can be large even when $\widehat{Y} = X\widehat{\beta}$ is stable.
If $d_j = 0$, then $\operatorname{rank}(X) < p$ and $\widehat{\beta}$ is not unique.

Example 5.4.11. *Quadratic Terms as a Lack-of-Fit Check*
Compare $M_1 : Y_i = \beta_0 + \beta_1 x_i + e_i$ with $M_2 : Y_i = \beta_0 + \beta_1 x_i + \beta_2 x_i^2 + e_i$.
If $t_2 = \widehat{\beta}_2 / s_{\widehat{\beta}_2}$ is small and residual curvature is absent, retain M_1.
If $|t_2|$ is large and residual curvature decreases under M_2, use the quadratic term.
Add x^2 only when residual structure or scale supports $\beta_2 \neq 0$.

5.5 Random Design, Bootstrap, and Extensions

The fixed-design model conditions on the observed predictor values. Many observational studies are more naturally viewed as sampling random predictor-response pairs, with the fixed-design analysis recovered after conditioning on the realised design.

Definition 5.5.1. *Random-Design Linear Regression*
Let $[n] := \{1, \dots, n\}$, $(Y_i, \xi_i)_{i \in [n]}$ be independent copies of (Y, ξ), $\xi \in \mathbb{R}^p$, $\beta \in \mathbb{R}^p$, and $\sigma^2 > 0$.
A *Random-Design Linear Regression* is an iid sample $(Y_i, \xi_i)_{i \in [n]}$ satisfying $\mathbb{E}(Y \mid \xi = x) = x^t\beta$
and $\operatorname{Var}(Y \mid \xi = x) = \sigma^2$ for $x \in \operatorname{supp}(\xi)$.
Structural Commentary: Conditioning on $X_{i\cdot} = \xi_i^t$ gives $Y_{1:n} = X\beta + e$ with $e_i = Y_i - \xi_i^t\beta$.

Remark 5.5.2. *Unconditional Variability Can Differ*
Under random design, if $\mathbb{E}(\widehat{\beta} \mid X) = \beta$, then $\mathbb{E}\widehat{\beta} = \beta$.
Moreover, $\operatorname{Var}(\widehat{\beta}) = \mathbb{E}[\operatorname{Var}(\widehat{\beta} \mid X)] + \operatorname{Var}(\mathbb{E}[\widehat{\beta} \mid X]) = \sigma^2\mathbb{E}[(X^tX)^{-1}]$, not generally $\sigma^2(X^tX)^{-1}$ for frozen design.

Method 5.5.3. *Pairs Bootstrap for Random-Design Regression*
Let $D := \{(Y_i, x_i) : i \in [n]\}$, $x_i \in \mathbb{R}^p$, and let $T(D)$ be a fitted coefficient, prediction, or smooth statistic.

(i) Draw $D_b^* := \{(Y_{i_m}, x_{i_m}) : m \in [n]\}$ with $i_1, \dots, i_n$ sampled iid from $[n]$.
(ii) Fit least squares on D_b^* and compute $T_b^* := T(D_b^*)$.
(iii) Repeat for $b \in [B]$ and estimate $\operatorname{se}(T(D))$ by $\widehat{\operatorname{se}}_*(T) := \left(\frac{1}{B-1} \sum_{b=1}^{B} (T_b^* - \overline{T}^*)^2 \right)^{1/2}$, where $\overline{T}^* := B^{-1} \sum_{b=1}^{B} T_b^*$.

Perspective 5.5.4. *Extensions Beyond Ordinary Least Squares*

(i) *Robust regression*: Replace $\sum_i \widehat{e}_i^2$ by $\sum_i \Psi(\widehat{e}_i)$; $\Psi(u) = u^2$ gives least squares.
(ii) *Variable selection*: For selected predictors $S \subseteq \{1, \dots, p\}$, $\widehat{\beta}_S$ and $\operatorname{se}(\widehat{\beta}_S)$ are conditional on S.
(iii) *Influence*: Large leverage $h_{ii} = x_i^t(X^tX)^{-1}x_i$ can make observation i dominate $\widehat{\beta}$.
(iv) *Inverse calibration*: Given a fitted response curve $\widehat{m}$ and measured response y_0,
estimating x_0 from $\widehat{m}(x_0) = y_0$ is an inverse problem with uncertainty beyond $\operatorname{se}(\widehat{\beta})$.

Part XXI
Statistical Learning and Deep Learning

Statistical learning studies prediction rules, representation maps, and trained systems as mathematical objects. The statistical foundations of Parts 15 and 16 remain the language for experiments, inference, and model assessment; here the emphasis is on risk, generalization, optimization, architectures, and evaluation of learned predictors.

1 Learning Problems and Risk

1.1 Prediction, Loss Functions, and Risk

A learning problem turns observations into an action rule. Unlike inferential problems, the primary object is often the future loss of a predictor rather than a confidence statement about a parameter.

Definition 1.1.1. *Prediction Problem and Risk*
Inputs lie in $(\mathcal{X}, \mathcal{A})$, outputs in $(\mathcal{Y}, \mathcal{B})$, and $(X, Y) \sim P$ on $\mathcal{X} \times \mathcal{Y}$. Let $(\mathcal{A}_0, \mathcal{C})$ be an action space.

(i) *Predictor*: A predictor is a measurable map $f : \mathcal{X} \to \mathcal{A}_0$.
(ii) *Loss and risk*: For loss $\ell : \mathcal{A}_0 \times \mathcal{Y} \to [0, \infty]$, define $R(f) := \mathbb{E}_P \ell(f(X), Y)$.
(iii) *Bayes risk*: $R^* := \inf_f R(f)$, over measurable $f : \mathcal{X} \to \mathcal{A}_0$.

Definition 1.1.2. *Supervised Learning Terminology*
Let $S := \{(x_i, y_i) : 1 \le i \le n\}$ with $x_i = (x_{i1}, \dots, x_{ip})^\top \in \mathcal{X}$ and $y_i \in \mathcal{Y}$.

(i) *Features*: Coordinates x_{ij} are variables, inputs, predictors, independent variables, or features.
(ii) *Response*: Values y_i are outputs, responses, targets, or dependent variables.
(iii) *Regression*: If $\mathcal{Y} \subseteq \mathbb{R}^q$, the task is quantitative prediction.
(iv) *Classification*: If $\mathcal{Y} = \mathcal{G}$ is a finite unordered label set, the task is classification.
(v) *Ordered labels*: If $\mathcal{Y}$ is ordered categorical, order matters but arithmetic on labels usually does not.
(vi) *One-hot coding*: For $|\mathcal{G}| = K$, encode class g by $t_g \in \{0, 1\}^K$ with $(t_g)_g = 1$.
Classify vector scores $s(x) \in \mathbb{R}^K$ by $\operatorname{argmax}_k s_k(x)$.

If y_i are unobserved, the problem is unsupervised and targets structure in $\{x_i\}_{i=1}^n$.

Example 1.1.3. *Representative Learning Problems*

(i) *Email filtering*: x contains word and punctuation frequencies, $y \in \{\text{spam}, \text{ham}\}$, and asymmetric loss can penalize false deletion more than missed spam.
(ii) *Clinical regression*: $y = \log(\text{PSA})$ and x contains log cancer volume, prostate weight, age, and related measurements; correlated predictors are common.
(iii) *Digit recognition*: $x \in [0, 1]^{16 \times 16}$ or $[0, 1]^{256}$ and $y \in \{0, \dots, 9\}$; action set may add rejection option $\perp$.
(iv) *Microarrays*: An expression matrix $X \in \mathbb{R}^{G \times n}$ has genes as rows and samples as columns.
Typical first tasks are unsupervised clustering of genes or samples.

Example 1.1.4. *Common Prediction Losses*

(i) Regression commonly uses squared loss $\ell(a, y) = \|a - y\|_2^2$ or absolute loss $\ell(a, y) = |a - y|$.
(ii) Binary classification with labels in $\{-1, 1\}$ uses zero-one loss $\mathbf{1}_{\{ay \le 0\}}$ for a signed score a.
(iii) Probabilistic classification uses log loss $-\log q_y$ when q is a predicted distribution on labels.

Definition 1.1.5. *Bayes Predictors*

(i) *Conditional risk*: For action a, set $r_x(a) := \mathbb{E}[\ell(a, Y) \mid X = x]$; any $f^*(x) \in \operatorname{argmin}_a r_x(a)$ is Bayes.
(ii) *Squared loss*: If $\ell(a, y) = (a - y)^2$ and $\mathbb{E}[|Y| \mid X = x] < \infty$, then $f^*(x) = \mathbb{E}[Y \mid X = x]$.
(iii) *Absolute loss*: If $\ell(a, y) = |a - y|$, any conditional median $m(x)$
with $\mathbb{P}(Y \le m(x) \mid X = x) \ge \frac{1}{2}$ and $\mathbb{P}(Y \ge m(x) \mid X = x) \ge \frac{1}{2}$ is Bayes.
(iv) *Zero-one loss*: For labels $\mathcal{G}$ and $\ell(g, y) = \mathbf{1}_{\{g \ne y\}}$, a Bayes classifier is $g^*(x) \in \operatorname{argmax}_{g \in \mathcal{G}} \mathbb{P}(Y = g \mid X = x)$.

Remark 1.1.6. *Risk as a Prediction Target*
Here risk means predictive loss $R(f) = \mathbb{E}_P \ell(f(X), Y)$ under a data law P.
Decision-theoretic risk instead studies $R(\theta, \delta) = \mathbb{E}_\theta L(\theta, \delta(X))$ over a model family.

1.2 Empirical Risk Minimization

The population risk is the target, but only a sample is observed. Empirical risk minimisation replaces the unknown expectation by an average over the training data.

Definition 1.2.1. *Empirical Risk Minimization*
Let $S := ((x_1, y_1), \dots, (x_n, y_n))$.

(i) *Empirical risk*: For loss ℓ, define $\widehat{R}_S(f) := n^{-1} \sum_{i=1}^n \ell(f(x_i), y_i)$.
(ii) *Hypothesis class*: Let $\mathcal{F}$ be the admissible predictor class.
(iii) *ERM*: Any $\widehat{f} \in \operatorname{argmin}_{f \in \mathcal{F}} \widehat{R}_S(f)$ is an empirical risk minimiser.

Definition 1.2.2. *Regularised Empirical Risk*
Let $\Omega : \mathcal{F} \to [0, \infty]$ be a complexity penalty and $\lambda \ge 0$.
Define $Q_\lambda(f) := \widehat{R}_S(f) + \lambda \Omega(f)$ and choose $\widehat{f}_\lambda \in \operatorname{argmin}_{f \in \mathcal{F}} Q_\lambda(f)$.
The penalty Ω may encode smoothness, sparsity, norm control, margin size, or architecture.

Theorem 1.2.3. *Finite-Class ERM Bound*
Let $S = ((X_1, Y_1), \dots, (X_n, Y_n))$ be i.i.d. from P, let $\emptyset \neq \mathcal{F}$ be finite.
Assume $0 \le \ell(f(X), Y) \le 1$ for all $f \in \mathcal{F}$, and fix $\delta \in (0,1)$. Set $\varepsilon_{n,\delta} := \sqrt{\log(2|\mathcal{F}|/\delta)/(2n)}$.

(i) Uniform deviation: With probability at least $1-\delta$, $\sup_{f\in\mathcal{F}} \left|R(f) - \widehat{R}_S(f)\right| \le \varepsilon_{n,\delta}$.

(ii) ERM excess risk: If $\widehat{f} \in \operatorname{argmin}_{f\in\mathcal{F}} \widehat{R}_S(f)$, then $R(\widehat{f}) \le \inf_{f\in\mathcal{F}} R(f) + 2\varepsilon_{n,\delta}$.

Proof.

(i) For fixed f, set $Z_i(f) := \ell(f(X_i), Y_i) \in [0,1]$, so $R(f) = \mathbb{E}Z_i(f)$ and $\widehat{R}_S(f) = n^{-1}\sum_{i=1}^n Z_i(f)$.
Hoeffding and a union bound give $\mathbb{P}(\sup_{f\in\mathcal{F}} \left|\widehat{R}_S(f) - R(f)\right| > \varepsilon) \le 2|\mathcal{F}| e^{-2n\varepsilon^2}$; set $\varepsilon = \varepsilon_{n,\delta}$.

(ii) On the uniform-deviation event, choose $f^* \in \operatorname{argmin}_{f\in\mathcal{F}} R(f)$.
Since $\widehat{R}_S(\widehat{f}) \le \widehat{R}_S(f^*)$, $R(\widehat{f}) \le \widehat{R}_S(\widehat{f}) + \varepsilon_{n,\delta} \le \widehat{R}_S(f^*) + \varepsilon_{n,\delta} \le R(f^*) + 2\varepsilon_{n,\delta}$.

Structural Commentary: Union-bounded concentration gives uniform control; ERM turns it into risk control.
Key Insight: Control every gap $\left|R - \widehat{R}_S\right|$ by $\varepsilon_{n,\delta}$; the ERM comparison pays this gap twice. □

Remark 1.2.4. *Statistical and Computational Error*
In practice the selected predictor may be only an approximate minimizer of the empirical criterion.
Its excess risk is then decomposed into approximation error, estimation error, and optimisation error.

1.3 Surrogate Losses and Calibration

Many prediction losses are discontinuous or combinatorial. Learning algorithms often optimise a smoother surrogate and rely on calibration to connect that surrogate to the target loss.

Definition 1.3.1. *Surrogate Loss*
For binary labels $y \in \{-1, 1\}$, let $g : \mathcal{X} \to \mathbb{R}$ be score function. Define $m_g(x, y) := yg(x)$ and $\widehat{y}_g(x) := \operatorname{sign}(g(x))$.
(i) *Zero-one loss*: $\ell_{01}(g(x), y) := \mathbf{1}_{\{m_g(x,y)\le 0\}}$.
(ii) *Surrogate*: $\ell_\phi(g(x), y) := \phi(m_g(x, y))$ for tractable $\phi : \mathbb{R} \to [0, \infty)$.

Example 1.3.2. *Margin Surrogates*
(i) Hinge loss: $\phi(t) = \max\{0, 1 - t\}$.
(ii) Logistic loss: $\phi(t) = \log(1 + \exp(-t))$.
(iii) Exponential loss: $\phi(t) = \exp(-t)$.
(iv) Squared margin loss: $\phi(t) = (1 - t)^2$.

Definition 1.3.3. *Classification Calibration*
Let $R_\phi(g) := \mathbb{E}\phi(Yg(X))$, $R_{01}(g) := \mathbb{P}(Yg(X) \le 0)$, $R^*_\phi := \inf_g R_\phi(g)$, and $R^*_{01} := \inf_g R_{01}(g)$.
Margin surrogate ϕ is classification calibrated if $R_\phi(g_m) \to R^*_\phi$ implies $R_{01}(g_m) \to R^*_{01}$ $\forall$ score sequence (g_m).
Equivalently, $R_\phi(g) - R^*_\phi \to 0$ forces $R_{01}(g) - R^*_{01} \to 0$.

Remark 1.3.4. *Proper Scoring Rules*
A scoring rule $S(q, y)$ is proper if $\operatorname{argmin}_q \mathbb{E}[S(q, Y) \mid X = x] = \mathcal{L}(Y \mid X = x)$.
Thus log and Brier losses learn calibrated conditional probabilities.

1.4 Bias-Variance and Approximation-Estimation Tradeoffs

Learning quality depends both on the richness of the model class and on the variability introduced by fitting that class from a finite sample.

Proposition 1.4.1. *Bias-Variance Decomposition*
Let $Y = f_0(X) + \varepsilon$ with $\mathbb{E}[\varepsilon \mid X = x] = 0$ and $\operatorname{Var}(\varepsilon \mid X = x) = \sigma^2(x)$.
Let random S produce $\widehat{f}_S$, set $\bar{f}(x) := \mathbb{E}_S\widehat{f}_S(x)$, and let $Y_x \perp S$ be a fresh response at x.
Then $\mathbb{E}_{S,Y_x}[(Y_x - \widehat{f}_S(x))^2] = \sigma^2(x) + (f_0(x) - \bar{f}(x))^2 + \operatorname{Var}_S(\widehat{f}_S(x))$.

Proof. Write $Y_x - \widehat{f}_S(x) = \varepsilon_x + f_0(x) - \widehat{f}_S(x)$, where $\varepsilon_x := Y_x - f_0(x)$.
Since $\mathbb{E}[\varepsilon_x] = 0$ and Y_x is conditionally independent of S, $\mathbb{E}_{S,Y_x}[\varepsilon_x\{f_0(x) - \widehat{f}_S(x)\}] = 0$.
Thus $\mathbb{E}_{S,Y_x}[(Y_x - \widehat{f}_S(x))^2] = \sigma^2(x) + \mathbb{E}_S[(f_0(x) - \widehat{f}_S(x))^2]$.
Finally, $\mathbb{E}_S[(f_0(x) - \widehat{f}_S(x))^2] = (f_0(x) - \bar{f}(x))^2 + \mathbb{E}_S[(\widehat{f}_S(x) - \bar{f}(x))^2]$.
Structural Commentary: Squared prediction error equals noise plus fitted-function error.
Key Insight: Center $\widehat{f}_S(x)$ at $\bar{f}(x)$; the remaining cross term has mean zero. □

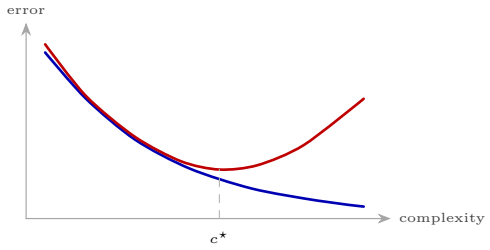

Figure 250: Bias–variance tradeoff: blue: training error, red: test error; dashed line marks test minimum.

Method 1.4.2. *Nearest-Neighbor Local Averaging*
Let $\mathcal{T} := \{(x_i, y_i) : 1 \le i \le n\}$ be training data in a metric space $(\mathcal{X}, d)$.
Let $N_k(x) \subseteq \{1, \dots, n\}$ be the indices of the k smallest distances $d(x_i, x)$.
For numerical responses, define the local average $\widehat{f}_k(x) := \frac{1}{k} \sum_{i \in N_k(x)} y_i$.
For class labels $g_i \in \mathcal{G}$, define $\widehat{p}_g(x) := \frac{1}{k} \sum_{i \in N_k(x)} \mathbf{1}_{\{g_i = g\}}$ and classify by $\widehat{g}_k(x) \in \operatorname{argmax}_{g \in \mathcal{G}} \widehat{p}_g(x)$.
Thus k-nearest neighbours replace conditioning at $X = x$ by averaging over $N_k(x)$.

Remark 1.4.3. *Locality in High Dimension*
The parameter k trades local bias against variance: small k reacts strongly to S, while large k averages more but may wash out local structure. In $[0,1]^p$, a subcube with volume fraction r has side length $e_p(r) = r^{1/p}$, so $e_{10}(0.01) \approx 0.63$ and $e_{10}(0.10) \approx 0.80$. For N uniform points in the unit ball, the median nearest-neighbour radius is $d(p, N) = (1 - 2^{-1/N})^{1/p}$, about 0.52 for $(p, N) = (10, 500)$. Thus high-dimensional neighbourhoods large enough to contain data may not be local; useful local methods need structure or an adapted metric.

Definition 1.4.4. *Approximation and Estimation Errors*
Let $R^* := \inf_f R(f)$ and $R^*_{\mathcal{F}} := \inf_{f \in \mathcal{F}} R(f)$.

(i) *Approximation error*: $\mathcal{A}(\mathcal{F}) := R^*_{\mathcal{F}} - R^*$.
(ii) *Estimation error*: For a data-dependent $\widehat{f} \in \mathcal{F}$, $\mathcal{E}(\widehat{f}; \mathcal{F}) := R(\widehat{f}) - R^*_{\mathcal{F}}$.
(iii) *Excess risk*: $R(\widehat{f}) - R^* = \mathcal{A}(\mathcal{F}) + \mathcal{E}(\widehat{f}; \mathcal{F})$.

Larger $\mathcal{F}$ usually lowers $\mathcal{A}(\mathcal{F})$ and raises estimation difficulty.

Remark 1.4.5. *Model Complexity*
As $c(\mathcal{F})$ grows, $\widehat{R}_S(\widehat{f}_{\mathcal{F}})$ usually decreases, while $R(\widehat{f}_{\mathcal{F}}) - R^* = \mathcal{A}(\mathcal{F}) + \mathcal{E}(\widehat{f}_{\mathcal{F}}; \mathcal{F})$ trades smaller approximation error for larger estimation error. For zero-one loss, the relevant failure is crossing the wrong side of the decision boundary, not an additive squared-error bias–variance split.

2 Generalization Theory

2.1 Uniform Convergence and VC Theory

Generalisation asks when small training loss implies small population loss. Uniform convergence controls the gap for all predictors in a class at once.

Definition 2.1.1. *Uniform Convergence*
For samples S_n of size n and bounded loss, $\mathcal{F}$ has uniform convergence
if $\sup_{f \in \mathcal{F}} \left| R(f) - \widehat{R}_{S_n}(f) \right| \to 0$ in probability, or almost surely, as $n \to \infty$.

Definition 2.1.2. *Shattering and VC Dimension*
For $\mathcal{C} \subseteq 2^{\mathcal{X}}$, a finite $A \subseteq \mathcal{X}$ is shattered if $\{A \cap C : C \in \mathcal{C}\} = 2^A$,
and $\operatorname{VCdim}(\mathcal{C})$ is the supremum of $|A|$ over finite shattered $A \subseteq \mathcal{X}$.

Example 2.1.3. *Shattering Examples*
For $\mathcal{H}_p := \{\{x \in \mathbb{R}^p : a^\top x + b \ge 0\} : a \in \mathbb{R}^p, b \in \mathbb{R}\}$, $\operatorname{VCdim}(\mathcal{H}_p) = p + 1$; in particular, $\mathcal{H}_2$ shatters any three noncollinear points and shatters no four-point set.
Parameter count not decisive: one-parameter class $\mathcal{C} := \{\{x \in \mathbb{R} : \sin(\alpha x) > 0\} : \alpha \in \mathbb{R}\}$ has infinite VCdim.

Theorem 2.1.4. *VC Generalization Bound Form*
Let $\mathcal{F} \subseteq \{0,1\}^{\mathcal{X}}$ have $1 \le d := \operatorname{VCdim}(\mathcal{F}) < \infty$, let $S_n = ((X_i, Y_i))_{i=1}^n$ be i.i.d., and use $\ell_f(x, y) := \mathbf{1}_{\{f(x) \ne y\}}$, $R(f) := \mathbb{E}\ell_f(X, Y)$, and $\widehat{R}_{S_n}(f) := \frac{1}{n} \sum_{i=1}^n \ell_f(X_i, Y_i)$.
Define $\Pi_{\mathcal{F}}(m) := \max |\{(f(x_1), \dots, f(x_m)) : f \in \mathcal{F}\}|$, where the maximum is over $x_1, \dots, x_m \in \mathcal{X}$.

(i) Growth bound: If $m \ge d \ge 1$, then $\Pi_{\mathcal{F}}(m) \le \sum_{j=0}^{d} \binom{m}{j} \le \left(\frac{em}{d}\right)^d$.

(ii) Uniform deviation: For every $\delta \in (0,1)$ and $n \ge d$, with probability at least $1 - \delta$,

$$\sup_{f \in \mathcal{F}} \left| R(f) - \widehat{R}_{S_n}(f) \right| \le C \sqrt{\frac{d \log\left(\frac{2en}{d}\right) + \log\left(\frac{1}{\delta}\right)}{n}}$$

for a universal constant C.

Proof.

(i) *Growth bound*: Since no set of size $d+1$ is shattered, Sauer's lemma gives $\Pi_{\mathcal{F}}(m) \le \sum_{j=0}^{d} \binom{m}{j}$,
and the binomial-sum bound gives $\sum_{j=0}^{d} \binom{m}{j} \le \left(\frac{em}{d}\right)^d$ for $m \ge d$.

(ii) *Uniform deviation*: Symmetrization with an independent ghost sample and Hoeffding's inequality on the at most $\Pi_{\mathcal{F}}(2n)$ realized labelings give $\mathbb{P}(\sup_{f\in\mathcal{F}}\left|R(f)-\widehat{R}_{S_n}(f)\right|>\varepsilon)\le 8\Pi_{\mathcal{F}}(2n)\exp(-cn\varepsilon^2)$ for a universal $c>0$; applying (i) with $m=2n$ and solving the right side at level δ yields (ii).

Structural Commentary: VC dimension polynomially bounds sample labelings.
Key Insight: In finite-class concentration, use $|\mathcal{F}|\rightsquigarrow\Pi_{\mathcal{F}}(2n)\le\left(\frac{2en}{d}\right)^d$. □

Remark 2.1.5. *Growth Functions*
For $d=\mathrm{VCdim}(\mathcal{F})$, $\Pi_{\mathcal{F}}(m)$ is the effective number of labelings on m sample points. Sauer's lemma gives $\log\Pi_{\mathcal{F}}(m)\le d\log\left(\frac{em}{d}\right)$, so VC bounds replace $\log|\mathcal{F}|$ by the sample-level complexity $\log\Pi_{\mathcal{F}}(m)$.

Method 2.1.6. *Structural Risk Minimization*

(i) *Model ladder*: Choose $\mathcal{F}_1\subseteq\mathcal{F}_2\subseteq\cdots$ with complexities c_m, such as $c_m=\mathrm{VCdim}(\mathcal{F}_m)$.
(ii) *Uniform penalties*: Choose $\delta_m>0$ with $\sum_m\delta_m\le\delta$ and penalties $\psi_m(n,\delta_m)$ such that $\mathbb{P}(\sup_{f\in\mathcal{F}_m}\left|R(f)-\widehat{R}_{S_n}(f)\right|\le\psi_m(n,\delta_m))\ge 1-\delta_m$.
(iii) *SRM rule*: Choose $(\widehat{m},\widehat{f})\in\operatorname{argmin}_{m\in\mathbb{N},f\in\mathcal{F}_m}\{\widehat{R}_{S_n}(f)+\psi_m(n,\delta_m)\}$.

Larger m improves fit but raises ψ_m; SRM balances flexibility against search cost.

2.2 Rademacher Complexity and Covering Numbers

For real-valued predictors, complexity is often measured by how well the class can fit random noise.

Definition 2.2.1. *Rademacher Complexity*
Let $\mathcal{F}\subseteq\mathbb{R}^{\mathcal{X}}$, fix $S_n=(x_1,\dots,x_n)\in\mathcal{X}^n$, and let $\sigma_1,\dots,\sigma_n$ be i.i.d. Rademacher signs, $\mathbb{P}(\sigma_i=1)=\mathbb{P}(\sigma_i=-1)=\frac{1}{2}$. The empirical Rademacher complexity is $\widehat{\mathfrak{R}}_{S_n}(\mathcal{F}):=\mathbb{E}_\sigma\sup_{f\in\mathcal{F}}\frac{1}{n}\sum_{i=1}^n\sigma_i f(x_i)$.

If $X_1,\dots,X_n\sim P_X$ i.i.d., the population complexity is $\mathfrak{R}_n(\mathcal{F}):=\mathbb{E}_{S_n}\widehat{\mathfrak{R}}_{S_n}(\mathcal{F})$.

Definition 2.2.2. *Covering Number*
For a metric space (T,d) and $\varepsilon>0$, $N(\varepsilon,T,d):=\inf\{m:\exists t_1,\dots,t_m\in T,\ T\subseteq\bigcup_{j=1}^m\overline{B}_d(t_j,\varepsilon)\}$.

The entropy $\log N(\varepsilon,T,d)$ measures metric size at scale ε, not parameter count.

Remark 2.2.3. *Entropy Methods*
Bounds on $\log N(\varepsilon,\mathcal{F},d)$ can be integrated over scales to control empirical processes.
This is the route from functional-analytic compactness to statistical-learning rates.

2.3 Concentration and Stability

Generalization can also follow from concentration of the training criterion or from stability of the learning algorithm itself.

Definition 2.3.1. *Subgaussian Random Variable*
Centered random variable Z is *subgaussian* with variance proxy σ^2 if $\mathbb{E}\exp(\lambda Z)\le\exp(\lambda^2\sigma^2/2)\ \forall\lambda\in\mathbb{R}$.
Subgaussian variables have Gaussian-type tail bounds.

Theorem 2.3.2. *Bounded Differences Inequality*
Let $X_1,\dots,X_n$ be independent, $X:=(X_1,\dots,X_n)$, and $F:\prod_{i=1}^n\mathcal{X}_i\to\mathbb{R}$.
For $x=(x_1,\dots,x_n)$, write $x^{(i\leftarrow x_i')}:=(x_1,\dots,x_{i-1},x_i',x_{i+1},\dots,x_n)$.
Assume $\left|F(x)-F(x^{(i\leftarrow x_i')})\right|\le c_i$ for all i,x,x_i', and set $v:=\sum_{i=1}^n c_i^2$.
Then, for every $t>0$, $\mathbb{P}\{F(X)-\mathbb{E}F(X)\ge t\}\le\exp\left(-\frac{2t^2}{v}\right)$ and $\mathbb{P}\{|F(X)-\mathbb{E}F(X)|\ge t\}\le 2\exp\left(-\frac{2t^2}{v}\right)$.

Proof. Let $\mathcal{G}_i:=\sigma(X_1,\dots,X_i)$, $M_i:=\mathbb{E}(F(X)\mid\mathcal{G}_i)$, and $\Delta_i:=M_i-M_{i-1}$.
Then $M_0=\mathbb{E}F(X)$, $M_n=F(X)$, and the bounded-differences hypothesis implies that, conditionally on $\mathcal{G}_{i-1}$, Δ_i has mean 0 and lies in an interval of length at most c_i. By Hoeffding's lemma, $\mathbb{E}(\exp(\lambda\Delta_i)\mid\mathcal{G}_{i-1})\le\exp\left(\frac{\lambda^2c_i^2}{8}\right)$ for $\lambda>0$. Iterating, $\mathbb{E}\exp(\lambda(F(X)-\mathbb{E}F(X)))\le\exp\left(\frac{\lambda^2v}{8}\right)$.
By Chernoff's bound, $\mathbb{P}\{F(X)-\mathbb{E}F(X)\ge t\}\le\exp\left(-\lambda t+\frac{\lambda^2v}{8}\right)$, optimised at $\lambda=\frac{4t}{v}$.
Applying the same bound to $-F$ and taking a union bound gives the two-sided inequality.
Structural Commentary: Coordinate sensitivity plus independence makes $F(X)$ subgaussian.
Key Insight: Doob increments reduce global concentration to bounds on one-coordinate changes c_i. □

Theorem 2.3.3. *Rademacher Generalization Bound*
Let $Z_i=(X_i,Y_i)\in\mathcal{Z}:=\mathcal{X}\times\mathcal{Y}$ be i.i.d. from P.
Let $S_n=(Z_1,\dots,Z_n)$, $\mathcal{G}:=\{g_f:\mathcal{Z}\to[0,1]:g_f(x,y)=\ell(f(x),y),f\in\mathcal{F}\}$.
For $g\in\mathcal{G}$, write $Pg:=\mathbb{E}g(Z)$ and $P_ng:=\frac{1}{n}\sum_{i=1}^n g(Z_i)$.

(i) Uniform deviation: $\forall\delta\in(0,1)$, with probability at least $1-\delta$, $\sup_{g\in\mathcal{G}}(Pg-P_ng)\le 2\widehat{\mathfrak{R}}_{S_n}(\mathcal{G})+3\sqrt{\frac{\log\left(\frac{2}{\delta}\right)}{2n}}$.

(ii) Risk bound: Hence, simultaneously for all $f\in\mathcal{F}$, $R(f)\le\widehat{R}_{S_n}(f)+2\widehat{\mathfrak{R}}_{S_n}(\ell\circ\mathcal{F})+3\sqrt{\frac{\log\left(\frac{2}{\delta}\right)}{2n}}$.

Proof.

(i) Let $\Phi(S_n) := \sup_{g\in\mathcal{G}}(Pg - P_n g)$. Changing one Z_i changes Φ and $\widehat{\mathfrak{R}}_{S_n}(\mathcal{G})$ by at most $1/n$, so McDiarmid gives $\Phi \le \mathbb{E}\Phi + \varepsilon$ and $\mathfrak{R}_n(\mathcal{G}) \le \widehat{\mathfrak{R}}_{S_n}(\mathcal{G}) + \varepsilon$ with probability at least $1-\delta$, for $\varepsilon := \sqrt{\frac{\log\left(\frac{2}{\delta}\right)}{2n}}$.
Symmetrisation gives $\mathbb{E}\Phi \le 2\mathfrak{R}_n(\mathcal{G})$, hence $\Phi \le 2\widehat{\mathfrak{R}}_{S_n}(\mathcal{G}) + 3\varepsilon$.

(ii) For $z = (x, y)$ and $g_f(z) = \ell(f(x), y)$, $Pg_f = R(f)$ and $P_n g_f = \widehat{R}_{S_n}(f)$.
Applying (i) to every $g_f \in \mathcal{G}$ gives the stated simultaneous bound.

Structural Commentary: Rademacher complexity measures sample-wise noise fitting.

Key Insight: Symmetrization turns $P - P_n$ into $\mathbb{E}_\sigma \sup_{g\in\mathcal{G}} \frac{1}{n}\sum_{i=1}^{n} \sigma_i g(Z_i)$. □

Definition 2.3.4. *Uniform Stability*
A learning algorithm A has *uniform stability* β_n for loss ℓ if, for any samples $S, S' \in \mathcal{Z}^n$ differing in one coordinate, $\sup_{z\in\mathcal{Z}} |\ell(A(S), z) - \ell(A(S'), z)| \le \beta_n$.

Remark 2.3.5. *Algorithm-Dependent Generalisation*
Stability controls generalisation through the map $S \mapsto A(S)$, not only through $\mathcal{F}$.
Thus regularisation or optimisation can generalise well even when the ambient class is large.

2.4 PAC-Bayes and Information-Theoretic Bounds

PAC-Bayes bounds analyze randomized predictors by comparing a data-dependent posterior distribution on hypotheses to a fixed prior.

Definition 2.4.1. *Randomised Predictor*
Let $\mathcal{H}$ be a hypothesis space and $Q \in \mathcal{P}(\mathcal{H})$. The *randomised predictor* Q samples $h \sim Q$ before prediction, with risk $R(Q) := \mathbb{E}_{h\sim Q} R(h)$ and empirical risk $\widehat{R}_S(Q) := \mathbb{E}_{h\sim Q}\widehat{R}_S(h)$.

Theorem 2.4.2. *PAC-Bayes Bound Form*
Let $S_n = (Z_1, \dots, Z_n)$ be i.i.d., let $\ell(h, Z) \in [0, 1]$, and let $\Pi \in \mathcal{P}(\mathcal{H})$ be independent of S_n.
For $Q \ll \Pi$, set $\mathrm{KL}(Q\|\Pi) := \mathbb{E}_Q \log \frac{dQ}{d\Pi}$ and $\mathrm{kl}(a, b) := a \log \frac{a}{b} + (1-a)\log\frac{1-a}{1-b}$.

(i) With probability at least $1-\delta$, every posterior $Q \ll \Pi$ satisfies $\mathrm{kl}(\widehat{R}_{S_n}(Q), R(Q)) \le \frac{\mathrm{KL}(Q\|\Pi) + \log\left(\frac{n+1}{\delta}\right)}{n}$.

(ii) On the same event, $R(Q) \le \widehat{R}_{S_n}(Q) + \sqrt{\frac{\mathrm{KL}(Q\|\Pi) + \log\left(\frac{n+1}{\delta}\right)}{2n}}$ for every $Q \ll \Pi$.

Proof.

(i) For fixed h, the bounded-loss kl moment bound gives $\mathbb{E}_{S_n} \exp(n\,\mathrm{kl}(\widehat{R}_{S_n}(h), R(h))) \le n+1$.
Thus $\mathbb{E}_{S_n}\mathbb{E}_{h\sim\Pi} \exp(n\,\mathrm{kl}(\widehat{R}_{S_n}(h), R(h))) \le n+1$, so Markov gives,
with probability at least $1-\delta$, $\mathbb{E}_\Pi \exp(n\,\mathrm{kl}(\widehat{R}_{S_n}(h), R(h))) \le \frac{n+1}{\delta}$.
On this event, the Donsker-Varadhan inequality with $\varphi(h) := n\,\mathrm{kl}(\widehat{R}_{S_n}(h), R(h))$ gives
$\mathbb{E}_Q\varphi \le \mathrm{KL}(Q\|\Pi) + \log \mathbb{E}_\Pi \exp\varphi \;\forall Q \ll \Pi$. By convexity of kl, $n\,\mathrm{kl}(\widehat{R}_{S_n}(Q), R(Q)) \le \mathbb{E}_Q\varphi$, proving (i).

(ii) If $R(Q) \ge \widehat{R}_{S_n}(Q)$, Pinsker gives $\mathrm{kl}(\widehat{R}_{S_n}(Q), R(Q)) \ge 2(R(Q) - \widehat{R}_{S_n}(Q))^2$.
if $R(Q) < \widehat{R}_{S_n}(Q)$, the claim is immediate. Combining with (i) gives (ii).

Structural Commentary: PAC-Bayes replaces class size by posterior-prior divergence.
Key Insight: A prior-average exponential tail plus $Q \ll \Pi$ yields all posteriors at cost $\mathrm{KL}(Q\|\Pi)$. □

Remark 2.4.3. *Prior and Posterior*
In PAC-Bayes, Π need not be subjective; it anchors the complexity term $\mathrm{KL}(Q\|\Pi)$.
Smaller $\mathrm{KL}(Q\|\Pi)$ means the data-dependent posterior Q stays closer to the fixed prior.

Definition 2.4.4. *Information-Theoretic Generalization*
Let $S_n = (Z_1, \dots, Z_n)$, $W = A(S_n)$ be learned output. *Information-theoretic generalization* bounds control $\mathrm{gen}(A) := \mathbb{E}[R(W) - \widehat{R}_{S_n}(W)]$ by dependence measures such as $I(W; S_n)$.

3 Unsupervised and Latent-Variable Learning

3.1 Clustering and Mixture Models

Unsupervised learning searches for structure in inputs without direct labels or a direct prediction loss. Clustering summarizes the input distribution by grouping observations, while mixture models replace hard groups by latent component probabilities.

Definition 3.1.1. *k-Means Clustering*
Let $x_1, \dots, x_n \in \mathbb{R}^d$ and $k \in \{1, \dots, n\}$. Put $\mathcal{C} = \{C : \{1, \dots, n\} \to \{1, \dots, k\}\}$, $\mathcal{M} = (\mathbb{R}^d)^k$,
$I_r(C) = \{i : C(i) = r\}$, and, for $m = (m_1, \dots, m_k)$, $\Phi(C, m) = \sum_{r=1}^{k} \sum_{i\in I_r(C)} \|x_i - m_r\|_2^2$.

(i) A *k-means solution* is any $(C^\star, m^\star) \in \operatorname{arg\,min}_{C\in\mathcal{C},\, m\in\mathcal{M}} \Phi(C, m)$.

(ii) Its *clusters* are $I_r^\star = I_r(C^\star)$, $r = 1, \dots, k$.

(iii) For fixed C, a *minimizing center* is $m_r = |I_r(C)|^{-1} \sum_{i\in I_r(C)} x_i$ if $I_r(C) \ne \varnothing$, and arbitrary if $I_r(C) = \varnothing$.

(iv) For fixed m, a *minimizing assignment* satisfies $C(i) \in \operatorname{arg\,min}_{1\le r\le k} \|x_i - m_r\|_2^2$ for each i.

Definition 3.1.2. *Object Dissimilarities*
Let $x_1, \dots, x_n$ be objects and let $d_{ii'} = d(x_i, x_{i'})$; when attributes are used, write $x_i = (x_{i1}, \dots, x_{ip})$.

(i) A *dissimilarity matrix* is $D = (d_{ii'}) \in [0,\infty)^{n\times n}$ with $d_{ii} = 0$ and $d_{ii'} = d_{i'i}$; directional inputs $a_{ii'}$ are symmetrized by $d_{ii'} = s(a_{ii'}, a_{i'i})$, where $s : [0,\infty)^2 \to [0,\infty)$ and $s(u,v) = s(v,u)$.

(ii) Given d_j and $w_j \geq 0$ with $\sum_{j=1}^{p} w_j = 1$, the *additive dissimilarity* is $d(x_i, x_{i'}) = \sum_{j=1}^{p} w_j d_j(x_{ij}, x_{i'j})$.

(iii) *Coordinate rules*: quantitative $d_j(a,b) = |a-b|$ or $(a-b)^2$; ordinal $r \mapsto (r-1/2)/M$ for $r = 1, \dots, M$; categorical $d_j(a,b) = L_j(a,b)$ with $L_j(a,a) = 0$ and $L_j(a,b) \geq 0$.

Remark 3.1.3. *Weights and Missing Values*
For $d(x_i, x_{i'}) = \sum_{j=1}^{p} w_j d_j(x_{ij}, x_{i'j})$, the empirical scale of coordinate j is $\bar{d}_j = \binom{n}{2}^{-1} \sum_{i<i'} d_j(x_{ij}, x_{i'j})$, so its effective contribution is $w_j \bar{d}_j$. If $O_{ii'} \subseteq \{1, \dots, p\}$ is the nonempty set of coordinates observed for both x_i and $x_{i'}$, pairwise deletion uses $d(x_i, x_{i'}) = \sum_{j \in O_{ii'}} \tilde{w}_{j,ii'} d_j(x_{ij}, x_{i'j})$ with $\tilde{w}_{j,ii'} = w_j / \sum_{\ell \in O_{ii'}} w_\ell$.
Alternatives are imputed values $\tilde{x}_{ij}$ before computing d or an added categorical level `missing`.

Definition 3.1.4. *Within- and Between-Cluster Scatter*
Fix $k \in \{1, \dots, n\}$ and a symmetric dissimilarity matrix $D = (d_{ii'})$.
Let $\mathcal{C}_k = \{C : \{1, \dots, n\} \to \{1, \dots, k\}\}$ and $I_r(C) = \{i : C(i) = r\}$.

(i) The *within-cluster scatter* is $W(C) = \frac{1}{2} \sum_{r=1}^{k} \sum_{i \in I_r(C)} \sum_{i' \in I_r(C)} d_{ii'}$ for $C \in \mathcal{C}_k$.

(ii) The *total scatter* is $T = \frac{1}{2} \sum_{i=1}^{n} \sum_{i'=1}^{n} d_{ii'}$.

(iii) The *between-cluster scatter* is $B(C) = T - W(C)$ for $C \in \mathcal{C}_k$.

As T is fixed, $\arg\min_{C \in \mathcal{C}_k} W(C) = \arg\max_{C \in \mathcal{C}_k} B(C)$.

Algorithm 2: k-Means Alternating Minimization

Require: Data $x_1, \dots, x_n \in \mathbb{R}^d$, number of clusters k, initial centers or assignments
Ensure: Cluster assignments $C(i)$ and centers $m_1, \dots, m_k$
repeat
Given assignments, set each m_r to the mean of the observations with $C(i) = r$
Given centers, assign each observation by $C(i) \leftarrow \arg\min_{1 \leq r \leq k} \|x_i - m_r\|_2^2$
until the assignments no longer change

Proposition 3.1.5. *k-Means Descent and Local Minima*
Let $\mathcal{C} = \{C : \{1, \dots, n\} \to \{1, \dots, k\}\}$, $\mathcal{M} = (\mathbb{R}^d)^k$, *and* $\Phi(C, m) = \sum_{r=1}^{k} \sum_{i : C(i) = r} \|x_i - m_r\|_2^2$.
Suppose $(C^t, m^t) \in \mathcal{C} \times \mathcal{M}$ *satisfies* $m^{t+1} \in \arg\min_{m \in \mathcal{M}} \Phi(C^t, m)$ *and* $C^{t+1} \in \arg\min_{C \in \mathcal{C}} \Phi(C, m^{t+1})$ *for each* t.

(i) The objective is nonincreasing: $\Phi(C^{t+1}, m^{t+1}) \leq \Phi(C^t, m^t)$.
(ii) If $C^{t+1} = C^t = C^\star$ *and* $m^{t+1} = m^t = m^\star$, *then* $(C^\star, m^\star)$ *is coordinatewise minimal:* $m^\star \in \arg\min_{m \in \mathcal{M}} \Phi(C^\star, m)$ *and* $C^\star \in \arg\min_{C \in \mathcal{C}} \Phi(C, m^\star)$.
Coordinatewise minimal need not be global; compare initialisations by terminal Φ.

Proof.
(i) By the center update, $\Phi(C^t, m^{t+1}) \leq \Phi(C^t, m^t)$. By the assignment update, $\Phi(C^{t+1}, m^{t+1}) \leq \Phi(C^t, m^{t+1})$. Combining gives the claim.
(ii) At a fixed point, $C^{t+1} = C^t = C^\star$ and $m^{t+1} = m^t = m^\star$ in the two update inclusions, giving the two coordinatewise optimality conditions.

Structural Commentary: Exact block minimization forces descent.
Key Insight: A stopped run certifies blockwise, not global, optimality. □

Algorithm 3: k-Medoids Alternating Representatives

Require: Pairwise dissimilarities $D(x_i, x_{i'})$, number of clusters k, initial assignments
Ensure: Cluster assignments $C(i)$ and representative indices $i_1^\star, \dots, i_k^\star$
repeat
for $r = 1, \dots, k$ **do**
Set $i_r^\star \leftarrow \arg\min_{i : C(i) = r} \sum_{C(i') = r} D(x_i, x_{i'})$
end for
Assign each observation by $C(i) \leftarrow \arg\min_{1 \leq r \leq k} D(x_i, x_{i_r^\star})$
until the assignments no longer change

Remark 3.1.6. *k-Medoids Versus k-Means*
Fix an assignment C and write $I_r = \{i : C(i) = r\}$.

(i) *k-means*: $m_r \in \arg\min_{m \in \mathbb{R}^d} \sum_{i \in I_r} \|x_i - m\|_2^2$, hence $m_r = |I_r|^{-1} \sum_{i \in I_r} x_i$ when $I_r \neq \varnothing$.

(ii) *k-medoids*: $i_r^\star \in \arg\min_{i \in I_r} \sum_{i' \in I_r} D(x_i, x_{i'})$, with representative $x_{i_r^\star}$.

k-medoids only requires pairwise dissimilarities and keeps representatives inside the data set.
Its representative update is usually costlier than the k-means empirical mean.

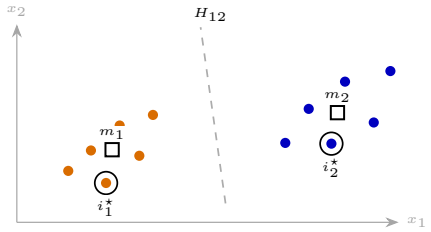

Figure 251: Open squares are centroids, circled points are medoids, the dashed line is nearest-center boundary.

Remark 3.1.7. *Choosing the Number of Clusters*
For k-means or k-medoids, choose k and an initialisation. Let W_k be terminal within-cluster scatter.
The elbow diagnostic inspects $k \mapsto W_k$; the gap statistic uses $G(k) = \mathbb{E}_0[\log W_k] - \log W_k$, where $\mathbb{E}_0$ is under a reference distribution on the data range.
With simulation standard error s'_{k+1}, one rule is $\widehat{k} = \min\{k : G(k) \geq G(k+1) - s'_{k+1}\}$.
This formalises the bend comparison but remains heuristic.

Method 3.1.8. *Hierarchical Clustering and Linkage*
Given dissimilarities $d_{ii'}$ and a linkage $L(G, H)$ between nonempty groups, agglomerative hierarchical clustering constructs nested partitions.

(i) Initialize $\mathcal{P}_0 = \{\{1\}, \ldots, \{n\}\}$.
(ii) At step t, choose distinct $G, H \in \mathcal{P}_t$ minimizing $L(G, H)$.
(iii) Set $\mathcal{P}_{t+1} = (\mathcal{P}_t \setminus \{G, H\}) \cup \{G \cup H\}$ and record merge height $L(G, H)$.
(iv) Stop at $\mathcal{P}_{n-1} = \{\{1, \ldots, n\}\}$.

For groups G, H with sizes N_G, N_H, common linkages are

(i) *Single*: $L_{\mathrm{SL}}(G, H) = \min_{i \in G,\, i' \in H} d_{ii'}$.
(ii) *Complete*: $L_{\mathrm{CL}}(G, H) = \max_{i \in G,\, i' \in H} d_{ii'}$.
(iii) *Group average*: $L_{\mathrm{GA}}(G, H) = (N_G N_H)^{-1} \sum_{i \in G} \sum_{i' \in H} d_{ii'}$.

Recorded merges form a dendrogram; divisive clustering reverses the process by recursive splits.

Remark 3.1.9. *Dendrograms and Cophenetic Distances*
For dendrogram merge height $h_T(i, i')$, the cut at height a partitions observations by $i \sim_a i'$ iff $h_T(i, i') \leq a$.
The cophenetic dissimilarity is $C_{ii'} = h_T(i, i')$, the first height at which i and i' share a cluster.
It is ultrametric: $C_{ii'} \leq \max\{C_{ih}, C_{i'h}\}$. Thus a dendrogram is an algorithmic hierarchical summary, not an exact representation of arbitrary input dissimilarities.

Method 3.1.10. *Self-Organizing Map*
A self-organizing map uses prototypes $m_1^t, \ldots, m_q^t \in \mathbb{R}^p$ indexed by grid locations $\ell_1, \ldots, \ell_q \in \mathcal{Q}_1 \times \mathcal{Q}_2$.
Let $\alpha_t > 0$ and $h_t : [0, \infty) \to [0, 1]$ be the learning rate and neighborhood kernel.

(i) Select an observation x_i.
(ii) Find a winner $j_t \in \arg\min_{1 \leq j \leq q} \left\| x_i - m_j^t \right\|_2^2$.
(iii) Update every prototype by $m_k^{t+1} = m_k^t + \alpha_t h_t(\|\ell_{j_t} - \ell_k\|_2)(x_i - m_k^t)$, $k = 1, \ldots, q$.
(iv) Increment t and repeat until the stopping rule or schedule terminates.

A common kernel is $h_t(s) = \mathbf{1}_{s \leq r_t}$ with decreasing radius r_t.
Early large neighborhoods enforce grid smoothness; if $h_t(s) = \mathbf{1}_{s=0}$, the method reduces to online k-means.

Remark 3.1.11. *Checking the Topological Constraint*
For q prototypes, compare $E_{\mathrm{SOM}} = \sum_i \left\| x_i - m_{C(i)} \right\|_2^2$ with the q-means optimum $E_q^\star = \min_{C, m} \sum_i \left\| x_i - m_{C(i)} \right\|_2^2$.
Since $E_q^\star \leq E_{\mathrm{SOM}}$, a large gap $E_{\mathrm{SOM}} - E_q^\star$ indicates an overly restrictive lattice constraint.

Method 3.1.12. *Spectral Clustering*
Given weights $w_{ii'} \geq 0$, set $W = (w_{ii'})$, $g_i = \sum_{i'=1}^{n} w_{ii'}$, $G = \mathrm{diag}(g_i)$, and $L = G - W$.
Often $w_{ii'} = s_{ii'} = \exp(-\frac{\|x_i - x_{i'}\|_2^2}{c})$ (restricted to mutual nearest-neighbor edges). For target k clusters:

(i) Construct W, G, and the Laplacian L.
(ii) Compute eigenvectors $u_1, \ldots, u_k$ for the k smallest nontrivial eigenvalues of L.
(iii) Form $U = (u_1, \ldots, u_k) \in \mathbb{R}^{n \times k}$ and represent observation i by row $U_{i\cdot}$.
(iv) Cluster the rows $U_{i\cdot}$ into k groups, typically by k-means.

$f^T L f = \frac{1}{2} \sum_{i=1}^{n} \sum_{i'=1}^{n} w_{ii'}(f_i - f_{i'})^2$, so small-eigenvalue directions are smooth across high-weight edges.

Remark 3.1.13. *Connected Components and Random Walks*
Let $L = G - W$ and, when $g_i > 0$, $P = G^{-1}W$.

(i) If the graph has components $A_1, \ldots, A_m$, then $\ker L = \mathrm{span}\{\mathbf{1}_{A_1}, \ldots, \mathbf{1}_{A_m}\}$.
(ii) The matrix P is a random-walk transition matrix.
A good spectral cluster A has large within-set transition mass $\sum_{i \in A} \sum_{i' \in A} P_{ii'}$ and small cross-set mass.

Nearly separated clusters replace exact zero eigenvalues by small eigenvalues.

Definition 3.1.14. *Finite Mixture Model*

Let $Z \in \{1, \dots, k\}$ be latent with $\mathbb{P}(Z = z) = \pi_z$, $\pi_z \geq 0$, and $\sum_{z=1}^{k} \pi_z = 1$.

Given component densities $p_z(\cdot; \theta_z)$, the marginal density is $p(x) = \sum_{z=1}^{k} \pi_z p_z(x; \theta_z)$.

Definition 3.1.15. *Mixture Responsibilities*

For fitted $(\widehat{\pi}_m, \widehat{\theta}_m)_{m=1}^{k}$, define $\widehat{r}_{im} = \widehat{\mathbb{P}}(Z_i = m \mid x_i) = \widehat{\pi}_m p_m(x_i; \widehat{\theta}_m) \left(\sum_{\ell=1}^{k} \widehat{\pi}_\ell p_\ell(x_i; \widehat{\theta}_\ell) \right)^{-1}$.

Then $\widehat{r}_i$ is soft membership and $\widehat{C}(i) \in \arg\max_{1 \leq m \leq k} \widehat{r}_{im}$ is a hard assignment.

Remark 3.1.16. *Mixtures as Density Estimates*

Gaussian mixtures give flexible density estimates $p(x) = \sum_{m=1}^{k} \pi_m \phi(x; \mu_m, \Sigma_m)$. If class-conditional mixtures $\widehat{p}_g(x)$ and class priors $\widehat{\pi}_g$ are fit separately, the Bayes classifier is $\widehat{g}(x) \in \arg\max_g \widehat{\pi}_g \widehat{p}_g(x)$.

Without labels, component-label agreement is discovered structure, not supervised training.

Remark 3.1.17. *Gaussian Mixtures as Soft k-Means*

For $p_m(x) = \phi(x; \mu_m, \sigma^2 I)$, the responsibility is $r_{im} = \pi_m \exp(-\frac{\|x_i - \mu_m\|_2^2}{2\sigma^2}) \left(\sum_{\ell=1}^{k} \pi_\ell \exp(-\frac{\|x_i - \mu_\ell\|_2^2}{2\sigma^2}) \right)^{-1}$.

Thus r_{im} is distance-weighted; as $\sigma^2 \downarrow 0$, it concentrates on nearest centers, yielding hard k-means assignments.

Method 3.1.18. *Expectation-Maximization*

Given $x_{1:n}$ and $p(x) = \sum_{m=1}^{k} \pi_m p_m(x; \theta_m)$, set $\ell(\pi, \theta) = \sum_{i=1}^{n} \log(\sum_{m=1}^{k} \pi_m p_m(x_i; \theta_m))$. EM alternates:

(i) *E-step*: compute $r_{im} = \frac{\pi_m p_m(x_i; \theta_m)}{\sum_{\ell=1}^{k} \pi_\ell p_\ell(x_i; \theta_\ell)}$.

(ii) *M-step*: update $\pi_m^{\text{new}} = n^{-1} \sum_{i=1}^{n} r_{im}$ and $\theta_m^{\text{new}} \in \arg\max_{\theta_m} \sum_{i=1}^{n} r_{im} \log p_m(x_i; \theta_m)$.

For Gaussian components, the M-step gives weighted means and variances or covariances.
With an exact M-step, ℓ is nondecreasing, but convergence may be to a local maximum.

Remark 3.1.19. *Identifiability*

For any permutation τ of $\{1, \dots, k\}$, $\sum_{m=1}^{k} \pi_m p_m(x; \theta_m) = \sum_{m=1}^{k} \pi_{\tau(m)} p_{\tau(m)}(x; \theta_{\tau(m)})$.

Thus labels are identifiable only up to permutation: density is invariant, component interpretation is not.

3.2 Dimension Reduction and Manifold Learning

Dimension reduction replaces high-dimensional observations, similarities, or dissimilarities by lower-dimensional coordinates that preserve selected structure. Linear methods preserve variance or inner products; manifold methods preserve neighborhoods, graph distances, or local affine geometry.

Definition 3.2.1. *Principal Component Analysis*

Let centered observations $x_1, \dots, x_n \in \mathbb{R}^p$ be the rows of $X \in \mathbb{R}^{n \times p}$, and let $1 \leq r \leq p$.

(i) Rank-r principal component analysis chooses $V = [v_1 \ \cdots \ v_r] \in \mathbb{R}^{p \times r}$, with $V^T V = I_r$ solving $\min_{V^T V = I_r} \|X - XVV^T\|_F^2$.

(ii) The columns $v_1, \dots, v_r$ are the principal directions, $\text{im}(V)$ is the rank-r principal subspace, and $x_i \mapsto VV^T x_i$ is the fitted projection.

(iii) Equivalently, V solves $\max_{V^T V = I_r} \text{tr}(V^T X^T X V)$,

with sequential directions $v_k \in \text{argmax}\{\sum_{i=1}^{n} (v^T x_i)^2 : \|v\|_2 = 1, \ v \perp v_1, \dots, v_{k-1}\}$.

Method 3.2.2. *PCA by SVD*

Let the centered observations be the rows of $X \in \mathbb{R}^{n \times p}$, and fix $1 \leq r \leq \min\{n, p\}$.

(i) Compute an SVD $X = UDV^T$ with singular values $d_1 \geq \cdots \geq 0$.
(ii) Set $V_r = [v_1 \ \cdots \ v_r]$, the first r right singular vectors.
(iii) Set the score matrix $Z_r = XV_r = U_r D_r$.
(iv) Set the fitted matrix $\widehat{X}_r = Z_r V_r^T = XV_r V_r^T = U_r D_r V_r^T$.

The columns of V_r are the rank-r PCA directions, Z_r contains the principal-component scores, and $\widehat{X}_r$ is the orthogonal rank-r reconstruction minimizing $\left\|X - \widehat{X}\right\|_F^2$.

Method 3.2.3. *Kernel PCA*

Let k be a positive definite kernel on observations $x_1, \dots, x_n$, fix r, and set $M = n^{-1}\mathbf{1}\mathbf{1}^T$.

(i) Form the Gram matrix $K = (k(x_i, x_{i'}))_{i,i'}$.
(ii) Center it by $\widetilde{K} = (I_n - M)K(I_n - M)$.
(iii) Compute $\widetilde{K} u_j = \lambda_j u_j$ with $\lambda_1 \geq \cdots \geq \lambda_r > 0$, and set $U_r = [u_1 \ \cdots \ u_r]$, $\Lambda_r = \text{diag}(\lambda_1, \dots, \lambda_r)$.
(iv) Return coordinates $Z = U_r \Lambda_r^{1/2}$.

Kernel PCA is spectral PCA on $\widetilde{K}$; radial kernels encode local similarity.

Method 3.2.4. *Sparse Principal Components*
Let centered data have rows x_i^T in $X \in \mathbb{R}^{n\times p}$, and let $v \in \mathbb{R}^p$ be a loading vector.

(i) *Variance form*: set $\mathcal{V}_t = \{a \in \mathbb{R}^p : a^T a = 1,\ \sum_{j=1}^{p} |a_j| \le t\}$ and choose $v \in \operatorname{argmax}_{a\in\mathcal{V}_t} a^T X^T X a$.

(ii) *Reconstruction form*: for one component, choose $(\theta, v) \in \operatorname{argmin}_{\|\theta\|_2=1} \sum_{i=1}^{n} \left\|x_i - \theta v^T x_i\right\|_2^2 + \lambda \|v\|_2^2 + \lambda_1 \|v\|_1$.

L_1 regularization sparsifies loadings; multiple components alternate sparse-loading and orthogonal-score updates.

Definition 3.2.5. *Multidimensional Scaling*
Let $D = (d_{ii'})$ be a symmetric dissimilarity matrix with $d_{ii} = 0$, fix $r < n$, and write $Z = (z_1^T, \dots, z_n^T)^T \in \mathbb{R}^{n\times r}$ with fitted distances $\delta_{ii'}(Z) = \|z_i - z_{i'}\|_2$. Multidimensional scaling chooses Z so that $\delta_{ii'}(Z)$ approximates $d_{ii'}$.

(i) *Least-squares MDS*, or Kruskal–Shepard scaling, minimizes $S_{\mathrm{MDS}}(Z) = \sum_{i\neq i'} (d_{ii'} - \delta_{ii'}(Z))^2$ over $Z \in \mathbb{R}^{n\times r}$.

(ii) *Sammon MDS*, defined when $d_{ii'} > 0$ for $i \neq i'$, minimizes $S_{\mathrm{Sammon}}(Z) = \sum_{i\neq i'} \frac{(d_{ii'} - \delta_{ii'}(Z))^2}{d_{ii'}}$ over $Z \in \mathbb{R}^{n\times r}$.

Sammon weighting penalizes relative errors more strongly for small dissimilarities.

Method 3.2.6. *Classical Scaling*
Let $H = I_n - n^{-1}\mathbf{1}\mathbf{1}^T$ and fix $r < n$.

(i) If centered similarities $S = (s_{ii'})$ are supplied, set $B = S$.
(ii) If Euclidean distances $\Delta = (\Delta_{ii'})$ are supplied, set $\Delta^{(2)} = (\Delta_{ii'}^2)$ and $B = -\frac{1}{2} H \Delta^{(2)} H$.
(iii) Compute $Be_j = \lambda_j e_j$ with $\lambda_1 \ge \cdots \ge \lambda_r > 0$, and set $E_r = [e_1\ \cdots\ e_r]$, $\Lambda_r = \operatorname{diag}(\lambda_1, \dots, \lambda_r)$.
(iv) Return $Z_r = E_r \Lambda_r^{1/2} \in \mathbb{R}^{n\times r}$, with row z_i^T as the coordinate of observation i.

The construction gives centered coordinates and fitted Gram matrix $Z_r Z_r^T = E_r \Lambda_r E_r^T$, the rank-$r$ positive-semidefinite approximation to B from its leading positive spectrum.

Method 3.2.7. *Nonmetric Scaling*
Given dissimilarities $D = (d_{ii'})$, coordinates $Z = (z_1^T, \dots, z_n^T)^T \in \mathbb{R}^{n\times r}$, and an increasing map θ, nonmetric scaling minimizes $S_{\mathrm{NM}}(Z, \theta) = \sum_{i\neq i'} (\|z_i - z_{i'}\|_2 - \theta(d_{ii'}))^2 / \sum_{i\neq i'} \|z_i - z_{i'}\|_2^2$.

(i) With θ fixed, update Z by minimizing $S_{\mathrm{NM}}(Z, \theta)$ over $Z \in \mathbb{R}^{n\times r}$.
(ii) With Z fixed, update θ by isotonic regression of the fitted distances $\|z_i - z_{i'}\|_2$ on the dissimilarities $d_{ii'}$.

Only the ordering of $d_{ii'}$ constrains $\theta(d_{ii'})$; their original scale is discarded.

Definition 3.2.8. *Encoder and Decoder*
Let $\mathcal{X}$ be a data space and $\mathcal{H}$ a representation space.

(i) An *encoder* is a map $e : \mathcal{X} \to \mathcal{H}$, with representation $h = e(x)$.
(ii) A *decoder* is a map $d : \mathcal{H} \to \mathcal{X}$, with reconstruction $\widehat{x} = d(h) = d(e(x))$.

Linear PCA is the case e, d linear with $\operatorname{im}(d)$ an orthogonal representation subspace.

Method 3.2.9. *Procrustes Shape Alignment*
Let $X_1, X_2 \in \mathbb{R}^{n\times p}$ have corresponding landmark rows.
Orthogonal Procrustes alignment solves $\min_{R^T R = I, \mu\in\mathbb{R}^p} \left\|X_2 - (X_1 R + \mathbf{1}\mu^T)\right\|_F$.

(i) Compute column means $\bar{x}_1, \bar{x}_2$ and centered matrices $\widetilde{X}_a = X_a - \mathbf{1}\bar{x}_a^T$, $a = 1, 2$.
(ii) Compute an SVD $\widetilde{X}_1^T \widetilde{X}_2 = U D V^T$.
(iii) Set $\widehat{R} = UV^T$ and $\widehat{\mu} = \bar{x}_2 - \widehat{R}^T \bar{x}_1$.
(iv) For scaled Procrustes, set $\widehat{\beta} = \operatorname{tr}(D) / \left\|\widetilde{X}_1\right\|_F^2$, $\widehat{\mu}_\beta = \bar{x}_2 - \widehat{\beta}\widehat{R}^T \bar{x}_1$, and use fitted configuration $\widehat{\beta} X_1 \widehat{R} + \mathbf{1}\widehat{\mu}_\beta^T$.

The unscaled solution uses $\widehat{\beta} = 1$ and preserves size; the scaled solution also matches overall scale.

Method 3.2.10. *Procrustes Shape Average*

For centered matched shapes $X_\ell \in \mathbb{R}^{n\times p}$, set $\Phi(M, \{R_\ell\}) = \sum_{\ell=1}^{L} \|X_\ell R_\ell - M\|_F^2$, $R_\ell^T R_\ell = I_p$.

A Procrustes shape average solves $\min_{M, \{R_\ell\}} \Phi(M, \{R_\ell\})$.

(i) Initialize $M^{(0)}$ as a centered observed shape or an initially aligned average.
(ii) Given $M^{(t)}$, compute $R_\ell^{(t)} \in \operatorname{argmin}_{R^T R = I_p} \left\|X_\ell R - M^{(t)}\right\|_F^2$ for each ℓ.
(iii) Update $M^{(t+1)} = L^{-1} \sum_{\ell=1}^{L} X_\ell R_\ell^{(t)}$.
(iv) Recenter $M^{(t+1)}$ and, when size is fixed, rescale it to the chosen norm.
(v) Repeat (ii)–(iv) until Φ changes by less than the chosen tolerance.

The template is determined only up to a common right rotation unless a final orientation convention is imposed.

Remark 3.2.11. *Manifold Hypothesis*
The manifold hypothesis asserts that observations $x_1, \dots, x_n \in \mathbb{R}^p$ satisfy $\operatorname{dist}(x_i, \mathcal{M}) \le \varepsilon$ for some r-dimensional set $\mathcal{M} \subset \mathbb{R}^p$, with $r \ll p$ and small $\varepsilon \ge 0$. For curved $\mathcal{M}$, ambient distances $\|x_i - x_j\|_2$ need not approximate intrinsic distances $d_{\mathcal{M}}(x_i, x_j)$. Manifold learning therefore estimates low-dimensional coordinates from neighborhoods, graph geodesics, or tangent spaces, rather than from global Euclidean variance alone.

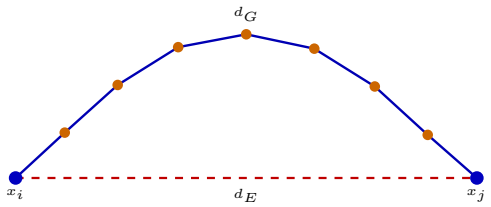

Figure 252: d_G follows nearby samples along the curve; d_E is the ambient shortcut.

Example 3.2.12. *Manifold Methods*
Isomap, locally linear embedding, Laplacian eigenmaps, and diffusion maps construct low-dimensional coordinates from a neighborhood graph or kernel on the sample.

Method 3.2.13. *Isomap*
Let $x_i \in \mathbb{R}^p$, fix r, set $H = I_n - n^{-1}\mathbf{1}\mathbf{1}^T$, and choose a connected neighborhood graph G on $[n]$.

(i) Assign edge weights $w_{ij} = \|x_i - x_j\|_2$ to neighboring pairs.
(ii) Compute shortest-path distances $d_G(i,j)$ and set $D_G^{(2)} = (d_G(i,j)^2)$.
(iii) Form the centered Gram estimate $B = -\frac{1}{2} H D_G^{(2)} H$.
(iv) Compute $Be_k = \lambda_k e_k$ with $\lambda_1 \geq \cdots \geq \lambda_r > 0$, set $E_r = [e_1 \ \cdots \ e_r]$, $\Lambda_r = \operatorname{diag}(\lambda_1, \ldots, \lambda_r)$.
(v) Return $Z = E_r \Lambda_r^{1/2}$.

Isomap replaces ambient distances by graph geodesic distances; the coordinate extraction is spectral.

Method 3.2.14. *Locally Linear Embedding*
Let $x_i \in \mathbb{R}^p$, fix K, r, and let $\mathcal{N}(i)$ be the K nearest neighbors of x_i.

(i) Set $\mathcal{W}_i = \{w : \sum_k w_k = 1,\ w_k = 0\ (k \notin \mathcal{N}(i))\}$ and $w_i \in \operatorname*{argmin}_{w \in \mathcal{W}_i} \left\| x_i - \sum_k w_k x_k \right\|_2^2$.
(ii) Form $W = (w_{ik})$ and $M = (I_n - W)^T (I_n - W)$.
(iii) Compute eigenvectors $u_1, \ldots, u_{r+1}$ of M for the smallest eigenvalues, with $u_1 \propto \mathbf{1}$.
(iv) Return $Y = [u_2 \ \cdots \ u_{r+1}] \in \mathbb{R}^{n \times r}$, with row y_i^T as the coordinate of x_i.

The affine constraint makes local weights translation-invariant; discarding u_1 gives mean-centered coordinates.

Method 3.2.15. *Local MDS*
Let $\mathcal{N} \subset \{(i,i') : i < i'\}$ be symmetric nearby pairs, let $z_i \in \mathbb{R}^r$, and fix $\tau > 0$.
Local MDS minimizes $S_{\text{local}}(Z) = \sum_{(i,i') \in \mathcal{N}} (d_{ii'} - \|z_i - z_{i'}\|_2)^2 - \tau \sum_{(i,i') \notin \mathcal{N}} \|z_i - z_{i'}\|_2$.

(i) The local stress term preserves distances on nearby pairs $(i,i') \in \mathcal{N}$.
(ii) The separation term penalizes collapse of non-neighboring pairs $(i,i') \notin \mathcal{N}$.

Thus the objective preserves local metric structure while repelling unrelated manifold regions.

Definition 3.2.16. *Principal Curves and Surfaces*
Let $X \in \mathbb{R}^p$ be a random vector and let $f : \Lambda \to \mathbb{R}^p$ be a smooth parametrized set.

(i) The *projection index* is $\lambda_f(x) \in \operatorname*{argmin}_{\lambda \in \Lambda} \|x - f(\lambda)\|_2$.
(ii) A *principal curve* has $\Lambda \subset \mathbb{R}$ and satisfies $f(\lambda) = \mathbb{E}\{X \mid \lambda_f(X) = \lambda\}$.
(iii) A *principal surface* is the same definition with $\Lambda \subset \mathbb{R}^q$, $q \geq 2$, and $f = (f_1, \ldots, f_p)$.

For finite data, alternate coordinate-wise smoothing against $\lambda_f(x_i)$ and reprojection onto $f(\Lambda)$.

Remark 3.2.17. *SOMs Versus Principal Surfaces*
Both self-organizing maps and principal surfaces approximate data by low-dimensional representatives.

(i) A principal surface is a smooth map $f : \Lambda \subset \mathbb{R}^q \to \mathbb{R}^p$ with fitted coordinates $\lambda_f(x_i)$.
(ii) A self-organizing map is a finite prototype family $\{m_a\}_{a \in A} \subset \mathbb{R}^p$ indexed by a lattice or graph A.

With many prototypes and kernel neighborhood weights, batch SOM updates resemble coordinate-wise surface smoothing, but one fit is smooth-parametric and the other is finite-prototype.

Remark 3.2.18. *Local versus Global Scaling*
Let $d_E(i,j) = \|x_i - x_j\|_2$ and let $\mathcal{N}$ be a neighborhood relation.

(i) *Global scaling* uses all pairs through $d_E(i,j)$ or centered inner products, and is appropriate when ambient distances encode the target geometry.
(ii) *Local scaling* uses $\mathcal{N}$, graph distances, or local reconstruction weights to preserve neighborhood order or local shape on a curved set.

Neighborhood scale is critical: too small disconnects, too large shortcuts.

3.3 Matrix Factorization and Topic Models

Many unsupervised models express data as combinations of latent factors.

Definition 3.3.1. *Low-Rank Matrix Factorization*
Let $X \in \mathbb{R}^{m \times n}$ and $1 \leq r \leq \min\{m,n\}$.
A *rank-r matrix factorization* is pair $(U,V) \in \mathbb{R}^{m \times r} \times \mathbb{R}^{n \times r}$ with fitted matrix $\widehat{X} = UV^\top$ and $\operatorname{rank}(\widehat{X}) \leq r$.
For a loss $\mathcal{L}$, choose (U,V) to minimize $\mathcal{L}(X, UV^\top)$; the columns encode latent row and column factors.

Definition 3.3.2. *Nonnegative Matrix Factorization*
Let $X \in \mathbb{R}_+^{n\times p}$ and $1 \le r \le \min\{n,p\}$.
A *nonnegative matrix factorization* is a pair $(W,H) \in \mathbb{R}_+^{n\times r} \times \mathbb{R}_+^{r\times p}$ with fitted matrix $\widehat{X} = WH$.
For loss $\mathcal{L}$, minimize $\mathcal{L}(X, WH)$ over $W, H \ge 0$, yielding additive parts-based factors.

Method 3.3.3. *Poisson NMF Multiplicative Updates*
For count data $X = (x_{ij})$, set $\mu = WH$ and $L(W,H) = \sum_{i,j}\{x_{ij}\log\mu_{ij} - \mu_{ij}\}$, up to constants.

(i) Initialize $W, H > 0$.
(ii) Set $\rho_{ik}^W = (\sum_j \frac{h_{kj}x_{ij}}{\mu_{ij}})/(\sum_j h_{kj})$ and update $w_{ik} \leftarrow w_{ik}\rho_{ik}^W$.
(iii) Recompute $\mu = WH$, set $\rho_{kj}^H = (\sum_i \frac{w_{ik}x_{ij}}{\mu_{ij}})/(\sum_i w_{ik})$, and update $h_{kj} \leftarrow h_{kj}\rho_{kj}^H$.
(iv) Repeat (ii)–(iii) until $L(W,H)$ stabilises.

The updates are local; different initialisations may give different NMF decompositions.

Remark 3.3.4. *NMF Non-Uniqueness*
An NMF $X = WH$ is not identifiable from nonnegativity alone: if A is invertible and $WA \ge 0$, $A^{-1}H \ge 0$, then $X = (WA)(A^{-1}H)$.
Interpretability therefore depends on additional geometry, constraints, or initialization.

Definition 3.3.5. *Archetypal Analysis*
Let $X \in \mathbb{R}^{n\times p}$ have observed rows x_i^T, and fix r archetypes.

(i) Observation weights $W = (w_{ik}) \in \mathbb{R}_+^{n\times r}$ satisfy $\sum_{k=1}^{r} w_{ik} = 1$.
(ii) Archetype weights $B = (b_{ki}) \in \mathbb{R}_+^{r\times n}$ satisfy $\sum_{i=1}^{n} b_{ki} = 1$.
(iii) Archetypes are the rows of $H = BX$, hence lie in $\mathrm{conv}\{x_1,\dots,x_n\}$.
(iv) Archetypal analysis chooses W, B minimising $J(W,B) = \|X - WBX\|_F^2$.

Archetypes are convex-hull extremes rather than central prototypes.

Remark 3.3.6. *Archetypes, k-Means, and NMF*
For prototype matrix H and assignment/mixture weights W:

(i) k-means uses one-hot rows of W.
(ii) NMF uses nonnegative W, H without requiring prototype rows of H to be observed-data mixtures.
(iii) Archetypal analysis uses simplex rows of W and constrains $H = BX$ with simplex rows of B.

Archetypes are convex-hull prototypes; k-means is hard-assigned and NMF is hull-free.

Definition 3.3.7. *Topic Model*
Fix K topics and a vocabulary of size p.

(i) Topic k is a word distribution $\beta_k \in \Delta_{p-1}$.
(ii) Document d has topic mixture $\theta_d \in \Delta_{K-1}$.
(iii) Token m in document d is generated by $z_{dm} \sim \mathrm{Cat}(\theta_d)$ and $w_{dm} \sim \mathrm{Cat}(\beta_{z_{dm}})$.
(iv) Latent Dirichlet allocation adds priors $\theta_d \sim \mathrm{Dir}(\alpha)$ and $\beta_k \sim \mathrm{Dir}(\eta)$.

Remark 3.3.8. *Regularized Factors*
For a factorization $X \approx UV^\top$, constraints select an identifiable and interpretable solution class.

(i) Low rank bounds latent dimension.
(ii) Sparsity restricts active variables or factors.
(iii) Nonnegativity enforces additive parts.
(iv) Probabilistic priors encode uncertainty and shrinkage.

These restrictions convert an underdetermined algebraic fit into a statistical learning problem.

3.4 Representation Learning Objectives

Representation learning trains maps that make downstream prediction, reconstruction, comparison, or generation easier.

Definition 3.4.1. *Autoencoder*
Let $x_1,\dots,x_n \in \mathcal{X}$ and let $\mathcal{H}$ be a representation space.

(i) An *autoencoder* is an encoder-decoder pair $e : \mathcal{X} \to \mathcal{H}$ and $d : \mathcal{H} \to \mathcal{X}$.
(ii) It is trained by minimizing a reconstruction loss such as $n^{-1}\sum_{i=1}^{n} \|x_i - d(e(x_i))\|_2^2$.

Bottlenecks, noise, sparsity, or latent-variable constraints rule out the unrestricted identity solution.

Definition 3.4.2. *Sparse Representation Objective*
Let $x_i \in \mathbb{R}^p$, dictionary $W \in \mathbb{R}^{p\times r}$, codes $h_i \in \mathbb{R}^r$, and $\lambda > 0$.
A *sparse representation objective* chooses $W, h_1,\dots,h_n$ to minimize $\sum_{i=1}^{n}\{\|x_i - Wh_i\|_2^2 + \lambda\|h_i\|_1\}$.
The reconstruction term fits x_i, while the L_1 term sparsifies h_i.

Definition 3.4.3. *Contrastive Objective*
Let $g : \mathcal{X} \to \mathbb{R}^r$ be a representation map, $s(u,v)$ a similarity score, and $\tau > 0$ a temperature.

(i) For an anchor x, sample a positive x^+ and negatives $x_1^-,\dots,x_K^-$.
(ii) With $a^+ = s(g(x), g(x^+))/\tau$ and $a_k^- = s(g(x), g(x_k^-))/\tau$, min loss i.e. $\log\left\{\exp(a^+) + \sum_{k=1}^{K}\exp(a_k^-)\right\} - a^+$.

The objective raises similarity to positives and lowers relative similarity to negatives.

3.5 Association Rules and Density-Ratio Views

Association-rule analysis searches for simple descriptions of regions where the input distribution has relatively large probability. The classical market-basket setting is the binary special case, but the same idea extends to conjunctions of coordinate conditions.

Definition 3.5.1. *Conjunctive Region*
Let $X = (X_1, \dots, X_p)$ take values in $\mathcal{S} = \prod_{j=1}^{p} \mathcal{S}_j$. For $\mathcal{J} \subseteq \{1, \dots, p\}$ and $s = (s_j)_{j \in \mathcal{J}}$ with $s_j \subseteq \mathcal{S}_j$, the *conjunctive region* is $R(\mathcal{J}, s) = \{x \in \mathcal{S} : x_j \in s_j \ \forall j \in \mathcal{J}\}$, with event $\{X \in R(\mathcal{J}, s)\} = \bigcap_{j \in \mathcal{J}} \{X_j \in s_j\}$.
Coordinates in $\{1, \dots, p\} \setminus \mathcal{J}$ are unrestricted; under the extension $s_j = \mathcal{S}_j$, they add no constraint.
For $\mathcal{S}_j \subseteq \mathbb{R}$, s_j is typically an interval; for categorical $\mathcal{S}_j$, s_j is typically a subset of levels.

Definition 3.5.2. *Market-Basket Item Sets*
Let $\mathcal{I} = \{1, \dots, K\}$ and $z_i = (z_{ik})_{k \in \mathcal{I}} \in \{0,1\}^{\mathcal{I}}$ for $i = 1, \dots, n$, where $z_{ik} = 1$ iff observation i contains item k.

(i) An *item set* is any $\mathcal{K} \subseteq \mathcal{I}$.
(ii) The containment indicator is $Y_i(\mathcal{K}) = \prod_{k \in \mathcal{K}} z_{ik}$; observation i contains $\mathcal{K}$ iff $Y_i(\mathcal{K}) = 1$.
(iii) The empirical support is $T(\mathcal{K}) = n^{-1} \sum_{i=1}^{n} Y_i(\mathcal{K})$.
(iv) For finite categorical supports, take $\mathcal{I} = \{(j, a) : 1 \le j \le p,\ a \in \mathcal{S}_j\}$, hence $K = \sum_{j=1}^{p} |\mathcal{S}_j|$.

Definition 3.5.3. *Association Rule, Confidence, and Lift*
Let $A, B \subseteq \mathcal{I}$ satisfy $A \cap B = \emptyset$, $A \neq \emptyset$, $B \neq \emptyset$, $T(A) > 0$, and $T(B) > 0$.
The *association rule* with antecedent A and consequent B is $A \Rightarrow B$.

(i) The rule support is $S(A \Rightarrow B) = T(A \cup B)$.
(ii) The confidence is $C(A \Rightarrow B) = \frac{T(A \cup B)}{T(A)}$.
(iii) The lift is $L(A \Rightarrow B) = \frac{C(A \Rightarrow B)}{T(B)} = \frac{T(A \cup B)}{T(A)T(B)}$.

Interpretation: $C(A \Rightarrow B)$ estimates prevalence of B given A; $L(A \Rightarrow B)$ compares it with $T(B)$.

Example 3.5.4. *A Market-Basket Rule*
Let $A = \{\text{peanut butter}, \text{jelly}\}$ and $B = \{\text{bread}\}$.

(i) Support $T(A \cup B) = 0.03$ means all three items appear in about 3% of baskets.
(ii) Confidence $C(A \Rightarrow B) = 0.82$ means about 82% of baskets containing A also contain bread.
(iii) If $T(B) = 0.43$, then $L(A \Rightarrow B) = 0.82/0.43 \approx 1.91$.

The rule predicts bread more often than its marginal prevalence.

Algorithm 4: Apriori Association-Rule Search

Require: Binary item data $z_1, \dots, z_n$, support threshold t, confidence threshold c
Ensure: Rules with support above t and confidence above c
Compute supports for all one-item sets and retain $\mathcal{F}_1 = \{\mathcal{K} : |\mathcal{K}| = 1,\ T(\mathcal{K}) > t\}$
Set $m \leftarrow 2$
while $\mathcal{F}_{m-1} \neq \emptyset$ **do**
  Form candidate item sets of size m whose every size-$(m-1)$ subset lies in $\mathcal{F}_{m-1}$
  Scan the data to compute $T(\mathcal{K})$ for each candidate
  Retain $\mathcal{F}_m = \{\mathcal{K} : |\mathcal{K}| = m,\ T(\mathcal{K}) > t\}$
  Set $m \leftarrow m + 1$
end while
For each retained item set $\mathcal{K}$, test nonempty proper antecedents $A \subset \mathcal{K}$
Report $A \Rightarrow \mathcal{K} \setminus A$ when $C(A \Rightarrow \mathcal{K} \setminus A) > c$

Remark 3.5.5. *Apriori Monotonicity and Limits*
Support is antitone: $\mathcal{L} \subseteq \mathcal{K} \Longrightarrow T(\mathcal{L}) \ge T(\mathcal{K})$.

(i) If $T(\mathcal{L}) < t$, then every $\mathcal{K} \supseteq \mathcal{L}$ also has $T(\mathcal{K}) < t$ and may be pruned.
(ii) A support threshold t can discard rules $A \Rightarrow B$ with large $C(A \Rightarrow B)$ or $L(A \Rightarrow B)$ but small $T(A \cup B)$.

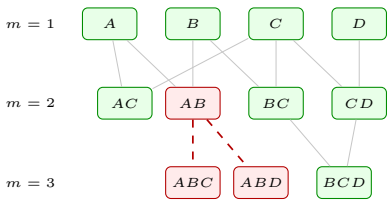

Figure 253: Apriori keeps frequent item sets; if $T(AB) \le t$, all supersets of AB are pruned.

Method 3.5.6. *Generalized Association Rules*
For $\mathcal{J} \subseteq \{1, \dots, p\}$ and $s_j \subseteq \mathcal{S}_j$, set $R(\mathcal{J}, s) = \bigcap_{j \in \mathcal{J}} \{X_j \in s_j\}$ and $\widehat{P}\{R(\mathcal{J}, s)\} = n^{-1} \sum_{i=1}^{n} \mathbf{1}\{x_{ij} \in s_j \ \forall j \in \mathcal{J}\}$.

(i) Allow s_j to be intervals for quantitative variables and subsets of levels for categorical variables.
(ii) Search over candidate regions with a heuristic rule learner.
(iii) Retain rules whose fitted score and observed support meet the chosen thresholds.

Method 3.5.7. *Unsupervised Learning as Supervised Density-Ratio Estimation*
Let g be the data density, g_0 a reference density, and $Y = 1$ label data while $Y = 0$ labels reference observations.

(i) Draw a reference sample from g_0 and pool it with the data, weighting the two classes equally.
(ii) Fit a probabilistic classifier $\widehat{\mu}(x) \approx \Pr(Y = 1 \mid X = x)$.
(iii) Use $\mu(x) = g(x)/(g(x) + g_0(x))$ to estimate the density ratio by $\widehat{g}(x)/g_0(x) = \widehat{\mu}(x)/(1 - \widehat{\mu}(x))$.

Uniform, Gaussian, and product-marginal g_0 target high density, nonnormality, and dependence, respectively.

Remark 3.5.8. *Rule Learners for Density Ratios*
After estimating $\widehat{g}/g_0$, any learner that returns regions $R = \bigcap_{j \in \mathcal{J}} \{X_j \in s_j\}$ can search for generalized item sets. Tree leaves and box-peeling regions have this conjunctive form.
The unsupervised target is large $\widehat{g}(x)/g_0(x)$ on R together with adequate empirical support, not predictive risk.

3.6 Graph Ranking and PageRank

Graph ranking turns link structure into a numerical importance score. PageRank is a spectral example: a page receives weight from incoming links, and a link from an already important page contributes more than a link from an unimportant one.

Definition 3.6.1. *PageRank Equations*

For pages indexed by $\{1, \dots, N\}$, define $L \in \{0,1\}^{N \times N}$ by $L_{ij} = 1$ iff page j links to page i, and set $c_j = \sum_{i=1}^{N} L_{ij}$.

Assume $c_j > 0$ for all j and fix $d \in (0,1)$.

A *PageRank score vector* is $p = (p_1, \dots, p_N) \in \mathbb{R}^N$ satisfying $p_i = (1-d) + d \sum_{j=1}^{N} \frac{L_{ij}}{c_j} p_j$ for $i = 1, \dots, N$.

Proposition 3.6.2. *PageRank Normalization*

Let $L \in \{0,1\}^{N \times N}$, $c_j = \sum_{i=1}^{N} L_{ij} > 0$, *and* $d \in (0,1)$.

If $p \in \mathbb{R}^N$ *satisfies* $p_i = (1-d) + d \sum_{j=1}^{N} \frac{L_{ij}}{c_j} p_j$ *for* $i = 1, \dots, N$, *then* $\sum_{i=1}^{N} p_i = N$.

Proof. Let $P = \sum_{i=1}^{N} p_i$. Summing over i gives $P = N(1-d) + dP$, since $\sum_{i=1}^{N} L_{ij} = c_j$.
Hence $(1-d)P = N(1-d)$, so $P = N$.
Structural Commentary: Column normalisation preserves total score up to the teleportation offset.
Key Insight: Summing cancels the link structure because each column has mass c_j. □

Method 3.6.3. *Eigenvector Form*
Let $\mathbf{e} = (1, \dots, 1)^T$, $D_c = \operatorname{diag}(c_1, \dots, c_N)$, and $A = (1-d)\frac{\mathbf{e}\mathbf{e}^T}{N} + dLD_c^{-1}$. The PageRank equations are $\mathbf{p} = A\mathbf{p}$ with $\mathbf{e}^T\mathbf{p} = N$. Since $\mathbf{e}^T A = \mathbf{e}^T$ and $A_{ij} \geq (1-d)/N > 0$, A is positive column-stochastic. Thus $\mathbf{p}$ is the positive eigenvector for eigenvalue 1 normalized by $\mathbf{e}^T\mathbf{p} = N$, and $\mathbf{p}/N$ is the stationary distribution in column-vector convention.

Algorithm 5: PageRank by Power Iteration

Require: Link matrix L, positive outlink counts c_j, damping parameter $0 < d < 1$, initial vector $\mathbf{p}_0 > 0$
Ensure: PageRank vector normalized by $\mathbf{e}^T\mathbf{p} = N$
  Form $A = (1-d)\mathbf{e}\mathbf{e}^T/N + dLD_c^{-1}$
  repeat
    $\mathbf{p}_k \leftarrow A\mathbf{p}_{k-1}$
    $\mathbf{p}_k \leftarrow N\mathbf{p}_k/(\mathbf{e}^T\mathbf{p}_k)$
  until the iterates stabilize

Remark 3.6.4. *Random-Surfer Normalization*

The probability-scale normalization uses $\pi_i = (1-d)/N + d \sum_{j=1}^{N} (L_{ij}/c_j)\pi_j$ and $\mathbf{e}^T\pi = 1$.

Equivalently, $p = N\pi$ satisfies the average-score form $\mathbf{e}^T\mathbf{p} = N$.
Random-surfer form: follow an outgoing link with probability d; jump uniformly with probability $1-d$.

Example 3.6.5. *Four-Page Network*
Let $d = 0.85$, $L = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}$, $\mathbf{c} = L^T\mathbf{e} = (2,1,1,1)^T$, and $D_c = \operatorname{diag}(\mathbf{c})$.
Solving $\mathbf{p} = (1-d)\mathbf{e} + dLD_c^{-1}\mathbf{p}$ gives $\widehat{\mathbf{p}} = (1.49, 0.78, 1.58, 0.15)^T$. Since $L_{4j} = 0$ for all j, $\widehat{p}_4 = 1 - d = 0.15$.

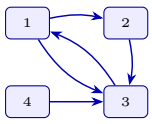

Figure 254: Four-page PageRank graph: $\widehat{\mathbf{p}} \approx (1.49, 0.78, 1.58, 0.15)^T$.

3.7 Latent Factor and Component Analysis

Latent factor methods model observed coordinates as mixtures of unobserved sources. The main question is which structure makes the sources interpretable: covariance structure, statistical independence, or non-Gaussian projections.

Definition 3.7.1. *Factor Analysis*
Let $X \in \mathbb{R}^p$ and $q < p$. A *factor-analysis model* is a representation $X = AS + \varepsilon$ with $A \in \mathbb{R}^{p\times q}$, $S \in \mathbb{R}^q$, $\varepsilon \in \mathbb{R}^p$, where: $\mathrm{Cov}(S) = I_q$, $\mathrm{Cov}(\varepsilon) = D_\varepsilon$ for diagonal $D_\varepsilon \in \mathbb{R}^{p\times p}$, and $\mathrm{Cov}(S, \varepsilon) = 0$.
The columns $a_1, \dots, a_q$ of A are the *factor loadings*, and $\Sigma := \mathrm{Cov}(X) = AA^T + D_\varepsilon$.
For any orthogonal $R \in \mathbb{R}^{q\times q}$, (A, S) and (AR^T, RS) yield the same Σ.
Hence (A, S) is identifiable only up to orthogonal rotation.

Definition 3.7.2. *Independent Component Analysis*
Let $X \in \mathbb{R}^p$. An *independent component model* is a representation $X = AS$ such that:

(i) $A \in \mathbb{R}^{p\times p}$ is nonsingular.
(ii) $S = (S_1, \dots, S_p)^T \in \mathbb{R}^p$ has mutually independent components.

If X is whitened, then $\mathrm{Cov}(X) = I_p$ and A may be taken orthogonal.
ICA estimates orthogonal A with $Y = A^T X$ approximately componentwise independent, typically via non-Gaussianity contrasts. Gaussian components are identifiable only up to orthogonal rotations.

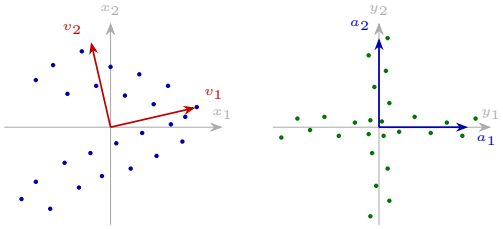

Figure 255: v_1, v_2: PCA variance axes; a_1, a_2: ICA rotation exposing independent non-Gaussian coordinates.

Method 3.7.3. *Entropy View of ICA*
For a density g, define $H(g) = -\int g(y) \log g(y)\, dy$.
Let $Y = (Y_1, \dots, Y_p)$ have joint density g_Y and marginal densities g_j.

(i) Set $H(Y) := H(g_Y)$, $H(Y_j) := H(g_j)$, and $I(Y) := \sum_{j=1}^p H(Y_j) - H(Y)$.
Then $I(Y) \geq 0$, with $I(Y) = 0$ iff $Y_1, \dots, Y_p$ are independent.
(ii) If X is whitened, A is orthogonal, and $Y = A^T X$, then $H(Y) = H(X)$.
Hence minimising $I(Y)$ over orthogonal A is equivalent to minimising $\sum_{j=1}^p H(Y_j)$.
(iii) Replace marginal-entropy minimisation by marginal non-Gaussianity maximisation,
e.g. through negentropy contrasts, since Gaussian marginals maximise entropy at fixed variance.

Remark 3.7.4. *Projection Pursuit and ICA*
Projection pursuit optimizes a non-Gaussianity index over $Y = a^T X$ or $Y = (a_1^T X, a_2^T X)$.
ICA uses the same type of index on $Y_j = a_j^T X$, but imposes an orthogonal system $(a_1, \dots, a_p)$ after whitening.

Method 3.7.5. *Product-Density ICA*
For whitened $X \in \mathbb{R}^p$ and orthogonal $A \in \mathbb{R}^{p\times p}$, set $Y = A^T X$.

(i) Assume the product density $f_Y(y) = \prod_{j=1}^p f_j(y_j)$.
(ii) Parameterize each marginal density by $f_j(s) = \phi(s)\exp(g_j(s))$ with $\int \phi(s)\exp(g_j(s))\, ds = 1$.
(iii) Estimate $A, g_1, \dots, g_p$ by penalized likelihood subject to $A^T A = I$.
For fixed A, the objective decomposes into p one-dimensional smooth density fits.

The roughness penalty shrinks g_j toward 0, the Gaussian baseline ϕ.

Algorithm 6: Product-Density ICA Alternation

Require: Whitened observations $x_1, \dots, x_n$, initial orthogonal matrix A
Ensure: Orthogonal unmixing matrix A and components $s_{ij} = a_j^T x_i$
repeat
  for each component j **do**
    Fit a smooth tilted-Gaussian density $f_j(s) = \phi(s)\exp(g_j(s))$ to the current scores $a_j^T x_i$
    Update $a_j \leftarrow \mathbb{E}\{X g_j'(a_j^T X)\} - \mathbb{E}\{g_j''(a_j^T X)\} a_j$
  end for
  Orthogonalize A: if $A = UDV^T$ is its SVD, set $A \leftarrow UV^T$
until the directions stabilize

4 Probabilistic Graphical and Causal Learning

4.1 Directed and Undirected Graphical Models

Graphical models use graph structure to encode conditional independence and to organize high-dimensional probability laws.

Definition 4.1.1. *Directed Graphical Model*
Let $G = (V, E)$ be a directed acyclic graph with $V = \{1, \dots, d\}$ and $\mathrm{pa}(j) = \{i \in V : i \to j \in E\}$.
For $x = (x_1, \dots, x_d)$, write $x_{\mathrm{pa}(j)} = (x_i)_{i\in \mathrm{pa}(j)}$. A law for $X = (X_1, \dots, X_d)$ with joint density or mass function p *factorizes according to* G if $p(x) = \prod_{j=1}^d p(x_j \mid x_{\mathrm{pa}(j)})$, with $p(x_j \mid x_\varnothing) := p(x_j)$.

Definition 4.1.2. *Markov Graph Vocabulary*
Let $G = (V, E)$ be an undirected graph, and let $A, B, C \subseteq V$ be disjoint.

(i) Vertices $j, k \in V$ are *adjacent* iff $\{j, k\} \in E$.
(ii) A *path* from u to v is $(v_0, \dots, v_m)$ with $v_0 = u$, $v_m = v$, and $\{v_{\ell-1}, v_\ell\} \in E$ for $\ell = 1, \dots, m$.
(iii) C *separates* A and B iff every path from $a \in A$ to $b \in B$ contains a vertex in C.
(iv) A *clique* is $K \subseteq V$ such that $\{j, k\} \in E$ for all distinct $j, k \in K$.
It is *maximal* iff no strictly larger clique contains K.

Definition 4.1.3. *Undirected Graphical Model*
Let $G = (V, E)$ be an undirected graph, let $\mathcal{C}$ be its maximal cliques, and let p be a positive joint density or mass function for $X = (X_j)_{j \in V}$. For $C \subseteq V$, write $x_C = (x_j)_{j \in C}$. The following are equivalent:

(i) p is *Markov with respect to* G: if $j \neq k$ and $\{j, k\} \notin E$, then $X_j \perp\!\!\!\perp X_k \mid X_{V \setminus \{j,k\}}$.
(ii) p factorizes as $p(x) = Z^{-1} \prod_{C \in \mathcal{C}} \psi_C(x_C)$ for clique potentials $\psi_C \geq 0$, with $Z = \sum_x \prod_{C \in \mathcal{C}} \psi_C(x_C)$ in the discrete case and $Z = \int \prod_{C \in \mathcal{C}} \psi_C(x_C)\, dx$ in the continuous case.

Proposition 4.1.4. *Gaussian Graphical Zeros*
Let $X \sim N_d(\mu, \Sigma)$ with $\Sigma \succ 0$ and $\Theta = \Sigma^{-1} = (\theta_{jk})$. For j, write $\theta_{-j,j} = (\theta_{\ell j})_{\ell \neq j}$ and $\mu_{-j} = (\mu_\ell)_{\ell \neq j}$. Then:

(i) For $z \in \mathbb{R}^{d-1}$, $\mathbb{E}[X_j \mid X_{-j} = z] = \mu_j - \frac{\theta_{-j,j}^T (z - \mu_{-j})}{\theta_{jj}}$.
(ii) For $j \neq k$, $X_j \perp\!\!\!\perp X_k \mid X_{-(j,k)}$ iff $\theta_{jk} = 0$.

Proof.

(i) Let $Y = X_j$ and $Z = X_{-j}$. Order coordinates as (Z, Y), with covariance block Σ_{ZZ}, cross-covariance σ_{Zj}.
Gaussian conditioning gives $\mathbb{E}[Y \mid Z = z] = \mu_j + (z - \mu_{-j})^T \Sigma_{ZZ}^{-1} \sigma_{Zj}$.
From $\Sigma\Theta = I$, the (Z, j) block gives $\Sigma_{ZZ}\theta_{-j,j} + \sigma_{Zj}\theta_{jj} = 0$, hence $\Sigma_{ZZ}^{-1}\sigma_{Zj} = -\frac{\theta_{-j,j}}{\theta_{jj}}$.
(ii) Let $A = \{j, k\}$ and $B = A^c$. The conditional Gaussian law of $X_A \mid X_B$ has precision $\Theta_{AA} = \begin{pmatrix} \theta_{jj} & \theta_{jk} \\ \theta_{jk} & \theta_{kk} \end{pmatrix}$. A bivariate Gaussian has independent coordinates iff its precision is diagonal, so $X_j \perp\!\!\!\perp X_k \mid X_B$ iff $\theta_{jk} = 0$.

Structural Commentary: Conditioning turns precision entries into regression interactions.
Key Insight: Gaussian conditional independence is zero conditional precision. □

Definition 4.1.5. *Ising Model*
Let $E \subseteq \{\{j, k\} : 1 \leq j < k \leq p\}$, set $x_0 = 1$, $\widetilde{E} = E \cup \{\{0, j\} : 1 \leq j \leq p\}$, and $\mathcal{N}(j) = \{k : \{j, k\} \in E\}$.
A *pairwise Ising model* for $X \in \{0, 1\}^p$ is specified by:

(i) Joint law $p_\Theta(x) = \exp\left\{ \sum_{\{j,k\} \in \widetilde{E}} \theta_{jk} x_j x_k - \Phi(\Theta) \right\}$, where $\Phi(\Theta) = \log \sum_{x \in \{0,1\}^p} \exp\left\{ \sum_{\{j,k\} \in \widetilde{E}} \theta_{jk} x_j x_k \right\}$.
(ii) Node conditionals $\mathbb{P}_\Theta(X_j = 1 \mid X_{-j} = x_{-j}) = \left(1 + \exp\left\{ -\theta_{0j} - \sum_{k \in \mathcal{N}(j)} \theta_{jk} x_k \right\}\right)^{-1}$ for $j = 1, \dots, p$.

For $\{j, k\} \in E$, θ_{jk} is the conditional log-odds interaction between nodes j and k.

Definition 4.1.6. *Restricted Boltzmann Machine*
Let $v \in \{0, 1\}^p$ be visible units, let $h \in \{0, 1\}^q$ be hidden units, and let $\sigma(t) = (1 + \exp(-t))^{-1}$.
A *restricted Boltzmann machine* is specified by:

(i) Graph restriction: no visible-visible or hidden-hidden edges.
(ii) Joint law $p(v, h) = Z^{-1} \exp(a^T v + b^T h + v^T W h)$ with $a \in \mathbb{R}^p$, $b \in \mathbb{R}^q$, and $W \in \mathbb{R}^{p \times q}$.
(iii) Conditional factorization: $p(v \mid h) = \prod_{j=1}^{p} \mathrm{Bern}(v_j; \sigma(a_j + W_{j\cdot} h))$ and $p(h \mid v) = \prod_{k=1}^{q} \mathrm{Bern}(h_k; \sigma(b_k + W_{\cdot k}^T v))$.

In supervised variants, v may concatenate feature and label units.

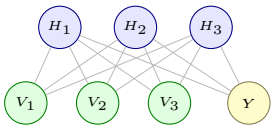

Figure 256: RBM: H_j connect only to visible features V_i and label Y; no within-layer edges.

Remark 4.1.7. *Separation*
For disjoint vertex sets A, B, C, separation is a graphical certificate for $X_A \perp\!\!\!\perp X_B \mid X_C$: DAGs use d-separation, while undirected graphs use path separation by C.
In a Markov graph, C separates A and B implies $X_A \perp\!\!\!\perp X_B \mid X_C$.
Missing edges give pairwise certificates; separation gives setwise certificates.

4.2 Inference and Learning in Graphical Models

Inference in a graphical model computes marginal, conditional, or most likely latent quantities from the joint law encoded by the graph.

Definition 4.2.1. *Inference Tasks*
Let $X = (X_j)_{j \in V}$ have joint law p, and let $A, B \subseteq V$ be disjoint. Standard *inference tasks* are:

(i) *Marginal inference*: compute $p(x_A)$.

(ii) *Conditional inference*: compute $p(x_A \mid x_B)$.
(iii) *MAP inference*: compute $x_A^\star \in \arg\max_{x_A} p(x_A \mid x_B)$, with $B = \varnothing$ for unconditional MAP.
(iv) *Latent posterior inference*: for latent Z and observed $X = x$, compute $p(z \mid x)$.

Method 4.2.2. *Message Passing*
Let $G = (V, E)$ be a graphical model with local potentials.

(i) *Tree belief propagation*: on trees, two-way edge messages yield exact node and edge marginals.
(ii) *Loopy belief propagation*: on cyclic graphs, iterated message updates yield approximate marginals.

Definition 4.2.3. *Variational Inference*
For latent-variable model $p(x, z)$, intractable $p(z \mid x)$, tractable family $\mathcal{Q}$, *variational inference* choose $q^\star \in \mathcal{Q}$:

(i) *KL projection*: $q^\star \in \arg\min_{q \in \mathcal{Q}} \mathrm{KL}(q(z) \| p(z \mid x))$.
(ii) *ELBO maximization*: equivalently, maximize $\mathcal{L}(q) := \mathbb{E}_q[\log p(x, z)] - \mathbb{E}_q[\log q(z)]$, since $\log p(x) = \mathcal{L}(q) + \mathrm{KL}(q(z) \| p(z \mid x))$.

Remark 4.2.4. *Learning Parameters and Structure*
Let G denote the graph and θ its model parameters.

(i) *Parameter learning*: for fixed G, estimate θ by likelihood or regularized likelihood.
(ii) *Structure learning*: estimate unknown G by optimizing a statistical score over graph candidates, often with structural penalties or combinatorial search.

Method 4.2.5. *Gaussian Graphical Model Learning*
For centered Gaussian data with empirical covariance S, let $\Theta = \Sigma^{-1} \succ 0$ and $\ell(\Theta) := \log\det\Theta - \mathrm{trace}(S\Theta)$.

(i) *Known graph*: for edge set E, estimate $\widehat{\Theta} \in \arg\max_{\Theta \succ 0} \ell(\Theta)$ subject to $\theta_{jk} = 0$ whenever $\{j, k\} \notin E$.
(ii) *Unknown graph*: graphical lasso solves $\widehat{\Theta} \in \arg\max_{\Theta \succ 0} \left\{ \ell(\Theta) - \lambda \sum_{j \neq k} |\theta_{jk}| \right\}$, penalise off-diagonal entries.

Graph selection is therefore shrinkage of inverse-covariance entries; zeros of $\widehat{\Theta}$ remove edges.

Figure 257: $\mathcal{D}$ is the data and S its empirical covariance. Y gives $X \perp \{Z, W\} \mid Y$; graphical lasso solves $\widehat{\Theta}_\lambda \in \arg\max_{\Theta \succ 0} \left\{ \log\det\Theta - \mathrm{tr}(S\Theta) - \lambda \sum_{j \neq k} |\theta_{jk}| \right\}$, and zeros of $\widehat{\Theta}_\lambda$ define missing edges in $\widehat{G}$.

Algorithm 7: Graphical Lasso by Block Coordinate Descent

Require: Empirical covariance $S \in \mathbb{R}^{p \times p}$, penalty $\lambda \geq 0$
Ensure: Covariance estimate W and sparse precision estimate $\widehat{\Theta} = W^{-1}$
Initialize $W \leftarrow S + \lambda I$ and keep the diagonal fixed
repeat
  for $j = 1, \ldots, p$ **do**
    Partition W into W_{11}, w_{12}, and w_{22} by isolating row and column j; partition S similarly to get s_{12}
    Define $\mathcal{S}_\lambda(z) = \mathrm{sign}(z)(|z| - \lambda)_+$
    repeat
      for $k = 1, \ldots, p-1$ **do**

$$\beta_k \leftarrow \frac{\mathcal{S}_\lambda\left(s_{12,k} - \sum_{\ell \neq k} (W_{11})_{k\ell}\beta_\ell\right)}{(W_{11})_{kk}}$$

      end for
    until β has converged for this block
    Update $w_{12} \leftarrow W_{11}\beta$ and symmetrically update row and column j of W
  end for
until W has converged
In the final cycle recover $\widehat{\theta}_{12} = -\widehat{\beta}\widehat{\theta}_{22}$ with $1/\widehat{\theta}_{22} = w_{22} - w_{12}^T\widehat{\beta}$

Method 4.2.6. *Discrete Markov Network Learning*
For a binary Markov network with edge statistic $T_{jk}(X) = X_j X_k$, likelihood equations are $\widehat{\mathbb{E}}T_{jk} = \mathbb{E}_\Theta T_{jk}$ for $\{j, k\} \in E$; exact $\mathbb{E}_\Theta$ sums over $x \in \{0, 1\}^p$.

(i) *Small graphs*: solve $\widehat{\mathbb{E}}T_{jk} = \mathbb{E}_\Theta T_{jk}$ by log-linear Poisson MLE, gradient/Newton updates, or iterative proportional fitting.
(ii) *Large graphs*: approximate $\mathbb{E}_\Theta T_{jk}$ by mean-field or Gibbs-sampling estimates.
(iii) *Hidden-node models*: use observed-data conditionals for $\widehat{\mathbb{E}}T_{jk}$; for RBMs, CD-$r$ starts at data and runs r alternating Gibbs steps $h \sim p(h \mid v)$, $v \sim p(v \mid h)$.

4.3 Causal Graphs, Interventions, and Identifiability

Causal learning asks which predictions remain valid under interventions, not merely under passive observation.

Definition 4.3.1. *Structural Causal Model*
Let J index endogenous variables $X = (X_j)_{j \in J}$ and exogenous disturbances $U = (U_j)_{j \in J}$.
A structural causal model is $M = (G, \{f_j\}_{j \in J}, P_U)$ such that:

(i) $G = (J, E)$ is a directed graph with $\mathrm{pa}(j) = \{k \in J : k \to j \in E\}$.

(ii) P_U is the joint law of U.
(iii) $X_j = f_j(X_{\mathrm{pa}(j)}, U_j)$ for every $j \in J$.
The edges $k \to j$ are the direct causal inputs to X_j.

Definition 4.3.2. *Intervention*
For $M = (G, \{f_k\}_{k\in J}, P_U)$ and $x \in \mathcal{X}_j$, set $\tilde{f}_j \equiv x$ and $\tilde{f}_k = f_k$ for $k \neq j$.
The *intervention* $\mathrm{do}(X_j = x)$ is the modified model $M_{j:=x} = (G_{j:=x}, \{\tilde{f}_k\}_{k\in J}, P_U)$, where $G_{j:=x}$ deletes all incoming edges to j; the induced law $P_{M_{j:=x}}$ is the interventional distribution.

Definition 4.3.3. *Identifiability*
Let $\mathcal{M}$ be the assumed model class and let P_M be the observational law induced by $M \in \mathcal{M}$.
A causal functional $\psi : \mathcal{M} \to \Theta$ is *identifiable* on $\mathcal{M}$ if $P_M = P_{M'}$ implies $\psi(M) = \psi(M')$ for all $M, M' \in \mathcal{M}$.

Remark 4.3.4. *Causal and Predictive Targets*
Let $\hat{y} = g(z)$ be trained under the observational law P_M. Small risk $R_{P_M}(g) = \mathbb{E}_{P_M}[\ell(Y, g(Z))]$ need not imply small interventional risk $R_{P_{M_{j:=x}}}(g)$ after $\mathrm{do}(X_j = x)$. Transport across regimes requires causal stability of the conditional mechanism used by g, not only predictive fit under P_M.

4.4 Counterfactuals and Policy Evaluation

Policy learning and evaluation combine prediction with causal questions about actions not actually taken.

Definition 4.4.1. *Potential Outcomes*
Let $A \in \mathcal{A}$ be a treatment.
(i) *Potential outcome*: $Y(a)$ is the outcome under $\mathrm{do}(A = a)$.
(ii) *Consistency*: $Y = Y(A)$.
(iii) *Individual effect*: for binary $A \in \{0, 1\}$, $\tau = Y(1) - Y(0)$.
(iv) *Average treatment effect*: $\mathrm{ATE} = \mathbb{E}[\tau]$.

Definition 4.4.2. *Ignorability and Propensity*
For binary treatment A and covariates X:
(i) *Ignorability*: $(Y(0), Y(1)) \perp\!\!\!\perp A \mid X$.
(ii) *Propensity score*: $e(x) = P(A = 1 \mid X = x)$.
(iii) *Overlap*: $0 < e(X) < 1$ almost surely.

Definition 4.4.3. *Off-Policy Evaluation*
Let $(X_i, A_i, Y_i)_{i=1}^n$ be logged under behavior policy $\mu(a \mid x)$, and let $\pi(a \mid x)$ be a target policy.
(i) *Target value*: $V(\pi) = \mathbb{E}_\pi[Y]$.
(ii) *Off-policy evaluation*: estimate $V(\pi)$ from data sampled under μ.
(iii) *Inverse-propensity weighting*: $\hat{V}_{\mathrm{IPW}}(\pi) = n^{-1} \sum_{i=1}^n \{\pi(A_i \mid X_i)/\mu(A_i \mid X_i)\} Y_i$.
(iv) *Overlap*: $\mu(a \mid x) > 0$ whenever $\pi(a \mid x) > 0$.

Remark 4.4.4. *Feedback*
If a predictor g induces actions through a policy $\pi_g(a \mid x)$, then future data are drawn from the post-deployment law P^{π_g} rather than the pre-deployment law P^0. Feedback is the dependence $g \mapsto \pi_g \mapsto P^{\pi_g}$; causal learning, reinforcement learning, and deployment monitoring all study or control this induced law.

5 Neural Network Foundations

5.1 Network Architectures and Expressivity

The migrated deep-feedforward-network notes describe neural networks as learned feature maps followed by prediction heads.

Definition 5.1.1. *Deep Feedforward Network*
Let $x \in \mathcal{X}$, set $h^{(0)} = x$, and fix depth L.
(i) *Layer recursion*: $h^{(k)} = g^{(k)}(W^{(k)} h^{(k-1)} + b^{(k)})$ for $k = 1, \ldots, L$.
(ii) *Network map*: $f_\theta : \mathcal{X} \to \mathcal{Y}$ is $f_\theta(x) = h^{(L)} = (f_L \circ \cdots \circ f_1)(x)$.
(iii) *Parameters*: $\theta = \{(W^{(k)}, b^{(k)})\}_{k=1}^L$.
(iv) *Training objective*: choose θ to minimize empirical risk $\hat{R}_n(f_\theta)$ or population risk $R(f_\theta)$.

Remark 5.1.2. *Learned Feature Maps*
Let ℓ be the task loss and let $R(f) = \mathbb{E}[\ell(Y, f(X))]$. Two representation parametrizations are:
(i) *fixed features*: $f_w(x) = a_w(\phi(x))$, with ϕ fixed and only the head parameter w optimized.
(ii) *learned features*: $f_{\theta,w}(x) = a_w(\phi_\theta(x))$, with θ and w optimized jointly.
Learning ϕ_θ adds adaptivity but usually destroys convexity.

Definition 5.1.3. *Projection Pursuit and Ridge Functions*
Let $x \in \mathbb{R}^p$.
(i) *Projection-pursuit form*: $f(x) = \sum_{m=1}^M g_m(\omega_m^T x)$ with $\|\omega_m\|_2 = 1$.
(ii) *Ridge coordinate*: $u_m = \omega_m^T x$.
(iii) *Ridge function*: $g_m(u_m)$ depends on x only through the scalar coordinate u_m.
(iv) *Learned components*: the directions ω_m and univariate profiles g_m are estimated from data.

Definition 5.1.4. *Output and Hidden Units*
Let $T \in \mathbb{R}^K$ denote output scores. Common output parametrizations are:
(i) *linear*: $f_k(x) = T_k$, for conditional means or real-valued responses.

(ii) *sigmoid*: $p(x) = \sigma(T) = \frac{1}{1+\exp(-T)}$, for Bernoulli probabilities.

(iii) *softmax*: $p_k(x) = \exp(T_k)/\sum_{\ell=1}^{K} \exp(T_\ell)$, for K-class probabilities.

Hidden units define activations $Z_m = \phi_m(a_m)$ from preactivations a_m, commonly using ReLU, leaky ReLU, maxout, tanh, or another nonlinear map.

Definition 5.1.5. *Single Hidden Layer Network*
Let $x \in \mathbb{R}^p$, $Z = (Z_1, \dots, Z_M)^T$, $T = (T_1, \dots, T_K)^T$. A single-hidden-layer feedforward network is defined by:

(i) $Z_m = \sigma(\alpha_{0m} + \alpha_m^T x)$ for $m = 1, \dots, M$.
(ii) $T_k = \beta_{0k} + \beta_k^T Z$ for $k = 1, \dots, K$.
(iii) $f_k(x) = g_k(T)$, with $g_k(T) = T_k$ for regression and $g_k(T) = \exp(T_k)/\sum_{\ell=1}^{K} \exp(T_\ell)$ for K-class classification.

In the classification case, $f(x) \in \Delta^{K-1}$.

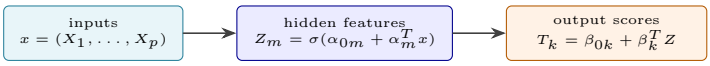

Figure 258: Single-hidden-layer feedforward network.

Remark 5.1.6. *Neural Networks as Ridge Expansions*
For scalar output, a one-hidden-layer network has $f(x) = \beta_0 + \sum_{m=1}^{M} \beta_m \sigma(\alpha_{0m} + \alpha_m^T x)$.
If $\alpha_m \neq 0$ and $\omega_m = \frac{\alpha_m}{\|\alpha_m\|_2}$, the mth term is $\beta_m \sigma(\alpha_{0m} + \|\alpha_m\|_2 \omega_m^T x)$, a ridge term in coordinate $\omega_m^T x$ with learned *direction* ω_m, *scale* $\|\alpha_m\|_2$, *threshold* α_{0m}, and *output coefficient* β_m.
Thus a shallow scalar network is a projection-pursuit expansion with parametrized ridge profiles.

Theorem 5.1.7. *Universal Approximation Theorem Form*
For compact $K \subset \mathbb{R}^d$, $h \in C(K)$, non-polynomial activation $\sigma : \mathbb{R} \to \mathbb{R}$, $\forall \varepsilon > 0$, $\exists\, M \in \mathbb{N}$, $a_m, b_m \in \mathbb{R}$, $w_m \in \mathbb{R}^d$ s.t. one-hidden-layer network $f_M(x) = \sum_{m=1}^{M} a_m \sigma(w_m^\top x + b_m)$ satisfies $\|f_M - h\|_\infty < \varepsilon$ on K.

Proof. Let $\mathcal{A}_\sigma := \operatorname{span}\{\sigma(w^\top x + b) : w \in \mathbb{R}^d,\ b \in \mathbb{R}\} \subset C(K)$.
The classical universal approximation theorem states that $\overline{\mathcal{A}_\sigma}^{\|\cdot\|_\infty} = C(K)$ for suitable non-polynomial σ.
Since $h \in C(K)$ and $\varepsilon > 0$, there is $f_M \in \mathcal{A}_\sigma$ with $\|f_M - h\|_\infty < \varepsilon$.
Thus $f_M(x) = \sum_{m=1}^{M} a_m \sigma(w_m^\top x + b_m)$ has one hidden layer and linear output.
Structural Commentary: Non-polynomial activations make ridge spans dense in $C(K)$.
Key Insight: Width supplies finite linear combinations of nonlinear ridge functions. □

Remark 5.1.8. *Depth and Expressivity*
Let $N_L(\varepsilon, h)$ be the minimum width of a depth-L network with $\|f - h\|_\infty \leq \varepsilon$ on a compact domain. Universal approximation gives $N_L(\varepsilon, h) < \infty$, not trainability; depth expressivity is $N_L(\varepsilon, h) \ll N_{L'}(\varepsilon, h)$ for some $L > L'$.

5.2 Backpropagation and Automatic Differentiation

Backpropagation is reverse-mode differentiation applied to the computational graph of the network and loss.

Definition 5.2.1. *Computational Graph*
A computational graph is a finite directed acyclic graph $G = (V, E)$ together with variables $(x_v)_{v \in V}$ and local maps $(f_v)_{v \in V \setminus S}$, where $\operatorname{pa}(v) = \{u \in V : (u, v) \in E\}$ and $S = \{v \in V : \operatorname{pa}(v) = \varnothing\}$.

(i) For $v \in S$, x_v is an input, parameter, or constant.
(ii) For $v \in V \setminus S$, $x_v = f_v((x_u)_{u \in \operatorname{pa}(v)})$.
(iii) An edge $u \to v$ records the direct dependence of x_v on x_u in f_v.

For scalar output $L = x_\ell$ and parameter sources $P \subseteq S$, reverse mode computes $(\partial L/\partial x_v)_{v \in V}$, hence $\nabla_{(x_p)_{p \in P}} L$.

Method 5.2.2. *Backpropagation*
Let $h^{(0)} = x$, $z^{(k)} = W^{(k)} h^{(k-1)} + b^{(k)}$, $h^{(k)} = \phi_k(z^{(k)})$ for $1 \leq k \leq K$, and $L = \ell(h^{(K)}, y)$.
Write $\bar{u} = \nabla_u L$ for the adjoint of u.

(i) Compute $z^{(k)}$ and $h^{(k)}$ for $k = 1, \dots, K$, then compute L.
(ii) Initialize $\bar{h}^{(K)} = \nabla_{h^{(K)}} \ell(h^{(K)}, y)$.
(iii) For $k = K, \dots, 1$, set $\bar{z}^{(k)} = J_{\phi_k}(z^{(k)})^T \bar{h}^{(k)}$ and $(\nabla_{W^{(k)}} L, \nabla_{b^{(k)}} L, \bar{h}^{(k-1)}) = (\bar{z}^{(k)} (h^{(k-1)})^T, \bar{z}^{(k)}, (W^{(k)})^T \bar{z}^{(k)})$.

Thus backpropagation is reverse-mode differentiation of L through the layerwise computational graph.

Method 5.2.3. *Single-Hidden-Layer Backpropagation Equations*
For one training case (x_i, y_i) in a single-hidden-layer network, let $m = 1, \dots, M$ index hidden units, $k = 1, \dots, K$ index output components, and $z_i = (z_{1i}, \dots, z_{Mi})^T$.

(i) Compute $a_{mi} = \alpha_{0m} + \alpha_m^T x_i$, $z_{mi} = \sigma(a_{mi})$, $t_{ki} = \beta_{0k} + \beta_k^T z_i$, and $f_k(x_i) = g_k(t_{ki})$.
(ii) Compute $R_i = \sum_{k=1}^{K} \{y_{ik} - f_k(x_i)\}^2$ and $\delta_{ki} = \frac{\partial R_i}{\partial t_{ki}} = -2\{y_{ik} - f_k(x_i)\} g_k'(t_{ki})$.
(iii) Compute $\nabla_{\beta_k} R_i = \delta_{ki} z_i$ and $\frac{\partial R_i}{\partial \beta_{0k}} = \delta_{ki}$.
(iv) Compute $s_{mi} = \frac{\partial R_i}{\partial a_{mi}} = \sigma'(a_{mi}) \sum_{k=1}^{K} \beta_{km} \delta_{ki}$.

(v) Compute $\nabla_{\alpha_m} R_i = s_{mi} x_i$ and $\frac{\partial R_i}{\partial \alpha_{0m}} = s_{mi}$.

Batch gradients are obtained by summing these per-case derivatives over i.

Remark 5.2.4. *Automatic Differentiation*
For an implemented graph map $F : \mathbb{R}^p \to \mathbb{R}^q$, automatic differentiation returns $DF(x)$ by chain-rule evaluation on the executed graph. It differentiates the floating-point computation up to roundoff, without finite differences or symbolic simplification.

5.3 Optimization for Deep Learning

The old optimization notes are migrated here only where the algorithms are used as training methods for neural networks. General numerical optimization belongs to Part 18.

Definition 5.3.1. *Neural Empirical Objective*

For data $(x_i, y_i)_{i=1}^n$, network $f_\theta : x \mapsto f(x;\theta)$, loss L, neural empirical objective is $J_n(\theta) = n^{-1} \sum_{i=1}^n L(f_\theta(x_i), y_i)$.

The population objective is $J(\theta) = \mathbb{E}[L(f_\theta(X), Y)]$ under the data-generating law.

Algorithm 8: Minibatch Backpropagation Step

Require: Minibatch B, parameters θ, learning rate η
Compute predictions $f(x;\theta)$ for all $(x, y) \in B$
Compute minibatch loss $\widehat{L}_B(\theta)$
Run reverse-mode automatic differentiation to compute $g = \nabla_\theta \widehat{L}_B(\theta)$
Update parameters $\theta \leftarrow \theta - \eta g$

Remark 5.3.2. *Deep Optimization Challenges*
For empirical loss $J_n(\theta)$, deep optimization is shaped by:

(i) *geometry*: large $\kappa(\nabla^2 J_n)$, saddles with $\nabla J_n \approx 0$ and indefinite $\nabla^2 J_n$, and plateaus with $\|\nabla J_n\| \approx 0$.
(ii) *gradient propagation*: large or small $\left\| \frac{\partial h^{(L)}}{\partial h^{(k)}} \right\|$ causes exploding or vanishing gradients.
(iii) *stochasticity*: $g_k = \nabla J_n(\theta_k) + \xi_k$, with $\mathbb{E}[\xi_k \mid \theta_k] = 0$ and $\mathrm{Var}(\xi_k \mid \theta_k) \neq 0$.
(iv) *stabilization*: initialization, normalization, gradient clipping, skip connections, and learning-rate schedules control scale, conditioning, and update variance.

These choices are part of the training specification, not post hoc implementation details.

Remark 5.3.3. *Second-Order Methods*
Let $J : \mathbb{R}^d \to \mathbb{R}$, $g_k = \nabla J(\theta_k)$, and $H_k = \nabla^2 J(\theta_k)$.

(i) *Newton*: choose p_k from $H_k p_k = -g_k$ and set $\theta_{k+1} = \theta_k + \eta_k p_k$.
(ii) *Conjugate gradient*: solve $H_k p = -g_k$ approximately using only products $H_k v$.
(iii) *BFGS/L-BFGS*: use $p_k = -B_k g_k$, where $B_k \approx H_k^{-1}$; L-BFGS stores few curvature pairs.

Large networks make explicit H_k storage or factorization prohibitive, so these methods usually act as preconditioners, curvature approximations, or analysis tools.

5.4 Regularization, Normalization, and Generalization

Deep-learning regularization combines penalties, stochastic training effects, architecture, and validation-based stopping.

Definition 5.4.1. *Parameter-Norm Regularization*
Minimize $\widetilde{J}_\lambda(\theta) = J(\theta) + \lambda \Omega(\theta)$, with $\lambda \geq 0$, $\Omega \geq 0$, and penalized non-intercept set $\mathcal{P}$.

(i) *ℓ^2 weight decay*: $\Omega_2(\theta) = \sum_{j \in \mathcal{P}} \theta_j^2$.
(ii) *ℓ^1 penalty*: $\Omega_1(\theta) = \sum_{j \in \mathcal{P}} |\theta_j|$.
(iii) *Single-hidden-layer weight decay*: for weights $\alpha_{m\ell}$ and β_{km}, $\Omega_2(\theta) = \sum_{m,\ell} \alpha_{m\ell}^2 + \sum_{k,m} \beta_{km}^2$.

Intercepts such as α_{0m} and β_{0k} are excluded unless explicitly included in $\mathcal{P}$.

Definition 5.4.2. *Dropout*
Let $h \in \mathbb{R}^d$, $q \in (0, 1]$, and $m_j \overset{\text{ind}}{\sim} \text{Bernoulli}(q)$.

(i) *Training mask*: replace h by $\widetilde{h} = \frac{m \odot h}{q}$.
(ii) *Subnetwork*: each mask $m \in \{0, 1\}^d$ selects the active coordinates $\{j : m_j = 1\}$ with shared parameters.
(iii) *Evaluation*: use the unmasked activation h when inverted dropout scaling is used in training.

Dropout optimizes an expected masked loss over tied-parameter subnetworks.

Method 5.4.3. *Early Stopping*
Let θ_t be the parameter after training step t and let $V(\theta)$ be the validation loss.

(i) Compute $V_t = V(\theta_t)$ after selected training steps t.
(ii) Select $t^\star \in \arg\min_{0 \leq t \leq T} V_t$.
(iii) Return $\widehat{\theta}_{\text{ES}} = \theta_{t^\star}$.

The stopping time $t^\star$ restricts the reachable parameter set and acts as an implicit regularization parameter.

Remark 5.4.4. *Starting Values, Scaling, and Multiple Fits*
For a nonconvex neural objective $J(\theta)$, the fitted parameter can depend on initialization and scaling.

(i) *Initialization*: avoid $\theta_0 = 0$ when symmetry identifies hidden units, and avoid large $\|\theta_0\|$ when $\sigma'(a) \approx 0$.
(ii) *Scaling*: standardize inputs, e.g. $x_j \leftarrow \frac{x_j - \hat{\mu}_j}{\hat{\sigma}_j}$, so coordinates have comparable optimization scale.
(iii) *Multiple fits*: run starts $r = 1, \ldots, R$, obtain $\widehat{\theta}^{(r)}$, and choose $\widehat{\theta}^{(r^\star)}$ by validation or penalized criterion.

Thus initialization law, preprocessing, and restart selection are part of the training specification.

Remark 5.4.5. *Hidden Units and Weight Decay*
Let M be hidden width, λ the weight-decay strength, and $t^\star$ the early-stopping time.

(i) *Small M*: the model class may have excessive approximation error.
(ii) *Large M*: overfitting can occur unless $\lambda > 0$, finite $t^\star$, or another constraint limits effective complexity.
(iii) *Selection*: choose $(M, \lambda, t^\star)$ by validation or another held-out criterion.

Weight decay and early stopping bias the fit toward smaller effective weights and simpler functions.

Definition 5.4.6. *Batch Normalization*
Let $H = (h_{ij}) \in \mathbb{R}^{b\times d}$ be minibatch activations, indexed by example i and coordinate j.

(i) *Batch statistics*: $\mu_j = \frac{1}{b}\sum_i h_{ij}$ and $s_j^2 = \frac{1}{b}\sum_i (h_{ij}-\mu_j)^2$.
(ii) *Normalization*: $\widehat{h}_{ij} = \frac{h_{ij}-\mu_j}{\sqrt{s_j^2+\varepsilon}}$.
(iii) *Affine output*: $y_{ij} = \gamma_j \widehat{h}_{ij} + \beta_j$, with learned γ_j, β_j.
(iv) *Evaluation*: replace μ_j and s_j^2 by running training estimates.

Remark 5.4.7. *Augmentation and Noise*
Let $\ell(y, f_\theta(x))$ be the task loss.

(i) *Data augmentation*: replace (X, Y) by $(T(X), Y)$ for random label-preserving transforms T.
(ii) *Label smoothing*: replace one-hot y by $y^{(\varepsilon)} = (1-\varepsilon)y + \varepsilon u$, where u is a reference class distribution.
(iii) *Noise injection*: train on $x + \xi$ or hidden activations $h + \xi$, with $\mathbb{E}\xi = 0$.
(iv) *Multitask learning*: minimize $\sum_{r=1}^{R} \omega_r \ell_r(y_r, f_{\theta,r}(x))$ with shared representation parameters.

These methods regularize through altered data, targets, perturbations, or shared representations.

6 Modern Deep Models

6.1 Convolutional and Geometric Architectures

The convolutional-network source is migrated here because convolution is an architectural prior for data with grid, group, or geometric structure.

Definition 6.1.1. *Convolution*
For $f, g : \mathbb{R} \to \mathbb{R}$ and $a, b : \mathbb{Z} \to \mathbb{R}$:

(i) *Continuous*: $f * g : D_c \ni t \mapsto \int_{-\infty}^{\infty} f(\tau) g(t-\tau)\, d\tau \in \mathbb{R}$; $D_c := \{t \in \mathbb{R} : \int_{\mathbb{R}} |f(\tau)g(t-\tau)|\, d\tau < \infty\}$.
(ii) *Discrete*: $a * b : D_d \ni n \mapsto \sum_{m\in\mathbb{Z}} a[m]b[n-m] \in \mathbb{R}$; $D_d := \{n \in \mathbb{Z} : \sum_{m\in\mathbb{Z}} |a[m]b[n-m]| < \infty\}$.

Definition 6.1.2. *Convolutional Neural Network*
Let $\Phi = L_k \circ \cdots \circ L_1$ be a neural network on array-valued activations.

(i) *Convolutional layer*: on $z : \mathbb{Z}^d \to \mathbb{R}^{C_{\text{in}}}$, $L_j z = \sigma(K * z + b)$ or $\sigma(K \star z + b)$, with finite-support K, $b \in \mathbb{R}^{C_{\text{out}}}$, pointwise σ, and cross-correlation $\star$.
(ii) *Convolutional neural network*: Φ is a CNN if at least one layer L_j is convolutional.
(iii) *Library convention*: many neural-network libraries implement $\star$ while naming the operation convolution.

Definition 6.1.3. *Sparse Interactions, Sharing, and Equivariance*
For $x : \mathbb{Z}^d \to \mathbb{R}^{C_{\text{in}}}$, finite $W \subset \mathbb{Z}^d$, kernels $K_w \in \mathbb{R}^{C_{\text{out}}\times C_{\text{in}}}$, $b \in \mathbb{R}^{C_{\text{out}}}$, and pointwise σ,
set $Lx(u) := \sigma(\sum_{w\in W} K_w x(u-w) + b)$ and $(\tau_a x)(u) := x(u-a)$.

(i) *Sparse interaction*: $Lx(u)$ depends only on $\{x(u-w) : w \in W\}$.
(ii) *Parameter sharing*: the same $(K_w)_{w\in W}$ and b define $Lx(u)$ for every u.
(iii) *Translation equivariance*: $L(\tau_a x) = \tau_a(Lx)$ for every $a \in \mathbb{Z}^d$ where defined.

Pooling with finite U applies ρ to $\{Lx(u+w) : w \in U\}$; shift-stable ρ gives local approximate invariance.

Definition 6.1.4. *Pooling, Padding, and Stride*
Let $x : \Omega \to \mathbb{R}^C$ on finite $\Omega \subset \mathbb{Z}^d$, with $W \subset \mathbb{Z}^d$, $p \in \mathbb{N}_0^d$, $s \in \mathbb{N}^d$, offset r, statistic $\rho : (\mathbb{R}^C)^W \to \mathbb{R}^{C'}$,
and $\Omega^{(p)} := \Omega + \prod_i \{-p_i, \dots, p_i\}$.

(i) *Padding*: an extension $\tilde{x} : \Omega^{(p)} \to \mathbb{R}^C$ with $\tilde{x}|_\Omega = x$ and a boundary rule on $\Omega^{(p)} \setminus \Omega$.
(ii) *Stride*: evaluation sites $\Omega_{s,r} := \{u \in \Omega^{(p)} : \forall i,\ u_i \equiv r_i \pmod{s_i},\ u + W \subset \Omega^{(p)}\}$.
(iii) *Pooling*: $P_{\rho,W,s,r} x : \Omega_{s,r} \ni u \mapsto \rho((\tilde{x}(u+w))_{w\in W}) \in \mathbb{R}^{C'}$.

Remark 6.1.5. *Geometric Extensions*
Let X be a domain with local neighborhoods $\mathcal{N}(x) \subset X$ and symmetry group G.

(i) *Graph neural networks*: on $\mathcal{G} = (V, E)$, $h_v^{(\ell+1)} = \phi(h_v^{(\ell)}, \text{Agg}_{u\in\mathcal{N}(v)}\, m_{uv}^{(\ell)})$ with invariant Agg.
(ii) *Equivariant networks*: Φ is G-equivariant if $\Phi(\rho_{\text{in}}(g)x) = \rho_{\text{out}}(g)\Phi(x)$ for every $g \in G$.
(iii) *Manifold architectures*: for a manifold M, layers use chart, tangent, or geodesic neighborhoods $\mathcal{N}(p) \subset M$.

Each variant builds locality or symmetry into the model class.

6.2 Sequence Models and Attention

Sequence models process ordered data where context and position matter.

Definition 6.2.1. *Recurrent Neural Network*
For dim d_x, d_h, d_y, parameters $\Theta = (W_x, W_h, b, \phi, \psi, h_0)$, $T \geq 1$, an RNN is a map $\Phi_T : (\mathbb{R}^{d_x})^T \to (\mathbb{R}^{d_y})^T$:

(i) *State update*: $h_t = \phi(W_x x_t + W_h h_{t-1} + b)$ for $t = 1, \ldots, T$, with shared (W_x, W_h, b).
(ii) *Readout*: $y_t = \psi(h_t)$ and $\Phi_T(x_{1:T}) = (y_1, \ldots, y_T)$.

Remark 6.2.2. *Long-Term Dependencies*
For $h_t = F_t(h_{t-1}, x_t)$, set $J_t := \partial h_t / \partial h_{t-1}$ and $P_{s:T} := \prod_{t=s+1}^{T} J_t$.
Then $\nabla_{h_s} \mathcal{L} = P_{s:T}^{\top} \nabla_{h_T} \mathcal{L}$; $\|P_{s:T}\| \ll 1$ vanishes gradients and $\|P_{s:T}\| \gg 1$ explodes them.

(i) *Gating*: gates $g_t \in [0,1]^{d_h}$ interpolate between copy and update.
(ii) *Gradient clipping*: replace a gradient g by $\min\{1, c/\|g\|\}g$, so the clipped norm is at most c.
(iii) *Skip paths*: use additive routes such as $h_t = h_{t-1} + F_t(h_{t-1}, x_t)$, giving transition Jacobian $I + \partial F_t / \partial h_{t-1}$.

These mechanisms keep the long-horizon Jacobian product numerically controlled.

Definition 6.2.3. *Attention*
For $Q \in \mathbb{R}^{n_q \times d}$, $K \in \mathbb{R}^{n_k \times d}$, $V \in \mathbb{R}^{n_k \times d_v}$, define $\mathrm{Attn}(Q, K, V) \in \mathbb{R}^{n_q \times d_v}$ row-wise:

(i) *Scores*: $S := d^{-1/2} Q K^{\top} \in \mathbb{R}^{n_q \times n_k}$.
(ii) *Weights*: $A := \mathrm{softmax}_{\mathrm{row}}(S)$, $A_{ij} := \exp(S_{ij}) / \sum_{\ell=1}^{n_k} \exp(S_{i\ell})$.
(iii) *Output*: $\mathrm{Attn}(Q, K, V) := AV$, equivalently $(\mathrm{Attn}(Q, K, V))_{i\cdot} = \sum_{j=1}^{n_k} A_{ij} V_{j\cdot}$.

Remark 6.2.4. *Attention as Routing*
For token matrix X, set $Q = XW_q$, $K = XW_k$, $V = XW_v$, $S = d^{-1/2} Q K^{\top}$, and $A = \mathrm{softmax}_{\mathrm{row}}(S)$.

(i) *Content routing*: $y_i = \sum_j A_{ij} v_j$ routes value vectors by query-key compatibility.
(ii) *Masking*: a mask $M_{ij} \in \{0, -\infty\}$ replaces S by $S + M$, forcing $A_{ij} = 0$ for forbidden interactions.
(iii) *Positional encoding*: absolute codes use $x_i + e_i$; relative codes add a position term to S_{ij}.

Thus attention replaces a fixed recurrence neighborhood by data-dependent communication.

6.3 Transformers and Large-Scale Training

Transformers combine attention, feedforward blocks, normalization, and residual connections into architectures that scale well on sequence and multimodal data.

Definition 6.3.1. *Self-Attention*
For $X \in \mathbb{R}^{T \times d}$, head dimension d_h, and projection matrices W_Q, W_K, W_V, W_O:

(i) *Self-attention*: $Q = XW_Q$, $K = XW_K$, $V = XW_V$, and $\mathrm{SA}(X) := \mathrm{Attn}(Q, K, V)$.
(ii) *Multi-head attention*: with heads $H_r := \mathrm{Attn}(XW_Q^{(r)}, XW_K^{(r)}, XW_V^{(r)})$, set $\mathrm{MHA}(X) := [H_1 | \cdots | H_R] W_O$.

Definition 6.3.2. *Transformer Block*
For $X \in \mathbb{R}^{T \times d}$, let MHA be multi-head attention, FFN positionwise feedforward, and $\mathrm{LN}_1, \mathrm{LN}_2$ layer normalizations. A pre-norm block $B : \mathbb{R}^{T \times d} \to \mathbb{R}^{T \times d}$ is:

(i) *Attention sublayer*: $Z := X + \mathrm{MHA}(\mathrm{LN}_1 X)$.
(ii) *Feedforward sublayer*: $B(X) := Z + \mathrm{FFN}(\mathrm{LN}_2 Z)$.

Stacking blocks gives $B_L \circ \cdots \circ B_1(X)$.

Remark 6.3.3. *Large-Scale Training*
For data $\mathcal{D} = \{z_i\}_{i=1}^N$, loss $\ell_i(\theta)$, mini-batch B_t, and gradient estimate $\hat{g}_t := |B_t|^{-1} \sum_{i \in B_t} \nabla_\theta \ell_i(\theta_t)$:

(i) *Optimization*: choose update $\theta_{t+1} = U_t(\theta_t, \hat{g}_t)$, batch size $|B_t|$, and schedule η_t.
(ii) *Data*: sampling, filtering, weighting, and augmentation define the empirical training law $\widehat{P}_{\mathcal{D}}$.
(iii) *Numerics*: mixed precision uses low-precision arithmetic with scaling or high-precision accumulators.
(iv) *Parallelism*: workers compute local gradients $g_t^{(p)}$ and synchronize $\bar{g}_t = P^{-1} \sum_{p=1}^{P} g_t^{(p)}$.
(v) *Memory*: checkpointing stores selected activations and recomputes the rest during backpropagation.
(vi) *Evaluation*: validation loss and task metrics estimate out-of-sample performance.

Remark 6.3.4. *Inductive Bias*
Let $I = \{1, \ldots, T\}$ index tokens, $W_i \subset I$ be a local window, and $A_{ij}(x)$ be attention weights.

(i) *Locality*: convolution uses $y_i = F((x_j)_{j \in W_i})$.
(ii) *Global interaction*: attention uses $y_i = \sum_{j \in I} A_{ij}(x) V x_j$.
(iii) *Domain-specific bias*: impose masks, recurrence, sparsity, or $\Phi(\rho_{\mathrm{in}}(g)x) = \rho_{\mathrm{out}}(g)\Phi(x)$.

Useful bias matches the task's locality, symmetry, and dependency scale.

6.4 Generative Models

Generative modeling learns distributions, simulators, or conditional samplers rather than only point predictions.

Definition 6.4.1. *Latent-Variable Generative Model*
Let $Z \in \mathcal{Z}$, $X \in \mathcal{X}$, prior $p(z)$, decoder $p_\theta(x \mid z)$, and data law P_{data}.

(i) *Joint law*: $p_\theta(x, z) := p_\theta(x \mid z) p(z)$.
(ii) *Marginal law*: $p_\theta(x) := \int_{\mathcal{Z}} p_\theta(x \mid z) p(z)\, dz$.
(iii) *Learning*: choose θ so p_θ approximates P_{data}, e.g. by maximizing $\sum_{i=1}^n \log p_\theta(x_i)$.

Definition 6.4.2. *Variational Autoencoder*
For prior $p(z)$, decoder $p_\theta(x \mid z)$, encoder $q_\phi(z \mid x)$, and data $\{x_i\}_{i=1}^n$:

(i) *Generative model*: $p_\theta(x, z) := p_\theta(x \mid z)p(z)$.
(ii) *Variational posterior*: $q_\phi(z \mid x)$ approximates $p_\theta(z \mid x)$.
(iii) *ELBO*: $\mathcal{L}(\theta, \phi; x) := \mathbb{E}_{q_\phi(z|x)}[\log p_\theta(x \mid z)] - \mathrm{KL}(q_\phi(z \mid x) \| p(z))$.
(iv) *Training*: maximize $\sum_{i=1}^n \mathcal{L}(\theta, \phi; x_i)$ over (θ, ϕ).

Definition 6.4.3. *Generative Adversarial Network*
Let $Z \sim p_Z$, data law P_{data}, generator $G_\theta : \mathcal{Z} \to \mathcal{X}$, and discriminator $D_\psi : \mathcal{X} \to (0, 1)$.

(i) *Generator*: G_θ induces $P_\theta := (G_\theta)_{\#} p_Z$ on $\mathcal{X}$.
(ii) *Discriminator*: $D_\psi(x)$ estimates the probability that $x \sim P_{\text{data}}$ rather than $x \sim P_\theta$.
(iii) *Adversarial game*: $\min_\theta \max_\psi \mathbb{E}_{x \sim P_{\text{data}}} \log D_\psi(x) + \mathbb{E}_{z \sim p_Z} \log(1 - D_\psi(G_\theta(z)))$.

Definition 6.4.4. *Diffusion Model*
Let $X_0 \sim P_{\text{data}}$ and $X_0, \ldots, X_T$ be a Markov chain on $\mathcal{X}$.

(i) *Forward noising*: fixed kernels $q_t(x_t \mid x_{t-1})$ define $q(x_{1:T} \mid x_0) = \prod_{t=1}^T q_t(x_t \mid x_{t-1})$.
(ii) *Reverse model*: learned kernels $p_\theta(x_{t-1} \mid x_t)$ define $p_\theta(x_{0:T}) = p_T(x_T) \prod_{t=1}^T p_\theta(x_{t-1} \mid x_t)$.
(iii) *Training*: fit θ so $p_\theta(x_{t-1} \mid x_t)$ approximates the reverse conditionals of q.
(iv) *Sampling*: draw $X_T \sim p_T$ and iterate $X_{t-1} \sim p_\theta(\cdot \mid X_t)$ for $t = T, \ldots, 1$.

6.5 Reinforcement Learning and Decision Systems

Reinforcement learning studies agents whose actions affect future observations and rewards.

Definition 6.5.1. *Markov Decision Process*
An MDP is a tuple $(\mathcal{S}, \mathcal{A}, P, r, \gamma)$ with:

(i) *State-action spaces*: states $s \in \mathcal{S}$ and actions $a \in \mathcal{A}$.
(ii) *Transition law*: $P(\cdot \mid s, a) \in \mathcal{P}(\mathcal{S})$ and $S_{t+1} \sim P(\cdot \mid S_t, A_t)$.
(iii) *Reward and discount*: $r : \mathcal{S} \times \mathcal{A} \to \mathbb{R}$ and $\gamma \in [0, 1)$.
(iv) *Policy*: $\pi(\cdot \mid s) \in \mathcal{P}(\mathcal{A})$ and $A_t \sim \pi(\cdot \mid S_t)$.

Definition 6.5.2. *Value Functions*
For policy π, define the discounted return $G_t := \sum_{k=0}^{\infty} \gamma^k r(S_{t+k}, A_{t+k})$.

(i) *State value*: $V^\pi(s) := \mathbb{E}_\pi[G_0 \mid S_0 = s]$.
(ii) *Action value*: $Q^\pi(s, a) := \mathbb{E}_\pi[G_0 \mid S_0 = s, A_0 = a]$.

Definition 6.5.3. *Bellman Equation*
For an MDP $(\mathcal{S}, \mathcal{A}, P, r, \gamma)$ and value function $V : \mathcal{S} \to \mathbb{R}$:

(i) *Policy Bellman equation*: $V^\pi(s) = \sum_a \pi(a \mid s)(r(s, a) + \gamma \sum_{s'} P(s' \mid s, a) V^\pi(s'))$.
(ii) *Optimal Bellman equation*: $V^\star(s) = \max_a (r(s, a) + \gamma \sum_{s'} P(s' \mid s, a) V^\star(s'))$.

Remark 6.5.4. *RL as a Learning System*
Let $\tau = (S_0, A_0, R_0, \ldots)$ denote a trajectory and P^π its law under policy π.

(i) *Prediction*: estimate V^π, Q^π, or transition/reward models from trajectories.
(ii) *Feedback*: policy changes alter the data law, $\pi \mapsto P^\pi$.
(iii) *Optimization*: choose π to maximize $J(\pi) := \mathbb{E}_{P^\pi} \sum_{t \geq 0} \gamma^t R_t$.
(iv) *Exploration*: sample actions to reduce uncertainty about rewards, transitions, or values.
(v) *Evaluation*: validate under sequential dependence and policy-induced distribution shift.

7 Learning Systems and Evaluation

7.1 Data Splitting, Validation, and Benchmarking

Evaluation estimates how the trained system behaves on data not used to fit it.

Definition 7.1.1. *Training, Validation, and Test Splits*
Let $\mathcal{D} = \mathcal{D}_{\text{tr}} \cup \mathcal{D}_{\text{val}} \cup \mathcal{D}_{\text{te}}$ be a disjoint partition of $\{(x_i, y_i)\}_{i=1}^n$, and fix a loss ℓ.

(i) Training: for each $\lambda \in \Lambda$, fit $\widehat{f}_\lambda$ using only $\mathcal{D}_{\text{tr}}$.
(ii) Validation: set $\widehat{\lambda} \in \arg\min_{\lambda \in \Lambda} \widehat{R}_{\text{val}}(\lambda)$, where $\widehat{R}_{\text{val}}(\lambda) = |\mathcal{D}_{\text{val}}|^{-1} \sum_{(x,y) \in \mathcal{D}_{\text{val}}} \ell(\widehat{f}_\lambda(x), y)$.
(iii) Test: after $\widehat{\lambda}$ is fixed, report $\widehat{R}_{\text{te}} = |\mathcal{D}_{\text{te}}|^{-1} \sum_{(x,y) \in \mathcal{D}_{\text{te}}} \ell(\widehat{f}_{\widehat{\lambda}}(x), y)$ as the final performance estimate.

If $\mathcal{D}_{\text{val}}$ is unavailable, cross-validation or bootstrap resampling approximates validation.
Any pre-reporting use of $\mathcal{D}_{\text{te}}$ makes $\widehat{R}_{\text{te}}$ adaptive and typically optimistic.

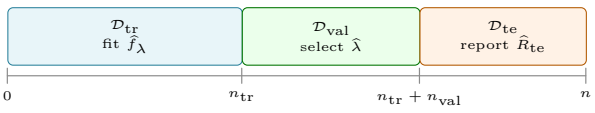

Figure 259: Train/validation/test split: $\mathcal{D} = \mathcal{D}_{\text{tr}} \sqcup \mathcal{D}_{\text{val}} \sqcup \mathcal{D}_{\text{te}}$, with $\mathcal{D}_{\text{tr}}$ fitting $\widehat{f}_\lambda$, $\mathcal{D}_{\text{val}}$ selecting $\widehat{\lambda}$, and $\mathcal{D}_{\text{te}}$ estimating final risk $\widehat{R}_{\text{te}}$.

Definition 7.1.2. *Model Selection and Model Assessment*
Let $\{\widehat{f}_\lambda : \lambda \in \Lambda\}$ be candidates, let $\widehat{R}_{\mathrm{val}}(\lambda)$ be validation error, and let $R(f) = \mathbb{E}\ell(f(X), Y)$.

(i) *Model selection*: choose $\widehat{\lambda} \in \Lambda$, typically $\widehat{\lambda} \in \arg\min_{\lambda\in\Lambda} \widehat{R}_{\mathrm{val}}(\lambda)$, and output $\widehat{f}_{\widehat{\lambda}}$.
(ii) *Model assessment*: after $\widehat{\lambda}$ is fixed, estimate $R(\widehat{f}_{\widehat{\lambda}})$ using data independent of training and selection.

Reusing selection data for assessment yields adaptive, typically optimistic error.

Definition 7.1.3. *Conditional and Expected Test Error*
Let $\widehat{f}_{\mathcal{T}}$ be trained on random $\mathcal{T}$, and let (X^0, Y^0) be an independent test point.

(i) *Conditional test error*: $\mathrm{Err}_{\mathcal{T}} = \mathbb{E}_{X^0,Y^0}[\ell(\widehat{f}_{\mathcal{T}}(X^0), Y^0) \mid \mathcal{T}]$.
(ii) *Expected test error*: $\mathrm{Err} = \mathbb{E}_{\mathcal{T}} \mathrm{Err}_{\mathcal{T}}$.

Reusable error estimators usually target Err, while $\mathrm{Err}_{\mathcal{T}}$ is the error conditional on the realized training set.

Method 7.1.4. *K-Fold Cross-Validation*
Let $\mathcal{D} = \{(x_i, y_i)\}_{i=1}^n$, loss ℓ, candidates Λ, and fold map $\kappa : \{1, \dots, n\} \to \{1, \dots, K\}$ be fixed.

(i) For each $\lambda \in \Lambda$ and $k = 1, \dots, K$, fit $\widehat{f}_\lambda^{-k}$ using only observations with $\kappa(i) \neq k$.
(ii) For each $\lambda \in \Lambda$, compute $\mathrm{CV}(\lambda) = n^{-1} \sum_{i=1}^n \ell(\widehat{f}_\lambda^{-\kappa(i)}(x_i), y_i)$.
(iii) Choose $\widehat{\lambda} \in \arg\min_{\lambda\in\Lambda} \mathrm{CV}(\lambda)$, or the one-standard-error candidate when that rule is specified.
(iv) Refit $\widehat{f}_{\widehat{\lambda}}$ on all of $\mathcal{D}$.

Leave-one-out has $K = n$; $K = 5$ or 10 often lowers variance and computation but fits on smaller training folds.

Remark 7.1.5. *What Cross-Validation Estimates*
For learning rule $\mathcal{A}$, let $\mathrm{Err}_{\mathcal{A}}(m) = \mathbb{E}_{\mathcal{T}_m,X^0,Y^0}\ell(\mathcal{A}(\mathcal{T}_m)(X^0), Y^0)$. K-fold cross-validation targets roughly $\mathrm{Err}_{\mathcal{A}}(n(1 - 1/K))$, not the conditional error of $\mathcal{A}(\mathcal{D})$. Leave-one-out has $m = n-1$ but dependent losses; fixed $K = 5$ or 10 lowers computation and often variance, with possible upward bias.

Definition 7.1.6. *Benchmark*
A benchmark is a fixed evaluation protocol $\mathcal{B} = (\mathcal{D}, \Pi, \mathcal{S}, m, \mathcal{R})$.

(i) *Data*: $\mathcal{D}$ specifies the population, sample, or data source.
(ii) *Preprocessing*: Π specifies transformations, filtering, feature construction, and allowed fitting scope.
(iii) *Splitting*: $\mathcal{S}$ specifies train-validation-test splits or resampling schemes.
(iv) *Metric*: m specifies the reported score.
(v) *Resources*: $\mathcal{R}$ specifies allowed external data, models, compute, and manual intervention.

Two reported scores are directly comparable only when computed under the same $\mathcal{B}$.

Remark 7.1.7. *Metric Choice*
Choose $m(f; \mathcal{D}_{\mathrm{te}})$ so its ordering of candidate rules matches the deployment objective $U(f)$.
Accuracy, log loss, calibration, ranking quality, cost, and latency need not agree.

Remark 7.1.8. *Data Leakage*
For protected evaluation data E, leakage is dependence of any pre-evaluation choice Z_{pre} on labels or covariates in E. Then error measured on E is adaptive, not honest out-of-sample error.

Method 7.1.9. *Cross-Validation with Screening or Preprocessing*
For a fold map $\kappa : \{1, \dots, n\} \to \{1, \dots, K\}$, set $\mathcal{D}_k = \{(x_i, y_i) : \kappa(i) = k\}$ and $\mathcal{D}_{-k} = \mathcal{D} \setminus \mathcal{D}_k$.
Data-dependent pipeline choices must be fold-local:

(i) For each k, learn preprocessing, screening, feature selection, and tuning from $\mathcal{D}_{-k}$ only.
(ii) Fit $\widehat{f}^{-k}$ on $\mathcal{D}_{-k}$ after applying exactly those fold-local choices.
(iii) Predict and score $\mathcal{D}_k$ using $\widehat{f}^{-k}$ and the same fold-local choices.
(iv) Average the held-out losses over $k = 1, \dots, K$.

Full-data supervised choices leak held-out labels into $\widehat{f}^{-k}$ and bias cross-validation downward.
The protocol should state whether unsupervised preprocessing is fold-local or full-covariate.

Method 7.1.10. *Bootstrap Estimates of Prediction Error*
Let $\mathcal{D} = \{(x_i, y_i)\}_{i=1}^n$; draw bootstrap samples S^{*b} and fit $\widehat{f}^{*b}$; set $C^{-i} = \{b : (x_i, y_i) \notin S^{*b}\}$, $I_{\mathrm{oob}} = \{i : C^{-i} \neq \varnothing\}$, and $\overline{\mathrm{err}} = n^{-1} \sum_i \ell(\widehat{f}(x_i), y_i)$.

(i) *Naive bootstrap*: $\widehat{\mathrm{Err}}_{\mathrm{boot}} = B^{-1} \sum_{b=1}^B n^{-1} \sum_{i=1}^n \ell(\widehat{f}^{*b}(x_i), y_i)$.
(ii) *Out-of-bag bootstrap*: $\widehat{\mathrm{Err}}^{(1)} = |I_{\mathrm{oob}}|^{-1} \sum_{i\in I_{\mathrm{oob}}} |C^{-i}|^{-1} \sum_{b\in C^{-i}} \ell(\widehat{f}^{*b}(x_i), y_i)$.
(iii) *.632 bootstrap*: $\widehat{\mathrm{Err}}^{(.632)} = .368\,\overline{\mathrm{err}} + .632\,\widehat{\mathrm{Err}}^{(1)}$.
(iv) *.632+ bootstrap*: $\widehat{\mathrm{Err}}^{(.632+)} = (1 - w_+)\overline{\mathrm{err}} + w_+\widehat{\mathrm{Err}}^{(1)}$, with $w_+ \in [.632, 1]$ increase with overfitting.

Naive reuse is most optimistic; out-of-bag and .632 variants reduce reuse bias.

Remark 7.1.11. *Limits of Reuse-Based Assessment*
Write $\widehat{R}_{\mathrm{reuse}}(\lambda) = R(\widehat{f}_\lambda) + b_\lambda + \varepsilon_\lambda$. Nearly constant b_λ can preserve candidate comparisons despite biased levels.
After choosing $\widehat{\lambda}$, estimating $R(\widehat{f}_{\widehat{\lambda}})$ requires data independent of all fitting, preprocessing, tuning, and iteration.

7.2 Robustness, Shift, and Distributional Uncertainty

Learning systems are deployed under distributions that may differ from the training law.

Definition 7.2.1. *Distribution Shift*
Let P be training law, Q deployment law on (X, Y). Distribution shift means $Q \neq P$; common cases are:

(i) *Covariate shift*: $Q_X \neq P_X$ and $Q_{Y|X} = P_{Y|X}$.
(ii) *Label shift*: $Q_Y \neq P_Y$ and $Q_{X|Y} = P_{X|Y}$.
(iii) *Concept shift*: $Q_{Y|X} \neq P_{Y|X}$.

Definition 7.2.2. *Adversarial Example*
Let $\mathcal{F}$ be a predictor class, ℓ a loss, $d_f : \mathcal{X} \to \mathcal{D}$ the decision rule induced by $f \in \mathcal{F}$, $\Delta(x)$ the admissible perturbation set at x, and $\mathcal{H}_y \subseteq \mathcal{D} \times \mathcal{D}$ the harmful decision-change relation for label y.

(i) *Adversarial example*: for fixed $f \in \mathcal{F}$ and (x, y), any $x' = x + \delta$ with $\delta \in \Delta(x)$ and $\big(\ell(f(x'), y) > \ell(f(x), y)\big) \vee \big((d_f(x), d_f(x')) \in \mathcal{H}_y\big)$.

(ii) *Adversarial training*: for $S = \{(x_i, y_i)\}_{i=1}^n$, choose $\widehat{f}_{\mathrm{adv}} \in \arg\min_{f \in \mathcal{F}} n^{-1} \sum_{i=1}^n \sup_{\delta \in \Delta(x_i)} \ell(f(x_i + \delta), y_i)$.

(iii) *Neural perturbation form*: minimize $\ell(y, f_\theta(x + \delta^\star))$, where $\delta^\star \in \arg\max_{\|\delta\| \le \rho} \ell(y, f_\theta(x + \delta))$.

Definition 7.2.3. *Distributionally Robust Optimization*
Let $\mathcal{F}$ be a hypothesis class, ℓ a loss, and $\mathcal{U} \subseteq \mathcal{P}(\mathcal{X} \times \mathcal{Y})$ an uncertainty set of deployment laws.

(i) *Robust risk*: for $Q \in \mathcal{U}$ and $f \in \mathcal{F}$, $R_Q(f) = \mathbb{E}_{(X,Y)\sim Q} \ell(f(X), Y)$ and $R_{\mathcal{U}}(f) = \sup_{Q \in \mathcal{U}} R_Q(f)$.

(ii) *DRO solution*: any $\widehat{f}_{\mathrm{DRO}} \in \arg\min_{f \in \mathcal{F}} R_{\mathcal{U}}(f)$.

Remark 7.2.4. *Uncertainty*
Let $\mathcal{T}$ be the training data, P_{tr} the training law, and P_{dep} the deployment law.

(i) *Aleatoric uncertainty*: irreducible variability in $Y \mid X = x$ under the data-generating law.
(ii) *Epistemic uncertainty*: uncertainty in f from finite $\mathcal{T}$, misspecification, or nonidentifiability.
(iii) *Out-of-distribution uncertainty*: uncertainty from $P_{\mathrm{dep}} \neq P_{\mathrm{tr}}$ or inputs outside the training support.

Robust systems calibrate probabilities and abstain when uncertainty exceeds a policy threshold.

7.3 Interpretability, Fairness, and Safety

Evaluation also asks whether a model can be understood, audited, and constrained in the setting where it is used.

Definition 7.3.1. *Interpretability*
Let $\mathcal{F}, \mathcal{C}, \mathcal{E}, \mathcal{A}, \mathcal{B}$ denote predictor, query-context, explanation, audience, and audit-task spaces.

(i) *Interpretability specification*: $\mathcal{I} = (\mathcal{E}, a, b, \Phi)$ with $(a, b) \in \mathcal{A} \times \mathcal{B}$ and $\Phi : \mathcal{F} \times \mathcal{C} \to \mathcal{E}$.
(ii) *Explanation*: for $(f, c) \in \mathcal{F} \times \mathcal{C}$, $e = \Phi(f, c)$.

Typical codomains $\mathcal{E}$ encode attributions, counterfactuals, surrogate rules, or representation summaries.

Definition 7.3.2. *Fairness Criteria*
Let A be a protected attribute, $\widehat{Y}$ a decision, S a score, and Y the outcome.
A group fairness criterion imposes equalities or tolerances across values of A; common examples are:

(i) *Demographic parity*: $\mathbb{P}(\widehat{Y} = 1 \mid A = a)$ is constant in a.
(ii) *Equalized odds*: $\mathbb{P}(\widehat{Y} = 1 \mid Y = y, A = a)$ is constant in a for each y.
(iii) *Group calibration*: $\mathbb{P}(Y = 1 \mid S = s, A = a) = s$ for each relevant s and a.

These criteria need not be mutually compatible; the chosen condition should match the policy goal.

Definition 7.3.3. *Safety Constraint*
An additional requirement $f \in \mathcal{C}$ or $R_{\mathrm{safe}}(f) \le \tau$ beyond average-case loss is a *safety constraint*.
$\mathcal{C}$ encodes abstention, monotonicity, action bounds, review triggers, or worst-case risk limits.

Remark 7.3.4. *Beyond Accuracy*
For a deployed predictor f, evaluation beyond accuracy is a specification $\mathcal{E} = (\mathcal{I}, \mathcal{F}, \mathcal{C})$.

(i) *Interpretability*: $\mathcal{I}$ specifies the explanation object, audience, and audit protocol.
(ii) *Fairness*: $\mathcal{F}$ specifies protected attributes, group metrics, and required parity or error constraints.
(iii) *Safety*: $\mathcal{C}$ specifies forbidden actions, abstention rules, human review triggers, or worst-case risk bounds.

A scalar score is incomplete unless the relevant components of $\mathcal{E}$ are stated.

7.4 Deployment, Monitoring, and Feedback Loops

Deployment turns a fitted model into part of a larger stochastic system.

Definition 7.4.1. *Monitoring*
Given deployed f and stream $Z_t = (X_t, \widehat{Y}_t, Y_t^*)$, monitoring outputs (M_t, a_t) with $a_t \in \{0, 1\}$.

(i) *Distribution*: compare $P_t(X)$ and $P_t(\widehat{Y})$ with validation baselines.
(ii) *Performance*: estimate loss, calibration, and subgroup error when labels Y_t^* arrive.
(iii) *Operations*: track latency, missingness, failures, and data-pipeline changes.

An alarm $a_t = 1$ indicates that validation assumptions or service constraints may no longer hold.

Definition 7.4.2. *Feedback Loop*
A deployed policy $A_t = \pi(f(X_t), H_t)$ is a *feedback loop* if $P(X_{t+1}, Y_{t+1} \mid A_t) \neq P(X_{t+1}, Y_{t+1})$.
Future data are then endogenous to f.

Method 7.4.3. *Model Update Policy*
Given deployed f_t, data $\mathcal{D}_{\le t}$, and diagnostics M_t, a model update policy maps f_t to f_{t+1}:

(i) *Trigger*: retrain only when a scheduled time, alarm M_t, or performance threshold calls for it.
(ii) *Eligibility*: choose the data subset $\mathcal{D}_{\mathrm{upd}} \subseteq \mathcal{D}_{\le t}$ allowed for training.
(iii) *Validation*: accept candidate $\widetilde{f}$ only if it passes the benchmark and safety criteria against f_t.
(iv) *Deployment*: replace f_t by $\widetilde{f}$ under a rollout plan and rollback rule.

The policy determines future training data and evaluation conditions.

Remark 7.4.4. *Human-System Boundary*
For human-supported decisions, the deployed policy is $\pi = (f, I, A, O, M, G)$, not just predictor f.

(i) *Interface*: I determines what predictions, explanations, and uncertainty are shown.

(ii) *Action rule*: A maps model output and human input to decisions.
(iii) *Override*: O specifies when humans may ignore or modify f.
(iv) *Monitoring*: M tracks errors, drift, latency, and misuse.
(v) *Governance*: G assigns review, audit, and accountability.

System evaluation should target π rather than f alone.

Part XXII
Classical Supervised Learning

1 Linear Prediction and Generalized Linear Models

1.1 Linear Predictors and Least Squares

Linear prediction reduces inputs to scores of the form "intercept plus weighted features." Regression reads scores as predictions; classification compares or transforms them. Its appeal is geometric: projections, hyperplanes, and feature maps.

Definition 1.1.1. *Linear Predictor*
For $x \in \mathbb{R}^p$, $w \in \mathbb{R}^p$, and $b \in \mathbb{R}$, the *linear predictor* is $f_{w,b}(x) := w^\top x + b$.
Regression uses $f_{w,b}$ directly; classification transforms it by g. Score level sets are parallel hyperplanes.

Definition 1.1.2. *Least-Squares Linear Regression*
For $X \in \mathbb{R}^{n\times d}$ and $y \in \mathbb{R}^n$, *least-squares linear regression* chooses $\widehat{\beta} \in \operatorname*{argmin}_{\beta\in\mathbb{R}^d} \|y - X\beta\|_2^2$ and $\widehat{y} := X\widehat{\beta}$.

If $X^\top X$ is nonsingular, then $\widehat{\beta} = (X^\top X)^{-1}X^\top y$. Columns of X may be raw variables, transformations, indicators, interactions, or basis functions; linearity is in β.

Geometrically, least squares moves y to the closest point in $\operatorname{col}(X)$.

Method 1.1.3. *Multiple-Output Least Squares*
For $Y \in \mathbb{R}^{n\times K}$ and $B \in \mathbb{R}^{d\times K}$, set $Y = XB + E$.

(i) *Least squares*: If $\operatorname{rank}(X) = d$, then $\widehat{B} = (X^\top X)^{-1}X^\top Y$.
(ii) *Decoupling*: Writing $Y = (y_1, \dots, y_K)$ gives $\widehat{B} = (\widehat{\beta}_1, \dots, \widehat{\beta}_K)$, where each $\widehat{\beta}_k$ is the OLS fit of y_k on X.

Shared responses can be pooled by low-rank B or common-direction shrinkage.

Method 1.1.4. *Canonical Correlation and Reduced-Rank Regression*

(i) *CCA*: Choose (v_j, u_j) with large $\operatorname{corr}(Xv_j, Yu_j)$, orthogonal across j; at most $\min(d, K)$ pairs.
(ii) *Rank constraint*: Fit $Y \approx XB$ with $\operatorname{rank}(B) \le m$, restricting fitted responses to m dimensions.
(iii) *Objective*: $\widehat{B}_m^{\mathrm{rr}} \in \operatorname*{argmin}_{\operatorname{rank}(B)\le m} \sum_i (y_i - B^\top x_i)^\top \widehat{\Sigma}^{-1}(y_i - B^\top x_i)$.
(iv) *Role of m*: $m = K$ gives separate OLS; smaller m pools shared response structure.

Reduced rank assumes the predictable response variation lies in a low-dimensional subspace.

1.2 Linear Classification and Generalized Linear Models

Definition 1.2.1. *Discriminant Functions and Linear Boundaries*
For $\mathcal{G} = \{1, \dots, K\}$ and scores $\delta_k : \mathcal{X} \to \mathbb{R}$, set $\widehat{G}(x) \in \operatorname{argmax}_{k\in\mathcal{G}} \delta_k(x)$. Only score differences matter.

(i) *Pairwise boundary*: The k versus ℓ boundary lies in $\{x : \delta_k(x) = \delta_\ell(x)\}$.
(ii) *Linear boundary*: If $\delta_k - \delta_\ell$ is affine in x for all k, ℓ, then all pairwise decision boundaries are hyperplanes.
(iii) *Binary log-odds*: If $\log \frac{\mathbb{P}(G=1|X=x)}{\mathbb{P}(G=2|X=x)} = \beta_0 + \beta^\top x$, then the boundary is $\{x : \beta_0 + \beta^\top x = 0\}$.

Method 1.2.2. *Indicator-Matrix Regression Classifier*
For classes $g_i \in \{1, \dots, K\}$, set $t_k = e_k \in \mathbb{R}^K$, $Y_i = t_{g_i}$, and $\widetilde{x}_i^\top = (1, x_i^\top)$, coding labels as Euclidean targets.

(i) *Least-squares fit*: Choose $\widehat{B} \in \operatorname{argmin}_B \sum_{i=1}^n \|Y_i - B^\top \widetilde{x}_i\|_2^2$; if $\widetilde{X}^\top\widetilde{X}$ is nonsingular, $\widehat{B} = (\widetilde{X}^\top\widetilde{X})^{-1}\widetilde{X}^\top Y$.
(ii) *Scores*: For a new x, set $\widetilde{x} = (1, x^\top)^\top$ and $\widehat{f}(x) := \widehat{B}^\top\widetilde{x}$.
(iii) *Classification*: Predict $\widehat{G}(x) \in \operatorname{argmax}_k \widehat{f}_k(x)$, equivalently nearest t_k.

With an intercept, $\sum_k \widehat{f}_k(x) = 1$, but $\widehat{f}_k(x)$ may leave $[0, 1]$ and, for $K \ge 3$, *mask* middle classes.

Definition 1.2.3. *Generalized Linear Model*
A *generalized linear model* gives $Y \mid X = x$ an exponential-family law and makes a linked mean linear: $g(\mu(x)) = w^\top x + b$. Logistic regression uses the Bernoulli law and logit link $g(\mu) = \log \frac{\mu}{1-\mu}$.

Thus a GLM separates score, mean scale, and likelihood.

Definition 1.2.4. *Multiclass Logistic Regression*
With class K as baseline, set $\eta_k(x) := \beta_{k0} + \beta_k^\top x = \log \frac{\mathbb{P}(G=k|X=x)}{\mathbb{P}(G=K|X=x)}$ for $k < K$.

(i) *Softmax probabilities*: For $k < K$, $p_k(x;\theta) := \frac{\exp(\eta_k(x))}{1+\sum_{\ell=1}^{K-1}\exp(\eta_\ell(x))}$, and $p_K(x;\theta) := \frac{1}{1+\sum_{\ell=1}^{K-1}\exp(\eta_\ell(x))}$.
(ii) *Likelihood*: Fit θ by maximising $\ell(\theta) := \sum_{i=1}^n \log p_{g_i}(x_i;\theta)$.

The softmax gives $p(x;\theta) \in \Delta^{K-1}$; the reference class changes only the parametrisation.

Method 1.2.5. *Binary Logistic Regression by IRLS*
For $y_i \in \{0, 1\}$ and intercept-augmented rows $x_i^\top$, set $p_i(\beta) := (1 + \exp(-x_i^\top\beta))^{-1}$.

(i) *Derivatives*: With $p = (p_i)$ and $W := \operatorname{diag}(p_i(1-p_i))$, $\nabla\ell(\beta) = X^\top(y - p)$ and $\nabla^2\ell(\beta) = -X^\top WX$.
(ii) *Adjusted response*: At β^{old}, set $z := X\beta^{\mathrm{old}} + W^{-1}(y - p)$.
(iii) *IRLS update*: Set $\beta^{\mathrm{new}} := (X^\top WX)^{-1}X^\top Wz$.

IRLS is Newton's method as weighted least squares.
The log-likelihood is concave when the MLE is finite; step-halving controls Newton overshoot.

Method 1.2.6. *L_1-Regularized Logistic Regression*
With unpenalized intercept, maximize $\ell_\lambda(\beta_0,\beta) := \sum_{i=1}^{n}\{y_i\eta_i - \log(1+\exp(\eta_i))\} - \lambda\sum_{j=1}^{p}|\beta_j|$, where $\eta_i := \beta_0 + x_i^\top\beta$.

(i) *Probabilities*: Set $p_i := (1+\exp(-\eta_i))^{-1}$ and residual $r := y - p$.
(ii) *KKT conditions*: If $\widehat{\beta}_j \neq 0$, then $x_j^\top r = \lambda\,\mathrm{sign}(\widehat{\beta}_j)$; if $\widehat{\beta}_j = 0$, then $\left|x_j^\top r\right| \le \lambda$.

The KKT conditions are thresholded feature–residual correlations.

1.3 Discriminant Analysis and Naive Bayes

Method 1.3.1. *Gaussian Discriminant Analysis*
If $X \mid G = k$ has density f_k and prior π_k, then $\mathbb{P}(G=k \mid X=x) = \frac{f_k(x)\pi_k}{\sum_{\ell=1}^{K} f_\ell(x)\pi_\ell}$.

(i) *Score*: If $X \mid G = k \sim N(\mu_k,\Sigma_k)$, compare $\delta_k(x) := -\frac{1}{2}\log|\Sigma_k| - \frac{1}{2}(x-\mu_k)^\top\Sigma_k^{-1}(x-\mu_k) + \log\pi_k$.
(ii) *LDA*: If $\Sigma_k = \Sigma$ for all k, equivalent linear scores are $\delta_k^{\mathrm{LDA}}(x) := x^\top\Sigma^{-1}\mu_k - \frac{1}{2}\mu_k^\top\Sigma^{-1}\mu_k + \log\pi_k$.
(iii) *QDA*: If Σ_k varies with k, the quadratic term remains and the rule is quadratic discriminant analysis.

Estimate π_k, μ_k, Σ_k from training data; pooled covariance gives LDA and classwise covariances give QDA.
Shared covariance makes the boundaries linear.

Method 1.3.2. *Regularized Discriminant Analysis*
For $0 \le \alpha \le 1$, set $\widehat{\Sigma}_k(\alpha) := \alpha\widehat{\Sigma}_k + (1-\alpha)\widehat{\Sigma}$.

(i) *Endpoints*: $\alpha = 0$ gives LDA and $\alpha = 1$ gives QDA.
(ii) *Scalar shrinkage*: For $0 \le \gamma \le 1$, replace $\widehat{\Sigma}$ by $\widehat{\Sigma}(\gamma) := \gamma\widehat{\Sigma} + (1-\gamma)\widehat{\sigma}^2 I$.

Shrinkage reduces variance when covariance estimation is unstable.

Definition 1.3.3. *Naive Bayes Classifier*
For $x = (x_1,\dots,x_p)$, assume $f_j(x) = \prod_{k=1}^{p} f_{jk}(x_k)$ for each class j.

(i) *Posterior*: With priors π_j, $p_j(x) := \mathbb{P}(G=j \mid X=x) \propto \pi_j \prod_{k=1}^{p} f_{jk}(x_k)$.
(ii) *Additive log odds*: Relative to class J, $\log\frac{p_\ell(x)}{p_J(x)} = \log\frac{\pi_\ell}{\pi_J} + \sum_{k=1}^{p}\log\frac{f_{\ell k}(x_k)}{f_{Jk}(x_k)}$.

On the log scale, features contribute additively.
Even misspecified independence can reduce variance enough to classify well near boundaries.

Remark 1.3.4. *Least Squares Versus LDA*
For $K = 2$, least-squares regression on any distinct label coding gives $\widehat{\beta} \propto \widehat{\Sigma}^{-1}(\widehat{\mu}_2 - \widehat{\mu}_1)$, the LDA direction.
The cutpoint may differ unless classes are balanced or tuned separately.
For $K > 2$, LDA uses pooled-Mahalanobis centroid distances and avoids masking.

Remark 1.3.5. *Logistic Regression Versus LDA*
Both can yield linear log-odds. Logistic regression models class probabilities directly and leaves P_X free; LDA fits a joint Gaussian mixture for (X,G) and uses Bayes' rule.

Remark 1.3.6. *Whitening and Reduced-Rank LDA*
With common covariance W, LDA compares $W^{-1/2}x$ to whitened centroids, adjusted by $\log\pi_k$.
The whitened centroids span dimension at most $K-1$, so LDA reduces to this centroid subspace.
Fisher directions maximize $\frac{a^\top Ba}{a^\top Wa}$, equivalently solve $Ba = \lambda Wa$, where B is between-class scatter.

Remark 1.3.7. *Feature Maps*
A feature map $\phi : \mathcal{X} \to \mathcal{H}$ gives linear prediction in feature space, $f(x) = w^\top\phi(x) + b$, which is generally nonlinear in x. Kernel methods choose ϕ implicitly; neural networks learn ϕ from data.

2 Regularisation and Model Selection

2.1 Penalized Linear Estimation

Regularisation controls model complexity by penalising unstable parameter directions or by constraining the feasible set.

Definition 2.1.1. *Penalised Linear Estimation*
For empirical loss $L_n(\beta)$, a penalised estimator solves $\widehat{\beta}_\lambda \in \arg\min_\beta\{L_n(\beta) + \lambda\Omega(\beta)\}$.
The choices $\Omega(\beta) = \|\beta\|_2^2$ and $\Omega(\beta) = \|\beta\|_1$ give ridge and lasso penalties.

Definition 2.1.2. *Subset Selection, Ridge, and Lasso*
Let $y \in \mathbb{R}^n$ be centered and let $X \in \mathbb{R}^{n\times p}$ have centered, standardised columns.

(i) *Best subset*: for a size m, solve $\widehat{\beta}_m^{\mathrm{sub}} \in \underset{|\,\mathrm{supp}(\beta)|\le m}{\arg\min} \|y - X\beta\|_2^2$
(ii) *Ridge*: for $\lambda \ge 0$, solve $\widehat{\beta}_\lambda^{\mathrm{ridge}} \in \arg\min_\beta\{\|y - X\beta\|_2^2 + \lambda\|\beta\|_2^2\}$
(iii) *Lasso*: for $\lambda \ge 0$, solve $\widehat{\beta}_\lambda^{\mathrm{lasso}} \in \arg\min_\beta\left\{\frac{1}{2}\|y - X\beta\|_2^2 + \lambda\|\beta\|_1\right\}$

Centering separates the unpenalised intercept, estimated by the mean on the raw scale.

Remark 2.1.3. *Penalty Geometry*
Assume $X^TX = I$ and set $z_j = x_j^T y$. For subset size m, best subset selection keeps the m largest $|z_j|$.
Ridge and lasso have coordinates $\widehat{\beta}_{\lambda,j}^{\mathrm{ridge}} = \frac{z_j}{1+\lambda}$ and $\widehat{\beta}_{\lambda,j}^{\mathrm{lasso}} = \mathrm{sign}(z_j)(|z_j| - \lambda)_+$.
Thus ℓ^2 shrinkage is smooth, while ℓ^1 shrinkage can set coefficients exactly to zero.

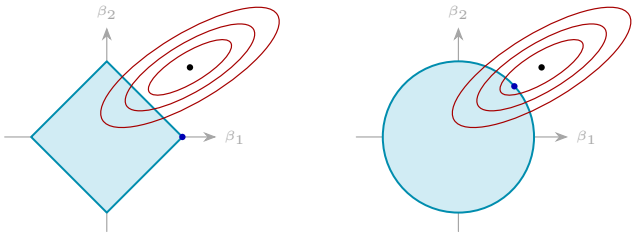

Figure 260: Left: lasso ℓ^1 diamond; right: ridge ℓ^2 disk.

Proposition 2.1.4. *Ridge Shrinkage and Effective Degrees*
Let $X \in \mathbb{R}^{n\times p}$ be centered with rank r and thin SVD $X = UDV^T$, where $D = \operatorname{diag}(d_1, \dots, d_r)$ and $d_j > 0$.
For $\lambda > 0$, set $S_\lambda := X(X^TX + \lambda I_p)^{-1}X^T$ and $s_j(\lambda) := \frac{d_j^2}{d_j^2+\lambda}$. Then $S_\lambda = U \operatorname{diag}(s_1(\lambda), \dots, s_r(\lambda))U^T$.
So $\widehat{y}_\lambda^{\text{ridge}} := X\widehat{\beta}_\lambda^{\text{ridge}} = S_\lambda y = \sum_{j=1}^{r} s_j(\lambda)u_j u_j^T y$ and $\operatorname{df}(\lambda) := \operatorname{tr}(S_\lambda) = \sum_{j=1}^{r} s_j(\lambda)$.

Proof. Since $X^TX = VD^2V^T$ and $X^T = VDU^T$, we have $V^T(X^TX + \lambda I_p)^{-1}V = (D^2 + \lambda I_r)^{-1}$.
Hence $S_\lambda = UDV^T(X^TX + \lambda I_p)^{-1}VDU^T = UD(D^2 + \lambda I_r)^{-1}DU^T = U \operatorname{diag}(s_1(\lambda), \dots, s_r(\lambda))U^T$.
Apply to y and take traces, using $U^TU = I_r$.
Structural Commentary: Ridge is diagonal in the left singular-vector basis of X.
Key Insight: Ridge keeps direction u_j by $s_j(\lambda)$; weak directions count less in the fit and $\operatorname{df}(\lambda)$. □

2.2 Validation and Selection Bias

Definition 2.2.1. *Model Selection by Validation*
Let $\mathcal{M}$ be a candidate set of models or hyperparameters.

(i) A *validation criterion* is $m \mapsto \widehat{R}_{\text{val}}(m)$; choose $\widehat{m} \in \arg\min_{m\in\mathcal{M}} \widehat{R}_{\text{val}}(m)$.

(ii) In *K-fold cross-validation*, take folds $I_1, \dots, I_K$ and fits $\widehat{f}_m^{(-k)}$.
Define $\ell_{ik}(m) := \ell(y_i, \widehat{f}_m^{(-k)}(x_i))$, $\widehat{R}_{\text{cv}}(m) := \frac{1}{n}\sum_{k=1}^{K}\sum_{i\in I_k} \ell_{ik}(m)$, and choose $\widehat{m}_{\text{cv}} \in \arg\min_{m\in\mathcal{M}} \widehat{R}_{\text{cv}}(m)$.

Method 2.2.2. *One-Standard-Error Rule*
Let $(\mathcal{M}, \preceq)$ order candidates by complexity, with $\widehat{R}_{\text{cv}}, \widehat{\text{se}} : \mathcal{M} \to \mathbb{R}$.

(i) Choose $\widehat{m}_{\min} \in \arg\min_{m\in\mathcal{M}} \widehat{R}_{\text{cv}}(m)$ and set $\widehat{R}_{\min} := \widehat{R}_{\text{cv}}(\widehat{m}_{\min})$.
(ii) Define $\mathcal{M}_{1\text{se}} := \{m \in \mathcal{M} : \widehat{R}_{\text{cv}}(m) \le \widehat{R}_{\min} + \widehat{\text{se}}(\widehat{m}_{\min})\}$.
(iii) Select $\widehat{m}_{1\text{se}}$ as the $\preceq$-minimal element of $\mathcal{M}_{1\text{se}}$; use any final test set only after this choice.

Example 2.2.3. *A Selection and Shrinkage Workflow*
Let $D = \{(x_i, y_i)\}_{i=1}^n$, where $y_i = \log(\text{PSA}_i)$ and $x_i = (\text{lcavol}_i, \text{lweight}_i, \text{age}_i, \text{lbph}_i, \text{svi}_i, \text{lcp}_i, \text{gleason}_i, \text{pgg45}_i)$.
Split indices into training and test sets T, E, standardize X_T, and choose each complexity parameter by cross-validation on T: subset size m, ridge/lasso penalty λ, or PCR/PLS dimension M.
The selected fit $\widehat{f}$ is then evaluated once on E by $\widehat{R}_{\text{test}} := |E|^{-1}\sum_{i\in E} \ell(y_i, \widehat{f}(x_i))$.

Remark 2.2.4. *Selection Bias*
If $\widehat{m} \in \arg\min_{m\in\mathcal{M}} \widehat{R}_V(m)$ is chosen on validation set V, then $\widehat{R}_V(\widehat{m})$ is optimistically biased for $R(\widehat{m})$.
Estimate the selected model with an independent set E, using $\widehat{R}_E(\widehat{m})$, or use nested validation.

2.3 Derived Input Directions and Regularization Paths

Method 2.3.1. *Derived Input Directions*
Let X, y be centered. A derived-direction method chooses $Z_M = (z_1, \dots, z_M)$ with $z_m = Xv_m$ or data-adaptive analogues, then fits $\widehat{y}_M = P_{Z_M} y$, where $P_{Z_M} := Z_M(Z_M^TZ_M)^{-1}Z_M^T$; M is selected by validation.

(i) *Principal components regression*: for $X = UDV^T$, take $v_1, \dots, v_M$ as the leading right singular vectors,
set $z_m = Xv_m = d_m u_m$, and fit $\widehat{y}_M^{\text{pcr}} = \sum_{m=1}^{M} z_m \frac{z_m^T y}{z_m^T z_m} = \sum_{m=1}^{M} u_m u_m^T y$.

(ii) *Partial least squares*: set $X^{(0)} = X$ and, for $m = 1, \dots, M$, define $z_m = X^{(m-1)}X^{(m-1)T}y$ and
$X^{(m)} = (I - P_{z_m})X^{(m-1)}$, where $P_{z_m} := \frac{z_m z_m^T}{z_m^T z_m}$. With $Z_M = (z_1, \dots, z_M)$, fit $\widehat{y}_M^{\text{pls}} = P_{Z_M} y$.

Algorithm 9: Partial Least Squares Directions

Require: Centered response y, standardized columns $x_1, \dots, x_p$, number of directions $M \le p$
Ensure: Fitted vectors $\widehat{y}^{(1)}, \dots, \widehat{y}^{(M)}$
Set $\widehat{y}^{(0)} \leftarrow 0$ and $x_j^{(0)} \leftarrow x_j$ for $j = 1, \dots, p$
for $m = 1, \dots, M$ **do**
$z_m \leftarrow \sum_{j=1}^{p} (x_j^{(m-1)})^T y\, x_j^{(m-1)}$
$\widehat{\theta}_m \leftarrow \frac{z_m^T y}{z_m^T z_m}$
$\widehat{y}^{(m)} \leftarrow \widehat{y}^{(m-1)} + \widehat{\theta}_m z_m$

for $j = 1, \dots, p$ **do**
$x_j^{(m)} \leftarrow x_j^{(m-1)} - \frac{z_m^T x_j^{(m-1)}}{z_m^T z_m} z_m$
end for
end for

Remark 2.3.2. *PLS Versus PCR*
PCR chooses v_m from $X^T X v_m = d_m^2 v_m$, so directions are ordered only by predictor variance d_m^2.
PLS chooses $z_m = X^{(m-1)} X^{(m-1)T} y$ and deflates $X^{(m)} = (I - P_{z_m}) X^{(m-1)}$, so each direction depends on both variance in $X^{(m-1)}$ and covariance with y.

Method 2.3.3. *Piecewise-Linear Path Algorithms*
Let $\widehat{\beta}(\lambda) \in \arg\min_\beta \{R(\beta) + \lambda J(\beta)\}$.

(i) If R is quadratic or piecewise quadratic and J is piecewise linear, fixed active-set and sign regions give affine KKT equations in λ, so $\widehat{\beta}(\lambda)$ is piecewise linear.
(ii) *Least angle regression*: with residual $r = y - X\beta$ and active set $\mathcal{A}$, move $\beta_\mathcal{A}$ in a direction keeping $|x_j^T r|$ tied for $j \in \mathcal{A}$ until a new variable ties or the least-squares fit is reached.
(iii) *Lasso path*: follow the same tied-correlation path and remove $j \in \mathcal{A}$ when β_j reaches 0.
(iv) *Coordinate descent*: for fixed λ, update $\beta_j \leftarrow \arg\min_t \{\frac{1}{2} \|y - X_{-j}\beta_{-j} - x_j t\|_2^2 + \lambda(|t| + \|\beta_{-j}\|_1)\}$ and warm-start along $\lambda_1 > \cdots > \lambda_L$.

Method 2.3.4. *LAR, Lasso, and Correlation Ties*
Let $\widehat{\beta}_\lambda \in \arg\min_\beta \{\frac{1}{2} \|y - X\beta\|_2^2 + \lambda \|\beta\|_1\}$, $r_\lambda := y - X\widehat{\beta}_\lambda$, and $\mathcal{A}_\lambda := \{j : \widehat{\beta}_{\lambda,j} \neq 0\}$.

(i) *KKT*: $x_j^T r_\lambda = \lambda \operatorname{sign}(\widehat{\beta}_{\lambda,j})$ for $j \in \mathcal{A}_\lambda$, and $|x_j^T r_\lambda| \le \lambda$ for $j \notin \mathcal{A}_\lambda$.
(ii) *Correlation ties*: active predictors satisfy $|x_j^T r_\lambda| = \lambda$; inactive predictors satisfy $|x_j^T r_\lambda| \le \lambda$.
(iii) *LAR*: with $C = \|X^T r\|_\infty$, move in the equiangular active direction preserving $|x_j^T r| = C$ for $j \in \mathcal{A}$ until some $k \notin \mathcal{A}$ reaches $|x_k^T r| = C$.
(iv) *Lasso path*: on a fixed active set and sign pattern, the KKT equations are affine in λ. When some $\widehat{\beta}_{\lambda,j}$ reaches 0, remove j and recompute the active direction.

Algorithm 10: Least Angle Regression Path

Require: Centered response y and standardized columns $x_1, \dots, x_p$ with $\|x_j\|_2 = 1$
Ensure: Piecewise-linear coefficient path $\{\beta(t)\}$
Initialize $\beta \leftarrow 0$, $r \leftarrow y$, $c \leftarrow X^T r$, $C \leftarrow \|c\|_\infty$, and $\mathcal{A} \leftarrow \{j : |c_j| = C\}$
repeat
$s_\mathcal{A} \leftarrow \operatorname{sign}(c_\mathcal{A})$, $\widetilde{X}_\mathcal{A} \leftarrow X_\mathcal{A} \operatorname{diag}(s_\mathcal{A})$, and $G_\mathcal{A} \leftarrow \widetilde{X}_\mathcal{A}^T \widetilde{X}_\mathcal{A}$
$\alpha_\mathcal{A} \leftarrow (\mathbf{1}^T G_\mathcal{A}^{-1} \mathbf{1})^{-1/2}$, $w_\mathcal{A} \leftarrow \alpha_\mathcal{A} G_\mathcal{A}^{-1} \mathbf{1}$, $u_\mathcal{A} \leftarrow \widetilde{X}_\mathcal{A} w_\mathcal{A}$, and $a \leftarrow X^T u_\mathcal{A}$
$\gamma \leftarrow \min\{C/\alpha_\mathcal{A}, \min_{j \notin \mathcal{A}}^+ \{(C - c_j)/(\alpha_\mathcal{A} - a_j), (C + c_j)/(\alpha_\mathcal{A} + a_j)\}\}$
Record $\beta_\mathcal{A}(t) = \beta_\mathcal{A} + t \operatorname{diag}(s_\mathcal{A}) w_\mathcal{A}$ for $0 \le t \le \gamma$
$\beta_\mathcal{A} \leftarrow \beta_\mathcal{A} + \gamma \operatorname{diag}(s_\mathcal{A}) w_\mathcal{A}$ and $r \leftarrow r - \gamma u_\mathcal{A}$
$c \leftarrow X^T r$, $C \leftarrow \|c\|_\infty$, and $\mathcal{A} \leftarrow \mathcal{A} \cup \{j \notin \mathcal{A} : |c_j| = C\}$
until $C = 0$ or $\mathcal{A} = \{1, \dots, p\}$

Algorithm 11: Incremental Forward Stagewise Regression

Require: Centered response y, standardized columns $x_1, \dots, x_p$, small step size $\varepsilon > 0$
Ensure: A stagewise coefficient path
Initialize $\beta \leftarrow 0$ and $r \leftarrow y$
repeat
Choose j maximizing $|x_j^T r|$
$\delta \leftarrow \varepsilon \operatorname{sign}(x_j^T r)$
$\beta_j \leftarrow \beta_j + \delta$
$r \leftarrow r - \delta x_j$
until the residual has negligible correlation with every predictor

Remark 2.3.5. *Stagewise and Lasso Paths*
Let $c = X^T r$ and $j \in \arg\max_k |c_k|$. Forward stagewise uses $\beta_j \leftarrow \beta_j + \varepsilon \operatorname{sign}(c_j)$ and $r \leftarrow r - \varepsilon \operatorname{sign}(c_j) x_j$; as $\varepsilon \downarrow 0$, it follows maximal-correlation directions, tracking LAR/lasso until a sign reversal is required.
Boosting applies the same greedy infinitesimal update to additive fits.

Algorithm 12: Pathwise Coordinate Descent for the Lasso

Require: Centered response y, standardized columns x_j with $\|x_j\|_2 = 1$, decreasing penalties $\lambda_1 > \cdots > \lambda_L \ge 0$
Ensure: Lasso coefficient vectors $\widehat{\beta}(\lambda_\ell)$ on the penalty grid
Define $S(z, \lambda) = \operatorname{sign}(z)(|z| - \lambda)_+$
Initialize $\beta \leftarrow 0$ and $r \leftarrow y - X\beta$
for $\ell = 1, \dots, L$ **do**
repeat
for $j = 1, \dots, p$ **do**
$r \leftarrow r + x_j \beta_j$
$z_j \leftarrow x_j^T r$
$\beta_j \leftarrow S(z_j, \lambda_\ell)$
$r \leftarrow r - x_j \beta_j$
end for
until the coefficient vector has converged
$\widehat{\beta}(\lambda_\ell) \leftarrow \beta$
end for

2.4 Effective Degrees and Information Criteria

Definition 2.4.1. *Effective Degrees of Freedom*
Let $\widehat{y} = S_\lambda y$ be a linear smoother with $S_\lambda = S_\lambda(X)$ independent of y.
Its *effective degrees of freedom* are $\mathrm{df}(\lambda) := \mathrm{trace}(S_\lambda)$. If $S_\lambda = P_V$ with $\dim V = m$, then $\mathrm{df}(\lambda) = m$.
For shrinkage smoothers, $\mathrm{df}(\lambda)$ need not be integral.

Remark 2.4.2. *Optimism of Training Error*
Assume $y = \mu + \varepsilon$, $\mathbb{E}\varepsilon = 0$, $\mathrm{Var}(\varepsilon) = \sigma^2 I$, and $\widehat{y} = S_\lambda y$ with $S_\lambda = S_\lambda(X)$.
Let $y^0 = \mu + \varepsilon^0$ be independent, $\mathrm{err}_{\mathrm{tr}}(\lambda) := n^{-1}\|y - \widehat{y}\|_2^2$, and $\mathrm{Err}_{\mathrm{in}}(\lambda) := n^{-1}\mathbb{E}_{y^0}\|y^0 - \widehat{y}\|_2^2$.
Then $\mathrm{Opt}(\lambda) := \mathbb{E}\{\mathrm{Err}_{\mathrm{in}}(\lambda) - \mathrm{err}_{\mathrm{tr}}(\lambda)\} = \frac{2}{n}\sum_{i=1}^n \mathrm{Cov}(\widehat{y}_i, y_i) = \frac{2\sigma^2}{n}\,\mathrm{trace}(S_\lambda)$.
Thus $\mathrm{df}(\lambda) = \mathrm{trace}(S_\lambda)$ is the covariance penalty.

Method 2.4.3. *AIC, C_p, and BIC Selection*
Let Λ be candidate tuning values. For a criterion $C : \Lambda \to \mathbb{R}$, select $\widehat{\lambda} \in \arg\min_{\lambda\in\Lambda} C(\lambda)$.

(i) For squared error, set $\overline{\mathrm{err}}(\lambda) := \frac{1}{n}\sum_{i=1}^n (y_i - \widehat{y}_{\lambda,i})^2$ and $d_\lambda := \mathrm{df}(S_\lambda)$; use $C_p(\lambda) := \overline{\mathrm{err}}(\lambda) + \frac{2\widehat{\sigma}^2}{n} d_\lambda$.
(ii) For likelihood fits with maximized log-likelihood ℓ_λ, use $\mathrm{AIC}(\lambda) := -\frac{2}{n}\ell_\lambda + \frac{2}{n} d_\lambda$.
(iii) Use $\mathrm{BIC}(\lambda) := -\frac{2}{n}\ell_\lambda + \frac{\log n}{n} d_\lambda$; the larger penalty favors smaller d_λ as n grows.

Remark 2.4.4. *Bayesian and MDL Readings of BIC*
For models $\mathcal{M}_m$ with dimension d_m, maximised likelihood L_m, and nearly uniform prior π_m,
set $\mathrm{BIC}_m := -2\log L_m + d_m \log n$. By laplace approximation, posterior weight is $\widehat{\mathbb{P}}(\mathcal{M}_m \mid Z) = \frac{\pi_m \exp\{-\mathrm{BIC}_m/2\}}{\sum_{\ell=1}^M \pi_\ell \exp\{-\mathrm{BIC}_\ell/2\}}$, so $\arg\min_m \mathrm{BIC}_m$ is an approximate MAP model.
In MDL form, $\frac{1}{2}\mathrm{BIC}_m$ is model code length plus fitted-discrepancy code length up to constants.

Method 2.4.5. *Generalized Cross-Validation*
Let Λ be candidate tuning values and $\widehat{y}_\lambda = S_\lambda y$.

(i) Define $e_{\lambda i} := y_i - \widehat{y}_{\lambda i}$, $h_{\lambda i} := S_{\lambda,ii}$, and $d_\lambda := \mathrm{trace}(S_\lambda)$.
(ii) The leave-one-out residual is $e_{\lambda i}^{(-i)} = y_i - \widehat{f}_\lambda^{(-i)}(x_i) = \frac{e_{\lambda i}}{1 - h_{\lambda i}}$.
(iii) *Generalized cross-validation* replaces $h_{\lambda i}$ by $\bar{h}_\lambda := d_\lambda/n$ and sets $\mathrm{GCV}(\lambda) := \frac{1}{n}\sum_{i=1}^n \left(\frac{e_{\lambda i}}{1 - d_\lambda/n}\right)^2$.
(iv) Select $\widehat{\lambda}_{\mathrm{gcv}} \in \arg\min_{\lambda\in\Lambda} \mathrm{GCV}(\lambda)$; this uses d_λ instead of the full leverage diagonal.

3 Basis Expansions, Splines, and Wavelets

3.1 Basis Expansions, Splines, and Wavelet Features

Basis expansions keep the fitting step linear while moving nonlinearity into the representation of the inputs.

Definition 3.1.1. *Linear Basis Expansion*

A *linear basis expansion* chooses $h = (h_1, \ldots, h_M) : \mathcal{X} \to \mathbb{R}^M$ and fits $f_\beta(x) := \beta^T h(x) = \sum_{m=1}^M \beta_m h_m(x)$.

Typical h_m include coordinates, powers, interactions, one-dimensional transforms, and region indicators.
The model is linear in $h(x)$, but generally nonlinear in x.

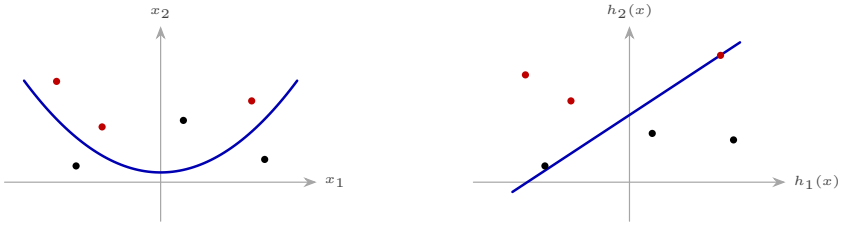

Figure 261: Basis expansion: boundary curved in x, linear in $h(x)$.

Remark 3.1.2. *Dictionaries Need Complexity Control*

For a dictionary $\mathcal{H} = \{h_m\}_{m=1}^M$, fitting $f_\beta(x) = \sum_{m=1}^M \beta_m h_m(x)$ is flexible but unstable when M is large or the h_m are nearly collinear. Complexity control restricts admissible fits: additive models impose $f(x) = \sum_j f_j(x_j)$, subset selection imposes $\|\beta\|_0 \le s$, and regularization minimizes empirical loss plus $\lambda\Omega(\beta)$.

Definition 3.1.3. *Regression Splines*
Let $\xi_1 < \cdots < \xi_K$ be knots.

(i) *Order-M regression spline* is piecewise polynomial $s : \mathbb{R} \to \mathbb{R}$ of degree $\le M-1$, $s \in C^{M-2}$ at knots.
(ii) *Cubic truncated-power basis* is basis $1, x, x^2, x^3, (x-\xi_1)_+^3, \ldots, (x-\xi_K)_+^3$ for cubic spline space.
(iii) *Natural cubic spline* is a cubic regression spline satisfying $s''(x) = 0$ for $x \notin [\xi_1, \xi_K]$.
(iv) *B-spline basis* is a locally supported basis for the same spline space.

Method 3.1.4. *Smoothing Splines as Penalized Fits*
Let $(x_i, y_i)_{i=1}^n \subset \mathbb{R}^2$, $y = (y_1, \ldots, y_n)^T$, $\lambda \ge 0$, and $\mathcal{F} := \{f : f'' \in L^2(\mathbb{R})\}$.

(i) The smoothing spline is $\widehat{f}_\lambda \in \arg\min_{f\in\mathcal{F}} \left\{\sum_{i=1}^n (y_i - f(x_i))^2 + \lambda \int_{\mathbb{R}} (f''(t))^2\, dt\right\}$.

(ii) $\widehat{f}_\lambda$ is a natural cubic spline with knots at the distinct observed inputs.
(iii) With $\widehat{y}_\lambda = (\widehat{f}_\lambda(x_1), \dots, \widehat{f}_\lambda(x_n))^T$, there is a smoother matrix S_λ such that $\widehat{y}_\lambda = S_\lambda y$ and $d_\lambda := \operatorname{trace}(S_\lambda)$.
(iv) For $e_{\lambda i} := y_i - \widehat{f}_\lambda(x_i)$ and $h_{\lambda i} := S_{\lambda,ii}$, leave-one-out CV is $\mathrm{CV}(\lambda) := \frac{1}{n}\sum_{i=1}^{n}\left(\frac{e_{\lambda i}}{1-h_{\lambda i}}\right)^2$.

Definition 3.1.5. *Tensor-Product and Thin-Plate Splines*
Let $\{h_{rj}\}_{j=1}^{J_r}$ be a univariate basis for coordinate x_r.
(i) A *two-way tensor-product basis* is $\{g_{jk}\}$ with $g_{jk}(x_1,x_2) := h_{1j}(x_1)h_{2k}(x_2)$ and dimension J_1J_2.
(ii) A *d-way tensor-product basis* is $\{g_{j_1,\dots,j_d}\}$ with $g_{j_1,\dots,j_d}(x) := \prod_{r=1}^{d} h_{rj_r}(x_r)$ and dimension $\prod_{r=1}^{d} J_r$.
(iii) A *thin-plate spline fit* is any $\widehat{f}_\lambda \in \arg\min_f Q_\lambda(f)$, where $Q_\lambda(f) := \sum_{i=1}^{n}(y_i - f(x_i))^2 + \lambda J(f)$, $D_{ab}f := \partial_a\partial_b f$, and $J(f) := \int_{\mathbb{R}^2}\{(D_{11}f)^2 + 2(D_{12}f)^2 + (D_{22}f)^2\}\,dx$.
(iv) A *thin-plate representer* is $\widehat{f}(x) = a_0 + a^\top x + \sum_{\ell=1}^{L} c_\ell\phi(\|x-\kappa_\ell\|)$; $\phi(r) := r^2\log r$, $\phi(0) := 0$, $\sum_{\ell=1}^{L} c_\ell(1,\kappa_\ell^\top) = 0$.

Method 3.1.6. *Spline-Filtered Logistic Features*
Let $(x_i, y_i)_{i=1}^n$ with $x_i \in \mathbb{R}^p$, $y_i \in \{0,1\}$, and let $H \in \mathbb{R}^{p\times M}$ be a smooth basis matrix with $M \ll p$.
(i) Restrict $\beta \in \mathbb{R}^p$ to $\mathrm{col}(H)$ by writing $\beta = H\theta$, $\theta \in \mathbb{R}^M$.
(ii) Define filtered features $z_i := H^T x_i$; then $x_i^T\beta = z_i^T\theta$.
(iii) Fit $\widehat{\theta}, \widehat{b} \in \arg\min_{\theta,b} \sum_{i=1}^{n}\{\log(1+\exp(b+z_i^T\theta)) - y_i(b+z_i^T\theta)\}$.
(iv) Set $\widehat{\beta} = H\widehat{\theta}$; smoothness is imposed by $\widehat{\beta} \in \mathrm{col}(H)$ and dimension drops from p to M.

Method 3.1.7. *Wavelet Shrinkage*
Let $y \in \mathbb{R}^n$ be observed on a regular lattice and let $W \in \mathbb{R}^{n\times n}$ be an orthonormal wavelet matrix.
(i) Transform y to wavelet coefficients $y^* := W^\top y$.
(ii) Estimate sparse coefficients by $\widehat{\theta}_\lambda \in \arg\min_{\theta\in\mathbb{R}^n} Q_\lambda(\theta)$, where $Q_\lambda(\theta) := \|y - W\theta\|_2^2 + 2\lambda\|\theta\|_1$.
(iii) Since $W^\top W = I$, $\widehat{\theta}_{\lambda,j} = \operatorname{sign}(y_j^*)(|y_j^*| - \lambda)_+$ for $j = 1,\dots,n$.
(iv) Reconstruct $\widehat{f}_\lambda := W\widehat{\theta}_\lambda = \sum_{j:|y_j^*|>\lambda}\operatorname{sign}(y_j^*)(|y_j^*|-\lambda)w_j$, where w_j is the jth wavelet atom.

4 Kernel Methods and RKHS Theory

4.1 Kernel Methods and RKHS Representations

Kernel methods keep the algorithm linear in an implicit feature space while computing only inner products.

Definition 4.1.1. *Positive Definite Kernel*
A map $k : \mathcal{X}\times\mathcal{X} \to \mathbb{R}$ is a *positive definite kernel* if:
(i) $k(x,y) = k(y,x)$ for all $x, y \in \mathcal{X}$;
(ii) for every $n \in \mathbb{N}$ and $x_1,\dots,x_n \in \mathcal{X}$, $K = (k(x_i,x_j))_{i,j=1}^n$ satisfies $a^\top Ka = \sum_{i,j=1}^{n} a_ia_jk(x_i,x_j) \ge 0\ \forall a \in \mathbb{R}^n$.

Example 4.1.2. *Common Kernels*
For $x, y \in \mathbb{R}^p$, common positive definite kernels include:
(i) *Polynomial*: for $d \in \mathbb{N}_{>0}$, $k_d(x,y) := (\langle x,y\rangle + 1)^d = \langle h_d(x), h_d(y)\rangle$, encoding monomials of degree $\le d$. If $p = 2$ and $d = 2$, one feature map is $h_2(x) = (1, \sqrt{2}x_1, \sqrt{2}x_2, x_1^2, x_2^2, \sqrt{2}x_1x_2) \in \mathbb{R}^6$.
(ii) *Gaussian RBF*: for $\nu > 0$, $k_\nu(x,y) := \exp(-\nu\|x-y\|_2^2)$; it is radial and translation invariant, with $k_\nu(x,y)$ decreasing as $\|x-y\|_2$ increases.

Definition 4.1.3. *Reproducing Kernel Hilbert Space*
A Hilbert space $\mathcal{H} \subseteq \mathbb{R}^{\mathcal{X}}$ is a *reproducing kernel Hilbert space* if point evaluation is continuous; explicitly:
(i) for every $x \in \mathcal{X}$, the evaluation map $E_x : \mathcal{H} \to \mathbb{R}$, $E_x(f) := f(x)$, is continuous;
(ii) by Riesz, $k_x \in \mathcal{H}$ denotes the unique representer of E_x, so $f(x) = \langle f, k_x\rangle_{\mathcal{H}}$ for all $f \in \mathcal{H}$;
(iii) the *reproducing kernel* is $k : \mathcal{X}\times\mathcal{X} \to \mathbb{R}$, $k(x,y) := k_x(y) = \langle k_x, k_y\rangle_{\mathcal{H}}$, with $k_x = k(x,\cdot)$.

Theorem 4.1.4. *Representer Theorem Form*
Let $\mathcal{H}$ be an RKHS on $\mathcal{X}$ with kernel k.
Let $(x_i,y_i)_{i=1}^n \subseteq \mathcal{X}\times\mathcal{Y}$, $\lambda > 0$, $\ell : \mathbb{R}\times\mathcal{Y} \to (-\infty,+\infty]$, and $\Phi : [0,\infty) \to \mathbb{R}$ nondecreasing.
For $J(f) := \sum_{i=1}^{n}\ell(f(x_i),y_i) + \lambda\Phi(\|f\|_{\mathcal{H}})$ and $S := \operatorname{span}\{k(x_i,\cdot) : 1 \le i \le n\}$, if $f^\star \in \operatorname{argmin}_{f\in\mathcal{H}} J(f)$, then $Pf^\star \in S$ is also a minimiser, where $P : \mathcal{H} \to S$ is orthogonal projection.
Hence some minimiser has $f^\star(\cdot) = \sum_{i=1}^{n}\alpha_ik(x_i,\cdot)$; if Φ is strictly increasing, every minimiser has this form.

Proof. Since S is finite-dimensional, it is closed, so P exists.
Write $f = f_S + f_\perp$ with $f_S := Pf \in S$ and $f_\perp \in S^\perp$.
For each i, $k(x_i,\cdot) \in S$, hence $f_\perp(x_i) = \langle f_\perp, k(x_i,\cdot)\rangle_{\mathcal{H}} = 0$ and $f_S(x_i) = f(x_i)$.
Thus the empirical loss in J is unchanged by $f \mapsto f_S$.
By orthogonality, $\|f\|_{\mathcal{H}}^2 = \|f_S\|_{\mathcal{H}}^2 + \|f_\perp\|_{\mathcal{H}}^2$, so $\|f_S\|_{\mathcal{H}} \le \|f\|_{\mathcal{H}}$, hence $J(f_S) \le J(f)$ by monotonicity of Φ.
Applying this to a minimiser $f^\star$ gives $J(Pf^\star) = J(f^\star)$, so $Pf^\star$ is a minimiser in S.
Since $S = \{\sum_{i=1}^{n}\alpha_ik(x_i,\cdot) : \alpha \in \mathbb{R}^n\}$, finite expansion follows. If Φ strictly increasing, $f_\perp \ne 0$, then $\|f_S\|_{\mathcal{H}} < \|f\|_{\mathcal{H}}$ while loss is

unchanged, so $J(f_S) < J(f)$, contradicting minimality.
Structural Commentary: $E : \mathcal{H} \to \mathbb{R}^n$, $Ef = (f(x_i))_{i=1}^n$, has $E|_{S^\perp} = 0$ and $Ef = E(Pf)$; only S is data-visible.
Key Insight: Regularisation kills $S^\perp$, so optimise over $\alpha \in \mathbb{R}^n$ via $f_\alpha = \sum_{i=1}^n \alpha_i k(x_i, \cdot)$ and $Ef_\alpha = K\alpha$. □

Method 4.1.5. *Kernel Ridge Regression*
Let $(x_i, y_i)_{i=1}^n \subseteq \mathcal{X} \times \mathbb{R}$, $y := (y_1, \dots, y_n)^\top$, $\lambda > 0$, and $K_{ij} := k(x_i, x_j)$.

(i) *RKHS problem*. Solve $\widehat{f} \in \operatorname{argmin}_{f \in \mathcal{H}} \sum_{i=1}^n (y_i - f(x_i))^2 + \lambda \|f\|_{\mathcal{H}}^2$.

(ii) *Representer reduction*. Write $\widehat{f}(\cdot) = \sum_{i=1}^n \widehat{\alpha}_i k(x_i, \cdot)$; then $\widehat{f}(x_j) = (K\widehat{\alpha})_j$ and $\left\|\widehat{f}\right\|_{\mathcal{H}}^2 = \widehat{\alpha}^\top K \widehat{\alpha}$.

(iii) *Finite problem*. Minimise $\widehat{\alpha} \in \operatorname{argmin}_{\alpha \in \mathbb{R}^n} \|y - K\alpha\|_2^2 + \lambda \alpha^\top K \alpha$.

(iv) *Solution*. Since $K \succeq 0$ and $\lambda > 0$, $K + \lambda I \succ 0$ and $\widehat{\alpha} = (K + \lambda I)^{-1} y$.
Hence $\widehat{y} = K\widehat{\alpha}$ and $\widehat{f}(x) = k_x^\top \widehat{\alpha}$, where $k_x := (k(x, x_1), \dots, k(x, x_n))^\top$.

Remark 4.1.6. *Localisation Kernels and RKHS Kernels*
Localisation kernel has weights $w_i(x_0) \propto K_\lambda(x_0, x_i)$. $w_i(x_0)$ is large when x_i close to x_0; small otherwise.
RKHS kernel is PSD: $K_{ij} = k(x_i, x_j)$ is Gram matrix, i.e., $k(x, y) = \langle h(x), h(y) \rangle_{\mathcal{F}}$ for some feature map h.
Thus: localisation kernels → local averaging; RKHS kernels → inner products for global regularisation.

Example 4.1.7. *Radial Basis Expansions*
Let $\xi_1, \dots, \xi_M \in \mathbb{R}^p$, $\lambda_j > 0$, $\beta \in \mathbb{R}^M$, and let $D : [0, \infty) \to [0, \infty)$ be a radial profile.

(i) *Unnormalized basis*: $\varphi_j(x) := D(\frac{\|x - \xi_j\|_2}{\lambda_j})$ and $f(x) := \sum_{j=1}^M \beta_j \varphi_j(x)$.

(ii) *Normalized basis*: for $\lambda_j = \lambda$, set $h_j(x) := D(\frac{\|x - \xi_j\|_2}{\lambda})/s(x)$, where $s(x) := \sum_{k=1}^M D(\frac{\|x - \xi_k\|_2}{\lambda}) > 0$.

Then $h_j(x) \geq 0$ and $\sum_{j=1}^M h_j(x) = 1$.

(iii) *Training-point centers*: $M = n$, $\xi_i = x_i$, $\beta_i = Y_i$ give $\widehat{f}(x) := \sum_{i=1}^n Y_i h_i(x)$ (Nadaraya–Watson local avg).

Remark 4.1.8. *Spline and Kernel Viewpoints*
Common form: $\min_f \sum_{i=1}^n \ell(f(x_i), y_i) + \lambda \|Pf\|_{\mathcal{H}}^2$, where P removes an unpenalised $\mathcal{U}$, gives $\widehat{f} = u + \sum_{i=1}^n \alpha_i k(x_i, \cdot)$ with $u \in \mathcal{U}$. Splines choose P, kernel methods choose k, and SVMs choose a margin loss ℓ.

5 Support Vector Machines and Margin Methods

5.1 Margins and SVM Primal Problems

Margin methods prefer classifiers that separate classes with a buffer, not merely with zero training error. The support-vector construction makes this preference explicit by trading margin width against margin violations.

Definition 5.1.1. *Affine Hyperplane and Signed Distance*
Let $w \in \mathbb{R}^p \setminus \{0\}$, $b \in \mathbb{R}$, and $q_{w,b}(x) := w^\top x + b$.

(i) *Affine hyperplane*: $H_{w,b} := \{x \in \mathbb{R}^p : q_{w,b}(x) = 0\}$, with normal direction w.

(ii) *Signed distance*: $d_{w,b}(x) := \frac{q_{w,b}(x)}{\|w\|_2}$.

(iii) *Scale invariance*: for $c > 0$, $H_{cw,cb} = H_{w,b}$ and $q_{cw,cb} = c q_{w,b}$.

Definition 5.1.2. *Margin*
Let $y_i \in \{-1, 1\}$ and $q(x) := w^\top x + b$.

(i) *Functional margin*: $\gamma_i(q) := y_i q(x_i)$.

(ii) *Geometric margin*: for $w \neq 0$, $\rho_i(w, b) := \frac{y_i(w^\top x_i + b)}{\|w\|_2}$.

(iii) *Correct classification*: $\gamma_i(q) > 0$; larger $\gamma_i(q)$ means larger signed confidence at fixed score scale.

Definition 5.1.3. *Hard-Margin Support Vector Machine*
For separable $(x_i, y_i)_{i=1}^n \subseteq \mathbb{R}^p \times \{-1, 1\}$:

(i) *Unit-margin scale*: $y_i(w^\top x_i + b) \geq 1$ for all i.

(ii) *Hard-margin primal*: $(\widehat{w}, \widehat{b}) \in \operatorname{argmin}_{w,b} \frac{1}{2}\|w\|_2^2$ subject to $y_i(w^\top x_i + b) \geq 1$, $i = 1, \dots, n$.

(iii) *Margin width*: the slab $-1 \leq w^\top x + b \leq 1$ has width $\frac{2}{\|w\|_2}$, so the primal maximises geometric margin.

Definition 5.1.4. *Soft-Margin Support Vector Machine*
For possibly nonseparable $(x_i, y_i)_{i=1}^n \subseteq \mathbb{R}^p \times \{-1, 1\}$ and $C > 0$:

(i) *Slack variables*: $\xi_i \geq 0$ and $y_i(w^\top x_i + b) \geq 1 - \xi_i$, $i = 1, \dots, n$.

(ii) *Soft-margin primal*: $(\widehat{w}, \widehat{b}, \widehat{\xi}) \in \operatorname{argmin}_{w,b,\xi} \{\frac{1}{2}\|w\|_2^2 + C \sum_{i=1}^n \xi_i\}$ subject to the slack constraints.

(iii) *Penalty parameter*: C prices $\sum_{i=1}^n \xi_i$; larger C penalises violations more strongly.

Remark 5.1.5. *Why the Standard Slack Scaling*
Before score normalisation, additive slack uses $y_i(w^\top x_i + b) \geq M - \xi_i$, relative slack uses $y_i(w^\top x_i + b) \geq M(1 - \xi_i)$.
Setting $M = 1$ gives convex constraint $y_i(w^\top x_i + b) \geq 1 - \xi_i$, $\xi_i \geq 0$.
Thus ξ_i measures margin failure: 0 on/outside the margin, $(0, 1]$ inside but correct, and > 1 misclassified.

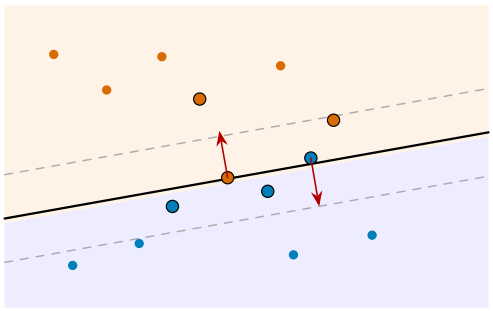

Figure 262: Soft-margin SVM: orange $y=+1$, blue $y=-1$; solid $f(x)=0$, dashed $f(x)=\pm 1$; circled support vectors, red slack arrows ξ_i.

Proposition 5.1.6. *Hinge-Loss Penalty Form*
Let $(x_i,y_i)_{i=1}^n \subseteq \mathbb{R}^p \times \{-1,1\}$, $C>0$, $f_{w,b}(x) := w^\top x + b$, and $\lambda := 1/C$. For soft-margin primal $\min_{w,b,\xi}\{\frac{1}{2}\|w\|_2^2 + C\sum_{i=1}^n \xi_i\}$ *subject to $\xi_i \geq 0$ and $y_i f_{w,b}(x_i) \geq 1-\xi_i$, eliminating ξ and scaling by $\frac{1}{C}$ gives* $\min_{w,b}\sum_{i=1}^n [1-y_i f_{w,b}(x_i)]_+ + \frac{\lambda}{2}\|w\|_2^2$. *For fixed (w,b), minimal feasible slack is $\xi_i^\star = [1-y_i f_{w,b}(x_i)]_+$.*

Proof. Fix (w,b) and put $r_i := 1-y_i f_{w,b}(x_i)$. Feasibility gives $\xi_i \geq 0$ and $\xi_i \geq r_i$, hence $\xi_i \geq \max\{0,r_i\} = [r_i]_+$.
Since $C>0$, the objective is strictly increasing in each ξ_i, so $\xi_i^\star = [r_i]_+$.
Substitution yields $\frac{1}{2}\|w\|_2^2 + C\sum_{i=1}^n [1-y_i f_{w,b}(x_i)]_+$.
Multiply by $1/C>0$ preserves minimisers, $\sum_{i=1}^n [1-y_i f_{w,b}(x_i)]_+ + \frac{1}{2C}\|w\|_2^2 = \sum_{i=1}^n [1-y_i f_{w,b}(x_i)]_+ + \frac{\lambda}{2}\|w\|_2^2$.
Structural Commentary: The ξ_i decouple; eliminate them pointwise.
Key Insight: Soft-margin SVM is hinge empirical risk plus an ℓ_2 penalty on w; the intercept b is unpenalized. □

5.2 Dual Problems and Kernelization

Proposition 5.2.1. *Hard-Margin Dual and Support Vectors*
Let $(x_i,y_i)_{i=1}^n \subseteq \mathbb{R}^p \times \{-1,1\}$ be linearly separable. The primal P : $\min_{w,b}\frac{1}{2}\|w\|_2^2$ subject to $y_i(w^\top x_i+b)\geq 1$ has dual D : $\max_{\alpha\in\mathbb{R}_+^n}\sum_{i=1}^n \alpha_i - \frac{1}{2}\sum_{i=1}^n\sum_{j=1}^n \alpha_i\alpha_j y_i y_j x_i^\top x_j$ subject to $\sum_{i=1}^n \alpha_i y_i = 0$.
At any optimum, $\widehat{w} = \sum_{i=1}^n \widehat{\alpha}_i y_i x_i$ and $\widehat{\alpha}_i > 0 \Rightarrow y_i(\widehat{w}^\top x_i + \widehat{b}) = 1$; these active points are the support vectors.

Proof. Let $g_i(w,b) := y_i(w^\top x_i + b) - 1$ and $\alpha_i \geq 0$. The Lagrangian is $L(w,b,\alpha) = \frac{1}{2}\|w\|_2^2 - \sum_{i=1}^n \alpha_i g_i(w,b)$.
Stationarity gives $0 = \nabla_w L = w - \sum_{i=1}^n \alpha_i y_i x_i$ and $0 = \partial_b L = -\sum_{i=1}^n \alpha_i y_i$, hence $w = \sum_{i=1}^n \alpha_i y_i x_i$ and $\sum_{i=1}^n \alpha_i y_i = 0$.
Substituting into L gives $D(\alpha) = \sum_{i=1}^n \alpha_i - \frac{1}{2}\sum_{i=1}^n\sum_{j=1}^n \alpha_i\alpha_j y_i y_j x_i^\top x_j$, with $\alpha \geq 0$ and $\sum_i \alpha_i y_i = 0$.
Strong duality holds by convexity and strict feasibility.
Complementary slackness gives $\widehat{\alpha}_i[y_i(\widehat{w}^\top x_i + \widehat{b}) - 1] = 0$, so $\widehat{\alpha}_i > 0$ forces $y_i(\widehat{w}^\top x_i + \widehat{b}) = 1$.
Structural Commentary: Stationarity leaves α; data enter via $y_i y_j x_i^\top x_j$ and $\sum_i \alpha_i y_i = 0$.
Key Insight: $\alpha_i > 0$ marks margin support; these points form $\widehat{w}$ and fix the separator. □

Proposition 5.2.2. *Soft-Margin Dual and Support Types*
Let $(x_i,y_i)_{i=1}^n \subseteq \mathbb{R}^p \times \{-1,1\}$ and $C>0$. The primal P : $\min_{w,b,\xi}\frac{1}{2}\|w\|_2^2 + C\sum_{i=1}^n \xi_i$ subject to $y_i(w^\top x_i+b)\geq 1-\xi_i$ and $\xi_i \geq 0$ has dual D : $\max_{\alpha\in[0,C]^n}\sum_{i=1}^n \alpha_i - \frac{1}{2}\sum_{i=1}^n\sum_{j=1}^n \alpha_i\alpha_j y_i y_j x_i^\top x_j$ subject to $\sum_{i=1}^n \alpha_i y_i = 0$.
At any optimum, $\widehat{w} = \sum_{i=1}^n \widehat{\alpha}_i y_i x_i$. With $\widehat{f}(x) := \widehat{w}^\top x + \widehat{b}$, $\widehat{\alpha}_i = 0 \Rightarrow y_i\widehat{f}(x_i) \geq 1$, $0 < \widehat{\alpha}_i < C \Rightarrow y_i\widehat{f}(x_i) = 1$, and $\widehat{\alpha}_i = C \Rightarrow y_i\widehat{f}(x_i) = 1 - \widehat{\xi}_i \leq 1$. The support vectors are exactly $\{i : \widehat{\alpha}_i > 0\}$.

Proof. Let $\alpha_i \geq 0$ multiply $y_i(w^\top x_i + b) - 1 + \xi_i \geq 0$ and $\mu_i \geq 0$ multiply $\xi_i \geq 0$.
The Lagrangian is $L = \frac{1}{2}\|w\|_2^2 + C\sum_i \xi_i - \sum_i \alpha_i[y_i(w^\top x_i + b) - 1 + \xi_i] - \sum_i \mu_i\xi_i$.
Stationarity gives $w = \sum_i \alpha_i y_i x_i$, $\sum_i \alpha_i y_i = 0$, and $C - \alpha_i - \mu_i = 0$, hence $0 \leq \alpha_i \leq C$.
Substitution gives dual; Slater gives strong duality.
Complementary slackness gives $\alpha_i[y_i f(x_i) - 1 + \xi_i] = 0$ and $(C-\alpha_i)\xi_i = 0$.
Thus $\alpha_i = 0$ implies $\xi_i = 0$ and $y_i f(x_i) \geq 1$; $0 < \alpha_i < C$ implies $\xi_i = 0$ and $y_i f(x_i) = 1$.
Hence $\alpha_i = C$ implies $y_i f(x_i) = 1 - \xi_i \leq 1$.
Structural Commentary: Slacks become box constraints $0 \leq \alpha_i \leq C$.
Key Insight: α_i labels type: 0 outside, $(0,C)$ on-margin, C inside/wrong-side. □

Method 5.2.3. *Kernelized Support Vector Classifier*
Let $(x_i, y_i)_{i=1}^n \subseteq \mathcal{X} \times \{-1, 1\}$, $C > 0$, $h : \mathcal{X} \to \mathcal{F}$, and $k(x, x') := \langle h(x), h(x') \rangle_{\mathcal{F}}$.
The kernelized dual is $\widehat{\alpha} \in \underset{\alpha \in [0,C]^n}{\operatorname{argmax}} \sum_{i=1}^n \alpha_i - \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j y_i y_j k(x_i, x_j)$ subject to $\sum_{i=1}^n \alpha_i y_i = 0$.
The fitted score and classifier are $\widehat{f}(x) = \sum_{i=1}^n \widehat{\alpha}_i y_i k(x, x_i) + \widehat{b}$ and $\widehat{G}(x) = \operatorname{sign}(\widehat{f}(x))$.
If $0 < \widehat{\alpha}_s < C$, then $\widehat{b} = y_s - \sum_{i=1}^n \widehat{\alpha}_i y_i k(x_s, x_i)$; average this over all such s for stability.

Proof. In feature space, the soft-margin primal uses $v \in \mathcal{F}$ and score $f_{v,b}(x) = \langle v, h(x) \rangle_{\mathcal{F}} + b$.
Its Lagrangian stationarity gives $v = \sum_{i=1}^n \alpha_i y_i h(x_i)$ and $\sum_{i=1}^n \alpha_i y_i = 0$, while slack stationarity gives $0 \le \alpha_i \le C$.
Substitution yields $\sum_i \alpha_i - \frac{1}{2} \left\| \sum_i \alpha_i y_i h(x_i) \right\|_{\mathcal{F}}^2 = \sum_i \alpha_i - \frac{1}{2} \sum_i \sum_j \alpha_i \alpha_j y_i y_j k(x_i, x_j)$.
Hence $\widehat{f}(x) = \langle \widehat{v}, h(x) \rangle_{\mathcal{F}} + \widehat{b} = \sum_i \widehat{\alpha}_i y_i k(x, x_i) + \widehat{b}$.
If $0 < \widehat{\alpha}_s < C$, KKT gives zero slack and $y_s \widehat{f}(x_s) = 1$, so $\widehat{f}(x_s) = y_s$ and the stated $\widehat{b}$ follows.
Structural Commentary: Coordinates vanish; optimisation uses only $K_{ij} = k(x_i, x_j)$.
Key Insight: The classifier is finite and support-vector based: only indices with $\widehat{\alpha}_i > 0$ contribute to $\widehat{f}$. □

Remark 5.2.4. *Hinge Loss and Probability-Oriented Losses*
Let $\eta(x) := \mathbb{P}(Y = 1 \mid X = x)$ and $m := yf(x)$.
(i) *Hinge*: $[1 - m]_+$ targets $\operatorname{sign}(2\eta(x) - 1)$ and is zero for $m \ge 1$.
(ii) *Logistic*: $\log(1 + e^{-m})$ targets $\log(\eta(x)/(1 - \eta(x)))$ and keeps a smooth positive tail.
(iii) *Squared*: squared loss targets $\mathbb{E}[Y \mid X = x] = 2\eta(x) - 1$ and keeps residual-magnitude leverage.

Method 5.2.5. *SVM Regularization Path View*
set $\lambda := 1/C$; as $\lambda \downarrow 0$ ($C \uparrow \infty$), hinge loss dominates norm regularisation.
(i) *Fit*: for each λ, solve for $f_\lambda(x) := w_\lambda^\top x + b_\lambda$ and multipliers $\alpha_i(\lambda)$.
(ii) *Classify states*: with $m_i(\lambda) := y_i f_\lambda(x_i)$, $m_i > 1 \Rightarrow \alpha_i = 0$, $m_i = 1 \Rightarrow 0 \le \alpha_i \le C$, and $m_i < 1 \Rightarrow \alpha_i = C$.
(iii) *Track*: fixed active set $\Rightarrow \alpha_i(\lambda)$ and f_λ are linear.
(iv) *Kernelize*: replace $w_\lambda^\top x$ by $\sum_{i=1}^n \alpha_i(\lambda) y_i k(x, x_i)$, so $f_\lambda(x) = \sum_{i=1}^n \alpha_i(\lambda) y_i k(x, x_i) + b_\lambda$.

5.3 Support Vector Regression and Perceptrons

Method 5.3.1. *Epsilon-Insensitive Support Vector Regression*
Let $(x_i, y_i)_{i=1}^n \subseteq \mathbb{R}^p \times \mathbb{R}$, $\epsilon > 0$, $\lambda > 0$, and $f_{w,b}(x) := w^\top x + b$.
(i) *Define loss*: for residual r, set $V_\epsilon(r) := [|r| - \epsilon]_+$.
(ii) *Fit*: solve $\min_{w,b} \sum_{i=1}^n V_\epsilon(y_i - f_{w,b}(x_i)) + \frac{\lambda}{2} \|w\|_2^2$.
(iii) *Read tube*: $|r_i| \le \epsilon \Rightarrow V_\epsilon(r_i) = 0$ and $|r_i| > \epsilon \Rightarrow V_\epsilon(r_i) = |r_i| - \epsilon$.
(iv) *Kernelize*: $\widehat{f}(x) = \sum_{i=1}^n (\widehat{\alpha}_i^* - \widehat{\alpha}_i) k(x, x_i) + \widehat{b}$; tube sides have opposite signs.

Method 5.3.2. *Perceptron Update as a Contrast*
Choose $(w_0, b_0) \in \mathbb{R}^p \times \mathbb{R}$ and learning rate $\rho > 0$.
(i) *Scan*: at step t, choose (x_i, y_i) and compute $m_i(t) := y_i(w_t^\top x_i + b_t)$.
(ii) *Update*: if $m_i(t) \le 0$, set $(w_{t+1}, b_{t+1}) := (w_t, b_t) + \rho y_i (x_i, 1)$.
(iii) *Keep*: if $m_i(t) > 0$, set $(w_{t+1}, b_{t+1}) := (w_t, b_t)$.
(iv) *Contrast*: perceptron may separate but is order-dependent; SVM solves a convex max-margin problem.

Remark 5.3.3. *Support Vectors*
Let $\widehat{f}(x) = \sum_{i=1}^n \widehat{\alpha}_i y_i k(x, x_i) + \widehat{b}$ and $S := \{i : \widehat{\alpha}_i > 0\}$.
Then $\widehat{f}(x) = \sum_{i \in S} \widehat{\alpha}_i y_i k(x, x_i) + \widehat{b}$, and KKT gives $i \in S \Rightarrow y_i \widehat{f}(x_i) \le 1$. Thus only support vectors enter $\widehat{f}$.

Remark 5.3.4. *Margins and Generalization*
Let $m_i(f) := y_i f(x_i)$ and $\widehat{R}_\gamma(f) := n^{-1} \sum_{i=1}^n \mathbf{1}\{m_i(f) \le \gamma\}$.
Bounds control $R(f) := \mathbb{P}(Yf(X) \le 0)$ by $\widehat{R}_\gamma(f)$ plus a complexity proxy $\mathcal{C}_\gamma(f) \asymp \|f\|^2 / \gamma^2$.
For linear $f_{w,b}$ with $\min_i m_i(f) \ge 1$, the geometric margin is $\rho = 1/\|w\|_2$.

6 Trees and Ensemble Averaging

6.1 Tree Models and Bagging

Tree-based methods partition the input space into simple regions and fit a local rule in each region. Ensemble averaging methods keep this local modelling idea but stabilise it by resampling, voting, and decorrelating the individual trees.

Definition 6.1.1. *Decision Tree*
Let $\mathcal{X} \subseteq \mathbb{R}^p$ and let $\mathcal{A}$ be the prediction space.
A decision tree T is a finite binary recursive partition of $\mathcal{X}$ with a leaf value in $\mathcal{A}$ on each terminal region.
(i) *Split*: a split at node $R \subseteq \mathcal{X}$ is a feature-threshold pair (j, t) with $j \in \{1, \dots, p\}$ and $t \in \mathbb{R}$.
It produces children $R_L := R \cap \{x : x_j \le t\}$ and $R_R := R \cap \{x : x_j > t\}$.

(ii) *Terminal partition*: after splitting stops, the leaves of T are nonempty regions $R_1(T), \dots, R_M(T)$ with $\mathcal{X} = \bigcup_{m=1}^{M} R_m(T)$ and $R_m(T) \cap R_{m'}(T) = \varnothing$ for $m \neq m'$.

(iii) *Leaf rule*: a leaf assignment $a_m \in \mathcal{A}$ for $m = 1, \dots, M$ defines $\widehat{f}_T : \mathcal{X} \to \mathcal{A}$ by $\widehat{f}_T(x) := a_m$ for the unique m such that $x \in R_m(T)$.

6.2 CART Splits and Pruning

Definition 6.2.1. *CART Regression-Tree Notation and Scores*
Let $D_n = \{(x_i, y_i)\}_{i=1}^n \subseteq \mathcal{X} \times \mathbb{R}$. For $R \subseteq \mathcal{X}$, set $I_R := \{i : x_i \in R\}$ and $n_R := |I_R|$.

(i) *Cell loss*: if $n_R > 0$, define $\bar{y}_R := n_R^{-1} \sum_{i \in I_R} y_i$ and $\mathrm{SSE}(R) := \sum_{i \in I_R} (y_i - \bar{y}_R)^2$.

(ii) *Tree predictor*: if T has leaves $R_1(T), \dots, R_{|T|}(T)$, let $m_T(x)$ be the unique $m \in \{1, \dots, |T|\}$ with $x \in R_m(T)$ and set $\widehat{f}_T(x) := \bar{y}_{R_{m_T(x)}(T)}$.

(iii) *Split children*: for $a = (j, s) \in \{1, \dots, p\} \times \mathbb{R}$, set $R_L(a) := R \cap \{x : x_j \le s\}$ and $R_R(a) := R \cap \{x : x_j > s\}$.

(iv) *Admissible splits*: set $\mathcal{A}_R := \{a \in \{1, \dots, p\} \times \mathbb{R} : n_{R_L(a)} > 0, n_{R_R(a)} > 0\}$.

(v) *Split score*: for $a \in \mathcal{A}_R$, set $S_R(a) := \mathrm{SSE}(R_L(a)) + \mathrm{SSE}(R_R(a))$.

(vi) *Pruning score*: for $\alpha \ge 0$, set $C_\alpha(T) := \sum_{m=1}^{|T|} \mathrm{SSE}(R_m(T)) + \alpha |T|$.

Method 6.2.2. *CART-Style Regression Trees*

(i) *Grow*: split eligible leaves by $a_R \in \operatorname{argmin}_{a \in \mathcal{A}_R} S_R(a)$ until stopping, yielding T_0.

(ii) *Prune*: for each $\alpha \ge 0$, choose $T_\alpha \in \operatorname{argmin}_{T \preceq T_0} C_\alpha(T)$.

(iii) *Select*: choose $\widehat{\alpha} \ge 0$ by validation or cross-validation and return $T_{\widehat{\alpha}}$.

Deep growth lowers bias; the cost-complexity penalty $\alpha|T|$ controls variance by subtree selection.

Definition 6.2.3. *Classification Tree Impurity*
For node m, let $N_{mk} := |\{i : x_i \in R_m, y_i = k\}|$, $N_m := \sum_{k=1}^K N_{mk}$, $\widehat{p}_{mk} := \frac{N_{mk}}{N_m}$. Common impurity scores are:

(i) *Misclassification*: $I_{\mathrm{mis}}(m) := 1 - \max_{1 \le k \le K} \widehat{p}_{mk}$.

(ii) *Gini*: $I_{\mathrm{Gini}}(m) := \sum_{k=1}^K \widehat{p}_{mk}(1 - \widehat{p}_{mk}) = 1 - \sum_{k=1}^K \widehat{p}_{mk}^2$.

(iii) *Entropy*: $I_{\mathrm{ent}}(m) := -\sum_{k : \widehat{p}_{mk} > 0} \widehat{p}_{mk} \log \widehat{p}_{mk}$.

The usual leaf prediction is the majority class, $\widehat{k}(m) \in \operatorname{argmax}_{1 \le k \le K} \widehat{p}_{mk}$.
With unequal losses $L_{kk} = 0$, choose the class minimizing expected loss, $\widehat{\ell}(m) \in \operatorname{argmin}_{1 \le \ell \le K} \sum_{k=1}^K L_{k\ell} \widehat{p}_{mk}$.

Remark 6.2.4. *Tree Practicalities*
For categorical levels $\mathcal{A}_j$, split $B \subset \mathcal{A}_j$ versus B^c.
For binary responses, set $I_a := \{i : X_{ij} = a\}$ and order levels by $\widehat{p}_a := |I_a|^{-1} \sum_{i \in I_a} Y_i$.
Missing values can be an NA level or use a surrogate split g' maximising $\sum_i \mathbf{1}\{g'(x_i) = g(x_i)\}$.
Many candidate splits inflate gain; control growth with $N_m \ge n_{\min}$, depth limits, validation, or pruning.

6.3 Ensembles, Random Forests, and Stacking

Definition 6.3.1. *Bagging and Random Forests*
Let $D_n = \{(x_i, y_i)\}_{i=1}^n$, $B \ge 1$, and $m \le p$.

(i) *Bagging*: draw $D_1^*, \dots, D_B^*$ from D_n, fit $T_1, \dots, T_B$, and aggregate $\widehat{f}_{\mathrm{bag}}(x) := B^{-1} \sum_{b=1}^B T_b(x)$ for regression, with voting or averaged probabilities for classification.

(ii) *Random forest*: in addition to bagging, at each node R of T_b choose $M_{b,R} \subseteq \{1, \dots, p\}$ with $|M_{b,R}| = m$ and optimise the split over features in $M_{b,R}$ only.

Bagging averages bootstrap perturbations; random split-feature subsets reduce $\mathrm{corr}(T_b, T_{b'})$ before averaging.

Method 6.3.2. *Bagged Prediction and Votes*
Let $D_n := \{(x_i, y_i)\}_{i=1}^n$ and $B \ge 1$; base outputs are $\widehat{f}$ for regression and $(\widehat{g}, \widehat{p}_1, \dots, \widehat{p}_K)$ for classification.

(i) For $b = 1, \dots, B$, draw a bootstrap sample D_b^* from D_n and fit the base learner, giving $\widehat{f}^{*b}$ or $(\widehat{g}^{*b}, \widehat{p}_{b1}, \dots, \widehat{p}_{bK})$.

(ii) Return the task-specific aggregate: for regression, $\widehat{f}_{\mathrm{bag}}(x) := B^{-1} \sum_{b=1}^B \widehat{f}^{*b}(x)$; for classification, either $\widehat{g}_{\mathrm{vote}}(x) \in \operatorname{argmax}_{1 \le k \le K} \sum_{b=1}^B \mathbf{1}\{\widehat{g}^{*b}(x) = k\}$ or $\bar{p}_k(x) := B^{-1} \sum_{b=1}^B \widehat{p}_{bk}(x)$ with $\widehat{g}_{\mathrm{prob}}(x) \in \operatorname{argmax}_{1 \le k \le K} \bar{p}_k(x)$.

Averaging reduces perturbation variance for unstable base learners.
Random split-feature subsets additionally reduce $\mathrm{corr}(T_b, T_{b'})$.

Theorem 6.3.3. *Squared-Error Benefit of Averaging*
Fix x, let $Z := \widehat{f}^*(x)$ be perturbation-random and independent of $Y \mid X = x$, and set $f_{\mathrm{ag}}(x) := \mathbb{E}_* Z$.
If $\mathbb{E}_* Z^2 < \infty$ and $\mathbb{E}_Y Y^2 < \infty$, then $\mathbb{E}_{*,Y}[(Y - Z)^2] = \mathbb{E}_Y[(Y - f_{\mathrm{ag}}(x))^2] + \mathbb{E}_*[(Z - f_{\mathrm{ag}}(x))^2]$.

Proof. Let $\mu := f_{\mathrm{ag}}(x) = \mathbb{E}_* Z$.
Since $Y - \mu$ and $Z - \mu$ are independent and $\mathbb{E}_*(Z - \mu) = 0$, $\mathbb{E}_{*,Y}[(Y - \mu)(Z - \mu)] = \mathbb{E}_Y(Y - \mu)\mathbb{E}_*(Z - \mu) = 0$.
Expanding $Y - Z = (Y - \mu) - (Z - \mu)$ gives $\mathbb{E}_{*,Y}[(Y - Z)^2] = \mathbb{E}_Y[(Y - \mu)^2] + \mathbb{E}_*[(Z - \mu)^2]$.

For independent fits Z_b, the average $\widehat{f}_B(x) := B^{-1}\sum_{b=1}^{B} Z_b$ has mean μ and perturbation variance $\mathrm{Var}_*(Z)/B$.

Structural Commentary: squared loss decomposes into target risk plus perturbation variance.
Key Insight: bagging estimates $\mathbb{E}_*\widehat{f}^*(x)$; unstable base learners gain most because $\mathrm{Var}_*(Z)$ is large. □

Theorem 6.3.4. *Correlated Ensemble Variance*
Let $Z_1,\dots,Z_B$ *have* $\mathrm{Var}(Z_b)=\sigma^2>0$ *and* $\mathrm{Corr}(Z_b,Z_c)=\rho$ *for* $b\neq c$.
For $\bar{Z}_B := \frac{1}{B}\sum_{b=1}^{B} Z_b$, $\mathrm{Var}(\bar{Z}_B)=\rho\sigma^2+\frac{1-\rho}{B}\sigma^2$; *hence, if* $\rho\geq 0$, $\mathrm{Var}(\bar{Z}_B)\to\rho\sigma^2$ *as* $B\to\infty$.

Proof. Since $\mathrm{Cov}(Z_b,Z_c)=\rho\sigma^2$ for $b\neq c$, $\mathrm{Var}(\bar{Z}_B)=B^{-2}\left\{\sum_{b=1}^{B}\mathrm{Var}(Z_b)+2\sum_{1\leq b<c\leq B}\mathrm{Cov}(Z_b,Z_c)\right\}$.
Substitution gives $\mathrm{Var}(\bar{Z}_B)=B^{-2}\left\{B\sigma^2+B(B-1)\rho\sigma^2\right\}=\rho\sigma^2+\frac{1-\rho}{B}\sigma^2$.
Structural Commentary: $\mathrm{Var}(\bar{Z}_B)=\rho\sigma^2+(1-\rho)\sigma^2/B$ separates shared and idiosyncratic variance.
Key Insight: increasing B shrinks only $(1-\rho)\sigma^2/B$; Random Forest lowers ρ by split randomisation. □

Algorithm 13: Random Forest

Require: Training data $(x_i,y_i)_{i=1}^n$, number of trees B, candidate split count $m\leq p$, tree stopping rule
Ensure: Trees $T_1,\dots,T_B$ and an aggregated predictor
  for $b=1,\dots,B$ **do**
    Draw a bootstrap resample S^{*b} of size n
    Grow a tree T_b on S^{*b}
    for each nonterminal node while growing T_b **do**
      Select m of the p predictors at random
      Choose the best split using only those m predictors
      Split the node and continue until the stopping rule is met
    end for
  end for
  For regression, return $\widehat{f}_{\mathrm{rf}}(x)=B^{-1}\sum_{b=1}^{B}T_b(x)$
  For classification, return a majority vote or averaged class-probability rule from $T_1(x),\dots,T_B(x)$

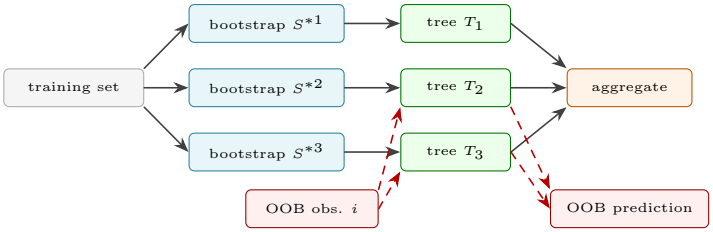

Figure 263: Blue bootstraps train green trees with m split candidates; black arrows aggregate, red dashed arrows give OOB prediction for i.

Method 6.3.5. *Out-of-Bag Error and Forest Importance*
Let I_b^* index bootstrap sample for T_b, $O_i := \{b : i\notin I_b^*\}$, $\mathcal{I}_{\mathrm{oob}} := \{i : |O_i|>0\}$, and L be prediction loss.

(i) For each $i\in\mathcal{I}_{\mathrm{oob}}$, construct $\widehat{h}_{\mathrm{oob}}(x_i)$: for regression, set $\widehat{h}_{\mathrm{oob}}(x_i) := |O_i|^{-1}\sum_{b\in O_i} T_b(x_i)$; for classification, use an OOB vote or averaged class-probability vector over $b\in O_i$.
(ii) Set $\widehat{R}_{\mathrm{oob}} := |\mathcal{I}_{\mathrm{oob}}|^{-1}\sum_{i\in\mathcal{I}_{\mathrm{oob}}} L(y_i,\widehat{h}_{\mathrm{oob}}(x_i))$ and update the estimate as B changes.

For feature j, let $\mathcal{S}_{bj}$ be j-splits of T_b, with gains ΔQ_{bs} and OOB losses $R_b^{\mathrm{oob}}, R_{bj}^{\pi}$ before/after permuting X_j.
Define $I_j^{\mathrm{split}} := \sum_{b=1}^{B}\sum_{s\in\mathcal{S}_{bj}}\Delta Q_{bs}$ and $I_j^{\pi} := B^{-1}\sum_{b=1}^{B}(R_{bj}^{\pi}-R_b^{\mathrm{oob}})$.
Both are fitted-forest summaries; I_j^{π} is not a refit-without-X_j loss contrast.

Remark 6.3.6. *Proximities, Tuning, and Overfitting*
Let $L_b(i)$ denote the terminal leaf of x_i in T_b, and set $O_{ij} := \{b : i,j\notin I_b^*\}$.
Define $P_{ij} := B^{-1}\sum_{b=1}^{B}\mathbf{1}\{L_b(i)=L_b(j)\}$ and, when $|O_{ij}|>0$, $P_{ij}^{\mathrm{oob}} := |O_{ij}|^{-1}\sum_{b\in O_{ij}}\mathbf{1}\{L_b(i)=L_b(j)\}$.
Thus P is a fitted-forest similarity; it is neither data-intrinsic nor generally a metric.
Tuning effects are parameter-specific: $m\downarrow$ lowers $\mathrm{corr}(T_b,T_{b'})$ and can raise bias; $n_{\min}\uparrow$ smooths terminal leaves; $B\uparrow$ lowers finite-ensemble Monte Carlo error but does not regularise the limiting forest.
Defaults $m_{\mathrm{cls}}\approx\sqrt{p}$ and $m_{\mathrm{reg}}\approx p/3$ are starting values only.

Method 6.3.7. *Error-Correcting Output Codes*
For training data $(x_i,y_i)_{i=1}^n$ with $y_i\in\{1,\dots,K\}$, let d_H denote Hamming distance.
A code matrix $C\in\{0,1\}^{K\times L}$ assigns class k the row $C_{k\cdot}$, and column ℓ induces binary labels $z_{i\ell} := C_{y_i\ell}$.

(i) Choose C with distinct rows, equivalently $d_H(C_{k\cdot},C_{k'\cdot})>0$ for $k\neq k'$.
(ii) For each $\ell=1,\dots,L$, fit $\widehat{p}_\ell(x)\approx\mathbb{P}(Z_\ell=1\mid X=x)$ to $(x_i,z_{i\ell})_{i=1}^n$.
(iii) For a test point x, compute $\delta_k(x) := \sum_{\ell=1}^{L}|C_{k\ell}-\widehat{p}_\ell(x)|$ for $k=1,\dots,K$ and return $\widehat{k}(x)\in\operatorname{argmin}_{1\leq k\leq K}\delta_k(x)$.

Row separation gives error correction; redundant columns reduce variance and absorb column errors.

Method 6.3.8. *Stacking and Bumping*
Let $\widehat{f}_1, \dots, \widehat{f}_M$ be fitted candidates, $\widehat{f}_m^{-i}(x_i)$ the out-of-sample prediction for observation i from candidate m, $\mathcal{W} \subseteq \mathbb{R}^M$ the admissible weight set, and L a loss. Commonly $\mathcal{W} := \{w \in \mathbb{R}^M : w_m \geq 0, \sum_{m=1}^{M} w_m = 1\}$.

(i) *Stacking*: set $R_{\mathrm{st}}(w) := \sum_{i=1}^{n} (y_i - \sum_{m=1}^{M} w_m \widehat{f}_m^{-i}(x_i))^2$.

Choose $\widehat{w}^{\mathrm{st}} \in \operatorname{argmin}_{w \in \mathcal{W}} R_{\mathrm{st}}(w)$, and return $\widehat{f}_{\mathrm{st}}(x) := \sum_{m=1}^{M} \widehat{w}_m^{\mathrm{st}} \widehat{f}_m(x)$.

(ii) *Bumping*: fit bootstrap candidates $\widehat{f}^{*1}, \dots, \widehat{f}^{*B}$, set $R_b^* := \sum_{i=1}^{n} L(y_i, \widehat{f}^{*b}(x_i))$.

Choose $\widehat{b} \in \operatorname{argmin}_{1 \leq b \leq B} R_b^*$, and return $\widehat{f}^{*\widehat{b}}$.

Coordinate weights $w = e_m$ give cross-validated model selection; general $w \in \mathcal{W}$ gives model averaging.
Stacking averages fixed candidates; bumping selects among resampled fits.

7 Additive Models and Adaptive Basis Methods

Additive and adaptive basis methods sit between rigid linear models and fully local learners. They keep prediction interpretable by building the fitted function from one-dimensional effects, boxes, hinges, or soft routing weights.

7.1 Generalized Additive Models

Definition 7.1.1. *Generalized Additive Model*
Let $X = (X_1, \dots, X_p)$, $x = (x_1, \dots, x_p)$, $\mu(x) := \mathbb{E}[Y \mid X = x]$, $\alpha \in \mathbb{R}$, and $f_j : \mathcal{X}_j \to \mathbb{R}$.

(i) *Additive mean*: $\mu(x) = \alpha + \sum_{j=1}^{p} f_j(x_j)$.

(ii) *Generalized additive model*: for a link g on the range of μ, $g(\mu(x)) = \alpha + \sum_{j=1}^{p} f_j(x_j)$.

(iii) *Identifiability*: with data $x_i = (x_{i1}, \dots, x_{ip})$, require $\sum_{i=1}^{n} f_j(x_{ij}) = 0$ for all j; this separates α from the f_j.

(iv) *Standard links*: Gaussian $g(t) = t$; binomial $g(t) = \log\left(\frac{t}{1-t}\right)$ or $\Phi^{-1}(t)$; counts $g(t) = \log t$.

Algorithm 14: Backfitting for an Additive Regression Model

Require: Training data $(x_i, y_i)_{i=1}^n$, univariate smoothers S_j for predictors $j = 1, \dots, p$
Ensure: Centered component fits $\widehat{f}_1, \dots, \widehat{f}_p$ and intercept $\widehat{\alpha}$
Set $\widehat{\alpha} \leftarrow n^{-1} \sum_{i=1}^n y_i$ and initialize $\widehat{f}_j(x_{ij}) \leftarrow 0$
repeat
  for $j = 1, \dots, p$ **do**
    $r_{ij} \leftarrow y_i - \widehat{\alpha} - \sum_{k \neq j} \widehat{f}_k(x_{ik})$ for $i = 1, \dots, n$
    $\widehat{f}_j \leftarrow S_j(r_{1j}, \dots, r_{nj})$
    Center $\widehat{f}_j$ by subtracting $n^{-1} \sum_i \widehat{f}_j(x_{ij})$
  end for
until the component functions change by less than the chosen tolerance

Method 7.1.2. *Local Scoring for Additive Logistic Regression*
For binary data $(x_i, y_i)_{i=1}^n$, $y_i \in \{0, 1\}$, use the additive predictor $\eta_i = \alpha + \sum_{j=1}^{p} f_j(x_{ij})$.

(i) *Mean*: set $p_i = \frac{1}{1+\exp(-\eta_i)}$ for $i = 1, \dots, n$.

(ii) *Working pair*: set $z_i = \eta_i + \frac{y_i - p_i}{p_i(1-p_i)}$ and $w_i = p_i(1 - p_i)$.

(iii) *Weighted fit*: update $(\alpha, f_1, \dots, f_p)$ by weighted backfitting, minimizing $\sum_{i=1}^{n} w_i \{z_i - \alpha - \sum_{j=1}^{p} f_j(x_{ij})\}^2$.

(iv) *Iteration*: recompute η_i and repeat (i)–(iii) until the additive predictor converges.

7.2 Adaptive Basis and Rule Methods

Method 7.2.1. *MARS: Adaptive Piecewise-Linear Basis Search*
For data $(x_i, y_i)_{i=1}^n$ and $x \in \mathbb{R}^p$, use reflected hinges $(x_j - t)_+$ and $(t - x_j)_+$ with knots $t \in \{x_{ij} : i = 1, \dots, n\}$.
A MARS fit is $\widehat{f}(x) = \widehat{\beta}_0 + \sum_{m=1}^{M} \widehat{\beta}_m h_m(x)$, with each h_m a selected hinge product of order $\leq d_{\max}$.

(i) *Forward pass*: add the admissible hinge pair or product giving the largest decrease in $\sum_{i=1}^{n} (y_i - \widehat{f}(x_i))^2$.

(ii) *Backward pass*: prune the forward sequence.

Score model λ by $\mathrm{GCV}(\lambda) = \frac{\sum_{i=1}^{n} (y_i - \widehat{f}_\lambda(x_i))^2}{\{1 - M(\lambda)/n\}^2}$, with effective size $M(\lambda)$.

(iii) *Selection*: choose the pruned model with smallest GCV.

The cap $d_{\max}$ controls interaction order; $d_{\max} = 1$ gives an additive piecewise-linear model.

Method 7.2.2. *PRIM Box Peeling*
For data $(x_i, y_i)_{i=1}^n$, a box $B = \prod_{j=1}^p [a_j, b_j]$, set $I(B) = \{i : x_i \in B\}$ and $\bar{y}(B) = |I(B)|^{-1} \sum_{i \in I(B)} y_i$.

Fix peeling fraction $\rho \in (0,1)$ and minimum size $m_{\min}$.

(i) *Initialise*: take B to be the full training box.
(ii) *Peel*: while $|I(B)| > m_{\min}$, replace B by the one-face deletion $B' \subset B$ removing a ρ fraction of $I(B)$ with maximal $\bar{y}(B')$.
(iii) *Paste*: expand a face when the resulting box B' increases $\bar{y}(B')$.
(iv) *Select*: choose B^* from the peeling-pasting path by validation or constraints; remove $I(B^*)$ and repeat for additional boxes.

PRIM returns high-mean rectangular regions rather than a recursive partition.

Algorithm 15: Patient Rule Induction Method

Require: Data $(x_i, y_i)_{i=1}^n$, peel fraction ρ, minimum size $m_{\min}$, box count q
Ensure: Selected boxes $\mathcal{S} = (B_1^*, \dots, B_q^*)$
  $D \leftarrow \{1, \dots, n\}$, $\mathcal{S} \leftarrow ()$
  for $r = 1, \dots, q$ **do**
    $I_D(B) := \{i \in D : x_i \in B\}$, $\bar{y}_D(B) := |I_D(B)|^{-1} \sum_{i \in I_D(B)} y_i$
    $B \leftarrow \prod_{j=1}^p [\min_{i \in D} x_{ij}, \max_{i \in D} x_{ij}]$, $\mathcal{P} \leftarrow \{B\}$
    repeat
      $\mathcal{C}_\rho(B) \leftarrow \{B' \subset B : |I_D(B')| \geq (1-\rho)|I_D(B)|\}$ among one-face deletions
      $B \leftarrow \operatorname{argmax}_{B' \in \mathcal{C}_\rho(B)} \bar{y}_D(B')$, $\mathcal{P} \leftarrow \mathcal{P} \cup \{B\}$
    until $|I_D(B)| \leq m_{\min}$
    $\mathcal{E}(B) \leftarrow \{B' \supset B : \bar{y}_D(B') > \bar{y}_D(B)\}$ among one-face expansions
    if $\mathcal{E}(B) \neq \varnothing$ **then**
      $B \leftarrow \operatorname{argmax}_{B' \in \mathcal{E}(B)} \bar{y}_D(B')$, $\mathcal{P} \leftarrow \mathcal{P} \cup \{B\}$
    end if
    $B_r^* \leftarrow \text{Select}(\mathcal{P})$, $\mathcal{S} \leftarrow (\mathcal{S}, B_r^*)$, $D \leftarrow D \setminus I_D(B_r^*)$
  end for

Remark 7.2.3. *Adaptive Structure Versus Tree Structure*

(i) *CART*: represents $\mathcal{X}$ by a binary-tree partition; leaves carry constant local fits.
(ii) *PRIM*: represents high-response regions by boxes $B \subset \mathcal{X}$ without requiring a tree partition.
(iii) *MARS*: represents $\widehat{f}$ by hinge products h_m and coefficients $\widehat{\beta}_m$, linear in $\widehat{\beta}$.

CART emphasizes tree interpretability; PRIM keeps box rules; MARS trades boxes for smoother hinge bases.

Remark 7.2.4. *Soft Trees and Mixtures of Experts*
Let node v have children $1, \dots, K_v$, gates γ_{vk}, leaves $\mathcal{L}$, leaf path $P(\ell)$, and expert $m_\ell(x; \theta_\ell)$.

(i) *Gate*: $g_{vk}(x) = \frac{\exp(\gamma_{vk}^\top x)}{\sum_{r=1}^{K_v} \exp(\gamma_{vr}^\top x)}$, so $\sum_{k=1}^{K_v} g_{vk}(x) = 1$.
(ii) *Leaf weight*: $\pi_\ell(x) = \prod_{(v,k) \in P(\ell)} g_{vk}(x)$.
(iii) *Prediction*: $\widehat{m}(x) = \sum_{\ell \in \mathcal{L}} \pi_\ell(x) m_\ell(x; \theta_\ell)$.
(iv) *Fitting*: estimate (γ, θ) by maximizing the mixture likelihood, often via EM-type alternating updates.

Soft trees replace hard branch indicators by input-dependent probabilities while retaining tree-local experts.

Remark 7.2.5. *Missing Predictors*
For observation i, let $O_i = \{j : x_{ij} \text{ observed}\}$ and $M_i = \{1, \dots, p\} \setminus O_i$; specify prediction from x_{i,O_i}.

(i) *Trees*: use surrogate splits or a categorical missing level.
(ii) *Single imputation*: replace x_{ij}, $j \in M_i$, by $\widehat{x}_{ij}$ before fitting additive or basis models.
(iii) *Model-based imputation*: estimate $\widehat{x}_{ij}$ from a feature model $\widehat{m}_j(x_{i,O_i})$.
(iv) *Multiple imputation*: fit on completed data sets $X^{(1)}, \dots, X^{(L)}$ to propagate imputation uncertainty.

Single imputation treats $\widehat{x}_{ij}$ as observed; multiple imputation propagates missing-data uncertainty.

8 Boosting and Additive Trees

8.1 Stagewise Boosting

Boosting is a stagewise way to build a strong predictor from simple base learners. The key object is an additive score: later terms are trained against the current fit rather than fit independently.

Definition 8.1.1. *Boosting*
Let $\mathcal{H}$ be a weak-learner class and set $F_0 \equiv 0$.

(i) *Additive score*: $F_M(x) = \sum_{m=1}^M \alpha_m h_m(x)$, with $h_m \in \mathcal{H}$ and $\alpha_m \in \mathbb{R}$.
(ii) *Stagewise update*: choose (α_m, h_m) using residuals, gradients, or weights from F_{m-1}; $F_m = F_{m-1} + \alpha_m h_m$.
(iii) *Prediction*: regression uses $F_M(x)$; binary classification uses $\operatorname{sign} F_M(x)$; multiclass scores use $\operatorname{argmax}_k F_{Mk}(x)$.

Boosting is the stagewise construction of F_M from weak learners.

Method 8.1.2. *Forward Stagewise Additive Modeling*
Let $b(x; \gamma)$ range over a basis class and let $L(y, f)$ be a pointwise loss.

(i) *Initialize*: choose f_0.

(ii) *Fit step*: at stage m, take $(\beta_m, \gamma_m) \in \operatorname{argmin}_{\beta,\gamma} \sum_{i=1}^{n} L\{y_i, f_{m-1}(x_i) + \beta b(x_i;\gamma)\}$.
(iii) *Update*: set $f_m(x) = f_{m-1}(x) + \beta_m b(x;\gamma_m)$.
(iv) *Stop*: after M stages, return f_M.

Previously added terms are fixed; for squared-error loss, step (ii) fits the current residuals.

Remark 8.1.3. *Stagewise Paths and Lasso Geometry*

Let $\mathcal{T} = \{T_1, \dots, T_K\}$ be a tree dictionary and $f_\alpha(x) = \sum_{k=1}^{K} \alpha_k T_k(x)$.

For large K, direct least squares is ill posed; a penalized target is $\min_\alpha \{\sum_{i=1}^{n} (y_i - f_\alpha(x_i))^2 + \lambda J(\alpha)\}$.

With $J(\alpha) = \sum_{k=1}^{K} |\alpha_k|$, active trees are sparse.

Small-step boosting traces a forward-stagewise path through this dictionary; shrinkage shortens each move.

8.2 AdaBoost and Exponential Loss

Algorithm 16: AdaBoost.M1

Require: Binary training data (x_i, y_i) with $y_i \in \{-1, 1\}$, weighted classification learner, iterations M
Ensure: Classifier $G(x)$

```
Initialize w_i ← 1/n for i = 1, ..., n
for m = 1, ..., M do
    Fit a classifier G_m using observation weights w_i
    err_m ← (Σ_{i=1}^n w_i 1_{y_i ≠ G_m(x_i)}) / (Σ_{i=1}^n w_i)
    α_m ← log((1 − err_m)/err_m)
    for i = 1, ..., n do
        w_i ← w_i exp{α_m 1_{y_i ≠ G_m(x_i)}}
    end for
end for
return G(x) = sign(Σ_{m=1}^M α_m G_m(x))
```

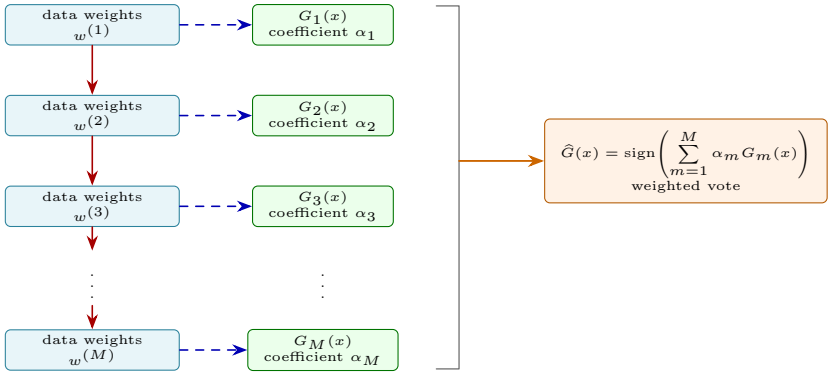

Figure 264: AdaBoost alternates fitting weak learners with updating observation weights, then aggregates them by a weighted vote.

Proposition 8.2.1. *AdaBoost as Exponential-Loss Stagewise Fitting*

For $y_i \in \{-1, 1\}$, use $L(y, f) = \exp(-yf)$. Fix stage m, current score f_{m-1}, weights $w_i^{(m)} := \exp\{-y_i f_{m-1}(x_i)\}$, and classifier $G : \mathcal{X} \to \{-1, 1\}$. Set $Q_m(\beta, G) := \sum_{i=1}^{n} L\{y_i, f_{m-1}(x_i) + \beta G(x_i)\}$ and $E_m(G) := \sum_{i=1}^{n} w_i^{(m)} \mathbf{1}_{\{y_i \neq G(x_i)\}}$.

(i) For fixed $\beta > 0$, $\operatorname{argmin}_G Q_m(\beta, G) = \operatorname{argmin}_G E_m(G)$.

(ii) If $G_m \in \operatorname{argmin}_G E_m(G)$ and $\mathrm{err}_m := E_m(G_m) / \sum_{i=1}^{n} w_i^{(m)}$, then $\beta_m = \frac{1}{2} \log\left(\frac{1-\mathrm{err}_m}{\mathrm{err}_m}\right)$ minimizes $Q_m(\beta, G_m)$.

(iii) The induced weights satisfy $w_i^{(m+1)} = w_i^{(m)} \exp\{-\beta_m y_i G_m(x_i)\}$. With $\alpha_m = 2\beta_m$, a misclassified point has relative factor $\exp(\alpha_m)$.

Remark 8.2.2. *Exponential Loss and Class Probabilities*

For $Y \in \{-1, 1\}$ and $\eta(x) = \mathbb{P}(Y = 1 \mid X = x)$, the population minimizer of $\mathbb{E}\{\exp(-Yf(X)) \mid X = x\}$ is $f^*(x) = \frac{1}{2} \log \frac{\eta(x)}{1-\eta(x)}$. Hence $\operatorname{sign} f^*(x)$ is the Bayes rule. The binomial deviance $\log\{1 + \exp(-2Yf(X))\}$ has the same minimizer but penalizes large negative margins less aggressively on finite samples.

8.3 Gradient Boosted Trees and Rule Ensembles

Definition 8.3.1. *Additive Tree Expansion*

Let $R_1, \dots, R_J$ be terminal regions, $\gamma_j \in \mathbb{R}$, and $\Theta = \{(R_j, \gamma_j) : 1 \le j \le J\}$.

(i) *Tree*: $T(x;\Theta) = \sum_{j=1}^{J} \gamma_j \mathbf{1}_{\{x \in R_j\}}$.

(ii) *Additive expansion*: $f_M(x) = \sum_{m=1}^{M} T(x;\Theta_m)$.

(iii) *Terminal fit*: with regions R_{jm} fixed, $\widehat{\gamma}_{jm} \in \operatorname{argmin}_{\gamma} \sum_{x_i \in R_{jm}} L\{y_i, f_{m-1}(x_i) + \gamma\}$.

Algorithm 17: Gradient Tree Boosting

Require: Training data (x_i, y_i), differentiable loss $L(y, f)$, tree sizes J_m, learning rate $0 < \nu \leq 1$, iterations M
Ensure: Additive predictor f_M

$f_0(x) \leftarrow \arg\min_{\gamma} \sum_{i=1}^{n} L(y_i, \gamma)$
for $m = 1, \ldots, M$ **do**
  for $i = 1, \ldots, n$ **do**
    $r_{im} \leftarrow -\left[\frac{\partial L(y_i, f(x_i))}{\partial f(x_i)}\right]_{f=f_{m-1}}$
  end for
  Fit a regression tree to targets r_{im}, giving terminal regions R_{jm}, $j = 1, \ldots, J_m$
  for $j = 1, \ldots, J_m$ **do**
    $\gamma_{jm} \leftarrow \arg\min_{\gamma} \sum_{x_i \in R_{jm}} L\{y_i, f_{m-1}(x_i) + \gamma\}$
  end for
  $f_m(x) \leftarrow f_{m-1}(x) + \nu \sum_{j=1}^{J_m} \gamma_{jm} \mathbf{1}_{\{x \in R_{jm}\}}$
end for
return f_M

Remark 8.3.2. *Pseudo-Residuals*
At stage m, pseudo-residuals are negative pointwise gradients $r_{im} := -\partial_f L(y_i, f)|_{f=f_{m-1}(x_i)}$.
Gradient boosting fits the next tree to (x_i, r_{im}).

(i) *Squared error*: $r_{im} = y_i - f_{m-1}(x_i)$.
(ii) *Absolute error*: $r_{im} = \operatorname{sign}\{y_i - f_{m-1}(x_i)\}$, away from zero residuals.
(iii) *Multinomial deviance*: $r_{ikm} = \mathbf{1}_{\{y_i = \mathcal{G}_k\}} - p_k(x_i)$, where p_k is the current softmax probability.

Algorithm 18: Gradient Boosting for K-Class Classification

Require: Encoded labels $y_{ik} \in \{0, 1\}$, classes $k = 1, \ldots, K$, tree sizes J_m, iterations M
Ensure: Class-score functions $\widehat{f}_1, \ldots, \widehat{f}_K$
Initialize $f_{k0}(x) \leftarrow 0$ for $k = 1, \ldots, K$
for $m = 1, \ldots, M$ **do**
  $p_k(x) \leftarrow \frac{\exp(f_{k,m-1}(x))}{\sum_{\ell=1}^{K} \exp(f_{\ell,m-1}(x))}$ for $k = 1, \ldots, K$
  for $k = 1, \ldots, K$ **do**
    Compute $r_{ikm} \leftarrow y_{ik} - p_k(x_i)$ for $i = 1, \ldots, n$
    Fit a regression tree to targets r_{ikm}, giving terminal regions R_{jkm}, $j = 1, \ldots, J_m$
    for $j = 1, \ldots, J_m$ **do**
      $\gamma_{jkm} \leftarrow \frac{K-1}{K} \frac{\sum_{x_i \in R_{jkm}} r_{ikm}}{\sum_{x_i \in R_{jkm}} |r_{ikm}|(1 - |r_{ikm}|)}$
    end for
    $f_{km}(x) \leftarrow f_{k,m-1}(x) + \sum_{j=1}^{J_m} \gamma_{jkm} \mathbf{1}_{\{x \in R_{jkm}\}}$
  end for
end for
return $\widehat{f}_k(x) = f_{kM}(x)$ for $k = 1, \ldots, K$

Remark 8.3.3. *Tree Size, Shrinkage, and Subsampling*
Boosted-tree complexity is controlled by iterations M, terminal counts J_m, shrinkage ν, and sampling.

(i) *Iterations*: larger M adds more trees and increases model capacity.
(ii) *Tree size*: a common J caps interactions; stumps ($J = 2$) give main effects, and larger J allows order up to $J - 1$.
(iii) *Shrinkage*: use $f_m = f_{m-1} + \nu T_m$ with $0 < \nu \leq 1$; smaller ν usually requires larger M.
(iv) *Subsampling*: fit T_m on random observations to reduce cost and add averaging-like randomness.

These tuning choices trade optimization speed, interaction depth, and test risk.

Method 8.3.4. *Relative Importance and Partial Dependence*
Let f be a fitted tree ensemble. For $S \subset \{1, \ldots, p\}$, write $C = S^c$ and $x_i = (x_{iS}, x_{iC})$.

(i) *Relative importance*: for predictor j, sum the split-improvement scores over tree nodes splitting on j.
For an ensemble, average over trees and rescale if desired.

(ii) *Partial dependence*: define $f_S(x_S) = \mathbb{E}_{X_C}\{f(x_S, X_C)\}$ and estimate $\widehat{f}_S(x_S) = n^{-1} \sum_{i=1}^{n} f(x_S, x_{iC})$.

Partial dependence averages over the marginal distribution of X_C.
It equals $\mathbb{E}\{f(X) \mid X_S = x_S\}$ only under compatible dependence structure.

Principle 8.3.5. *Bet on Sparsity*

Let $\mathcal{T} = \{T_1, \ldots, T_K\}$ and $f_\alpha = \sum_{k=1}^{K} \alpha_k T_k$, with support $S(\alpha) = \{k : \alpha_k \neq 0\}$.

An ℓ^1 penalty is useful when a low-risk predictor has $|S(\alpha)| \ll K$ and $|S(\alpha)|$ is small relative to n and noise.
Dense signals with many small α_k remain hard to estimate.
Sparsity is meaningful only relative to n, noise level, and $\mathcal{T}$.

Method 8.3.6. *Lasso Post-Processing of Ensembles*
Let a fitted ensemble generate the fixed dictionary $\mathcal{T}_L = \{T_1, \dots, T_M\}$ and let L be the chosen prediction loss.

(i) *Fit path*: compute $\widehat{\alpha}(\lambda) \in \operatorname{argmin}_{\alpha}\{\sum_{i=1}^{n} L(y_i, \alpha_0 + \sum_{m=1}^{M} \alpha_m T_m(x_i)) + \lambda \sum_{m=1}^{M} |\alpha_m|\}$.
(ii) *Select*: choose λ by validation or an information criterion.
(iii) *Return*: use $\widehat{f}_\lambda(x) = \widehat{\alpha}_0 + \sum_{m:\widehat{\alpha}_m(\lambda)\neq 0} \widehat{\alpha}_m(\lambda) T_m(x)$.

The post-processed model can use fewer trees.
A useful generated dictionary is relevant and not nearly duplicated, with subsampling one way to diversify it.

Figure 265: An ensemble generator $\mathcal{A}_{\text{ens}}$ builds the dictionary $\mathcal{T}_L$; lasso selects the active set $\widehat{S}_\lambda$ for the sparse predictor $\widehat{f}_\lambda$.

Method 8.3.7. *Rule Ensembles*
Let $T_1, \dots, T_M$ be fitted trees. A node path p defines the rule $r_p(x) = \mathbf{1}_{\{x \text{ satisfies all splits on } p\}}$.

(i) *Extract*: form $\mathcal{T}^m_{\text{rule}} = \{r_p : p \text{ is a node path in } T_m\}$.
(ii) *Aggregate*: set $\mathcal{T}_{\text{rule}} = \bigcup_{m=1}^{M} \mathcal{T}^m_{\text{rule}}$.
(iii) *Fit*: regress y on $\mathcal{T}_{\text{rule}}$ by lasso or another regularized linear method.
(iv) *Augment*: optionally add original variables x_j as linear terms.

Rules encode split interactions; added linear terms encode main linear effects.

9 High-Dimensional Supervised Learning

High-dimensional supervised learning studies prediction problems in which the number of candidate features is comparable to, or much larger than, the number of observations. The central difficulty is not merely computational size: many rules can fit the training data too well, while the scientific question often asks which features or feature groups are driving the prediction.

9.1 High-Dimensional Linear Rules

Principle 9.1.1. *Less Fitting in the $p \gg n$ Regime*
Let $X \in \mathbb{R}^{n\times p}$, $r = \operatorname{rank}(X)$, and $p \gg n$.

(i) If $r < p$, least-squares coefficients are nonunique since $\ker(X) \neq \{\mathbf{0}\}$.
(ii) Full-covariance discriminant rules are singular when covariance rank is $< p$.
Pooled rank is $\leq n - K$, and class-k rank is $\leq n_k - 1$.
(iii) Impose effective dimension $< p$ via shrinkage, diagonal covariance, row-space fitting, sparsity, or screening.

Measure complexity by $\operatorname{df}(\lambda)$, as in Proposition 2.1.4: ridge keeps coordinates; sparse rules select features.

Method 9.1.2. *Diagonal LDA and Nearest Shrunken Centroids*
For classes $k = 1, \dots, K$ and features $j = 1, \dots, p$, let $\bar{x}_{kj}$ be the class mean, $\bar{x}_{\cdot j}$ the overall mean, s_j the pooled within-class standard deviation, π_k the class prior, n_k the class size, $m_k := (\frac{1}{n_k} - \frac{1}{n})^{1/2}$, and $s_0 > 0$.

(i) *Diagonal LDA*: score x by $\delta_k(x) := -\sum_{j=1}^{p} \frac{(x_j - \bar{x}_{kj})^2}{s_j^2} + 2\log \pi_k$ and set $\widehat{G}(x) := \arg\max_k \delta_k(x)$.
(ii) *Nearest shrunken centroids*: for $\Delta \geq 0$, set $d_{kj} := \frac{\bar{x}_{kj} - \bar{x}_{\cdot j}}{m_k(s_j + s_0)}$, $d'_{kj} := \operatorname{sign}(d_{kj})(|d_{kj}| - \Delta)_+$,
and $\bar{x}'_{kj} := \bar{x}_{\cdot j} + m_k(s_j + s_0)d'_{kj}$; evaluate the diagonal LDA score with $\bar{x}'_{kj}$ in place of $\bar{x}_{kj}$.

Diagonal LDA is nearest-centroid classification after coordinatewise standardization. In nearest shrunken centroids, feature j is removed iff $d'_{kj} = 0$ for all k; increasing Δ increases shrinkage and sparsity.

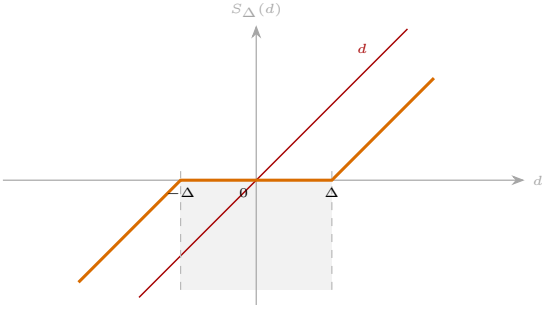

Figure 266: Soft thresholding $S_\Delta(d) = \operatorname{sign}(d)(|d| - \Delta)_+$. The shaded band $|d| \leq \Delta$ maps to zero; outside it, contrasts shrink toward zero by Δ.

Method 9.1.3. *Quadratic Regularization for Linear Rules*
Let $\eta_k(x) := \beta_{k0} + x^T\beta_k$, $\lambda > 0$, and $\gamma \in [0,1]$.

(i) *L_2 multinomial logits*: set $p_{\beta,k}(x) := \frac{\exp(\eta_k(x))}{\sum_{\ell=1}^{K}\exp(\eta_\ell(x))}$ and choose $\widehat{\beta} \in \arg\max_{\beta}\{\sum_{i=1}^{n}\log p_{\beta,g_i}(x_i) - \frac{\lambda}{2}\sum_{k=1}^{K}\|\beta_k\|_2^2\}$; leave β_{k0} unpenalized.
(ii) *Covariance shrinkage*: set $\widehat{\Sigma}_\gamma := \gamma\widehat{\Sigma} + (1-\gamma)\operatorname{diag}(\widehat{\Sigma})$ and use $\widehat{\Sigma}_\gamma$ in the discriminant score.

Both variants impose quadratic stabilization without sparsity. The endpoint $\gamma = 0$ gives diagonal LDA; increasing γ reintroduces off-diagonal covariance information.

Proposition 9.1.4. *Row-Space Reduction for Quadratic Penalties*
Let $X \in \mathbb{R}^{n\times p}$ have rank r and thin SVD $X = UDV^T = RV^T$, where $R := UD \in \mathbb{R}^{n\times r}$ and $V^TV = I_r$.
Fix $y \in \mathbb{R}^n$ and $\lambda > 0$.

(i) Ridge regression satisfies $\widehat{\beta}_\lambda^{\text{ridge}} = V(R^TR + \lambda I_r)^{-1}R^Ty$.
(ii) If $F(\beta_0,\beta) := \sum_{i=1}^{n} L(y_i, \beta_0 + x_i^T\beta) + \lambda\|\beta\|_2^2$ has a minimiser, then one satisfies $\widehat{\beta} \in \operatorname{row}(X) = \operatorname{col}(V)$.

Thus quadratic-penalty fitting may be performed in the r row-space coordinates r_i^T and mapped back by $\widehat{\beta} = V\widehat{\theta}$.

Proof. Every $\beta \in \mathbb{R}^p$ decomposes uniquely as $\beta = V\theta + z$, where $\theta = V^T\beta$ and $z \in \operatorname{col}(V)^\perp = \ker(X)$.
Then $X\beta = R\theta$ and $\|\beta\|_2^2 = \|\theta\|_2^2 + \|z\|_2^2$.

(i) For ridge, dropping z preserves fitted values and weakly decreases the penalty, so a minimiser has $z = 0$.
Thus $\widehat{\theta} \in \arg\min_{\theta}\{\|y - R\theta\|_2^2 + \lambda\|\theta\|_2^2\}$, giving $\widehat{\theta} = (R^TR + \lambda I_r)^{-1}R^Ty$ and $\widehat{\beta} = V\widehat{\theta}$.
(ii) If $(\widehat{\beta}_0, \widehat{\beta})$ minimises F and $\widehat{\beta} = V\widehat{\theta} + \widehat{z}$, then $F(\widehat{\beta}_0, V\widehat{\theta}) \le F(\widehat{\beta}_0, \widehat{\beta})$, with the same linear predictors and no larger penalty. Hence $(\widehat{\beta}_0, V\widehat{\theta})$ is also a minimiser and $V\widehat{\theta} \in \operatorname{col}(V)$.

Structural Commentary: Kernel components affect only the quadratic penalty, not the fitted values.
Key Insight: Quadratic penalties reduce fitting to $\operatorname{row}(X)$. □

9.2 Sparse and Structured Penalties

Method 9.2.1. *Sparse and Structured Penalties*
Let $\lambda, \lambda_1, \lambda_2 \ge 0$ and $\alpha \in [0,1]$. Sparse penalties replace quadratic shrinkage by nonsmooth coordinate penalties.

(i) *Lasso multinomial logits*: maximize $\sum_{i=1}^{n}\log\mathbb{P}(g_i \mid x_i) - \lambda\sum_{k=1}^{K}\sum_{j=1}^{p}|\beta_{kj}|$.
(ii) *Elastic net*: replace $|\beta_{kj}|$ by $\alpha|\beta_{kj}| + (1-\alpha)\beta_{kj}^2$.
(iii) *Fused lasso*: for ordered features, use $\lambda_1\sum_{j=1}^{p}|\beta_j| + \lambda_2\sum_{j=1}^{p-1}|\beta_{j+1} - \beta_j|$.

The L_1 term selects coordinates; the quadratic term shrinks correlated features.
Adjacent differences favor piecewise-constant coefficients.

Method 9.2.2. *Dantzig Selector*
Assume centered y and standardised columns x_j of X.
For residual $r(\beta) := y - X\beta$, the Dantzig selector has two equivalent constrained forms.

(i) *Correlation budget*: choose $\widehat{\beta}_s^{\text{DS}} \in \arg\min_{\beta}\|\beta\|_1$ subject to $\|X^Tr(\beta)\|_\infty \le s$.
(ii) *Coefficient budget*: choose $\widehat{\beta}_t^{\text{DS}} \in \arg\min_{\|\beta\|_1\le t}\|X^Tr(\beta)\|_\infty$.

Both Dantzig and lasso control $\|\beta\|_1$ and monitor residual correlations $x_j^Tr(\beta)$.
Lasso minimises residual sum of squares, while Dantzig directly bounds $\|X^Tr(\beta)\|_\infty$.

Method 9.2.3. *Grouped Lasso*
Let $\{1,\dots,p\} = G_1 \sqcup \cdots \sqcup G_L$, with $|G_\ell| = p_\ell$, design block $X_\ell \in \mathbb{R}^{n\times p_\ell}$, coefficient block $\beta_\ell \in \mathbb{R}^{p_\ell}$, and $\lambda \ge 0$.
The grouped lasso solves $(\widehat{\beta}_0, \widehat{\beta}_1, \dots, \widehat{\beta}_L) \in \arg\min_{\beta_0,\beta_1,\dots,\beta_L}\left\{\left\|y - \beta_0\mathbf{1} - \sum_{\ell=1}^{L}X_\ell\beta_\ell\right\|_2^2 + \lambda\sum_{\ell=1}^{L}\sqrt{p_\ell}\,\|\beta_\ell\|_2\right\}$.
Since $\|\beta_\ell\|_2 = 0$ iff $\beta_\ell = \mathbf{0}$, the penalty selects or removes entire groups; $\sqrt{p_\ell}$ normalizes group size.

Method 9.2.4. *Relaxed, Adaptive, and Nonconvex Lasso Variants*
Let $\widehat{\beta}_\lambda^{\text{lasso}}$ be the lasso estimate, $A_\lambda := \{j : \widehat{\beta}_{\lambda,j}^{\text{lasso}} \ne 0\}$, $\widetilde{\beta}$ an initial estimate, $\nu > 0$, and $a \ge 2$.

(i) *Relaxed lasso*: fit the lasso to get A_λ, then refit on X_{A_λ} by least squares or with penalty $\phi\lambda$, $0 \le \phi \le 1$.
(ii) *Adaptive lasso*: set $w_j := \frac{1}{|\widetilde{\beta}_j|^\nu}$ and minimize $\frac{1}{2}\|y - X\beta\|_2^2 + \lambda\sum_{j=1}^{p}w_j|\beta_j|$.
(iii) *SCAD*: use the nonconvex penalty $J_{a,\lambda}$ with $J'_{a,\lambda}(t) := \lambda\operatorname{sign}(t)\left[\mathbf{1}_{\{|t|\le\lambda\}} + \frac{(a\lambda - |t|)_+}{(a-1)\lambda}\mathbf{1}_{\{|t|>\lambda\}}\right]$.

All three reduce lasso shrinkage bias for large signals.
Relaxed and adaptive lasso keep convex refits or weighted convex fits, while SCAD is nonconvex.

Remark 9.2.5. *Three Roles for Feature Selection*
In high-dimensional learning, feature selection has three distinct roles.

(i) *Preprediction screening*: reduce variance before fitting, as in nearest shrunken centroids.
(ii) *Sparse prediction*: estimate a sparse predictive rule, as in lasso or elastic-net logistic regression.
(iii) *Scientific discovery*: report selected features for separate assessment.
Multiplicity control is then inferential, not predictive.

9.3 Latent Factors and Distance-Based Classifiers

Algorithm 19: Supervised Principal Components

Require: Standardized feature matrix X, outcome y, association scores s_j, thresholds $0 \le \theta_1 < \cdots < \theta_K$, candidate component counts $\mathcal{M}$
Ensure: A selected principal-component predictor
  for $k = 1, \dots, K$ **do**
    $A_k \leftarrow \{j : |s_j| > \theta_k\}$
    for $m \in \mathcal{M}$ **do**
      Compute the first m principal components of the submatrix X_{A_k}
      Fit the outcome model using those components as predictors
      Estimate held-out prediction error by cross-validation
    end for
  end for
  Choose (θ_k, m) by the cross-validation criterion and refit using the selected columns

Remark 9.3.1. *Screening Before Components*
Let s_j measure the marginal association between feature x_j and outcome y, and set $A_\theta := \{j : |s_j| > \theta\}$.
Supervised principal components compute PCs of X_{A_θ} rather than all of X.

(i) *Regression score*: take s_j as a standardized univariate regression coefficient for y on x_j.
(ii) *Survival score*: take s_j as the one-feature Cox score for x_j.

Ordinary PCs follow variance in X alone; screening makes the component outcome-guided.
The resulting component is a denoised latent factor from weak but aligned features.

Method 9.3.2. *Preconditioned Lasso*
Given X, y, and $\lambda > 0$, preconditioning uses a denoised response before sparse refitting.

(i) Fit supervised principal components and compute fitted values $\widehat{y} = (\widehat{y}_1, \dots, \widehat{y}_n)^T$.
(ii) Fit $\widehat{\beta}^{\mathrm{pre}} \in \arg\min_\beta \{\frac{1}{2} \|\widehat{y} - X\beta\|_2^2 + \lambda \|\beta\|_1\}$.

Stage (i) denoises the target; stage (ii) selects original features that reproduce $\widehat{y}$.

Method 9.3.3. *Inner-Product and Distance-Only Classifiers*
Let $K_{ii'} := \langle x_i, x_{i'} \rangle$ be a positive semidefinite Gram matrix, g_i class labels, $n_k = \#\{i : g_i = k\}$, and $M := \frac{1}{n}\mathbf{1}\mathbf{1}^T$.

(i) *Nearest neighbor*: compute $\|x_i - x_{i'}\|^2 = K_{ii} + K_{i'i'} - 2K_{ii'}$.
(ii) *Nearest centroid*: for test point x_0, compute $\|x_0 - \bar{x}_k\|^2 = \langle x_0, x_0 \rangle - \frac{2}{n_k} \sum_{g_i = k} \langle x_0, x_i \rangle + \frac{1}{n_k^2} \sum_{g_i = k} \sum_{g_{i'} = k} \langle x_i, x_{i'} \rangle$.
(iii) *Distance-only input*: for squared distances $\Delta_{ii'}^2$, set $B_{ii'} := -\frac{1}{2}\Delta_{ii'}^2$ and $\widetilde{K} := (I - M)B(I - M)$.

Thus nearest-neighbor, nearest-centroid, kernel PCA, and related classifiers require only inner products or centered distances, not explicit feature vectors.

Example 9.3.4. *String Kernels*
For strings over a finite alphabet, let $\mathcal{A}_m$ be the set of length-m substrings, and let $\phi_a(x)$ count occurrences of a in string x. Define $\Phi_m(x) := (\phi_a(x))_{a \in \mathcal{A}_m}$ and $K_m(x, x') := \langle \Phi_m(x), \Phi_m(x') \rangle$.
Although $|\mathcal{A}_m|$ grows exponentially in m, $K_m(x, x')$ can often be computed without forming $\Phi_m(x)$.
Thus support-vector or centroid classifiers can use sequence similarities directly.

10 Prototype and Nearest-Neighbor Methods

Prototype and nearest-neighbor classifiers are model-free rules built from distances in feature space. They can fit irregular decision boundaries and are often strong predictors, but their behavior is controlled by geometry: scaling, metric choice, neighborhood size, and storage of representative points. The local-averaging view appears in Method 1.4.2; this section records the classification and metric-design side.

10.1 Prototype Classifiers

Definition 10.1.1. *Labeled Prototype Rule*
Let $\mathcal{D}_n = \{(x_i, g_i)\}_{i=1}^n$ with $x_i \in \mathbb{R}^p$ and $g_i \in \{1, \dots, K\}$. Fix prototype counts $R_1, \dots, R_K$, distance d on $\mathbb{R}^p$.

(i) A labeled prototype set is $\mathcal{M} = \{(m_j(k), k) : m_j(k) \in \mathbb{R}^p,\ 1 \le j \le R_k,\ 1 \le k \le K\}$.
(ii) For $x \in \mathbb{R}^p$, choose $(\widehat{j}, \widehat{k}) \in \arg\min_{1 \le k \le K,\ 1 \le j \le R_k} d(x, m_j(k))$ and define $\widehat{G}(x) = \widehat{k}$.
(iii) If $\mathcal{M} = \{(x_i, g_i) : 1 \le i \le n\}$, then $\widehat{G}$ is the one-nearest-neighbor classifier.

For quantitative features, Euclidean distance requires comparable coordinate scales.

Method 10.1.2. *k-Means Prototypes*
Let $I_k = \{i : g_i = k\}$, fix R prototypes per class, and use $d(x, z) = \|x - z\|_2$.

(i) For each $k = 1, \dots, K$, choose $m_1(k), \dots, m_R(k) \in \mathbb{R}^p$ to minimize $\sum_{i \in I_k} \min_{1 \le j \le R} \|x_i - m_j(k)\|_2^2$.
(ii) For $x \in \mathbb{R}^p$, choose $(\widehat{j}, \widehat{k}) \in \arg\min_{1 \le k \le K,\ 1 \le j \le R} \|x - m_j(k)\|_2$ and set $\widehat{G}(x) = \widehat{k}$.

The stored labeled prototype set is $\mathcal{M} = \{(m_j(k), k) : 1 \le j \le R,\ 1 \le k \le K\}$.
The rule has piecewise-linear Euclidean decision boundaries; since classes are compressed independently, prototypes need not move away from competing classes near a boundary.

Algorithm 20: Learning Vector Quantization

Require: Labeled data $(x_i, g_i)_{i=1}^n$, prototypes per class R, learning rates $\epsilon_t \downarrow 0$

Ensure: Labeled prototypes $m_j(k)$
  Initialize $m_1(k), \dots, m_R(k)$ from training observations in class k, for each k
  for $t = 1, 2, \dots$ **do**
    Sample a training index i
    Choose the closest prototype (j, k) to x_i over all classes and prototype indices
    if $g_i = k$ **then**
      $m_j(k) \leftarrow m_j(k) + \epsilon_t\big(x_i - m_j(k)\big)$
    else
      $m_j(k) \leftarrow m_j(k) - \epsilon_t\big(x_i - m_j(k)\big)$
    end if
  end for

Remark 10.1.3. *Boundary-Aware Prototype Motion*
For a sampled pair (x_i, g_i), let $(j^\star, k^\star) \in \underset{1\le k\le K,\ 1\le j\le R_k}{\arg\min} d(x_i, m_j(k))$ and let $\epsilon_t > 0$.

(i) If $g_i = k^\star$, set $m_{j^\star}(k^\star) \leftarrow m_{j^\star}(k^\star) + \epsilon_t(x_i - m_{j^\star}(k^\star))$.
(ii) If $g_i \neq k^\star$, set $m_{j^\star}(k^\star) \leftarrow m_{j^\star}(k^\star) - \epsilon_t(x_i - m_{j^\star}(k^\star))$.

Thus every sampled class can move the nearest prototype of any class.
Unlike classwise k-means, LVQ is an online algorithmic rule rather than exact minimization of a fixed criterion.

Method 10.1.4. *Gaussian Mixtures as Soft Prototypes*
Let $\varphi_p(\cdot; \mu, \Sigma)$ be the p-variate Gaussian density. For class k, fix a prior ρ_k, component weights α_{kj}, centers $\mu_{kj} \in \mathbb{R}^p$, covariances $\Sigma_{kj} \succ 0$, and $j = 1, \dots, R_k$, with $\rho_k, \alpha_{kj} \ge 0$, $\sum_{k=1}^{K} \rho_k = 1$, and $\sum_{j=1}^{R_k} \alpha_{kj} = 1$.

(i) Define the class density $f_k(x) = \sum_{j=1}^{R_k} \alpha_{kj} \varphi_p(x; \mu_{kj}, \Sigma_{kj})$.

(ii) For $x \in \mathbb{R}^p$, set $Z(x) = \sum_{\ell=1}^{K} \rho_\ell f_\ell(x) = \sum_{\ell=1}^{K} \sum_{r=1}^{R_\ell} \rho_\ell \alpha_{\ell r} \varphi_p(x; \mu_{\ell r}, \Sigma_{\ell r})$.

(iii) Compute $\tau_k(x) = \frac{\rho_k f_k(x)}{Z(x)}$ and $\omega_{kj}(x) = \frac{\rho_k \alpha_{kj} \varphi_p(x; \mu_{kj}, \Sigma_{kj})}{Z(x)}$. Set $\widehat{G}(x) \in \underset{1\le k\le K}{\arg\max}\, \tau_k(x)$.

The pairs (μ_{kj}, Σ_{kj}) are soft prototypes and $\omega_{kj}(x)$ gives fractional membership.
If $\Sigma_{kj} = \sigma^2 I$ and all $\rho_k \alpha_{kj} > 0$, then as $\sigma^2 \downarrow 0$ the dominant component is nearest center μ_{kj} away from ties.

10.2 Nearest Neighbors

Method 10.2.1. *k-Nearest-Neighbor Classification*
Fix a distance d on the feature space and an integer $k \in \{1, \dots, n\}$.

(i) For a query x_0, compute $d_i = d(x_i, x_0)$ for $i = 1, \dots, n$.
(ii) Let $N_k(x_0) \subset \{1, \dots, n\}$ be indices of k smallest values among $d_1, \dots, d_n$. Set $\widehat{G}(x_0) \in \underset{g\in\{1,\dots,K\}}{\arg\max} \sum_{i\in N_k(x_0)} \mathbf{1}_{\{g_i = g\}}$.

Small k gives lower bias and higher variance; larger k smooths the decision boundary by averaging over more labels. The tuning parameter k is usually chosen by validation or cross-validation.

Proposition 10.2.2. *Asymptotic One-Nearest-Neighbor Error*
Assume $K \ge 2$ and fix x. Let $p_k = \mathbb{P}(G = k \mid X = x)$, choose $k^\star \in \underset{1\le k\le K}{\arg\max} p_k$, and set $L^\star(x) = 1 - p_{k^\star}$.

In the asymptotic one-nearest-neighbor idealisation, the query label G and nearest-neighbor label G' are independent draws from $(p_1, \dots, p_K)$, and the classifier predicts G'.

(i) $L_{1\mathrm{NN}}(x) = \mathbb{P}(G' \neq G) = \sum_{k=1}^{K} p_k(1 - p_k) = 1 - \sum_{k=1}^{K} p_k^2$.

(ii) $L^\star(x) \le L_{1\mathrm{NN}}(x) \le 2L^\star(x) - \frac{K}{K-1}\big(L^\star(x)\big)^2 \le 2L^\star(x)$.

Proof.

(i) Independence gives $\mathbb{P}(G' = G) = \sum_{k=1}^{K} p_k^2$, hence $L_{1\mathrm{NN}}(x) = 1 - \sum_{k=1}^{K} p_k^2$.

(ii) Let $p_\star = p_{k^\star}$ and $q = 1 - p_\star = L^\star(x)$.

Since $p_k \le p_\star$ for every k, $\sum_{k=1}^{K} p_k^2 \le p_\star \sum_{k=1}^{K} p_k = p_\star$, so $L_{1\mathrm{NN}}(x) \ge 1 - p_\star = L^\star(x)$.

Also $\sum_{k\neq k^\star} p_k = q$, so Cauchy-Schwarz gives $\sum_{k\neq k^\star} p_k^2 \ge \frac{q^2}{K-1}$.

Therefore $\sum_{k=1}^{K} p_k^2 \ge (1-q)^2 + \frac{q^2}{K-1}$ and $L_{1\mathrm{NN}}(x) \le 2q - \frac{Kq^2}{K-1} \le 2q = 2L^\star(x)$.

Structural Commentary: Dominant mass gives the lower bound; uniform residual mass gives the upper bound. *Key Insight*: One-nearest-neighbor error is label-disagreement probability at fixed x. □

Example 10.2.3. *Tuning Depends on the Problem*
Let $X = (X_1, \dots, X_{10})$ have independent $\mathrm{Unif}(0, 1)$ coordinates and let $Y \in \{0, 1\}$.

(i) *Halfspace*: $Y = \mathbf{1}_{\{X_1 > 1/2\}}$; the decision boundary is the single hyperplane $X_1 = 1/2$.
(ii) *Checkerboard*: $Y = \mathbf{1}_{\{\mathrm{sign}(\prod_{j=1}^{3}(X_j - 1/2)) > 0\}}$.

The planes $X_j = 1/2$ for $j = 1, 2, 3$ form eight cells with alternating labels.

Across repeated simulations, the preferred neighborhood size k or prototype count R depended on the case. For memory-based and prototype rules, tuning is geometry-dependent, not a universal complexity constant.

Example 10.2.4. *Image Scene Classification by Local Pixel Features*
For each pixel s, let $b_s \in \mathbb{R}^4$ be its four spectral-band vector and let $g_s \in \{1, \dots, 7\}$ be its land-use label.
Replace b_s by the local feature vector $z_s = (b_t : t \in \mathcal{N}_3(s)) \in \mathbb{R}^{36}$, where $\mathcal{N}_3(s)$ is the 3×3 pixel patch centered at s. A five-nearest-neighbor rule on the features z_s had reported test error about 9.5%, showing that local spatial features can make nearest-neighbor classification competitive for irregular class boundaries.

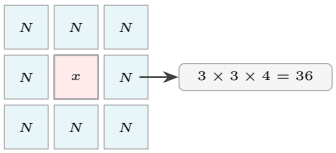

Figure 267: A 3×3 patch over four bands gives 36 features per pixel.

10.3 Invariant Distances and Adaptive Neighborhoods

Method 10.3.1. *Invariant Metrics and Tangent Distance*
Let $x, x' \in \mathbb{R}^p$, let $\mathcal{A}$ be a transformation family, and write $T_\alpha x$ for the transformed input.
For local transformations, let $V_x \in \mathbb{R}^{p \times r_x}$ span the tangent directions at x.

(i) *Orbit metric*: $d_{\text{inv}}(x, x') = \inf_{\alpha, \beta \in \mathcal{A}} \left\| T_\alpha x - T_\beta x' \right\|_2$ compares the transformation orbits of x and x'.

(ii) *Tangent metric*: $d_{\tan}(x, x') = \inf_{a,b} \|x + V_x a - x' - V_{x'} b\|_2$ compares tangent affine spaces.

The tangent metric discounts small local transformations without making large transformations cost-free.
Data augmentation encodes similar invariance by storing transformed copies, which becomes costly when many transformation directions are needed.

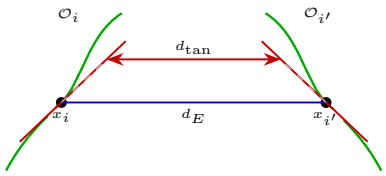

Figure 268: Tangent distance uses local tangents instead of orbits; d_E is ordinary distance.

Method 10.3.2. *Discriminant Adaptive Nearest Neighbors*
DANN replaces the fixed Euclidean metric by a query-dependent quadratic metric.
For a query x_0, choose a pilot index set $P(x_0)$, final neighbor count h, and $\epsilon > 0$. From $\{(x_i, g_i) : i \in P(x_0)\}$ estimate local class proportions π_k, class means $\bar{x}_k$, local mean $\bar{x}$, and pooled within-class covariance $\mathbf{W} \succ 0$.

(i) Compute the local between-class covariance $\mathbf{B} = \sum_{k=1}^{K} \pi_k (\bar{x}_k - \bar{x})(\bar{x}_k - \bar{x})^T$.

(ii) Form $\mathbf{B}^\star = \mathbf{W}^{-1/2} \mathbf{B} \mathbf{W}^{-1/2}$ and $\mathbf{\Sigma}_{x_0} = \mathbf{W}^{-1/2} (\mathbf{B}^\star + \epsilon I) \mathbf{W}^{-1/2}$.

(iii) With $D_{x_0}(x_i, x_0) = (x_i - x_0)^T \mathbf{\Sigma}_{x_0} (x_i - x_0)$, let $N_h(x_0)$ index h smallest distances.

(iv) Set $\widehat{G}(x_0) \in \arg\max_{g \in \{1, \dots, K\}} \sum_{i \in N_h(x_0)} \mathbf{1}_{\{g_i = g\}}$.

Whitening by $\mathbf{W}$ removes local within-class scale.
$\mathbf{B}^\star + \epsilon I$ stretches neighborhoods along directions with weak local class separation, and ϵ prevents degeneracy.

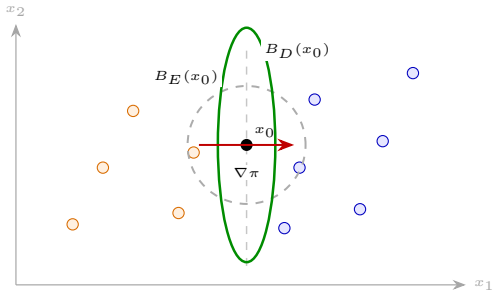

Figure 269: DANN replaces the Euclidean ball by a local ellipsoid, narrow along the class-change direction and elongated where class probabilities vary slowly.

Method 10.3.3. *Global Dimension Reduction for Nearest Neighbors*
Fix a target dimension $L \le p$. Let $\mathbf{B}_i$ be the local between-class matrix estimated at training point x_i.

(i) Compute the global class-separation matrix $\overline{\mathbf{B}} = N^{-1} \sum_{i=1}^{N} \mathbf{B}_i$.

(ii) Let $(\theta_\ell, e_\ell)_{\ell=1}^{p}$ be eigenpairs of $\overline{\mathbf{B}}$ with $\theta_1 \ge \cdots \ge \theta_p$.

(iii) Project by $P_L x = (e_1^T x, \dots, e_L^T x) \in \mathbb{R}^L$ and run nearest-neighbor classification on $P_L x_i$.

The rank-L summary $\overline{\mathbf{B}}_{[L]} = \sum_{\ell=1}^{L} \theta_\ell e_\ell e_\ell^T$ solves $\min_{\mathrm{rank}(M)=L} \sum_{i=1}^{N} \mathrm{trace}[(\mathbf{B}_i - M)^2]$.
The reduced space is selected from local class-separation information, not unsupervised variance alone.

Remark 10.3.4. *Computation and Storage*
With N stored observations in $\mathbb{R}^p$, direct nearest-neighbor search costs $O(Np)$ per query and stores $O(Np)$ coordinates. Storage can be reduced by replacing the retained set $S \subset \{1, \dots, N\}$.

(i) *Prototype compression*: store learned representatives rather than all training observations.
(ii) *Editing*: delete observations whose local neighborhoods have inconsistent labels.
(iii) *Condensing*: grow a small retained set by adding i only if it misclassifies (x_i, g_i).

Fast search reduces query cost in favorable geometries; compression, editing, and condensing reduce storage by keeping representatives or boundary-relevant observations.

11 Flexible and Mixture Discriminant Analysis

11.1 Flexible and Mixture Discriminant Rules

Linear discriminant analysis is useful partly because it is simple: each class is represented by a centroid, distances are measured in a common covariance metric, and the decision boundaries are linear. Its limitations are equally structural. A single centroid may not represent an inhomogeneous class, linear boundaries may be too rigid, and high-dimensional predictors may require smoothness or shrinkage beyond ordinary covariance pooling. Flexible, penalized, and mixture discriminant methods keep the LDA comparison geometry while changing the regression fit, the metric, or the number of class prototypes.

Method 11.1.1. *Flexible and Penalized Discriminant Analysis*
Optimal scoring represents LDA by regressions from x_i to transformed labels.
Let $g_i \in \{1, \dots, K\}$, $1 \le L \le K-1$, label scores $\theta_\ell : \{1, \dots, K\} \to \mathbb{R}$, and fitted score maps $\eta_\ell : \mathcal{X} \to \mathbb{R}$, with centering and orthogonality constraints on the θ_ℓ removing constant score directions.

(i) *Flexible discriminant analysis*: minimize $\mathcal{L}_{\mathrm{FDA}} = n^{-1} \sum_{\ell=1}^{L} \sum_{i=1}^{n} \{\theta_\ell(g_i) - \eta_\ell(x_i)\}^2 + \lambda \sum_{\ell=1}^{L} J(\eta_\ell)$ over θ_ℓ and η_ℓ from a chosen smoother class: linear, spline, additive, MARS, kernel, or similar.
(ii) *Penalized discriminant analysis*: impose $\eta_\ell(x) = h(x)^\top \beta_\ell$ and roughness penalty $\beta_\ell^\top \Omega \beta_\ell$.
Equivalently classify by $D_\lambda(x,k) = \big(h(x) - \bar{h}_k\big)^\top (\widehat{\Sigma}_{W,h} + \lambda\Omega)^{-1} \big(h(x) - \bar{h}_k\big)$, with $\bar{h}_k$ and $\widehat{\Sigma}_{W,h}$ the class-k centroid and pooled within-class covariance in h-coordinates.

For $\eta_\ell(x) = x^\top \beta_\ell$ and no roughness penalty, the fitted directions recover LDA up to scale; FDA changes the regression class to obtain nonlinear boundaries, while PDA shrinks rough or unstable h-directions.

Algorithm 21: FDA Coordinates by Optimal Scoring

Require: Class labels $g_i \in \{1, \dots, K\}$, indicator response matrix $Y \in \mathbb{R}^{n \times K}$, linear smoother S_λ for the chosen regression method
Ensure: Nonconstant discriminant coordinate functions $\eta_1, \dots, \eta_{K-1}$
Fit the multivariate regression of Y on the features: $\widehat{Y} \leftarrow S_\lambda Y$
Let $\eta^*(x)$ denote the K fitted regression functions evaluated at a new input x
Set $D_\pi \leftarrow Y^T Y / n$
Solve $Y^T \widehat{Y} \theta = \gamma D_\pi \theta$ and normalize eigenvectors so that $\Theta^T D_\pi \Theta = I$
Discard the constant scoring direction
for each remaining eigenvector θ_ℓ **do**
  Set $\eta_\ell(x) \leftarrow \theta_\ell^T \eta^*(x)$
end for

Remark 11.1.2. *FDA as LDA After a Regression Map*
Let $\eta = (\eta_1, \dots, \eta_L) : \mathcal{X} \to \mathbb{R}^L$ and $z = \eta(x)$. FDA applies LDA in z-space, so linear discriminants in z pull back to decision boundaries in x determined by the regression class for η.
Polynomial η gives algebraic boundaries, quadratic η gives quadratic boundaries, and additive, spline, or kernel η gives the corresponding structured nonlinear boundaries.

Method 11.1.3. *Mixture Discriminant Analysis*
Mixture discriminant analysis replaces the class-k LDA prototype by R_k Gaussian subclasses while sharing one covariance Σ. Let $\pi_{kr} \ge 0$, $\sum_{r=1}^{R_k} \pi_{kr} = 1$, centers μ_{kr}, class prior ρ_k, $f_k(x) = \sum_{r=1}^{R_k} \pi_{kr} \phi(x; \mu_{kr}, \Sigma)$, and $p_k(x) = \Pr(G = k \mid X = x) = \rho_k f_k(x) / \sum_{j=1}^{K} \rho_j f_j(x)$.
If $R_k = 1$ for all k, this is ordinary common-covariance Gaussian discrimination.

(i) *E-step*: for $g_i = k$, set $r_{ikr} = \pi_{kr} \phi(x_i; \mu_{kr}, \Sigma) / \sum_{s=1}^{R_k} \pi_{ks} \phi(x_i; \mu_{ks}, \Sigma)$ for $r = 1, \dots, R_k$.
(ii) *M-step*: update π_{kr}, μ_{kr}, and Σ by weighted Gaussian maximum likelihood with weights r_{ikr}.
(iii) *Blurred-response variant*: use subclass columns c_{kr} and row i equal to $(r_{ik1}, \dots, r_{ikR_k})$ on class-k columns, zero elsewhere; then fit weighted DA with optional rank restrictions, FDA, or PDA.

Remark 11.1.4. *MDA and Prototype Rules*
MDA is a probabilistic prototype classifier with prototypes μ_{kr}, weights π_{kr}, and shared metric Σ^{-1}. It assigns x by posterior scores $p_k(x) \propto \rho_k \sum_{r=1}^{R_k} \pi_{kr} \phi(x; \mu_{kr}, \Sigma)$, not by a hard nearest-center rule.
Relative to classwise k-means, it estimates π_{kr} and Σ; relative to an unconstrained Gaussian mixture, each component (k, r) is nested inside the observed class k.

Definition 11.1.5. *Kernel Density Classification*
Let $G \in \{1, \dots, J\}$ be the class label.
Estimate $\pi_j := \mathbb{P}(G = j)$ by $\widehat{\pi}_j$ and $f_j(x) := f_{X \mid G=j}(x)$ by a kernel density estimate $\widehat{f}_j(x)$.

(i) *Posterior*: Define $\widehat{p}_j(x) := \widehat{\mathbb{P}}(G = j \mid X = x) := \dfrac{\widehat{\pi}_j \widehat{f}_j(x)}{\sum_{k=1}^{J} \widehat{\pi}_k \widehat{f}_k(x)}$ whenever the denominator is positive.
(ii) *Classifier*: The plug-in Bayes rule is $\widehat{g}(x) \in \operatorname{argmax}_{1 \le j \le J} \widehat{p}_j(x)$.

Full density estimation is unnecessary if only the boundary is needed.

Remark 11.1.6. *Computational Scale*
Let N be the sample size, p the predictor dimension, and T_{fit} the cost of the chosen smoother.

(i) *LDA/PDA*: covariance-scale linear algebra costs about $Np^2 + p^3$ before low-rank reduction.
(ii) *FDA*: cost is T_{fit}; additive or adaptive basis fits can be nearly linear in N for fixed model size, while dense kernel or spline smoothers can cost at least an $N \times N$ solve.
(iii) *MDA*: cost multiplies the common-covariance discriminant fit by EM iterations and depends on initialization because mixture likelihoods are nonconvex.
